Camilla Scott
Principal Environmental Officer
Energy and Extractive Resources | Environmental Services and Regulation
Department of Environment, Tourism, Science and Innovation
Level 7, 400 George Street
BRISBANE QLD 4001

Dear Camilla,

Application for a new site-specific Environmental Authority – PL 1123

Santos Ventures Pty Ltd (Santos), on behalf of its joint venture partners, has prepared the attached application for a new site-specific Environmental Authority (EA) to authorise petroleum production operations on proposed Petroleum Lease (PL) 1123.

Santos is the principal applicant, and we have undertaken formal pre-lodgement with respect to this application with DETSI 16th May 2025.

PL 1123 will wholly replace all existing blocks of Authority to Prospect (ATP) 2053, which is an existing exploration tenure operated by Santos. Santos proposes to develop PL 1123 as part of the Santos Roma Phase 7-7B-SD20 Development (Project). The Project will involve the progressive construction, operation, decommissioning and rehabilitation of up to 24 Coal Seam Gas (CSG) wells and associated infrastructure located in PL 1123.

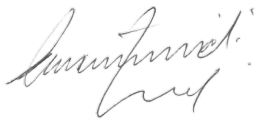
Due to varying joint venture and commercial arrangements, PL 1123 cannot be added to any of the existing adjacent Santos EAs as an authorised tenure. The holders of Santos operated petroleum tenures surrounding PL 1123 are different to those of PL 1123, and therefore PL 1123 cannot be added as an authorised tenure to their respective EAs. Santos is therefore seeking a new site-specific EA to authorise petroleum production on proposed PL 1123.

Given the proximity of PL 1123 to existing Santos petroleum operations in the Roma region, the Project is proposed to be carried out as a single integrated operation with existing authorised petroleum tenures and activities authorised under the existing Santos Roma Shallow Gas Project Area (RSGPA) EA (EPPG00898213). Santos is therefore seeking EA conditions consistent with those of the RSGPA EA to ensure operational and compliance consistency across adjacent tenure boundaries RSGPA EA conditions are predominately based on the DETSI *streamlined model conditions for petroleum activities* (ESR/2016/1989).

Santos is also requesting the following Environmentally Relevant Activity (ERA) is authorised on the new EA:

- Schedule 3 – 3 – A petroleum activity that is likely to have a significant impact on a category A or B Environmentally Sensitive Area.

Further, the Project was referred to the Commonwealth Department of Climate Change, Energy, the Environment and Water (DCCEEW) for assessment under the requirements of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act). The Project was determined not to be a Controlled Action (NCA) by DCCEEW on 22nd December 2025 (EPBC 2025/10227).



The following information is attached in support of the application:

- Appendix 1 – EPBC Act referral – decision notice;
- Appendix 2 – Application form for a site specific application for a new EA for a resource activity; and
- Appendix 3 – Supporting information report.

The prescribed fee for this application is $754.00, plus 30% of the annual fee for the relevant activity ($118,314.00), which totals $36,248.20.

Please contact Alex Clarke, Senior Environmental Advisor, at alex.clarke@santos.com, should you have any questions in relation to the application.

Yours sincerely,

William Inonda

Team Leader Environment – Eastern Queensland and NSW

Appendix 1

EPBC Act Referral – Decision Notice

Australian Government
Department of Climate Change, Energy, the Environment and Water

Notification of referral decision – not controlled action

Roma Phase 7-7B-SD20 Development, near Wallumbilla, Queensland (EPBC 2025/10227)

This decision is made under section 75 of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

Proposed action

person proposing to take the action	SANTOS VENTURES PTY LTD ABN: 123 982 749
proposed action	Progressive construction, operation, decommissioning and rehabilitation of up to 24 CSG wells and associated infrastructure. The proposed site is located 5 kilometres east of Wallumbilla, central-eastern Queensland, within the Maranoa Regional Council area (See EPBC Act referral 2025/10227).

Referral decision: not a controlled action

status of proposed action	The proposed action is not a controlled action.

Person authorised to make decision

name and position	Mark Say Acting Branch Head Environment Assessments Queensland Branch
signature	
date of decision	22 December 2025

Santos

Appendix 2

Application form for a site specific application for a new EA for a resource activity

Application Form

Environmental Protection Act 1994

Site specific application for a new environmental authority for a resource activity

This is the approved form to make a site-specific application for an environmental authority under sections 124, 125, 126 and 126A of the Environmental Protection Act 1994 *(EP Act) for an environmentally relevant activity (ERA) which is a resource activity*

Note: You can apply to the Department of the Environment, Tourism, Science and Innovation (the Department) through Online Services at: https://www.business.qld.gov.au/running-business/environment/online-services.

It is recommended that you read the information on what to provide with an application, prior to making an application. This information is located on the Business Queensland website at www.business.qld.gov.au (use the search term "environmental licence"). This website also has a diagnostic tool called a "Forms and fees finder" which will take you through a series of questions and provide a customised result which will identify any forms, fees and supporting information you need to make an application.

Only use this application form if you are applying for a new environmental authority (EA) where:

- ☑ *All applicants are registered as suitable operators*[1]*. A suitable operator is a person or a corporation assessed under section 318I of the EP Act as being suitable to carry out an ERA and is listed on the suitable operator register*[2]*.*
- ☑ The ERA/s being applied for is/are a resource activity/activities, which involves: (a) a geothermal activity, (b) a greenhouse gas (GHG) storage activity, (c) a mining activity or (d) a petroleum activity. Note a resource activity is taken to include ancillary activities (prescribed ERAs) and other activities carried out under the authority as a resource activity.
- ☑ An application for a relevant resource tenure has been made or will be made at the same time as this application.
- ☑ The applicant/s for the resource tenure are exactly the same as the applicant/s for this EA application.
- ☑ The ERA/s being applied for will not form part of an ERA project under an existing EA.
- ☑ If more than one ERA is being applied for:
    - the ERAs being applied for will be carried out under the day to day management of a single responsible person (e.g. a site manager or operations manager); and
    - all of the ERAs are operationally interrelated, that is, the operation cannot function without all of the ERAs. Separate applications will need to be made for the ERAs that cannot be carried out as a single integrated operation; and
    - the ERA/s are, or will be, carried out at one or more places; and
    - the places where the ERAs will be carried out are close enough to make the integrated day to day management of the activities feasible.

---

[1] Your EA application must be refused if you are not a registered suitable operator when the application is decided. To become a registered suitable operator apply using the form Application to be a suitable registered operator (ESR/2015/1771).

[2] The Registered Suitable Operators register is available on the Queensland Government website.

DELIVERING FOR QUEENSLAND | Queensland Government

OR

☑ The administering authority has refused your amendment application and requires you to make a site-specific application for a new EA to replace your existing EA.

It is recommended that you have a pre-lodgement meeting about this application:

- Please fill out and lodge the form Application for pre-lodgement services (ESR/2015/1664), prior to lodging this application for an EA.

The fields marked with an asterisk * are mandatory, if they are not completed then your application may be considered not properly made under section 128 of the EP Act.

1 Applicant details

Is there more than one applicant?*	☐ No, please provide applicant's details here. ☒ Yes, please provide the principal applicant's details here and other applicants' details at attachment 1—Joint applicants and appointment of principal applicant
Name—individual or contact person if applicant is an organisation* Alex Clarke	
Organisation name, including any trading name (*if an organisation) Santos Ventures Pty Ltd	ABN/ACN (*if an organisation) 60123982749 / 123982749
Residential or registered business address (not a post office box)* Level 22, Santos Place, 32 Turbot Street, Brisbane, Queensland 4000 AUSTRALIA	ABN/ACN (*if an organisation) Insert.
Residential or registered business address (not a post office box)* Insert.	Phone* (07) 3838 3000
Postal address (if same as above, write "AS ABOVE")* GPO Box 1010 BRISBANE QLD 4001	Facsimile Insert.
Email* alex.clarke@santos.com	☒ *Indicate if you want to receive correspondence via email*

1.1 Nomination of an agent for this application

I/we nominate the below agent to act on my/our behalf and to receive correspondence relating to this application.

Do you want to nominate an agent for this application?* ☒ No → Go to *Question 2*. ☐ Yes → Complete the agent's details here.	
Name of agent—individual or contact person if the agent is an organisation Insert.	
Organisation name, including any trading name (if an organisation) Insert.	ABN/ACN (if an organisation) Insert.

Postal address Insert.	Phone Insert.
Email Insert.	☐ *Indicate if you want to receive correspondence via email*

2 Registered suitable operator status

A suitable operator is a person or a corporation assessed under Part 4, Chapter 5A of the EP Act as being suitable to carry out an ERA and is listed on the suitable operator register[3].

Are all applicants registered as a suitable operator?*	
☒ Yes	Suitable operator reference number* RSO000499 The suitable operator reference number provided must belong to the individual/organisation with the exact same name, DOB or ABN/ACN as the applicant. If there is more than one applicant, include all applicants' suitable operator reference numbers on Attachment 1.
☐ No	You must apply to be a registered suitable operator by completing the form Application to be a suitable registered operator (ESR/2015/1771) . Note: If there is more than one applicant, a separate form must be submitted for each applicant.

3 Details of the activity/activities being applied for

Complete the tables below by advising which activities you are applying for and the locations where they will be conducted.

Resource activity name as it appears in Schedule 3 of the Environmental Protection Regulation 2019 (EP Reg) * **For example, 1—Activities under a GHG injection and storage lease under the GHG storage Act, 3—A petroleum activity that is likely to have a significant impact on a category A or B environmentally sensitive area, 6—A petroleum activity carried out on a site containing a high hazard dam or a significant hazard dam,13—Mining black coal, 16—Mining gold ore**	**Tenure number(s)***
3 – A petroleum activity that is likely to have a significant impact on a category A or B Environmentally Sensitive Area.	PL 1123
Insert.	Insert.
Insert.	Insert.
Insert.	Insert.
Insert.	Insert.
Insert.	Insert.
Insert.	Insert.

[3] The register is available on the Queensland Government website at www.qld.gov.au, using the search term "suitable operator register".

Insert.	Insert.

Insert.	Insert.	Insert.	Insert date.
Insert.	Insert.	Insert.	Insert date.
Insert.	Insert.	Insert.	Insert date.
Insert.	Insert.	Insert.	Insert date.
Insert.	Insert.	Insert.	Insert date.

GPS coordinates (*if known): Insert.
Provide a description of land below or on an attachment e.g. environmental values, bioregions and regional ecosystems, terrain, shallow ground water systems, floodplains, springs and soil descriptions* Refer to Appendix 3 – Supporting Information

☒ I have attached a description of land

5 Details of contaminated land

Is there a site management plan in effect for contaminated land that relates to the land that is the subject of this application?*		
☒ No	Go to *Question* ***Error! Reference source not found.***.	
☐ Yes	Description of land*	
	Lot and plan number(s)	LGA
	Lot Insert.	Plan Insert.
	Lot Insert.	Plan Insert.
	Lot Insert.	Plan Insert.
	Lot Insert.	Plan Insert.
	If you are not able to provide all relevant details above, please attach them to this application and indicate you have done so below: ☐ I have attached the description of the land for which a site management plan is in effect.	

6 Regional interests development approval

A regional interests development approval (RIDA) is required when a resource activity is proposed in an area of regional interest under the *Regional Planning Interests Act 2014*. Further information, including application forms, can be found on the Department of State Development, Infrastructure and Planning (DSDIP) website at https://www.planning.qld.gov.au/planning-issues-and-interests/areas-of-regional-interest.

Is the resource activity located anywhere within an area of regional interest? *	
☐ No	
☒ Yes	Which regional interest area, has or will require a RIDA? ☐ Priority Agricultural Areas (PAAs) ☐ Priority Living Areas (PLAs) ☐ Strategic Environmental Areas (SEAs) ☒ Strategic Cropping Area (SCA) ☐ No RIDA required, I am an exempt activity.
	If you have applied for a RIDA, provide the application reference below: Insert.

7 Environmental offsets

An environmental offset, under the *Environmental Offsets Act 2014*, may be required for an ERA where, despite all reasonable measures to avoid and minimise impacts on certain environmental matters, there is still likely to be significant residual impact on one or more of those matters.

You must verify the presence, whether temporary or permanent, of those environmental matters. For more information refer to the Queensland Environmental Offsets Policy and the Significant Residual Impact Guideline at the Queensland Government website at www.qld.gov.au, using the search term "environmental offsets".

Will the ERA/s being applied for result in a significant residual impact to a matter of State environmental significance (MSES)?*	
☒ No	Go to *Question 8*
☐ Yes	Please attach supporting information that: 1. Details the magnitude and duration of the likely significant residual impact on each prescribed environmental matter (other than matters of local environmental significance) for the entire activity; and 2. Demonstrates that all reasonable measures to avoid and minimise impacts on each of those matters will be undertaken.

7.1 Notice of election

Has a notice of election been submitted to the administering authority, or is being submitted as part of this application?	
☒ No	Go to *Question 7.2*
☐ Yes	You can attach the notice of election, if it has not already been submitted. Go to *Question 7.3*.

7.2 Staged environmental offsets

Offset delivery can be staged, however for this to occur, the condition of any approved EA needs to state that both the activity and the offset may be staged. As part of your notice of election for each stage under the *Environmental Offsets Act 2014*, you are required to provide a detailed assessment of the quantum of impact of that stage and the offset obligation requirement to be delivered for that stage.

Will the proposed activity/activities and delivery of an environmental offset be undertaken in stages?	
☒ No	
☐ Yes	You **must** attach supporting information that details of how the activity/activities are proposed to be staged.

7.3 Nature conservation environmental offset

Has another authority issued under the *Nature Conservation Act 1992* required an environmental offset for the same, or substantially the same, impact and the same, or substantially the same, MSES?	
☒ No	
☐ Yes	Provide permit number: Insert.

7.4 Marine parks environmental offset

Has marine park permit issued under the *Marine Parks Act 2004* required an environmental offset for the same, or substantially the same, impact and the same, or substantially the same, MSES?	
☒ No	
☐ Yes	☐ You **must** attach a copy of the marine park permit to this application.

8 Matters of national environmental significance

There are currently nine matters of national environmental significance (MNES) which have been defined in the *Environmental Protection and Biodiversity Conservation Act 1999 (Cth)* (EPBC Act). These are:

- world heritage properties
- national heritage places
- wetlands of international importance (listed under the Ramsar Convention)
- listed threatened species and ecological communities
- migratory species protected under international agreements
- Commonwealth marine areas
- the Great Barrier Reef Marine Park
- nuclear actions (including uranium mines)
- a water resource, in relation to coal seam gas development and large coal mining development

To determine whether the proposed activity/activities will have a significant impact on MNES and for referral requirements, please refer to the guidance provided by the Federal Government's Department of Agriculture, Water and the Environment on www.environment.gov.au.

Would the carrying out of the proposed activity/activities be likely to have a significant impact on a MNES? *	
☒ No	Go to *Question 9*.
☐ Yes	Has the proposal been referred to the Federal Department of Agriculture, Water and the Environment for formal assessment and approval? ☐ No → Go to *Question 9.* ☒ Yes → Go to *Question 8.1*.

8.1 EPBC Act approval for environmental offsets

Has an approval been issued under the EPBC Act required an environmental offset for the same, or substantially the same, impact and the same, or substantially the same, MSES?	
☒ No	Go to *Question 9*.
☐ Yes	☒ I have attached a copy of the approval under the EPBC Act.
	Are there any MNES which were assessed under the EPBC Act which are the same, or substantially the same as an MSES, but that were not conditioned in the approval? ☒ No → Go to *Question 10*. ☐ Yes → List these MNES: Insert.

9 ANZSIC Code for the activity

The Australian and New Zealand Industrial Classification (ANZSIC) is used by the Australian Bureau of Statistics.

What is the ANZSIC code for the activity?*	
☐ 1101 Black coal mining	☐ 1313 Copper ore mining
☐ 1102 Brown coal mining	☐ 1314 Gold ore mining
☐ 1311 Iron ore mining	☐ 1315 Mineral sand mining
☐ 1312 Bauxite mining	☐ 1316 Nickel ore mining
☐ 1317 Silver-lead-zinc ore mining	☒ 1200 Oil and gas extraction
☐ 1319 Metal ore mining (other metallic mineral ores)	☐ Other Insert.

10 Environmental Impact Statement and Impact Assessment Report under the *State Development and Public Works Organisation Act 1971*

Certain stages of the EA application process may not apply if the proposed activities were assessed as part of a coordinated project (an Environmental Impact Statement (EIS) or Impact Assessment Report (IAR) process) declared by the Coordinator-General under the *State Development and Public Works Organisation Act 1971* (SDPWO Act). You are only required to answer Questions 10.2 to 10.4 if your project is being, or was assessed, as part of a coordinated project under the SDPWO Act.

10.1 Coordinated project status

Has the Coordinator-General declared that the project the subject of this application is a coordinated project for which an EIS or IAR under that Act is required?	
☐ No	Go to *Question 11.*
☐ Yes	What is the name of the project? Insert. Go to *Question 10.2*

10.2 Has the EIS or IAR process been completed?

Has the EIS or IAR process under the SDPWO Act been completed? *		
☐ No	Go to *Question 13.*	
☐ Yes	Was the EIS or IAR completed for all activities that are the subject of this application?	
	☐ No	Please list the activities that were not included in the EIS or IAR or attach documentation with this information to this application: Insert. ☐ I have attached the required supporting information Go to *Question 10.3*
	☐ Yes	Go to *Question 10.3*

10.3 Environmental risks

Have the environmental risks or the way the activity/activities are proposed to be carried out changed since the EIS or IAR was completed?*	
☐ No	Go to *Question 10.4*
☐ Yes	I have attached supporting information. Go to *Question 10.4*

10.4 Coordinator-General's conditions

Are there conditions contained within an evaluation report that relate to the activities being applied for?*	
☐ No	Go to *Question 13.*
☐ Yes	Date Coordinator-General's evaluation report issued: Insert. Lapse date of report: Insert.

11 EIS under the EP Act

Certain stages of the EA application process may not apply if the proposed activities were assessed by EIS under the EP Act.

Note: You do not need to complete this section if you have indicated in Question 10 that the proposed activities are being, or have been assessed by the Coordinator-General as part of an EIS under SDPWO Act.

For this section, if the EIS assessment process for your project is complete please answer Questions 11.1-11.2. If the EIS assessment process has not been completed, please complete Questions 11.3 and 11.4.

Further information about the EIS process is available at www.qld.gov.au using the search term 'environmental impact statements'.

11.1 Completed EIS process

Has an EIS process under Chapter 3 of the EP Act been completed?*		
☐ No	Go to *Question 11.3.*	
☐ Yes	Was the EIS process completed for all activities that are the subject of this application?	
	☐ No	Please list the activities that were not included in the EIS or attach documentation with this information to this application: Insert. ☐ I have attached the required supporting information Go to *Question 11.2*
	☐ Yes	Go to *Question 11.2*

11.2 Environmental risks

Have the environmental risks or the way the activity/activities are proposed to be carried out changed since the EIS was completed?*	
☐ No	Go to *Question 13.*
☐ Yes	I have attached supporting information. Go to *Question 13.*

11.3 Current EIS process

11.3.1 Have you applied for a decision on whether an EIS would be required under the EP Act for an EA application under Part 3, Chapter 3?	
☐ No	*Go to question 11.3.2*
☐ Yes	What was the decision? ☐ EIS would be required. ☐ EIS would not be required Go to *Question 13*

11.3.2 Have you applied to voluntarily prepare an EIS under either Part 2 or Part 3 of Chapter 3 of the EP Act?		
☐ No	*Go to question 12*	
☐ Yes	What was the outcome of the application?	
	☐ Refused	Go to *question 13*
	☐ Approved	Have you submitted a draft TOR to the department? ☐ Yes Insert date of submission ☐ No Go to *Question 13*
		Do you intend to prepare an EIS under chapter 3, EP Act? ☐ Yes ☐ No Go to *Question 13*

12 EIS criteria

The information provided here will assist in determining whether an EIS (under the EP Act) is required. If your response to any question is yes, you must attach details of how the criterion is triggered including details of the impact. You do not need to fill this out if you have an approval to voluntarily prepare an EIS under Part 2 or Part 3 of Chapter 3 or received a decision that an EIS would not be required for an EA application for this application under Part 3, Chapter 3 **OR** if you have indicated in question 10 that the proposed activities are being or have been assessed by the Coordinator General as part of an EIS for a coordinated project. For further information refer to the guideline Criteria for environmental impact statements for resource projects under the *Environmental Protection Act 1994* (ESR/2016/2167).

#	**Criteria—EIS triggers (*if applicable)** **This question is not applicable if an EIS process under either the SDPOW Act or the EP Act has been completed for all the activities that are the subject of this application, and the environmental risks of the activities and the way they are proposed to be carried out has not changed since the EIS was completed.**	**Response**
	*Questions 12.1-12.3 are mandatory for **mining activities only**. If your proposed activity/activities is not a mining activity, tick N/A and proceed to *Question 12.4*.	☐ N/A
12.1*	Is the ERA project for a mining activity which involves the removal of two million tonnes/year or more of run-of-mine (ROM)[4] ore or coal?	☐ YES ☐ NO
12.2*	Is the ERA project for a mining activity that involves the removal of 1 million tonnes per year or more of run-of-mine (ROM) ore or coal on or under a floodplain or a coastal hazard area?	☐ YES ☐ NO
12.3*	Is the ERA project for a mining activity which involves the introduction of a novel or unproven resource extraction process, technology or activity[5]?	☐ YES ☐ NO
	*Questions 12.4-12.6 are mandatory for **petroleum and gas activities only**. If your proposed activity/activities is not a petroleum and gas activity, tick N/A and go to Question 0.	☐ N/A
12.4*	Is the ERA project for a petroleum and gas activity that is likely to have a total disturbance area of greater than 2000 hectares at any one time during the life of the proposed project? This includes areas occupied by well pads (single or multi-directional), access tracks and roads, water storages, and process plants?	☐ YES ☐ NO
12.5*	Is the ERA project for a petroleum and gas activity that is likely to involve the construction of a high pressure pipeline over a distance of 300 kilometres or greater?	☐ YES ☐ NO
12.6*	Is the ERA project for a petroleum and gas activity that is likely to involve the construction of a liquefied natural gas plant?	☐ YES ☐ NO
☐ I have attached details of how the criterion is triggered including details of the impact.		
There are numerous criteria used to make the EIS decision. Further information about the EIS process is available at www.qld.gov.au using the search term 'environmental impact statements'.		

[4] ROM ore or coal means the material excavated but prior to washing or chemical concentration. It does not include overburden.

[5] For example: underground coal gasification; in-seam coal slurrying; a new method of ore concentration. This will be decided on a case-by-case basis and this trigger is not intended to discourage innovation.

13 Progressive rehabilitation and closure plan (PRC plan) under the EP Act

Is this application for a new site-specific EA for a mining activity relating to a mining lease? *

☒ No

☐ Yes

If yes, this application **must** be accompanied by a PRC plan complying with 126C and submitted in the approved form unless:

- In relation to an EIS process under EP Act:
    - the administering authority has approved the voluntary preparation of an EIS under Part 2 or Part 3, Chapter 3 of the EP Act and the EIS has started (draft Terms of Reference submitted), or you stated in this application (question 11.3.2) that an EIS will be prepared; OR
    - The Department has made a decision that an EIS is required for this application under Part 3, Chapter 3 of the EP Act; OR
- In relation to an EIS process under SDPWO Act:
    - The Coordinator-General has declared that the project the subject of this application is a coordinated project for which an EIS is required.

In the above circumstances, the intention is for the PRC plan to be provided in the EIS. Following the EIS assessment process, the PRC plan should be formally lodged in the approved form.

The approved form for Submission of a progressive rehabilitation and closure plan (ESR/2019/4957) can be obtained here.

14 Assessment of the environmental impact

This question is **not applicable if any** of the following apply. If relevant, please tick which scenario is relevant to your project:

In relation to an EIS process under SDPWO Act:

☐ an EIS process has been completed for all the activities that are the subject of this application **and** the environmental risks of the activities and the way they are proposed to be carried out has not changed since the EIS was completed.

OR

☐ the Coordinator-General has declared that the project the subject of the application is a coordinated project for which an EIS under that Act is required.

OR

In relation to an EIS process under EP Act:

☐ an EIS process has been completed for all the activities that are the subject of this application **and** the environmental risks of the activities and the way they are proposed to be carried out has not changed since the EIS was completed.

OR

☐ an application to the chief executive to decide if an EIS was required for an EA application for the application was approved (Chapter 3, Part 3)

OR

☐ chief executive approved application to voluntarily prepare an EIS under either Part 2 or Part 3 of Chapter **and either**

- Proponent has submitted a draft TOR

  OR

  You stated in question 11.3.2 of this form that you (the applicant) intend to prepare an EIS under chapter 3, EP Act.

You must attach to this application an assessment of the likely impact of each ERA on environmental values (*if applicable), including:

- a description of the environmental values likely to be affected by each relevant activity
- details of any emissions or releases likely to be generated by each relevant activity
- a description of the risk and likely magnitude of impacts on the environmental values
- details of the management practices proposed to be implemented to prevent or minimise adverse impacts
- if you answered 'No' to Question 0, details of how the land the subject of the application will be rehabilitated after each relevant activity ceases

☒ I have attached an assessment of the environmental impact and specific supporting information.

15 Details of waste management

Describe the proposed measures for minimising and managing waste generated by the activity/activities below or on an attachment*
Refer to Appendix 3 – supporting information

☐ I have attached the proposed measures.

16 Coal seam gas activities

This question is **not applicable if** an EIS process under the SDPWO Act has been completed for all the activities that are the subject of this application **and** the environmental risks of the activities have not changed since the EIS was completed.

<table>
<tr><th colspan="3">Does the application relate to coal seam gas (CSG) activities? (*if applicable)</th></tr>
<tr><td>☐ No</td><td colspan="2">You will not be authorised to undertake CSG activities. Go to Question 17.</td></tr>
<tr><td rowspan="3">☒ Yes</td><td colspan="2">Will CSG water be generated by the proposed activities? (*if applicable)</td></tr>
<tr><td colspan="2">☐ No</td></tr>
<tr><td>☒ Yes</td><td>You must attach documentation detailing:
the quantity of CSG water the applicant reasonably expects will be generated in connection with carrying out each relevant CSG activity; and
the flow rate at which the applicant reasonably expects the water will be generated; and
the quality of the water, including changes in the water quality the applicant reasonably expects will happen while each relevant CSG activity is carried out; and
the proposed management of the water including, for example, the use, treatment, storage or disposal of the water; and
the measurable criteria (the management criteria) against which the applicant will monitor and assess the effectiveness of the management of the water, including, for example, criteria for each of the following:
(i) the quantity and quality of the water used, treated, stored or disposed of
(ii) protection of the environmental values affected by each relevant CSG activity
(iii) the disposal of waste, including, for example, salt, generated from the management of the water; and</td></tr>
</table>

		• the action proposed to be taken if any of the management criteria are not complied with. This will also need to include actions to make sure that the management criteria will be able to be complied with in the future; and • whether the proposed management of the CSG water is consistent with the Coal Seam Gas Water Management Policy 2012 (ESR/2016/2381), including the prioritisation hierarchy for managing and using CSG water; or • if the proposed management of the coal seam gas water is inconsistent with the prioritisation hierarchy for managing and using CSG water—the reason for managing the CSG water in the proposed way.
	Will brine or salt be generated by the proposed activities? (*if applicable)	
	☐ No	
	☒ Yes →	You **must** attach documentation detailing: • whether the proposed management of the salt or brine is consistent with the Coal Seam Gas Water Management Policy 2012 (ESR/2016/2381) including the prioritisation hierarchy for managing saline waste; or • if the proposed management of the salt or brine is inconsistent with the prioritisation hierarchy for managing saline waste—the reason for managing the salt or brine in the proposed way.
	Is a CSG evaporation dam proposed in connection with carrying out the CSG activity? (*if applicable)	
	☒ No	
	☐ Yes →	You **must** attach documentation detailing: (a) an evaluation of best practice environmental management for managing the CSG water; and (b) an evaluation of alternative ways for managing the water; and (c) how the evaluation demonstrates that there is no feasible alternative to a CSG evaporation dam for managing the water.
☐ I have attached the documentation to support all 'Yes' responses provided above.		

17 Exercising underground water rights

Underground water rights provide the tenure holder with a statutory right to take or interfere with underground water in the area of the tenure if the taking or interference with that water is necessarily and unavoidably obtained in the process of extracting the resource.

For more information about exercising underground water rights or the associated application requirements please refer to the guideline Requirements for site-specific and amendment applications-underground water rights (ESR/2016/3275).

If the activity/activities are proposed to be undertaken on a mineral development licence (MDL), mining lease (ML) or petroleum lease (PL), does the application propose to exercise underground water rights?*	
☐ N/A	The proposed activity/activities are not on a MDL, ML or PL. Go to *Question 18*.
☐ No	Go to *Question 18*.
☒ Yes	You **must** attach documentation detailing: • the areas in which underground water rights are proposed to be exercised; • for each aquifer affected, or likely to be affected, by the exercise of underground water rights: (i) a description of the aquifer; (ii) an analysis of the movement of underground water to and from the aquifer, including how the aquifer interacts with other aquifers and surface water; and (iii) a description of the area of the aquifer where the water level is predicted to decline because of the exercise of underground water rights; and (iv) the predicted quantities of water to be taken or interfered with because of the exercise of underground water rights during the period in which resource activities are carried out; • the environmental values that will, or may, be affected by the exercise of underground water rights and the nature and extent of the impacts on the environmental values; • any impacts on the quality of groundwater that will, or may, happen because of the exercise of underground water rights during or after the period in which resource activities are carried out; and • strategies for avoiding, mitigating or managing the predicted impacts on the environmental values or the impacts on the quality of groundwater.
☒ I have attached all relevant supporting documentation.	

18 Publication of application notice and documents

This question is only applicable if you are proposing to undertake a mining activity on a mining lease, or a geothermal, petroleum or greenhouse gas storage activity.

As the applicant, you may be required to make the application notice, application documents and the response to any information requests available on a website during the public notification period. By providing a website address below, you give permission for the administering authority to link to your website during the public access period.

What is the website address for the application notice and application documents (*if applicable)?		
https://www.santos.com/about-us/corporate-governance/public-notices/		
Details of contact person if technical assistance is required:		
Name: ALEX CLARKE	Phone: (07) 3838 3000	Email: ALEX.CLARKE@SANTOS.COM

19 Payment of fees

You are required to pay an application fee at the time of application. If your application is approved you will be required to pay a fee annually. Each ERA has a regulated fee and the annual fee will be the highest annual fee of any ERA associated with the project. The first annual fee will be invoiced when one or more of the tenures are granted. Information on fees is available on Forms and fees for environmental authorities | Business Queensland and in the information sheet Summary of fees for environmentally relevant activities (ESR/2015/1746).

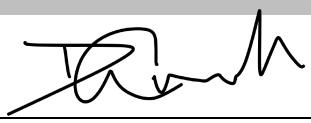
The application fee is:	$36248.20

Preferred

☐ Apply using Online Services – submit the application online and pay by credit card.

Alternatively

☒ Email the completed application with a request to pay the application fee by Bpoint. Please do not email your credit card details – we will send you a link to pay securely by credit card via BPoint.



For more information on payment options go to the Business Queensland website at www.business.qld.gov.au and search 'Forms and fees for mining and resources'.

20 Applicant declaration

I declare that the information I have provided is true and correct. I understand that it is an offence under the EP Act to give information that I know is false, misleading or incomplete.

I will comply with all conditions on my EA as well as any relevant provision in the EP Act.

I understand that I am responsible for managing the environmental impacts of these activities, and that approval of this application is not an endorsement by the administering authority of the effectiveness of the management practices proposed or implemented.

Applicant's full name*	**Applicant's position (*if an organisation)**
DAVID GORNALL	Manager Environment EA PNG, Eastern AU & PNG EHSR
Applicant's signature*	**Date***
	30/01/26

21 Important note: Estimated rehabilitation cost (ERC)

It is a condition of all environmental authorities for resource activities, under section 297 of the EP Act, that the holder must not carry out, or allow the carrying out of, a resource activity under the authority unless an ERC decision is in effect, and the holder has paid scheme assurance and complied with the requirements under the *Mineral and Energy Resources (Financial Provisioning) Act 2018* for paying this assurance. If your application for an EA is approved, you must lodge a separate application for an ERC decision either using Online Services[6]or by submitting the approved form Application for a decision on the estimated rehabilitation cost (ESR/2018/4426). For further information regarding the estimated rehabilitation cost, refer to the guideline Estimated rehabilitation cost under the *Environmental Protection Act 1994* (ESR/2018/4425).

[6] Certain applications to the Department can be made using Online Services. For more information and to register to use Online Services go to https://business.qld.gov.au/running-business/environment/online-services.

Submitting your completed application

Submit your completed application (in word searchable electronic PDF format) via email to palm@detsi.qld.gov.au or:

Privacy statement

The Department of the Environment, Tourism, Science and Innovation (the Department) and the Department of Natural Resources and Mines, Manufacturing, and Regional and Rural Development are collecting the information on this form in accordance with and as authorised by Chapter 5 of the EP Act.

Pursuant to section 540 of the EP Act, the Department is required to maintain a register of certain documents and information authorised under the EP Act. A copy of this document will be kept on the public register. The register is available for inspection by members of the public who are able to take extracts, or copies of the documents from the register. Documents that are required to be kept on the register are published in their entirety, unless alteration is required by the EP Act. There is no general discretion allowing the Department to withhold documents or information required to be kept on the public register. For more information on the Department's public register, search 'public register' at www.qld.gov.au. For queries about privacy matters please email privacy@detsi.qld.gov.au or telephone 13 74 68.

1.0 Introduction and Legislative Requirements

Santos Ventures Pty Ltd (Santos), on behalf of its joint venture (JV) partners TotalEnergies EP Australia II, KGLNG E&P Pty Ltd, TotalEnergies EP Australia and PAPL (Upstream) Pty Limited (the proponents) are applying for a new site-specific Environmental Authority (EA) to authorise petroleum production operations on proposed Petroleum Lease (PL) 1123. Santos is the principal applicant. PL 1123 will wholly replace all existing blocks of Authority to Prospect (ATP) 2053, which is an existing exploration tenure operated by Santos.

Santos proposes to develop PL 1123 as part of the Santos Roma Phase 7-7B-SD20 Development (Project). The Project will involve the progressive construction, operation, decommissioning and rehabilitation of up to 24 Coal Seam Gas (CSG) wells and associated infrastructure located in PL 1123 (the Project Area). Further detail on the proposed activities is provided in Section 2.2.

Further, the Project has been referred to the Commonwealth Department of Climate Change, Energy, the Environment and Water (DCCEEW) for assessment under the requirements of the *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act).

The title holders of PL 1123 are:

- Santos Ventures Pty Ltd (ABN: 60 123 982 749)
- PAPL (Upstream) Pty Limited (ABN: 58 131 318 888)
- TotalEnergies E&P Australia (ABN: 96 832 035 151)
- TotalEnergies E&P Australia II (ABN: 52 149 617 167); and
- KGLNG E&P Pty Ltd (ABN: 31 146 143 339).

This document has been prepared in accordance with Sections 125, 126 and 126A of the *Environmental Protection Act 1994* (EP Act) and the Department of Environment, Tourism, Science and Innovation's (DETSI) *Guideline - Application requirements for petroleum activities* (ESR/2016/2357, Version 4.01). Refer to Section 1.2 for legislative requirements.

1.1 Background

The Project Area is located approximately 43 kilometres (km) east of the town of Roma and 5km east of the town of Wallumbilla in southern inland Queensland (refer to Figure 1).

PL 1123 (Project Area) is bounded on all sides by existing Santos operated tenues, including PLs 281, 282, 315, 318 and 1020 (as shown in Figure 1). Santos has undertaken extensive exploration, appraisal and production activities on adjacent tenures including PLs 281, 282, 315, 318 and 1020, which has supported proving the prospectivity of the Project Area.

Petroleum activities on the abovementioned adjacent tenures are authorised under existing EPBC Act approval decisions for the Gladstone Liquified Natural Gas Field Development Project (GLNG GFD) (EPBC approval numbers 2008/4059 and 2012/6615). Further, petroleum activities undertaken on PLs 281 and 282 are authorised under the *Environmental Protection Act 1994* (EP Act) via the Roma Shallow Gas Project Area East (RSGPAE) EA EPPG00662213, and petroleum activities undertaken on PLs 314, 315, 318 and 1020 are authorised under the Roma Shallow Gas Project Area (RSGPA) EA EPPG00898213.

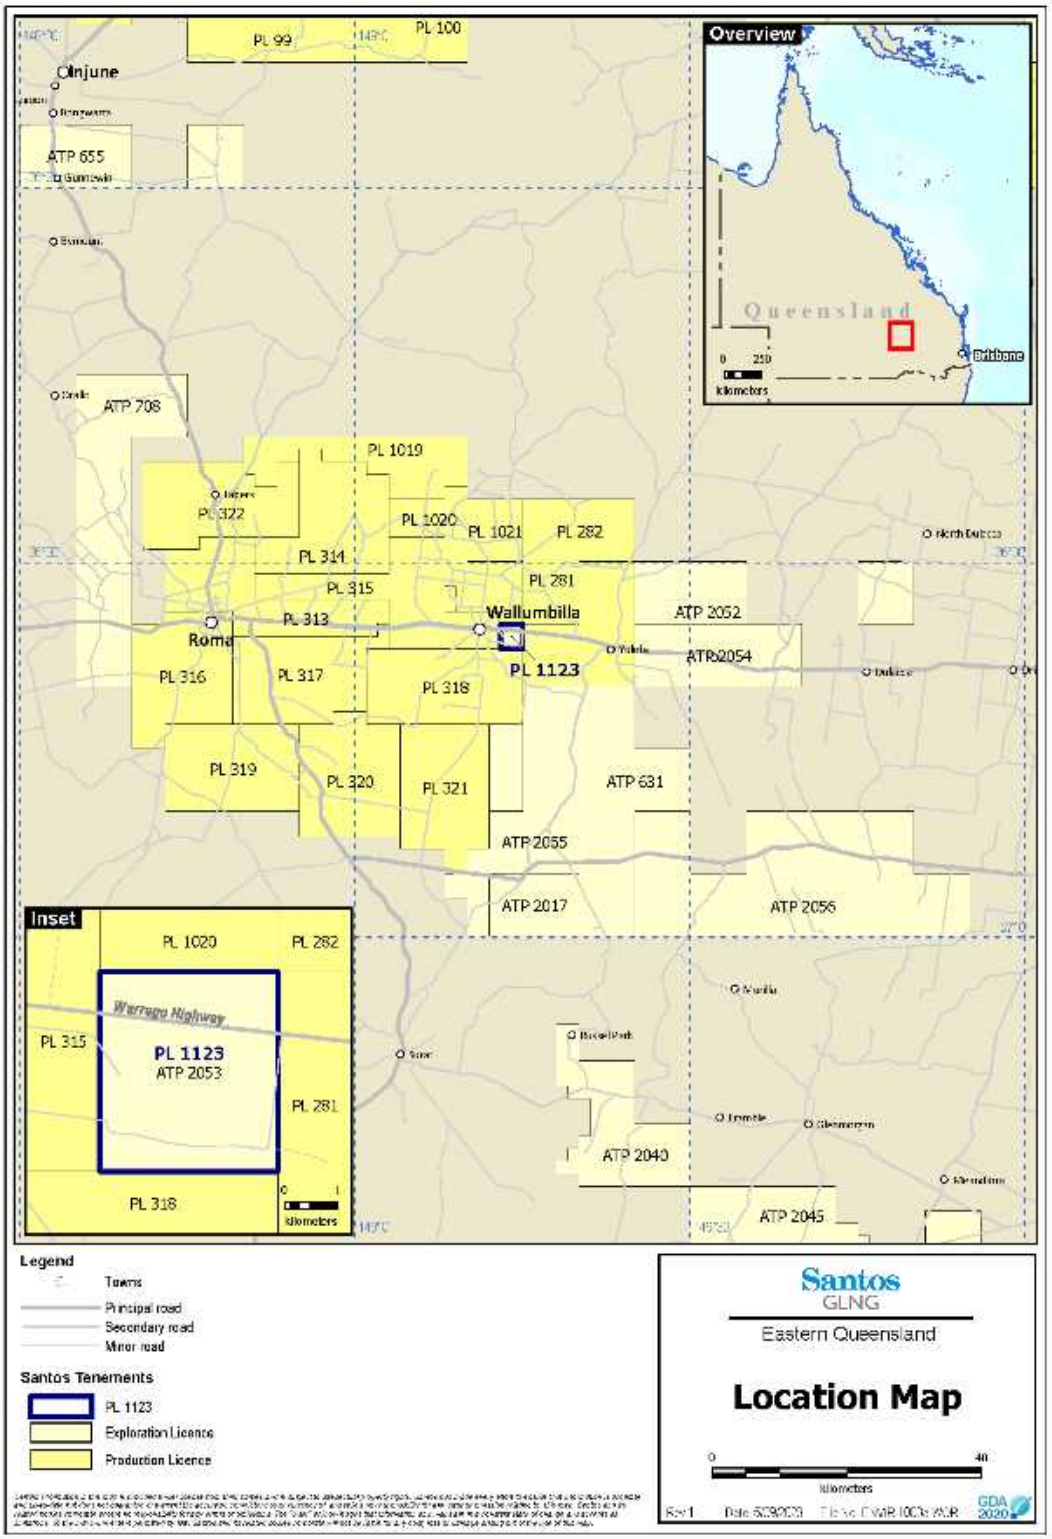

Figure 1: PL 1123 – Regional Location Map – (PL 1123)

1.2 Legislative Requirements

1.2.1 Environmental Protection Act 1994 (EP Act)

1.2.1.1 General Requirements for an EA application (s125 EP Act)

Section 125 of the EP Act specifies the general requirements for an EA application. These are addressed in Table 1.

Table 1: General requirements for an EA application (s125 EP Act)

Section 125 of the EP Act	Relevance to Application
(a) be made to the administering authority	This EA application has been submitted to DETSI who is the administering authority for the EP Act.
(b) be made in the approved form	The application was made using the approved form.
(c) describe all environmentally relevant activities for the application	Refer to Section 2.4.
(d) describe the land on which each activity will be carried out	Refer to Section 3.0.
(e) be accompanied by the fee prescribed under a regulation	The prescribed fee was paid at the time of submission.
(f) if 2 or more entities (joint applicants) jointly make the application—nominate 1 joint applicant as the principal applicant	The approved form nominates the principal applicant.
(g) state whether the application is— *(i) a standard application; or* *(ii) a variation application; or* *(iii) a site-specific application;*	The application is a site-specific application.
(h) state whether the applicant is a registered suitable operator	The approved form identifies the registered suitable operators.
(i) if a development permit under the Planning Act, or an SDA approval under the State Development Act, is required under either of those Acts for carrying out the environmentally relevant activities for the application—describe the permit or approval	N/A – there are no relevant approvals under the Planning Act or State Development Act.
(j) if the application is a standard or variation application—include a declaration that each relevant activity complies with the eligibility criteria	N/A
(k) if the application is a variation application—	N/A

Section 125 of the EP Act	Relevance to Application
(i) for a variation application under section 123(1)—state the standard conditions for the activity or authority the applicant seeks to change; or *(ii) for a variation application under section 123(2)—state the standard conditions that are not the same as the Coordinator-General's conditions;*	
(l) if the application is a variation or site-specific application— *(i) include an assessment of the likely impact of each relevant activity on the environmental values, including—* *(A) a description of the environmental values likely to be affected by each relevant activity;*	Refer to Section 4.0.
(B) details of any emissions or releases likely to be generated by each relevant activity;	Refer to Sections 4.0 and 5.0.
(C) a description of the risk and likely magnitude of impacts on the environmental values;	Refer to Sections 4.0 and 5.0.
(D) details of the management practices proposed to be implemented to prevent or minimise adverse impacts;	Refer to Sections 4.0 and 5.0.
(E) details of how the land the subject of the application will be rehabilitated after each relevant activity ceases;	Refer to Section 4.9.
(ii) include a description of the proposed measures for minimising and managing waste generated by each relevant activity;	Refer to Section 4.8.
(iii) include details of any site management plan that relates to the land the subject of the application;	N/A
(m) if the application is for a prescribed ERA—state whether the applicant wants any environmental authority granted for the application to take effect on a day nominated by the applicant; and	N/A
(n) if the application is a site-specific application for a mining activity relating to a mining lease—be accompanied by a proposed PRC plan; and	N/A

Section 125 of the EP Act	Relevance to Application
(o) include any other document relating to the application prescribed under a regulation	Refer to Sections 4.8.1 and 4.8.2, and the information throughout this document.

1.2.2 Requirements for site specific applications – CSG activities (s126 and 126A EP Act)

Section 126 of the EP Act specifies the requirements for a site-specific application for CSG activities. These are addressed in Table 2.

Section 126A of the EP Act specifies requirements for site-specific applications for resource activities which involve the exercise of underground water rights. These requirements are addressed in section 4.6.2.

Table 2: Requirements for CSG activities (s126 EP Act)

Section 126(1) and (2) of the EP Act	Relevance to Application
(1) A site-specific application for a CSG activity must also state the following— *(a) the quantity of CSG water the applicant reasonably expects will be generated in connection with carrying out each relevant CSG activity;*	The total estimated groundwater abstraction volume for the duration of the Project (with an expected operational life of 30-50 years) is estimated to be 645 ML (KCB, 2025).
(b) the flow rate at which the applicant reasonably expects the water will be generated;	Peak water production is predicted to occur in January 2028 at 0.24 ML/day (7.12 ML/month).
(c) the quality of the water, including changes in the water quality the applicant reasonably expects will happen while each relevant CSG activity is carried out;	Refer to Section 4.8.1.
(d) the proposed management of the water including, for example, the use, treatment, storage or disposal of the water;	Refer to Section 4.8.1.
(e) the measurable criteria (the management criteria) against which the applicant will monitor and assess the effectiveness of the management of the water, including, for example, criteria for each of the following— *(i) the quantity and quality of the water used, treated, stored or disposed of;*	Refer to Section 4.8.1 and Table 25.
(ii) protection of the environmental values affected by each relevant CSG activity;	Refer to Section 4.8.1 and Table 25.

Section 126(1) and (2) of the EP Act	Relevance to Application
(iii) the disposal of waste, including, for example, salt, generated from the management of the water;	No produced water (PW) treatment or disposal of waste products from the treatment of water would occur in the Project Area. With the exception of small volumes of PW to be stored in temporary portable tanks in the Project Area, the majority of PW from the Project Area is proposed to be gathered to the Pickanjinnie and/or Raslie Dams (located on adjacent PL 315). PW from Pickanjinnie / Raslie Dams will then be transferred to the existing water management / processing facilities located on PL 314 (Hub 2) to be processed. On PL 314, the water will be processed through a fines and sludge removal facility before being further processed, or bypassed around, the Roma Reverse Osmosis Plant (ROP) to meet re-use criteria in accordance with *End of Waste Code Irrigation of Associated Water (including coal seam gas water) (ENEW07546918, Version 1.07)* (DETSI, 2025a). Petroleum activities undertaken on PLs 314 and 315 are authorised under existing the Santos EA EPPG00898213 (RSGPA) (refer to Section 4.8.1 for further detail).
(f) the action proposed to be taken if any of the management criteria are not complied with, to ensure the criteria will be able to be complied with in the future.	In the event that any management criteria are not complied with, works/operations that potentially cause the non-compliance would be assessed (and paused if appropriate) and an investigation would commence to identify why the non-compliance has occurred, the effectiveness of existing controls, new controls to be applied where appropriate and any remedial actions to be taken.
(2) The proposed management of the water can not provide for using a CSG evaporation dam in connection with carrying out a relevant CSG activity unless *(a) the application includes an evaluation of—* *(i) best practice environmental management for managing the CSG water; and* *(ii) alternative ways for managing the water; and* *(b) the evaluation shows there is no feasible alternative to a CSG evaporation dam for managing the water.*	As discussed in Section 2.2, for the purposes of efficiency and to minimise land disturbance in the Project Area, gas and PW generated from the Project Area will utilise existing centralised water and gas processing facilities (including compression stations) located on adjoining RSGPA tenures (authorised under EA EPPG00898213). PW is proposed to be transferred to existing approved dams located on adjacent tenures. PW from these dams is then proposed to be transferred to existing approved water treatment facilities located on PL 314, where the water will be processed through a fines and sludge removal facility before being further processed, or bypassed around, the Roma Reverse Osmosis Plant (ROP) to meet re-use criteria in accordance with *End of Waste Code Irrigation of Associated Water* (ENEW07546918, Version 1.07) (DETSI, 2025a). The Roma ROP is located approx. 25 km northwest of the Project Area. Adequate water and brine storage and treatment capacity has been assessed to be available

Section 126(1) and (2) of the EP Act	Relevance to Application
	on adjacent tenures to manage peak water and brine production from the Project. Integration with the RSGPA activities will negate the requirement to locate large water management facilities within the Project Area. Accordingly, this will result in less major infrastructure being required to be located in the Project Area, which will minimise disturbance to remnant native vegetation and assist in minimising disruption to existing land uses i.e. cropping and grazing land. This arrangement represents the best practice environmental management for managing the CSG water and no feasible alternative arrangement is deemed otherwise suitable for the proposed activities. Small volumes of PW may be stored within the Project Area in portable tanks. A proportion of PW stored in tanks on site will be used for on-site activities such as water supply for drilling and hydraulic fracturing purposes, and/or to provide a water source for dust suppression / construction activities (where the water use meets proposed EA conditions and criteria). Approximately 158 ML of water will be required to develop the Project (this represents ~24% of estimated PW volume). Adequate water and brine storage and treatment capacity has been assessed to be available on adjacent tenures to manage peak water and brine production from the Project. Refer to Section 4.8.1 for further detail on produced water management.

1.2.3 Standard Criteria for Decision (s176 EP Act)

Section 176 of the EP Act requires the administering authority, in deciding a variation or site-specific EA application, to consider any relevant regulatory requirements having regard to:

a) the application
b) the standard conditions for the relevant activity or authority
c) any response given for an information request
d) the standard criteria.

The standard criteria (as defined by Schedule 4 of the EP Act) are required to be considered by the administering authority for deciding an application. Refer to Table 3 for consideration of the standard criteria.

The relevant regulatory requirements are contained in section 35 and schedule 8 of the *Environmental Protection Regulation 2019*. These regulatory requirements are addressed in Schedule G.

Proposed EA conditions are attached as Appendix A.

Table 3: Standard Criteria (EP Act)

Schedule 4 EP Act	Relevance
a) the following principles of environmental policy as set out in the Intergovernmental Agreement on the Environment – *(i) the precautionary principle;* *(ii) intergenerational equity;* *(iii) conservation of biological diversity and ecological integrity; and*	The precautionary principle was considered for the application. It is considered that the proposed activities will use 'proven' technology and sufficient scientific data exists that a reverse onus does not exist. The principle of intergenerational equity was considered for the application. It is considered that the proposed activities would not impact the use of environmental values by future generations. The principles of conservation of biological diversity and ecological integrity were considered for the application. The proposed application would not result in impacts to biological diversity or ecological integrity.
b) any Commonwealth or State government plans, standards, agreements or requirements about environmental protection or ecologically sustainable development	The proposed petroleum activities will be undertaken in accordance with the applicable requirements of the following: • EP Act; • *Environment Protection and Biodiversity Conservation Act 1999* (Cth); • *Nature Conservation Act 1992* (Qld); • *Vegetation Management Act 1999* (Qld); • *Environmental Offsets Act 2014* (Qld); • *Fisheries Act 1994* (Qld); and • *Planning Act 2016* (Qld).
d) any relevant environmental impact study, assessment or report	Not applicable – there is no environmental impact study relevant to this application.
e) the character, resilience and values of the receiving environment	Refer to Sections 3.0 to 4.0.
f) all submissions made by the application and submitters	Where required by DETSI, Santos would consider any submissions made on the application.
g) Best Practice Environmental Management (BPEM) for activities under any relevant instrument, or proposed instrument, as follows- *(i) an environmental authority;* *(ii) a transitional environmental program;* *(iii) an environmental protection order;* *(iv) a disposal permit;* *(v) a development approval;*	BPEM of the petroleum activities would be achieved through compliance with the scheduled environmental objectives and proposed conditions of the new EA. Potential impacts to any environmental value will be managed in accordance with the proposed EA conditions as well as the Santos Management System.
h) Financial implications of the requirements under an instrument, or proposed instrument, mentioned in paragraph (g) as they would relate to the type of activity or industry carried out, or	Santos will continue to provide adequate funds, equipment and staffing to comply with the conditions of the amended EA.

Schedule 4 EP Act	Relevance
proposed to be carried out under the instrument;	
i) Public Interest	The proposed EA is considered to be in the public interest. It will facilitate the ongoing production of gas to meet the needs of customers in Queensland and other Australian states / territories, and export markets in Asia and assist in the reduction of fossil fuel emissions by acting as a transitional fuel between coal and renewable energy whilst still maintaining published environmental objectives. Resources produced by Santos will generate taxes and royalties to the Queensland State Government, which provide an ongoing source of revenue to support Government services provided to the general public. Furthermore, in Australia and Queensland, gas plays an important role in domestic energy security and diversification, supporting intermittent renewable energy sources. Santos is a major supplier of natural gas to the domestic energy market, and has operated in Queensland for over 50 years and we're proud of the economic and social benefits being delivered by the projects in the Coopers, Surat and Bowen basins. One such project is the GLNG-GFD Project, which is led by Australian company Santos, in partnership with three of the world's leading energy companies – PETRONAS from Malaysia, Total from France, and KOGAS from South Korea. This project is a pioneering venture which produces natural gas from Queensland's coal seams and converts it into LNG. It involves ongoing gas field development in the Surat and Bowen Basins, a 420-kilometre gas transmission pipeline and a two-train LNG plant on Curtis Island, near Gladstone which has the capacity to produce 7.8 million tonnes of LNG per year. Santos GLNG is at the forefront of making Australia a world-leading LNG producer and will be worth billions of dollars to the Queensland and national economies over many decades. The billions to be paid in royalties will help pay for government frontline services across Queensland. It's one way the GLNG project is bringing renewed opportunities to Queensland. Project construction began in 2011 with the first shipment of LNG in October 2015. The project has taken more than 95 million work hours to date. More than 10,000 people have worked on the project which saw more than $15 billion invested Australia-wide, including $8 billion in Queensland alone of which $710 million was to the Maranoa, Toowoomba and Western Downs districts.

Schedule 4 EP Act	Relevance
	To ensure the delivery of commitments to the domestic and export markets Santos is in the process of optimising activities on existing tenements, along with the active expansion of new fields. This includes the Santos GLNG Project and the Gas Field Development Project which is not a new activity but an extension of the existing work being undertaken by Santos GLNG. One area of expansion is the Roma field which covers approximately 3,000 km^2. Sales gas from the Roma field is transported by pipeline to Gladstone, where it is converted into LNG for export to overseas markets. The major Roma Hub compression facility can produce 145 TJ of gas per day with ongoing development and compression capacity, such as this project, to add to production rates. Santos is committed to meaningfully contributing to the future strength and prosperity of the communities where we operate, building deep, long-lasting relationships with positive intergenerational benefits. We do this through implementing our community investment framework and by providing employment, training, education and enterprise opportunities associated with our industry. As a socially responsible company, our investment in local communities is part of our broader commitment to minimising the impact of our project activities and supporting programs and initiatives that benefit those who live in the areas where we operate. The GLNG community handbook which is a summary of the Santos GLNG Social Impact Management Plan (SIMP) as developed to explain the possible social impacts of our activities and what we are doing about them. Our objective is to work proactively and collaboratively with our host landholders and landowners across all areas of operation. We have a long history of strong and supportive landholder relationships in which we seek to support and enable long-term and intergenerational resilience. We are committed to working with Traditional Owners / clans and Indigenous communities to ensure they are fully informed prior to accessing land and address any issues raised promptly and transparently. We are proud to apply best practice in the assessment, identification and protection of cultural heritage and seek to identify suitable commercial opportunities for Indigenous businesses, as well as opportunities to employ and upskill Indigenous people. Santos recognises the scientific consensus of climate change assessed by the Intergovernmental Panel on Climate Change. We support the objective of the Paris Agreement to limit global temperature

Schedule 4 EP Act	Relevance
	rise to less than 2 degrees Celsius and pursue efforts to limit the temperature rise to 1.5 degrees Celsius. We believe that access to reliable and affordable energy is critical to meeting sustainable development goals and improving living standards and economic prosperity in developed and developing nations. Santos is committed to being part of the solution by supporting the twin objectives of limiting greenhouse gas emissions and providing cleaner fuels to domestic and global markets. Santos has a target of net-zero scope 1 and 2 greenhouse gas emissions by 2040. Our strategy focuses on natural gas as a reliable transition fuel source, and the development of technologies such as clean fuels like hydrogen as the foundation for our decarbonisation pathway. The application is in the public interest.
j) Any relevant site management plan	There are no SMPs applicable to the application.
k) Integrated environmental management system (IEMS) or proposed IEMS	The Santos Management System (SMS) will be implemented for the proposed activities.
l) Other matters prescribed under a regulation	The *Environmental Protection Regulation 2019* prescribes an environmental objective assessment relating to an environmental management decision as an additional matter for the standard criteria. This document has been prepared giving consideration to the above, and Sections 1.0 to 4.0 address the matters raised in the environmental objective assessment.

2.0 Application Description

This application is for a new site-specific EA to authorise petroleum activities under Section 109 of the *Petroleum and Gas (Production and Safety) Act 2004* on PL 1123 once granted. Santos applied for PL 1123 on 16 September 2022.

2.1 Existing Activities

Petroleum exploration activities currently undertaken on ATP 2053 (being proposed PL 1123) are authorised by EA 0002052. Exploration and appraisal activities undertaken by Santos on ATP 2053 to date include:

- drilling, completion and appraisal of 5 CSG wells (RM23-21-1, RM23-43-1, RM23-42-1, RM23-41-1 and RM23-46-1); and
- construction and operation of associated linear infrastructure (gas and water gathering lines, access tracks, power and communications lines).

This application considers total impacts and disturbances associated with 24 existing and proposed CSG wells (i.e. the existing 5 CSG wells form part of the proposed 24 CSG well development). Figure 2 outlines existing (and proposed) infrastructure locations in PL 1123.

2.2 Proposed Activities

The proposed development will initially include:

- progressive drilling (including hydraulic fracture stimulation), completion, and connection of up to 24 CSG exploration, appraisal, and development wells (with some multi-well leases)
- construction and operation of associated linear infrastructure (gas and water gathering lines, access tracks, power and communications lines). This infrastructure will be co-located wherever feasible, and will consist of:
    - buried gas and water gathering lines (these are typically co-located with power and communication lines); and
    - access tracks (typically co-located with gas and water gathering infrastructure) comprised of both new access tracks and the upgrade of existing access tracks.
- tie in of the existing wells to gas and water gathering lines to begin production; and
- other ancillary / incidental activities in support of the above activities.

No compression facilities are proposed, and no regulated structures will be required as part of the proposed activity.

Other activities proposed to be undertaken in the Project Area under the EA include but are not limited to construction and/or operation of the following:

- seismic surveys
- gas and water gathering systems / flowlines / pipelines
- powerlines and communication lines (above and/or below ground)

- access tracks and roads
- small-scale water management infrastructure i.e. portable tanks.
- a temporary worker's camp including a sewage treatment plant (STP) and associated irrigation (<21 EP); and
- other ancillary infrastructure / incidental activities such as laydowns, fencing and borrow pits/quarries.

CSG production may occur from a total of up to 24 CSG wells. For the purposes of minimising land disturbance to the Project Area, some well leases located in PL 1123 may host multiple CSG wells i.e. "multi-well leases". Figure 2 outlines existing (and proposed) infrastructure locations on PL 1123.

CSG and PW generated from the Project Area is proposed to be sent to existing approved centralised CSG and PW processing and storage facilities (including compression stations) located on adjoining Santos operated tenures. This is inclusive of beneficial reuse through existing irrigation schemes authorised under the *End of Waste Code Irrigation of Associated Water (including coal seam gas water) (ENEW07546918, Version 1.07)* (DETSI, 2025a). These surrounding tenures, infrastructure and petroleum activities are authorised under existing Santos EAs and EPBC Act decisions/approvals, those being EAs EPPG00898213 (RSGPA), EPPG00662213 (RSGPAE) and EPPG04323316 (Roma Backbone)), and EPBC approvals 2008/4059 and 2012/6615.

Small volumes of PW may be stored within the Project Area in portable tanks. A proportion of PW stored in tanks on site will be used for on-site activities such as water supply for drilling and hydraulic fracturing purposes, and/or to provide a water source for dust suppression / construction activities (where the water use meets proposed EA conditions and criteria). Approximately 158 ML of water will be required to develop the Project (this represents ~24% of estimated PW volume).

Adequate water and brine storage and treatment capacity has been assessed to be available on adjacent tenures to manage peak water and brine production from the Project. Refer to Section 4.8.1 for further detail on produced water management.

Not all CSG wells will be drilled and operational at once. Project execution and gas production is forecast to begin from late-2025 (pending EPBC and EP Act approvals), with an expected operational life of 30-50 years.

Progressive decommissioning and rehabilitation of wells and associated infrastructure will also occur as required throughout this period in accordance with regulatory requirements and industry standards.

Refer to Appendix B for a detailed description of proposed activities to be undertaken in the Project Area.

2.3 Disturbance Planning

Santos has undertaken significant planning and field surveys to locate existing and proposed infrastructure / disturbance in the Project Area to avoid disturbance to environmental values (EVs).

Santos has also developed a preliminary disturbance footprint (PDF) for the Project Area to locate proposed infrastructure to avoid and minimise disturbance to Matters of National Environmental Significance (MNES), Matters of State Environmental Significance (MNES) and other environmental and landholder values. Santos developed the PDF to refine the layout to avoid, where practical, disturbance to environmental and landholder values. Proposed infrastructure has predominantly been located in cleared agricultural land with only minor disturbance to MNES/MSES values required, and no disturbance to Threatened Ecological Communities (TECs) is proposed.

The PDF is displayed in Figure 2. The majority of existing and proposed disturbance has been located in non-remnant vegetation or previously cleared areas. Where disturbance to remnant and regrowth vegetation will be required, Santos has actively shifted or reduced disturbance widths and areas to mitigate disturbance to sensitivities wherever practicable. More specifically, Santos has minimised disturbance to be limited to:

- 0.30 ha of remnant and regrowth Regional Ecosystem (RE) 11.3.2
- 0.60 ha of general ephemeral wetland habitat (non-remnant) as part of the proposed development; and
- no disturbance to Threatened Ecological Communities (TECs).

Further, to minimise land disturbance, some well leases will host multiple CSG wells, and infrastructure has been placed along existing access tracks and fence lines to avoid disturbance to landholder activities and reduce disturbance to productive land i.e. cropping / grazing land.

The final configuration and location of infrastructure may change due to unforeseen constraints (e.g. cultural heritage sites) or engineering requirements. However, proposed maximum disturbance limits will not change beyond what is proposed in this application without further environmental approvals (e.g. EPBC Act or EP Act approvals).

Ultimately, the proposed development will impact a fraction of land in PL 1123. Existing and proposed disturbance to PL 1123 as part of the proposed development will constitute ~62 ha or ~5% of total land area in PL 1123 (1229 ha), which is almost wholly located on pre-disturbed land due to agriculture.

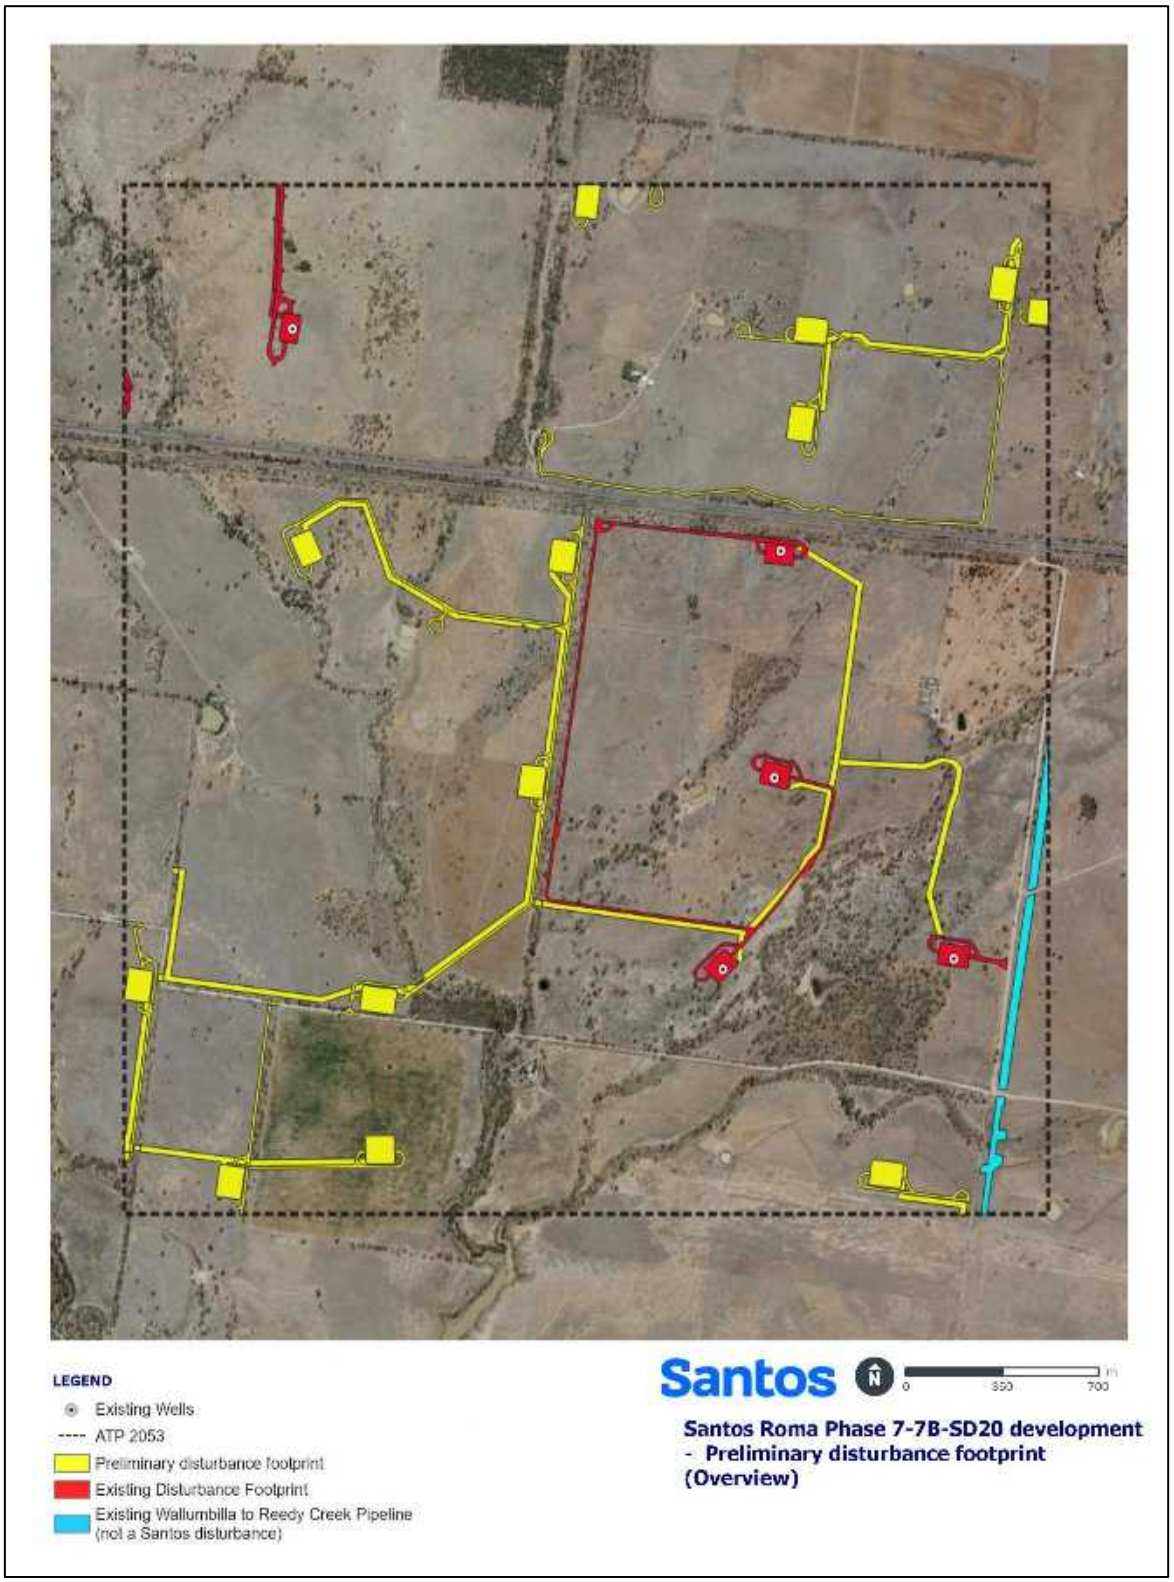

Figure 2: PL 1123 – Preliminary Disturbance Footprint (and Existing Disturbance Footprint)

2.4 Authorised Activities and Proposed EA Conditions

Due to varying joint venture and commercial arrangements, PL 1123 cannot be added to any of the existing adjacent EAs as an authorised tenure.

The holders of Santos operated petroleum tenures surrounding PL 1123 are different to those of PL 1123, and therefore PL 1123 cannot be added as an authorised tenure to their respective EAs.

Santos is therefore seeking a new site-specific EA to authorise petroleum production on proposed PL 1123. The proposed scale and intensity of activities, for inclusion in condition A1(a) of the EA, is detailed in Table 4.

Table 4: Scale and intensity for proposed activities in PL 1123

Petroleum activities and infrastructure	Scale (number of activities)	Intensity (maximum size in total)
Coal seam gas exploration, appraisal, and development wells	24	36 ha
Stimulation activities	All wells are subject to stimulation activities	

Given the proximity of the Project Area to the RSGPA and RSGPAE tenures (refer to Figure 1 and Figure 2), proposed development and operation of the Project Area will be carried out as a single integrated operation with existing authorised RSGPA and RSGPAE petroleum tenures and activities.

Santos is therefore seeking EA conditions consistent with those of the RSGPA EA (EPPG00898213), which are predominately based on streamlined model conditions for petroleum activities (DETSI, 2024).

Further, Santos requests the following Environmentally Relevant Activity (ERA) is authorised on the new EA (refer to Section 4.2 and Table 15 for further information on the requirement for this ERA):

- Schedule 3 – 3 – A petroleum activity that is likely to have a significant impact on a category A or B Environmentally Sensitive Area.

Proposed EA conditions, and a more detailed justification for the conditions, is attached as Appendix A of this report.

3.0 Project Area Description and Relevant Environmental Values

The Project Area is located approximately 43 km east of the town of Roma and 3 km east of the town of Wallumbilla in southern inland Queensland (refer to Figure 1). Further detail on the location, land use and climate of the Project Area is provided in Appendix C.

This section of the report provides a description of the EVs present within the Project Area where relevant to the scope of the EA application and proposed activities. For clarity, the proposed activities are those activities described in Section 2.2.

Desktop and field-based methods were used to assess relevant EVs within the Project Area as follows:

- field-based methods included detailed ecological field surveys undertaken by suitably qualified third-party ecologists (Boobook Ecological Consulting (Boobook)) to ground-truth government mapped vegetation and flora and fauna habitat within the Project Area; and
- desktop assessment methods included database searches and government environmental reports (refer to for Appendix D for further information).

Relevant EVs for this application and the Project Area include:

- land resources;
- Regional Ecosystems (REs);
- environmentally sensitive areas;
- flora and fauna;
- Matters of State Environmental Significance;
- surface waters and wetlands;
- groundwater;
- air quality and noise / vibration;
- waste; and
- rehabilitation.

No European heritage or community values have been identified within the Project Area.

Potential impacts to identified EVs resulting from the proposed activities, and impact mitigation measures to be implemented are described in Section 4.0.

3.1 Land Resources

The Project Area is located within the Southern Downs subregion of the Brigalow Belt bioregion within the Maranoa Region. The landscape is relatively flat with low relief (ranging from 300 – 320m Australian height datum (AHD)), comprising a broad floodplain with meandering drainage lines flanked by slightly elevated areas. Beyond the Project area, to the east, an abrupt north-south trending plateau rises up to 50m above the surrounds.

There is no outcropping rock within the Project Area, and the surface geology consists of Quaternary alluvial sediments (Qa) with an area of unconsolidated colluvial sediments derived from early Cretaceous mudstones of the Doncaster Member (Qs>Kud) in the east associated with the adjacent plateau (Boobook, 2025).

Soils are mapped as a homogenous sodosol (hard pedal brown duplex soils) as shown in Figure 3 (Atlas of Australian Soils, 2021). Field survey identified dark brown clay-loam and sandy clay-loam soils across much of the Project Area, with reddish clay-loams in the east (Boobook, 2025).

The Project Area is located in a Strategic Cropping Area and Strategic cropping land is mapped to be present in the Project Area (State of Queensland, 2025).

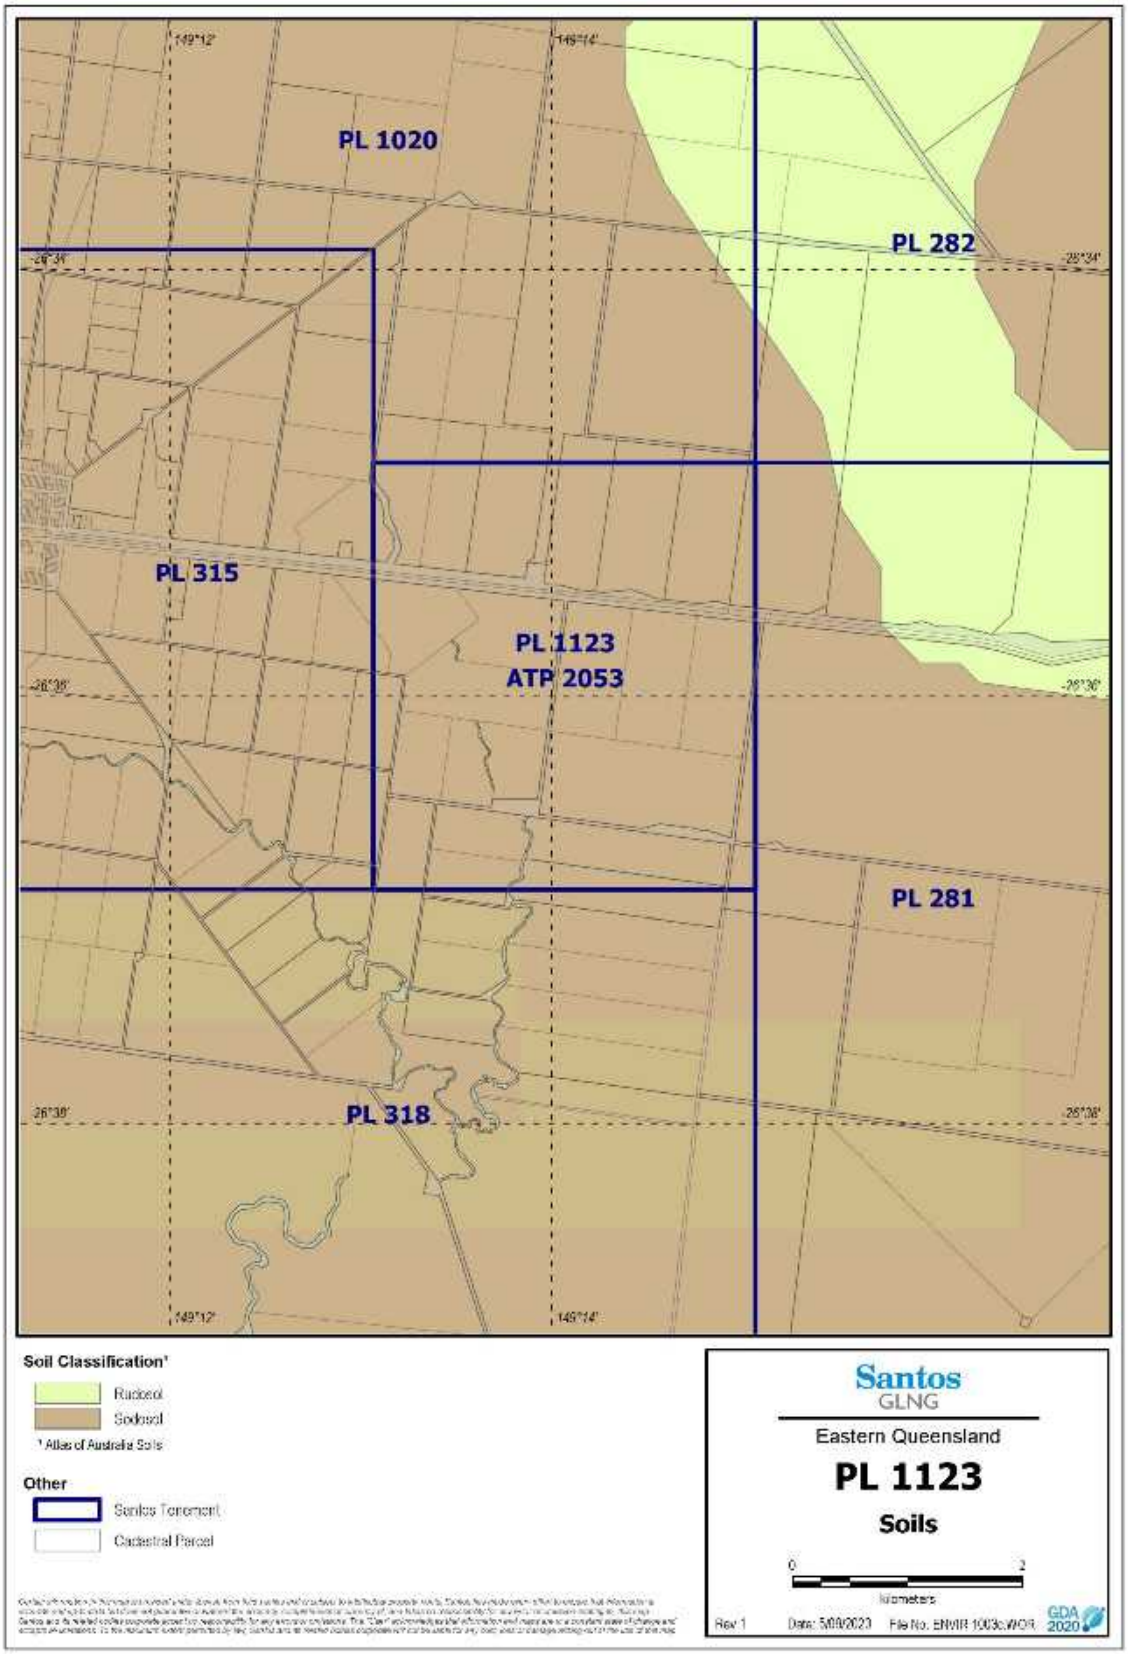

Figure 3: PL 1123 – Mapped Soils

3.2 Regional Ecosystems

Third-party ecological consultants (Boobook Ecological Consulting (Boobook)) undertook an ecological field survey and assessment of the Project Area. A summary of the ecological survey assessment methodology and findings is provided in this section. Refer to the Ecological Assessment Report (EAR) (Boobook, 2025) attached as Appendix D for further detailed information.

Boobook undertook initial desktop and then field-based ground-truthing assessments of vegetation located in the Project Area to confirm RE classification and status. Desktop assessment of REs included review of the Qld Government's (DETSI and Department of Resources (DoR)) RE mapping of the Project Area. No remnant (Category B) vegetation is mapped within the Project Area i.e. the Project Area is entirely mapped by government as non-remnant vegetation. Three areas of vegetation are mapped by DETSI to be VM Act Class Of Concern Category C high value regrowth vegetation consisting of mixed REs 11.3.2/11.3.17/11.3.25 (70/20/10) (Boobook, 2025).

Field assessments included identification and mapping of remnant and regrowth REs across the Project Area. Ground-truthing assessments (and confidence level scoring) of the RE designation was undertaken using the quaternary level of data collection as described by Neldner et al. (2022). Quaternary vegetation assessments were undertaken within 50m x 10m plots for the purpose of typifying the vegetation community under assessment. Plots were chosen within representative areas of each vegetation type encountered. Locations of quaternary assessment sites are displayed in Figure 4.

Vegetation community polygons were verified in accordance with Queensland RE description and biodiversity status as per the Regional Ecosystem Description Database (REDD) and classified as remnant RE, vegetation consistent with RE (regrowth) or non-remnant vegetation. For any identified regrowth (i.e. vegetation floristically equivalent to a RE but not meeting structural thresholds of remnant RE) an ecosystem functionality assessment was conducted. Bio-Condition assessments and scoring, Quaternary level vegetation structure assessments, and fauna habitat assessments were also undertaken at seven representative locations across the Project Area (for remnant and regrowth RE) as displayed on Figure 4. Bio-Condition assessment scores are used to provide an indication of ecosystem function relative to minimally disturbed benchmark sites (Queensland Herbarium data) within the same vegetation type.

Ground-truthing surveys confirmed the Project Area largely consists of non-remnant vegetation (non-remnant derived grassland dominated by introduced pastoral grasses with occasional native trees and shrubs), with most vegetation associated with drainage features. Minor areas of remnant vegetation occur as disturbed, irregular and discontinuous corridors along streams, road easements and fence line corridors. Five remnant REs were identified within the Project Area, these being REs 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (refer to Table 5 for further detail).

Regrowth vegetation comprises Poplar Box (*Eucalyptus populnea*) woodland in riparian corridors, on floodplains and gently undulating country. Vegetation in the southern section of the Project Area is located on Land Zone 3 (Quaternary alluvium) associated with streamlines and alluvial plains (REs 11.3.2, 11.3.17, 11.3.25). Vegetation in the northern section of the Project Area predominantly includes areas located on Land Zone 9 (Undulating country on fine-grained sedimentary rocks) (REs 11.9.7 and 11.9.10), with minor areas of Land Zone 3 (REs 11.3.2 and 11.3.25).

Within the Project Area, Bio-Condition assessment scores for all REs ranged from 0.47 – 0.60, which indicates the significant disturbance and consequent loss of ecosystem integrity relative to Bio-Condition benchmarks of each RE. These scores also reflect landscape level fragmentation of native vegetation i.e. small patch sizes, low connectivity and a low proportion of remnant and regrowth vegetation within the surrounding landscape. Ground-truthed REs identified in the Project Area are detailed in Table 5 and displayed on Figure 4.

Table 5: Ground-truthed REs within the Project Area (~1229 ha)

RE	RE Description	VM Act Status	BD Status	Structural Category	Extent Remnant (ha)	Extent Regrowth (ha)
11.3.2	*Eucalyptus populnea* woodland on alluvial plains	OC	OC	Sparse	19.41	65.38
11.3.17	*Eucalyptus populnea* woodland with *Acacia harpophylla* and/or *Casuarina cristata* on alluvial plains	OC	E	Sparse	10.81	0.00
11.3.25	*Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines	LC	OC	Sparse	20.94	0.00
11.9.7	*Eucalyptus populnea*, *Eremophila mitchellii* shrubby woodland on fine-grained sedimentary rocks	OC	OC	Sparse	0.61	1.30
11.9.10	*Eucalyptus populnea open forest with a secondary tree layer of Acacia harpophylla and sometimes Casuarina cristata on fine-grained sedimentary rocks*	OC	E	Mid-dense	23.96	2.34
				Totals	75.73	69.02

Key: Non VM class and BD status under the *Vegetation Management Act 1999*: NCAP – No Concern at Present, LC – Least Concern, OC – Of Concern, E – Endangered

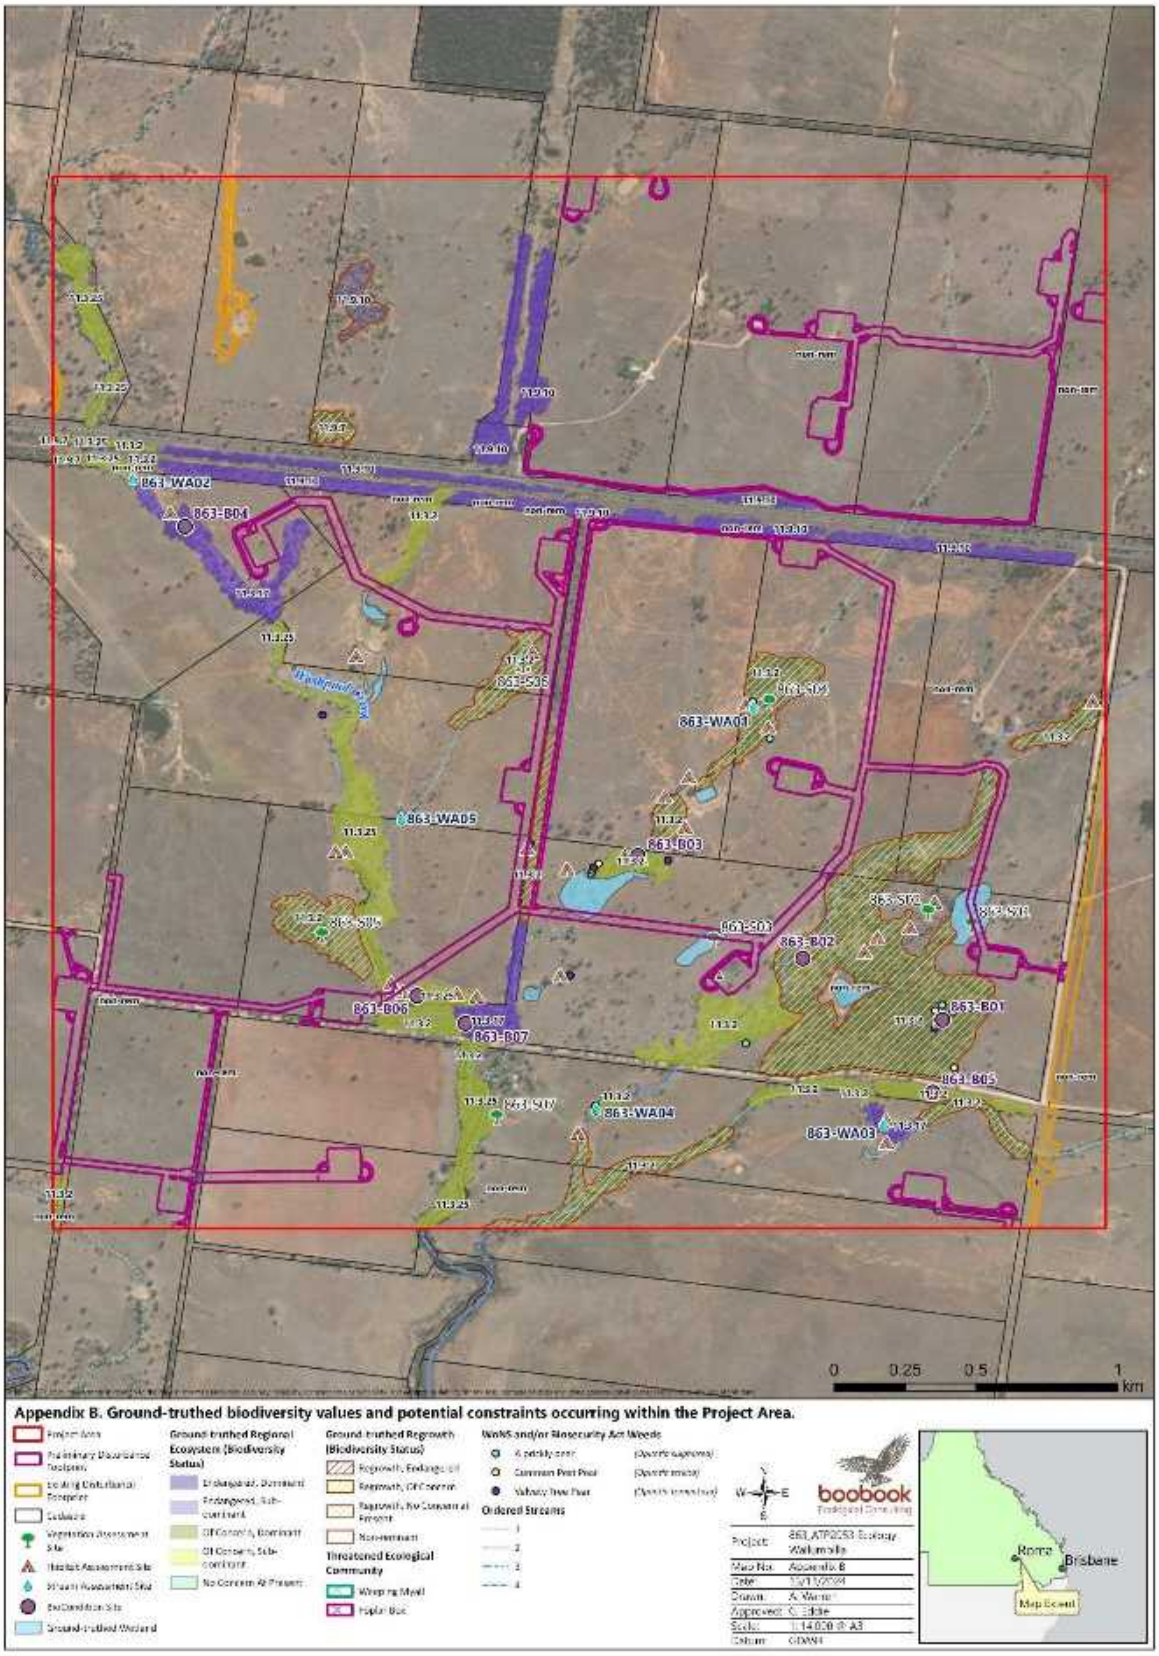

Figure 4: PL 1123 – Ground-truthed REs and Field Survey Sites (adapted from Boobook, 2025)

3.3 Environmentally Sensitive Areas

The following Category B Environmentally Sensitive Areas (ESA) are present within the Project Area:

- areas of ground-truthed Endangered RE (biodiversity status): 11.3.17 and 11.9.10.

The following Category C ESA are present within the Project Area:

- areas of ground-truthed Of Concern RE (biodiversity status): 11.3.2, 11.3.25 and 11.9.7.

3.3.1 Environmentally Sensitive Areas - Essential Habitat

As defined by Section 20AC (1) of the *Vegetation Management Act 1999* (VMA), the Essential Habitat Map is a map certified by the chief executive as the Essential Habitat Map for the State and showing, for the State, areas the chief executive reasonably believes are areas of Essential Habitat for protected wildlife. There is no Essential Habitat mapped within the project area on the Essential Habitat Map.

Further, as defined by Section 20AC (2) of the VMA, Essential Habitat, that is 'protected wildlife habitat', is a category A, B or C area shown on the *Regulated Vegetation Management Map* (RVMM) that has at least 3 essential habitat factors for the protected wildlife that must include any essential habitat factors that are stated as mandatory for the protected wildlife in the essential habitat database; or in which the protected wildlife, at any stage of its life cycle, is located. As per the definition imposed by DETSI on previous EAs '*essential habitat means section 20AC (2) of the VMA validated as 'protected wildlife habitat' from ground-truthing surveys for species of wildlife identified as critically endangered, endangered or vulnerable under the NCA).*

Only Category C (regrowth) Regulated Vegetation is present in the Project Area on the RVMM. Areas of mapped Regulated Vegetation were ground-truthed by Boobook (2025) to be REs 11.3.2, 11.3.25 and 11.9.10. These areas of RE / vegetation may provide potentially suitable habitat for five species (listed as endangered or vulnerable under the NCA) that may occur in the Project Area (Boobook, 2025).

The Project Area is not located within a High-Risk Area as shown on a Protected Plants Flora Survey Trigger Map (Boobook, 2025). There is no state government mapped Essential Habitat for NC Act-listed threatened flora within the Project Area (Boobook, 2025).

ESAs located in the Project Area are detailed in Table 6 and displayed in Figure 5 to Figure 6. Refer to the EAR (Boobook, 2025) attached as Appendix D for further detailed information.

Table 6: Ground-truthed ESAs within the Project Area

ESA Category	ESA Type	RE
Category B	Endangered REs	REs 11.3.17 / 11.9.10
Category C	Of Concern REs	REs 11.3.2 / 11.3.25 / 11.9.7
Category C	Essential Habitat – Protected Wildlife Habitat for Glossy Black-Cockatoo (*Calyptorhynchus lathami*). NCA listed Vulnerable	remnant and regrowth REs 11.3.2 / 11.3.25 / 11.9.10
Category C	Essential Habitat – Protected Wildlife Habitat for Koala (*Phascolarctos cinereus*). NCA listed Endangered	remnant and regrowth REs 11.3.2 / 11.3.25 / 11.9.10
Category C	Essential Habitat – Protected Wildlife Habitat for Yakka Skink (*Egernia rugosa*). NCA listed Vulnerable	remnant and regrowth REs 11.3.2 / 11.9.10
Category C	Essential Habitat – Protected Wildlife Habitat for Grey Snake (*Hemiaspis damelii*). NCA listed Endangered	remnant and regrowth REs 11.3.2 / 11.3.25
Category C	Essential Habitat – Protected Wildlife Habitat for White-throated Needletail (*Hirundapus caudacutus*). NCA listed Vulnerable	remnant and regrowth RE 11.3.2 / 11.3.25 / 11.9.10

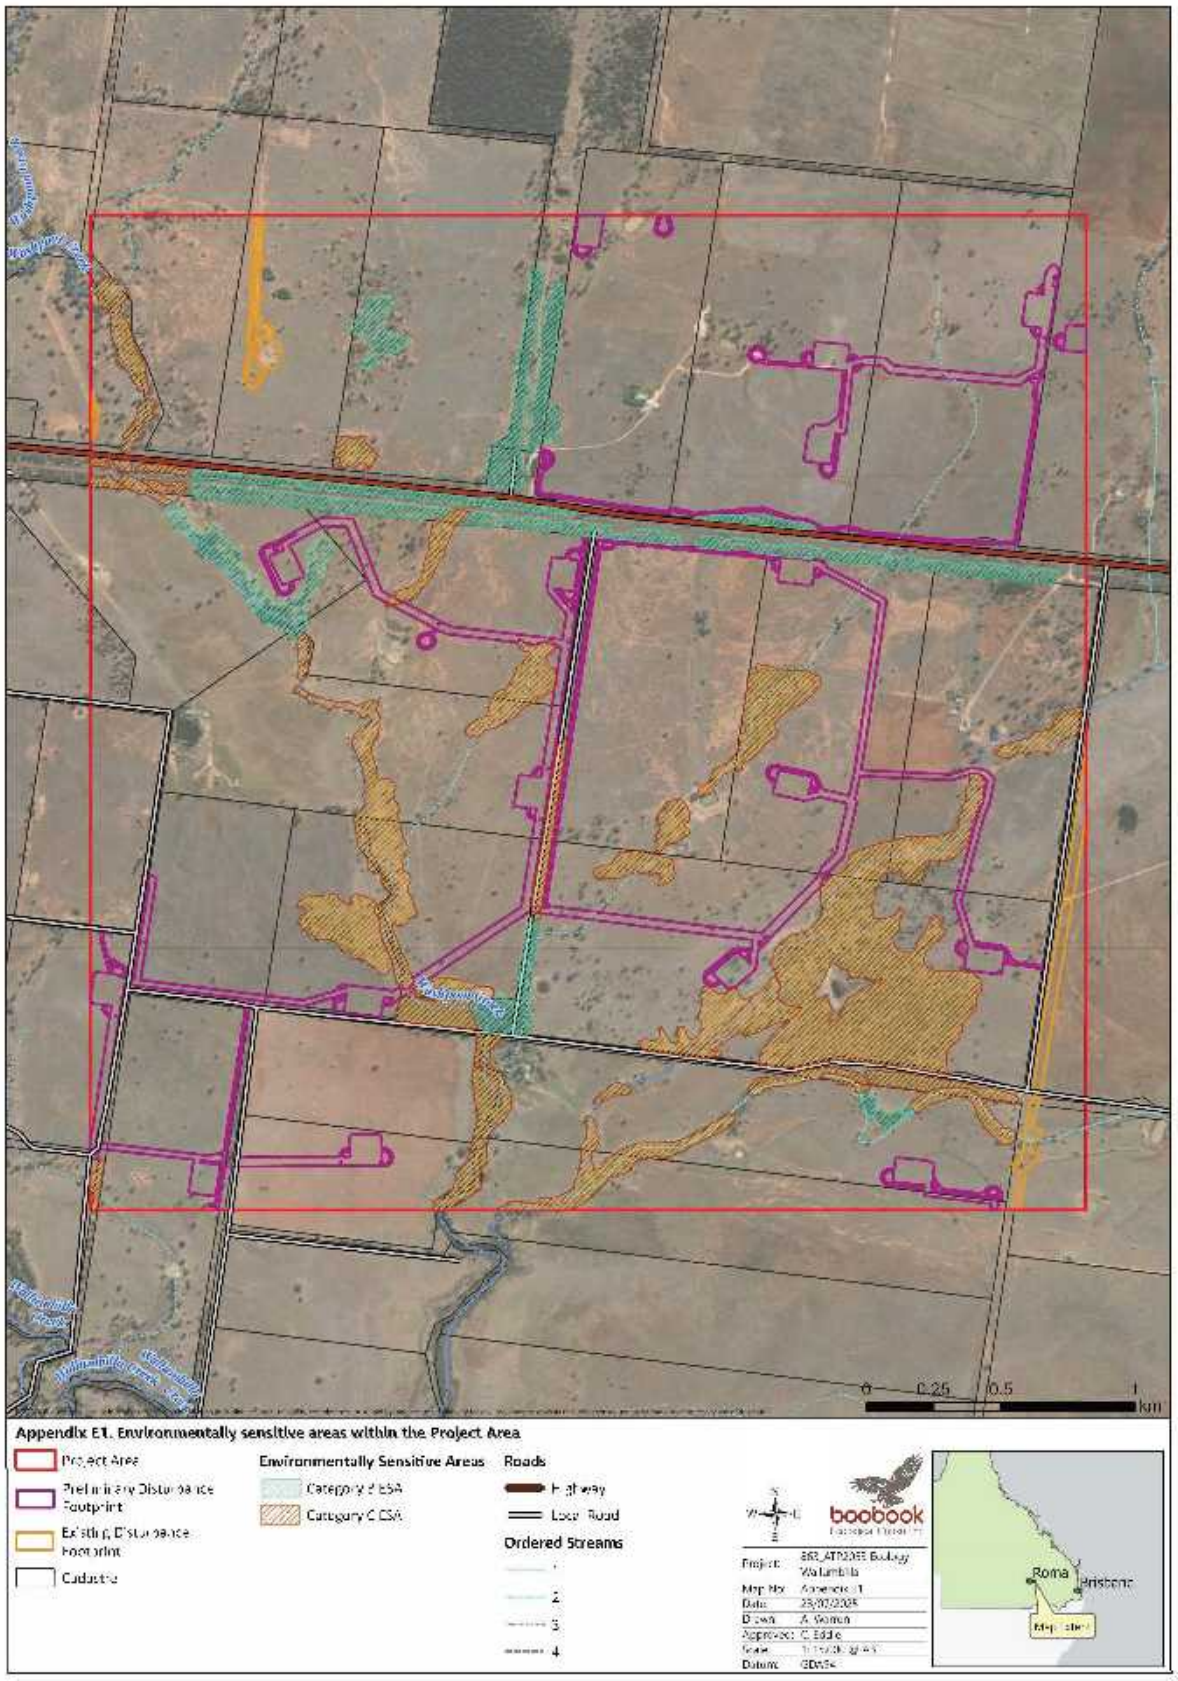

Figure 5: PL 1123 – Ground-truthed ESAs within the Project Area (adapted from Boobook, 2025)

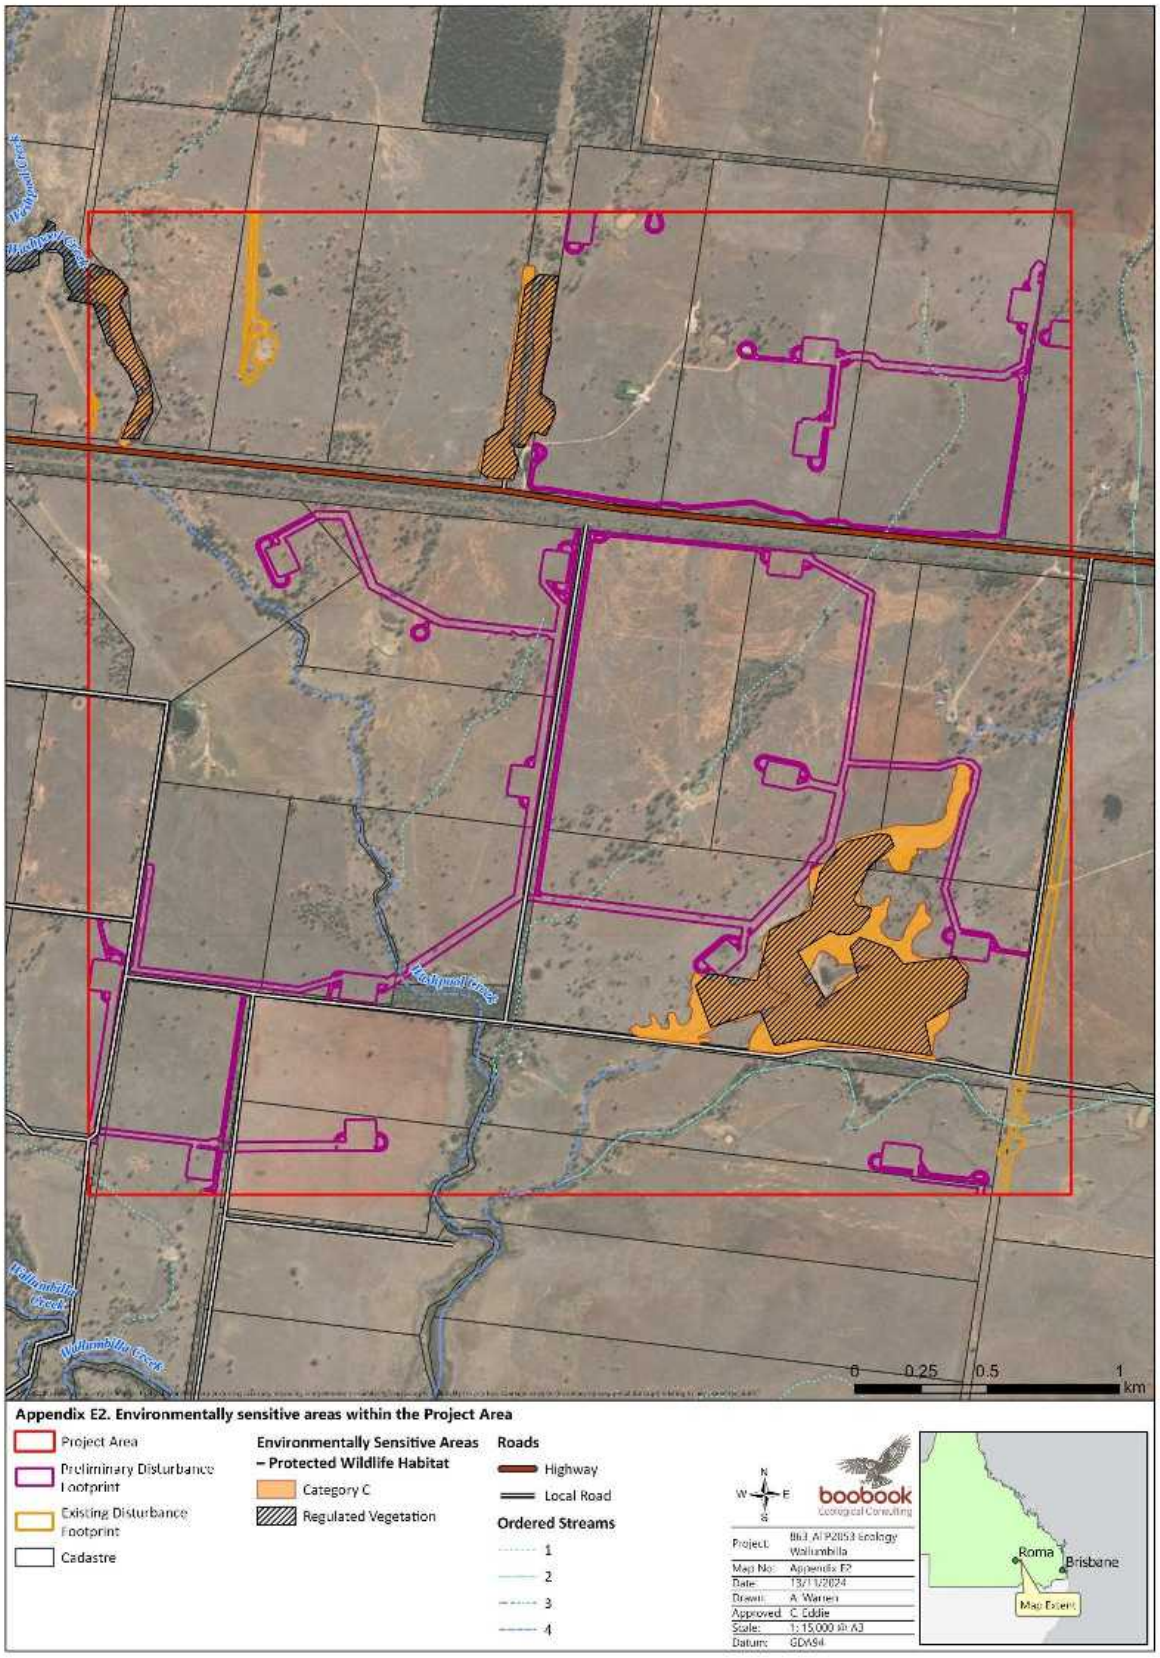

Figure 6: PL 1123 – Ground-truthed ESAs (Regulated Vegetation) within the Project Area

3.4 Threatened Ecological Communities

Several areas of Threatened Ecological Communities (TECs) were identified within the Project Area during field surveys including several small patches of Poplar Box Grassy Woodlands on Alluvial Plains TEC (Poplar Box TEC) and Weeping Myall Woodlands TEC (Weeping Myall TEC).

All areas of TEC within the Project Area are disturbed by grazing and edge effects such as tree death and encroachment by introduced pastoral grasses and other weeds. All Poplar Box TEC within the Project Area was assessed as Moderate Quality (Category C) with low native cover but retaining diverse native understorey plants and more than 10 mature trees per hectare (Boobook, 2025). Ground-truthed areas of TEC within the Project Area are detailed in Table 7 and displayed on Figure 4.

Table 7: Ground-truthed TECs within the Project Area

TEC Description	RE	Extent of TEC within the Project Area (ha)
Poplar Box grassy woodland on alluvial plains	11.3.2	46.71
Weeping Myall Woodlands	11.3.2	7.61
	Total	54.32

3.5 Flora and Fauna

Boobook (2025) undertook desktop-based searches of spatial biological databases (including Atlas of Living Australia, DESI Wildnet) for presence records of flora and fauna species listed under the NCA and EPBC Act. These database searches utilised a 10 km search radius around (and inclusive of) the Project Area). Boobook also utilised the Commonwealth protected matters search tool (PMST) for the purpose of identifying EPBC Act listed species with the predicted potential to occur in or near the Project Area. The searches were conducted using land parcel codes or central coordinates (26.60632S, 149.23120E, datum GDA94) as a geographic reference and including a 10 km buffer. Refer to the EAR (Boobook, 2025) attached as Appendix D for further detailed information.

3.5.1 Flora

The spatial biological database search results did not identify any presence records for NCA or EPBC Act listed threatened flora species located in or within 10 km of the Project Area (Boobook, 2025).

PMST search results (refer to Appendix B in the EAR attached as Appendix D) indicated the potential occurrence of four EPBC Act-listed flora species within the Project Area. As detailed in Table 8, these are also listed flora species under the NCA.

Boobook assessed the likelihood for NCA listed threatened flora species to occur within the Project Area. Refer to Section 3 of the Boobook report attached as Appendix D for further detailed information on the likelihood of occurrence assessment. The results of this assessment, combined with published information and suitably qualified ecologist knowledge of flora distribution and habitat preference in the region, were used to predict habitat suitability for nominated NCA listed threatened flora (of which was limited to one flora species – that being Plains Picris (*Picris barbarorum*), NCA listed Vulnerable). The likelihood of occurrence assessment for NCA and EPBC Act-listed threatened flora within the Project Area is presented in Table 8. Refer to Appendix D (Boobook, 2025) for further information.

Targeted field surveys for NCA threat-listed flora were informed by the spatial biological database / PMST search results and local experience. Field surveys for NCA / EPBC Act listed flora were carried

out within the Project Area at vegetation assessment sites and during random meanders in targeted habitat types (e.g. RE associations for each species), including areas of remnant and non-remnant vegetation. No NCA or EPBC Act threat-listed flora species were detected during field surveys.

Further, the Project Area does not fall within a High-Risk Area on the Protected Plants Flora Survey Trigger Map. Refer to the Boobook (2025) report attached as Appendix D for further detailed information.

No EPBC Act or NCA-listed threatened flora species were detected within the Project Area and no suitable habitat is present for species identified within desktop searches. The Project is therefore unlikely to impact on any threatened flora species, and no impact assessment is required (Boobook, 2025).

Table 8: Assessment of likelihood of occurrence for NCA and EPBC Act-listed threatened flora within the Project Area (adapted from Boobook, 2025)

Common & Scientific Name	EPBC Act Status	NCA Status	Potentially Suitable RE	Likelihood of Occurrence
Vincetoxicum forsteri listed as *Tylophora linearis* Slender Tylophora	E	E	None within the Project Area.	**Unlikely to be present.** There is no suitable habitat (i.e. dry shrubby woodland on land zones 5, 7 or 11) within the Project Area. This species does not occur in the vegetation types and landforms within the Project Area (i.e. grassy woodland on floodplains and low rises, land zones 3 and 9). The closest recorded occurrence is from Glenmorgan, 77 km south-southeast of the Project Area (Boobook, 2025).
Lepidium monoplocoides Winged Pepper-cress	V	C	None within the Project Area.	**Unlikely to be present.** There are no suitable semi-arid, sparsely vegetated areas on heavy clay soils within the Project Area. There are no areas dominated by chenopods, halophytes or Coolibah/Black Box woodland in the Project Area. The Project Area is outside the known range of this species, being over 260 km from the closest records around Yelarbon (Boobook, 2025).
Dichanthium setosum A bluegrass	V	C	None within the Project Area.	**Unlikely to be present.** There is no suitable habitat (i.e. basalt derived heavy clay soils – areas associated with landzone 8) within the Project Area or the vicinity. There are no records of the species within 200km of the Project Area (Boobook, 2025
Cadellia pentastylis Ooline	V	V	None within the Project Area.	**Unlikely to be present.** The Project Area does not include suitable habitat areas of SEVT (RE 11.9.4) or Brigalow dominated woodland on rises, hills and scarps (RE 11.7.1, 11.9.5). The closest specimen records are from around 50 km north of the Project Area (Boobook, 2025).
Picris barbarorum *Plains Picris*	-	V	None within the Project Area.	**Unlikely to be present.** Habitat at the known Sites is native grassland associated with heavy cracking clay soils. This habitat type is absent from the Project Area.

Key to Status: CE/CR = Critically Endangered; E = Endangered; V = Vulnerable; NT = Near Threatened; SL = Special Least Concern; C = Least Concern.

3.5.2 Fauna

The spatial biological database search results predicted twenty-four NCA and EPBC Act-listed threatened fauna species or habitat that might occur in or within 10 km of the Project Area. Wildlife Online and ALA searches (Boobook, 2025) produced records of one EPBC Act-listed threatened fauna species within the 10 km buffered desktop search area this being Koala (*Phascolarctos cinereus*).

Incidental surveys for NCA listed fauna were informed by the spatial biological database / PMST search results and local experience. Surveys were conducted through incidental observations and active searches at assessment sites located across the Project Area. No NCA or EPBC Act listed threatened fauna species were found/recorded present during the field survey.

Further, microhabitat assessments and other field-based habitat observations were conducted within the Project Area at each quaternary vegetation assessment site. Presence/absence, abundance or density of habitat features were recorded within a 50m x 10m plot at each survey site including:

- embedded and loose rocks and boulders (estimated % cover);
- logs (abundance);
- trees >18m height (abundance);
- logs with hollows (abundance);
- trees with hollows (abundance);
- trees and/or logs with loose bark (abundance);
- burrows, sinkholes and tunnel erosion (abundance);
- fallen bark (estimated % cover);
- shrub layer (estimated % cover);
- ground cover (estimated % cover);
- leaf litter (estimated % cover);
- termite mounds (abundance);
- mistletoe (abundance);
- rock structures (caves, overhangs and crevices);
- cliffs, escarpments and steep rocky slopes within 5km (presence);
- watercourses with permanent water, pools and riffles and abundant woody/rock cover (presence);
- cracking clays soils (presence);
- gilgai and ephemeral wetlands (presence); and
- canopy dominated by Myrtaceae species (presence).

In addition, representative fauna habitat features were recorded in non-remnant areas to indicate their type and occurrence throughout the Project Area. In general, fauna habitat features are expected to be most abundant in remnant and regrowth vegetation and these areas were addressed by assessment plots. Fauna habitat features present within the Project Area included hollow-bearing trees (dead and alive), hollow-bearing logs and piles of pushed timber. The locations of fauna habitat assessment sites are shown in Appendix C of the EAR (Boobook, 2025) (attached as Appendix D).

The results of these assessments, combined with published information and suitably qualified ecologist knowledge of fauna distribution and habitat use in the region, were used to predict habitat suitability for nominated listed threatened fauna. The likelihood of occurrence assessment for NCA and EPBC Act-listed threatened fauna within the Project Area is presented in Table 9.

For purposes of brevity, species listed in Table 9 have been limited to those assessed to likely or potentially occur within the Project Area. Refer to Section 3 of the EAR (attached as Appendix D) for further detailed information on the likelihood of occurrence assessment.

Table 9: Assessment of likelihood of occurrence for NCA and EPBC Act-listed threatened fauna within the Project Area (adapted from Boobook, 2025)

Common & Scientific Name	EPBC Act Status	NCA Status	Potentially Suitable RE	Likelihood of Occurrence
Aspidites ramsayi Woma	N/A	NT	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area).	**Potentially present.** There are several records of this species from the vicinity of the Project Area. The species can persist in disturbed and fragmented habitats providing prey and shelter sites are present (Boobook, 2025).
Calidris acuminata Sharp-tailed Sandpiper	V	SL	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Passage migrants are periodically reported from the area. Generally recorded around larger wetlands. However, suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area (Boobook, 2025).
Calyptorhynchus lathami lathami Glossy Black-Cockatoo (southeastern subspecies)	V	V	Primary feeding habitat - Remnant and regrowth: RE 11.3.17, 11.9.10. Sparse feed trees may occur in other remnant and regrowth vegetation and other non-remnant areas. Roosting and nesting habitat-remnant only: RE 11.3.2, 11.3.25, 11.9.7.	**Potentially present.** Belah (*Casuarina cristata*) is moderately abundant within the Project Area. No other She-Oak tree species were observed. Potential nest trees (large trees with hollows near food and water sources) occur sparsely in remnant woodland within the Project Area. No evidence of Glossy Black-Cockatoo (chewed cones) was found within the Project Area, but occasional visitors could occur (Boobook, 2025).
Egernia rugosa Yakka Skink	V	V	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.9.7, 11.9.10.	**Potentially present.** Possible shelter habitat features within the Project Area, such as logs, were present but not abundant. The species is known to occur in some areas of disturbed habitat where suitable shelter sites are present. The species has been recorded from similarly fragmented vegetation around 21 km north of the Project Area (Boobook, 2025).
Gallinago hardwickii Latham's Snipe	V	SL	None. Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Migrating individuals could potentially occur within the Project Area during wet periods. Suitable habitat for short-term visitors exists around dams and

				floodplain soaks within the Project Area (Boobook, 2025).
Hirundapus caudacutus White-throated Needletail	V	V	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area).	**Likely to be present.** The species occurs in the region and is likely to overfly the Project Area occasionally between September and April, following storm fronts. There are no hills within the Project Area and few large trees and therefore the species is unlikely to roost here. There are no specific habitat features that would attract the species to the Project Area (Boobook, 2025).
Phascolarctos cinereus Koala	E	E	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area).	**Potentially present.** Riparian remnant and regrowth woodland dominated by *E. camaldulensis* and *E. populnea* provides suitable habitat for transient individuals to move through the Project Area. The landscape is heavily fragmented, however Koala are capable of dispersing over land using scattered paddock trees and corridors along streams. Koala are sparsely distributed in this area but there is a record from similar habitat within 10 km of the Project Area (Boobook, 2025). No scratches or other evidence of Koala were observed during field surveys (Boobook, 2025).
Rostratula australis Australian Painted Snipe	E	E	None. Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Migrating individuals could potentially occur within the Project Area during wet periods. Suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area (Boobook, 2025).
Tachyglossus aculeatus Short-beaked Echidna	N/A	SL	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area).	**Likely to be present.** The species was not confirmed present within the Project Area. The species is likely to have a patchy occurrence in the Project Area and suitable habitat features such as logs and woody debris were scarce within the Project Area (Boobook, 2025).

Key to Status: CE/CR = Critically Endangered; E = Endangered; V = Vulnerable; NT = Near Threatened; SL = Special Least Concern; C = Least Concern.

3.6 Matters of State Environmental Significance

The DETSI Matters of State Environmental Significance (MSES) report and the EAR (Boobook, 2025) (both reports are attached as Appendix D) identified the following MSES to be present within the Project Area:

- Protected wildlife (fauna) habitat;
- Regulated Vegetation (prescribed REs that are Endangered and Of Concern); and
- Regulated Vegetation (a prescribed RE to the extent the ecosystem is located within a defined distance from the defining banks of a relevant watercourse).

3.6.1 Protected wildlife habitat

Refer to Sections 3.5.1 and 3.5.2 for further detail on potential protected wildlife habitat located in the Project Area.

3.6.2 Regulated Vegetation

Regulated vegetation is an MSES if it is a 'prescribed RE' that:

- is Endangered or Of Concern RE as defined under the *Vegetation Management Act 1999* (VMA); or
- intersects with a wetland identified on the '*vegetation management wetlands map*' as defined under the VMA*;* or
- REs located within the defined distance from the defining banks of a watercourse as identified on the '*vegetation management watercourse map'* as defined under the VMA.

In accordance with Schedule 2 of the *Environmental Offsets Regulation 2014* (EOR), a prescribed RE means an RE, other than an RE mentioned in the VMA at section 8(b) (which are grassland REs), located in a Category B area on the RVMM, to the extent the RE contains remnant vegetation.

Further, as stated in Schedule 2 of the EOR and in Section 2 (Regulated Vegetation) of the *Significant Residual Impact Guideline* (DEHP, 2014), the definition of a prescribed RE is in the EOR, and does not include regrowth vegetation.

Regulated vegetation mapped within the Project Area on the RVMM is entirely Category C (regrowth) (REs 11.3.2/11.3.17/11.3.25, high value regrowth vegetation) and Regulated Vegetation - intersecting a watercourse.

Category C regulated vegetation is not a prescribed RE or MSES PEM because it is not mapped as remnant vegetation (Category B). Therefore, this vegetation is not an MSES PEM for the purposes of SRI assessment under the EOR and *Significant Residual Impact Guideline* (DEHP, 2014).

Further, a prescribed RE is an MSES PEM to the extent the RE is mapped as remnant and is located within a defined distance from the defining banks of a relevant watercourse or relevant drainage feature.

The ecological field surveys, as documented in the EAR (Boobook, 2025), identified minor areas of remnant REs located within the defined distance from the defining banks of a watercourse as identified on the '*vegetation management watercourse map'* within the Project Area. Refer to Section 3.2 (Table 5 and Figure 4) for further detail and the location of REs ground-truthed to be present in the Project Area.

3.7 Surface Water and Wetlands

Santos commissioned expert hydrogeological consultants Klohn Crippen Berger Pty Ltd (KCB) to undertake a third-party Water Resources Impact Assessment Report (WRA) (KCB, 2025) of proposed activities to be undertaken in the Project Area (attached as Appendix E). The following section provides a summary of the findings of the KCB report as they relate to surface water and wetlands, refer to Appendix E (KCB, 2025) for further information.

The Project Area is located in the upper reaches of the Balonne River sub-basin, which is part of the wider Condamine-Balonne Basin). Key watercourses in the Project Area include Washpool Creek and Middle Creek which are tributaries of Wallumbilla Creek. These watercourses have a stream order (SO) of between 1 to 5. The PDF (linear infrastructure only) will cross mapped SO 1 watercourses at five locations, and will cross mapped SO 3 watercourses at two locations.

Watercourse flows in the Project Area are characteristically ephemeral and typically only flow during and immediately following significant rainfall events. Washpool Creek (SO3) is the largest watercourse in the Project Area, and it originates approximately 5 km north of the Project Area, and traverses from the north-western boundary to the south-central boundary, before converging with Wallumbilla Creek approximately 2km south of the Project Area. This is a consequence of the Project Area being in the uppermost reaches of the catchment, with limited runoff area. There are no identified third-party surface water users in the vicinity of the Project Area.

There are no wetlands of high or general ecological significance (HES or GES wetlands) located within the Project Area. Boobook (2025) identified several small ephemeral wetland areas in non-remnant vegetation (cleared paddocks) in the Project area. These areas may provide ephemeral potential habitat for wetland bird species such as Australian Painted Snipe (*Rostratula australis*) and Latham's Snipe (*Gallinago hardwickii*).

There is limited to no groundwater contribution from the regional groundwater system to watercourses as baseflow anticipated in the Project Area. There are no spring vents, spring complexes or watercourse springs recorded in or within a 25 km vicinity of the Project Area.

The EVs applicable to surface waters, as defined by the *Maranoa-Balonne River Basin Environmental Values and Water Quality Objectives* (DESI, 2020) and *Condamine River Basin Environmental Values and Water Quality Objectives* (DESI, 2020) are as follows:

- protection of the aquatic ecosystems;
- primary industries:
    - irrigation;
    - farm supply/use;
    - stock watering;
- human consumer;
- recreation and aesthetics:
    - primary and secondary recreation;
    - visual appreciation;
- drinking water;
- industrial use; and
- cultural, spiritual and ceremonial values.

3.8 Groundwater

As discussed in Section 3.7, Santos commissioned expert hydrogeological consultants KCB to undertake a third-party *Water Resources Impact Assessment* of proposed activities. The content and findings of the KCB report as they relate to groundwater are briefly summarised below. Refer to the KCB (2025) report attached as Appendix E for further information.

3.8.1 Geological Setting and Stratigraphy

The Project Area is located within the geographical extent of the Surat Basin, a basin of Jurassic-Cretaceous age, which is underlain by the Permo-Triassic Bowen Basin. Cenozoic-age formations are present overlying the Surat Basin formations. The Bowen Basin, which contains up to 10km of terrestrial and shallow marine sediments, is elongated, trending north-south, and extending over 160,000 km^2 from central Queensland, south beneath the Surat Basin, into New South Wales where it eventually connects with the Gunnedah and Sydney basins. The Surat Basin underlies approximately 180,000 km^2 of southeast Queensland and is connected to the Eromanga Basin in the west, the Clarence-Moreton Basin in the east and Mulgildie Basin to the northeast.

There are currently no formally recognised sub-basins for either the Bowen or Surat Basins. However, the Bowen and Surat Basins are divided into distinct regions based on the structural features that control both the location and thickness of the sedimentary sequences. The Project Area is located within the Maranoa-Balonne-Condamine subregion, in the centre of the Surat Cumulative Management Area, on the far western flanks of the Taroom Trough. The Surat Basin forms part of the Great Artesian Basin (GAB), which comprises several aquifers and confining aquitards. Aquifers of the Surat Basin are a significant source of water used for stock, public water and domestic supply. Refer to Appendix E for further information on regional geology and hydro-stratigraphy.

The Walloon Coal Measures (WCM) are the main gas bearing units within the Surat Basin and they are the target formation for proposed CSG production in PL 1123 and the broader Roma area (refer to Table 10 and Table 11). The thickness of the coal measures in the Roma area ranges from 100 to 460 m, at depths ranging from 170 to 933 metres below ground level (mbgl). The coal seams are separated by silty and tight sandstone, which restricts leakage between seams. Hydro stratigraphy of the Surat and Bowen Basins is outlined, and a summary of each unit is provided, in Table 11. Refer to Appendix E for further information.

Stratigraphic units of relevance to the Project Area and proposed activities include:

- Quaternary alluvial deposits located along Wallumbilla Creek and major tributaries;
- Cenozoic sediments;
- Cretaceous sediments of Wallumbilla Formation; and
- Jurassic aged sediments of the Gubberamunda Sandstone, Westbourne Formation, Springbok Sandstone, Walloon Coal Measures, Eurombah / Durabilla Formation, Hutton Sandstone, Evergreen Formation and Precipice Sandstone.

Table 10: Stratigraphic column for the Project Area (adapted from KCB, 2025)

Age		Formation			Hydro stratigraphic Description		Relevance to Project Area	
Quaternary		Alluvium			Partial Aquifer		Mapped associated with watercourses	
		Unconsolidated sediments					Deposits across Project area	
		Tertiary Sediments					3 km to the northeast and 8 km to east	
Cretaceous	**Early**	Wallumbilla Formation	Coreena Member		Tight Aquitard	Partial Aquifer	Outcrops 7 km south	
			Doncaster Member			Tight Aquitard	Outcrops within Project area	
		Blythesdale Group	Bungil Formation	Kingull Member	Partial Aquifer		Outcrops 9 km north	Outcrops 20 km northwest
				Minmi Member			Outcrops 2 km north	
				Nullawurt Sandstone Member			Outcrops 14 km northwest	
			Mooga Sandstone		Regional Aquifer		Outcrops 16km north	
			Orallo Formation		Tight Aquitard		Outcrops 26km north	
Jurassic			Gubberamunda Sandstone		Regional Aquifer		Outcrops 31km north	
	Late	Westbourne Formation			Tight Aquitard		Outcrops 33km north	
		Springbok Sandstone			Tight Aquifer		Outcrops 38km north	
	Middle	Walloon Subgroup	Walloon Coal Measures		Productive Coal Seam		Target CSG formation	
			Eurombah/Durabilla Formation		Tight Aquitard		Underlying aquitard of regional relevance	
		Hutton Sandstone	Upper Hutton Sandstone		Partial Aquifer		Underlying aquifer of regional relevance	
			Lower Hutton Sandstone		Tight Aquifer			
	Early	Evergreen Formation	Upper Evergreen FM		Tight Aquitard		Regional Relevance	
			Boxvale Sandstone		Partial Aquifer			
			Lower Evergreen FM		Tight Aquitard			
		Precipice Sandstone			Regional Aquifer		Regional Relevance	

Table 11: Summary description of stratigraphic units for the Project Area (adapted from KCB, 2025)

Unit	Description
Alluvium	Quaternary-age alluvium is mapped as occurring within proposed PL 1123. These alluvial deposits are associated with Washpool Creek, Middle Creek and Wallumbilla Creek and associated major tributaries. The alluvium consists of unconsolidated clay, silt, sand, and gravel. In the Surat CMA, sediments within the major river channels are typically narrow and range in thickness from 14 to 26 metres, with alluvium thickness generally decreasing in the smaller tributaries. No bores within the Project area are screened in the alluvium, thus the alluvial thickness is not known for Washpool Creek, Middle Creek, and Wallumbilla Creek.
Cenozoic Sediments	Thin accumulations of Cenozoic unconsolidated and semi-consolidated residual and colluvial sheetwash sediments occur within, and in the vicinity of the Project area, at thicknesses of less than 50 m.
Cretaceous Sediments – The Wallumbilla Formation	The Wallumbilla Formation is sub-divided in two sequences, the Coreena, and Doncaster Members. The upper Member (Coreena) is siltstone-dominated with minor coal seams. The lower Member (Doncaster) is mudstone dominated. The Coreena Member comprises interbedded siltstone, mudstone and fine to very fine-grained labile sandstone, limestone and coal deposited from shallow marine lagoons, shoreline swamps and estuaries, most likely reflecting a regional marine regression. The siltstone is in part calcareous, grading to silty limestone. The thickness of the Coreena Member averages 70 m and is conformably overlain by the Surat Siltstone. The Doncaster Member comprises dominantly blue-grey mudstone with glauconitic siltstone and fine-grained sandstone. The Doncaster Member accumulated with a rapid marine transgression with deep water conditions in the centre of the basin, grading to shallow marine coastal environments around the margins. Average thickness of the member is between 100 m and 150 m. The Doncaster Member of the Wallumbilla Formation and is a tight aquitard. The Coreena Member is a partial aquifer.
Jurassic Aged Sediments -The Bungil Formation	The Bungil Formation conformably overlies the Mooga Sandstone and outcrops 20 km northwest of the Project area. This unit is comprised of interbedded fine-grained lithic sandstones, siltstones, and mudstones with minor quartzose sandstone present. Day (1964b) identified three members: the Minmi, Nullawurt Sandstone and Kingull members, however, these are not easily recognised in the subsurface (Green et al. 1997, Exon 1976). Deposition of the Bungil Formation represents the initial marine transgression into the Surat Basin. The Bungil Formation is considered as an aquifer.
The Mooga Sandstone	The Mooga Sandstone generally conformably overlies the Orallo Formation, with local disconformities. Deposits generally consist of fine to medium grain size sand, although siltstones, mudstones, and shale are present. The Mooga Sandstone is at the base of the fifth major sedimentary cycle in the Surat Basin and was deposited in southwesterly flowing braided to meandering stream environments. Exon 1976, recognised three major subunits in outcrop. The upper Mooga Sandstone and lower Mooga Sandstone are considered aquifers. The middle Mooga Sandstone consists of siltstones, mudstones, and shale and is considered an aquitard. The Mooga Sandstone is considered a regional aquifer.
The Orallo Formation	The Orallo Formation conformably overlies the Gubberamunda Sandstone. It was deposited in a relatively low energy fluvial environment with local ponding. The Orallo Formation consists of fine to coarse-grained sandstone interbedded with clay, siltstone, silty mudstone, bentonite clay, and coal. The Orallo Formation is considered a tight aquitard.

Unit	Description
Gubberamunda Sandstone	Regionally, the Gubberamunda Sandstone conformably overlies the Westbourne Formation, but locally is disconformable, particularly around the margins of the basin. It was deposited by braided and meandering stream systems draining surrounding highlands. Consistent with a fluvial depositional environment, repeated packages of siltstone and fine to coarse sandstone were deposited. Deposits of carbonaceous shale along with minor coal fragments are typically present. Within the GAB, the Gubberamunda Sandstone is considered a usable aquifer.
Westbourne Formation	The Westbourne Formation conformably overlies the Springbok Sandstone. It was deposited in an environment with characteristics consistent with a low energy, lacustrine deltaic plain. The Westbourne Formation comprises predominately siltstone layers with thick interbeds of fine to medium-grained sandstone and minor mudstone. Small coal fragments, lenses and lamina are common throughout the formation. Within the GAB sequence, the Westbourne Formation is considered an aquitard.
Springbok Sandstone	The Springbok Sandstone overlies the Walloon Coal Measures and was deposited by streams and includes overbank and swamp deposits in the upper part of the unit which indicates streams becoming less energetic with time. The Springbok Sandstone consists mostly of feldspathic sandstones, commonly with calcareous cement. At the basin scale, the sandstones range from very fine to coarse-grained, although some very coarse-grained, poorly sorted pebbly beds also occur. Minor interbedded siltstones, mudstones, and thin coal seams are also present, primarily in the upper part of the unit. Within the GAB, the Springbok Sandstone is considered a usable water source, however it is highly variable in hydraulic properties and yield across the basin. The Springbok Sandstone also has a very high content of mudstone and siltstone at many locations with very low permeability.
The Walloon Coal Measures	The WCM of the Surat Basin are the target gas production formation for Santos PL 1123. Within the WCM, the two coal-dominated formations are the Juandah Coal Measures and the Taroom Coal Measures. A low permeability sandstone, siltstone and mudstone typically forms the base and is known as the Durabilla/Eurombah Formation. The WCM were deposited in a low energy meander-belt river system, with the coal layers deposited mainly in an overbank environment. Comprising of very fine to medium-grained argillaceous, siltstone, mudstone, and coal with minor calcareous sandstone, impure limestone, and ironstone. Typically, the coal layers are positioned in the upper half to three-quarters of the coal measures, with mudstones, siltstones, and lithic sandstones dominant in the lower part. At a regional scale the WCM are considered an interbedded aquitard.
Eurombah/Durabilla Formation	The Eurombah Formation, often referred to as the Durabilla Formation, conformably overlies the Hutton Sandstone. The depositional environment for this unit was fluvial with periods of rapid sedimentation. It is often difficult to differentiate the Eurombah Formation from the WCM. It is more restricted in extent than either the Hutton Sandstone or the WCM. The Eurombah Formation is considered an aquitard, consisting of siltstone, mudstone and fine to medium-grained poorly sorted sandstone, with almost no coal and consequently, little permeability.
The Hutton Sandstone	The Hutton Sandstone was deposited in a non-marine environment by meandering streams on a broad floodplain and consists mainly of sandstone with interbedded siltstone, shale, minor mudstone, and coal. The sandstone is white to light grey, fine to medium-grained, well sorted, generally quartz rich, partly porous with some pebble bands, shale, and siltstone clasts in the lower part. Siltstones and shales are light to dark grey, micaceous, carbonaceous and commonly interlaminated with very fine-grained sandstone. It is highly heterogeneous, with sand bodies limited in vertical and lateral extent.

Unit	Description
The Evergreen Formation	The Evergreen Formation conformably overlies the Precipice Sandstone and separates the Precipice Sandstone from the Hutton Sandstone. The upper and lower Evergreen Formations are considered aquitards and generally consists of mudstones laminated with fine-grained sandstone, siltstone, and shale.
The Precipice Sandstone	The Precipice Sandstone is the basal unit of the Surat Basin, which overlies the Moolayember Formation and sedimentary sequences of the Bowen Basin. Lower and upper subunits are recognised, often separated by a siltstone or shale unit. The layers with the coarsest grain sizes were deposited by transverse bars in a braided stream system and the sediment layers with finer grain sizes were deposited in a lower energy fluviatile meandering system. The lower subunit, also known as the Precipice Braided Stream Facies (or Precipice BSF), consists of white, fine to very coarse-grained, in part pebbly, thin to very thickly bedded, porous, quartz rich sandstone with a white clay matrix.

3.8.2 Aquifer Interconnectivity

The Surat Basin comprises layers of aquifers and aquitards of varying hydraulic properties. The formations predominantly comprise fluvial sedimentary deposits that have formed stratifications of sand, silt and clay within and across hydro-stratigraphic formations. Groundwater flow within the Surat Basin hydro-stratigraphic units is predominantly horizontal, as vertical flow is restricted by the spatial extent and continuity of aquitards, and by lower permeability horizons within the aquifers.

Across the Project Area, there is potential for interaction between the WCM, and the aquifers present at depth, and specifically those immediately above and below the WCM, such as the overlying Springbok Sandstone and underlying Hutton Sandstone (separated from the WCM by the Durabilla / Eurombah Formation). The Durabilla / Eurombah Formation is classed as a tight aquitard and is laterally extensive across the Project area, with a mean thickness of 51 m. This provides a significant vertical barrier between the WCM and underlying Hutton Sandstone. An upper WCM aquitard has been mapped by the Office of Groundwater Impact Assessment (OGIA) (the WCM non-productive zone) as being up to 25 m thick across the Project Area, separating the WCM coal seams from the overlying Springbok Sandstone (which is also classed as a tight aquifer due to its low horizontal permeability and significant proportions of siltstone and mudstone). Refer to Appendix E for further information on aquifer interconnectivity and aquitards relevant to the Project Area.

3.8.3 Groundwater Recharge

Recharge processes within the Surat Cumulative Management Area (CMA) are summarised in the 2021 Underground Water Impact Report (UWIR) (OGIA, 2021). Dominant recharge occurs along the zones of increased permeability in outcrop areas through fractures and permeable beds. Key processes of recharge include localised recharge, preferential pathway flow and diffuse recharge:

- localised recharge occurs beneath drainage features including rivers, and free-draining unconsolidated sedimentary cover, such as alluvium.
- preferential pathway flow arises from changes in permeability within aquifers and in overlying regolith, providing conduits for water to infiltrate. Zones of higher permeability may include fissures, faults, joints, tree roots and high-permeability beds within individual formations and along bedding planes. This mechanism is considered the dominant recharge process in the GAB; and
- diffuse recharge is the process by which high-intensity rainfall events and high-volume infiltrate and sufficiently saturate surficial sediments.

Recharge in the vicinity of the Project Area is expected to occur mainly as diffuse recharge with rainfall infiltration occurring at outcropping hydro-stratigraphic units within, and surrounding, the Project Area. Quaternary and Tertiary aged systems are also likely to be replenished during prolonged wet periods when the ephemeral creek system is flowing (where sufficient saturation and hydraulic head allows water to infiltrate into surficial aquifers).

Estimates of long-term mean recharge rates for the Surat CMA have been made by OGIA as part of the 2016 UWIR (OGIA, 2016) using the chloride mass balance recharge estimation method. From this work, OGIA estimates the majority of surficial recharge to flow towards watercourses and discharge locally to streams and rivers such that only 10% of their recharge reaches the deeper confined aquifer. Refer to KCB (2025) attached as Appendix E for further information on groundwater recharge relevant to the Project Area.

3.8.4 Groundwater Levels, Flow and Elevation

At a regional scale, groundwater flow within the Surat Basin is typically north to south, from the outcrop areas located to the north. Groundwater movement is slow in the GAB with flow velocities estimated to be 1 to 5 m/year. Generally, groundwater flow and movement occur as sub-horizontal flow, with limited vertical leakage across formations, where pressure differences may exist. Vertical flow generally only occurs downward in outcropping areas where recharge occurs. Local groundwater flow conditions may be different from regional flow conditions with potential steeper gradients and increased velocities in response to hydraulic stresses such as groundwater abstraction.

Groundwater levels in the vicinity of the Project Area have been considered using available records from the Queensland Groundwater Database (Queensland Government, 2025). A number of groundwater monitoring bores exist within the proximity of the Project Area; however transient groundwater level records are limited. The majority of monitoring bores are installed as part of the UWIR and other programs such as CSG monitoring program or CSG Net Program operated by the DNRME (KCB, 2025). Refer to Appendix E for detailed information on groundwater levels in the Project Area.

3.8.5 Groundwater Dependent Ecosystems

Surface expression Groundwater Dependent Ecosystems (GDEs) are not present in the Project Area, and there are no GDEs or spring vents or complexes located within the 25 km buffer of the Project Area. The closest watercourse springs are located along the Blyth and Yuleba Creeks (associated with the Mooga Sandstone) more than 20 km to the northeast and northwest of the Project Area, respectively.

Small patches of low confidence (1–80%) potential terrestrial GDEs (TGDEs) are mapped by the Queensland government within the Project Area (summarised in Table 12). Potential TGDEs in this area are indicated to intermittently connect to aquifers with brackish salinity and alkaline pH in unconsolidated Quaternary alluvial. Rooting depths identified for species present in identified RE's based on available literature reviews range to 22.6 m. The potential for groundwater dependence of identified REs in the Project Area was inferred using GDE assessment guidelines. Further, potential TGDEs located along the creek systems in and around the Project Area may be groundwater dependent as they occur within an alluvial system (associated with creeks), and the ecosystem is associated with drainage features. This alluvial system is likely replenished during prolonged wet periods when the ephemeral creek system is flowing.

Limited to no groundwater contribution from the regional groundwater system to watercourses as baseflow is anticipated in the Project Area.

Refer to Appendix E for further information on GDEs/TGDEs relevant to the Project Area.

Table 12: Potential TGDEs located in Project Area (adapted from KCB, 2025)

RE	Land Zone	Description	Rooting Depth
11.3.17	Alluvium (river and creek flats)	*Eucalyptus populnea* woodland with *Acacia harpophylla* and/or *Casuarina cristata* on alluvial plains; not a wetland	12.1 - 22.6 m
11.3.2		*Eucalyptus populnea* woodland on alluvial plains; may contain Palustrine wetlands	
11.3.25		*Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines; riverine wetland	

RE	Land Zone	Description	Rooting Depth
11.9.10	Undulating country on fine grained sedimentary rocks	*Eucalyptus populnea* open forest with a secondary tree layer of *Acacia harpophylla* and sometimes *Casuarina cristata* on fine-grained sedimentary rocks; not a wetland	No information available
11.9.7	Hills and lowlands on Metamorphic rocks	*Eucalyptus populnea, Eremophila mitchellii* shrubby woodland on fine grained sedimentary rocks;	No information available

3.8.6 Groundwater Users and Bores

Groundwater in the Surat CMA has multiple uses, including stock and domestic purposes, agriculture (general agriculture, irrigation, and stock-intensive), town water supplies, and industrial/mining activities. Groundwater abstraction for stock and domestic purposes is likely to be the dominant water use within the vicinity of the Project Area.

There are 427 registered groundwater bores located within a 25 km buffer of the Project Area. Of these bores, 376 are existing bores (which include water supply and monitoring bores), with the remainder either abandoned and destroyed, abandoned but usable or proposed.

Under the Queensland *Water Act 2000*, CSG proponents are required to undertake baseline assessments of water bores located within their petroleum tenures prior to commencement of production. Baseline assessments are undertaken in accordance with the *Baseline Assessment Guideline* (DES, 2017), to obtain information such as: bore status, type and purpose; information related to the construction of the bore, including depth installed, screen interval and source aquifer; groundwater level and quality and field gas measurement; and bore equipment including pump depth, pumping frequency and flow rate.

There is one operational water bore located within the Project Area. This bore is attributed to the Mooga Sandstone. The baseline assessment was undertaken in 2009 for RN 123195 (refer to Table 13). Another groundwater bore (RN208460) was drilled on the tenement in June 2024. This new bore is indicated as “no longer used”. Santos are in the process of revising their Baseline Assessment Plan, as required by the Queensland *Water Act*, with baseline assessment planned to occur in Q4 2025 (prior to commencement of the Project) if it is required.

Table 13: Baseline Assessment Bore Details

RN	Name	Property (Lot Plan)	Easting	Northing	Purpose	Baseline Assessment Date	Aquifer
			GDA 94				
123195	House Bore	123 WV468	722513	7057126	Domestic	4/11/2009	Mooga Sandstone
208460	N/A	126 WAL53678	723709	7056052	Domestic Stock	Q4 2025	Unknown

3.9 Air Quality and Noise

Air quality in the vicinity of the Project Area is representative of a rural area with a low population density and is likely to be largely influenced by activities such as:

- dust from agricultural and oil and gas exploration and production activities, including from stock and vehicle movements, land clearing, and cropping activities;
- particulates from naturally occurring events such as bushfires;
- vehicle and equipment exhaust fumes from roads, agriculture activities, industrial activities and towns; and
- emissions from resources activities operating in the area.

Consistent with the objectives of the *Environmental Protection (Air) Policy 2019* (EPP Air), the EVs relevant to the Project Area are:

- the qualities of the air environment that are conducive to protecting the health and biodiversity of ecosystems;
- the qualities of the air environment that are conducive to human health and well-being;
- the qualities of the air environment that are conducive to protecting the aesthetics of the environment, including the appearance of buildings, structures and other property; and
- the qualities of the air environment that are conducive to protecting agricultural use of the environment.

The existing noise environment for the Project Area is typical of rural areas, with low levels of background noise generally comprised of noises associated with rural based human occupation.

Noise levels in the vicinity of the Project Area are likely to be influenced by the following:

- the use of equipment and machinery during both agricultural activities and oil and gas exploration and production activities in the area;
- traffic noise from project vehicles and other traffic, including heavy transport vehicles associated with the Warrego Highway operating on a 24-hour basis;
- natural sources such as birds, insects, wind and other meteorological events;
- livestock; and
- resource exploration and development activities.

Consistent with the objectives of the *Environmental Protection (Noise) Policy 2019* (EPP Noise), the EVs are:

- the qualities of the acoustic environment that are conducive to protecting the health and biodiversity of ecosystems;
- the qualities of the acoustic environment that are conducive to human health and well being, including by ensuring a suitable acoustic environment for individuals to sleep, study or learn, or be involved in recreation (including relaxation and conversation); and
- the qualities of the acoustic environment which are conducive to protecting the amenity of the community.

Background noise monitoring has not been undertaken for the Project Area. In the absence of background noise monitoring, the deemed background levels nominated in the proposed conditions for the new EA and in Table 2 of the DETSI guideline *'Prescribing noise conditions for environmental authorities for petroleum activities*' (ESR/2016/1935, Version 2.05) (DETSI, 2025) are considered to be representative of the ambient acoustic environment associated with a rural setting.

3.10 Waste

EVs that may be impacted by waste from petroleum activities relate to:

- human health and wellbeing;
- land quality;
- water quality;
- visual amenity; and
- existing ecological processes and biodiversity.

Under Schedule 8, Part 3 of the *Environmental Protection Regulation 2019* (EP Reg), the environmental objective for activities with waste impacts is:

> *Any waste generated, transported, or received as part of carrying out the activity is managed in a way that protects all environmental values.*

Performance outcomes are:

- Waste generated, transported, or received, is managed in accordance with the waste and resource management hierarchy in the *Waste Reduction and Recycling Act 2011*; and
- If waste is disposed of, it is disposed of in a way that prevents or minimises adverse effects on environmental values.

Wastes potentially generated from project activities would include the following:

- batteries and electrical – lead acid batteries, gel type batteries, nickel cadmium batteries and alkaline batteries generated from equipment, vehicles, generators and electronics;
- chemical waste and chemical containers – chemical wastes may include herbicides, pesticides, paints and solvents. Chemical containers are those containing any volume of free chemical that is a regulated waste and may include waste oil containers and aerosol cans containing solvent or paint;
- concrete / aggregate / asphalt – concrete, aggregate and asphalt materials removed from demolished infrastructure that are not suitable for recycling;
- contaminated soil – contaminated soils may be generated where localised spills of hydrocarbons and other contaminants occur;
- cooking oil – waste cooking oil is generated from kitchen facilities at temporary mobile camps;
- drilling fluids and muds – waste drilling fluids, muds and cuttings are generated from the drilling process;
- general recycling – plastic bottles and food containers, glass bottles and jars, milk cartons, aluminum bottles and cans, metal lids from jars, tin cans, aluminum cans, plastic cups, cardboards and paper packaging, folders, envelopes, office paper, magazines, cereal boxes, clean paper towels, steel scraps;
- grease trap waste – grease trap waste is generated from kitchen facilities at temporary mobile camps;
- green waste – green waste produced from vegetation clearing activities;
- hydrostatic test water – spent water used in the hydrostatic testing of pipelines to test pipeline integrity;
- Intermediate bulk containers (IBCs) – containers used for transport of fluids and bulk materials;

- oily filters, rags, and absorbents - Oily filters, rags, and absorbents are generated from routine equipment and vehicle servicing, repair and filter changes;
- oily water – oily water may be produced from servicing equipment, machinery and vehicles;
- pipeline tape wrap – pipeline tape wrap protects the pipeline against corrosion;
- plastic liners - waste plastic liners associated with sumps and turkeys nest dams;
- PW – PW is primarily generated from the operation of wells;
- putrescible and other domestic waste – food scraps, food wrappers, packaging materials, textile materials, plastic wrapping film, plastic bags, facial tissues, ear plugs, pens and pencils, polystyrene, aluminum foil, waxy paper, cardboard, non-recyclable plastics, etc.;
- scrap steel and metal – scrap steel and metal may include steel piping, values and cabling;
- stimulation flowback water – this waste is generated when the fluids used in the stimulation process are brought back to the surface;
- timber – untreated timber derived from packaging and uses that cannot be reused or recycled;
- Triethylene glycol (TEG) / glycol / coolant – is generated from equipment and vehicle fluid changes;
- tyres – tyres and tubes are generated from tyre changes on work and vehicle equipment;
- used spill kits – used spill kits are generated from spill clean-up of chemicals and hydrocarbons;
- waste oil – small quantities of waste oil are generated routinely from vehicle and equipment oil changes; and
- wiring – electrical wiring and equipment not suitable for reuse.

Leftover fracture stimulation fluids would be removed from the Project Area for use on subsequent wells or taken offsite from the Project Area for authorised disposal. Where of an appropriate quality, some PW may be re-used for the purposes of dust suppression, and in drilling and hydraulic fracturing activities.

3.11 Rehabilitation

Rehabilitation and decommissioning of disturbed land would occur progressively in accordance with proposed EA conditions (refer to Schedule J in Appendix A). The objective of rehabilitation and decommissioning is to achieve a post development landform that is:

- safe for humans, native fauna and livestock
- non-polluting; and
- stable and able to sustain appropriate land use.

The rehabilitation works would aim to provide appropriate site conditions to facilitate revegetation.

Consistent with Santos' existing operations currently undertaken on adjacent Santos-operated PLs (e.g. PLs 315, 1020) authorised by EA EPPG0089821, a two-stage rehabilitation program approach would be pursued.

Stage 1 pertains to stabilisation works which would be completed post construction within the footprint of operational assets, predominantly pipeline easements. The land is stabilised to ensure the safe and effective operation of assets and to minimise the risk of erosion, soil loss and weed invasion. Where possible, land would be returned to the landholder for productive use (e.g. grazing and cropping). Stabilisation works would include:

- remediating areas of contaminated land resulting from petroleum activities
- re-establishing surface drainage lines and re-profiling contours for operational use
- establishing a safe landform for humans and livestock in areas of significant cut and fill
- reinstating top soil (where present)
- improving the condition of soil through the appropriate assessment and treatment of soils where required; and
- promoting the establishment of groundcover vegetation.

Stage 2 rehabilitation activities relate to disturbance footprints no longer required for operational purposes. Rehabilitation activities in Stage 2 would return remaining disturbance footprints to an appropriate land use in accordance with landholder needs and applicable regulatory requirements.

Agricultural land uses and natural areas comprising native vegetation are the two most common pre-disturbance land uses to be rehabilitated. Final rehabilitation of natural areas would be undertaken to achieve the final rehabilitation criteria conditions specified in the proposed EA (refer to Schedule J in Appendix A). Where appropriate infrastructure is to be left for the landholder, a written agreement will be submitted to DETSI alongside the Final Rehabilitation Report.

4.0 Potential Impacts, Mitigation Measures and Environmental Risk Assessment

As discussed in Section 1.2, impacts associated with the proposed activities are not new and are consistent with existing authorised petroleum activities and impacts currently being undertaken in the Project Area and surrounding region. Existing petroleum activities in the Project Area and surrounding region are authorised under EAs 0002052 and EPPG0089821.

Further, as discussed in Sections 2.1 to 2.2, Santos has invested significant time into planning and locating existing and proposed infrastructure in the Project Area to avoid unnecessary disturbance to native remnant and regrowth vegetation wherever practicable (given safety and engineering restrictions discussed in Section 2.3).

As can be seen in Figure 2 and Figure 4, the majority of existing and proposed disturbance has been located in non-remnant vegetation or previously cleared areas. Where disturbance to remnant and regrowth vegetation will be required, Santos has actively shifted or reduced disturbance widths and areas to mitigate disturbance to sensitivities wherever practicable. Further, to minimise land disturbance, some well leases will host multiple CSG wells, and infrastructure has been placed along existing access tracks and fence lines to avoid disturbance to landholder activities and reduce disturbance to productive land i.e. cropping / grazing land.

Ultimately, the proposed development will impact a fraction of land in PL 1123. Existing and proposed disturbance to PL 1123 as part of the proposed development will constitute ~62 ha or ~5% of total land area in PL 1123 (1229 ha).

This section provides the following:

- a description of potential impacts to relevant EVs (as described in Section 3.0);
- mitigation and management measures to minimise potential impacts to relevant EVs; and
- an environmental risk assessment; and
- an assessment against Schedule 8 (Parts 1 and 2) of the EP Reg (Environmental Objective Assessment and Performance Outcomes) (attached as Appendix G).

To assess environmental risks associated with the proposed activities, a risk assessment for each relevant environmental value has been completed. The environmental risk assessment is based on risk factors associated with both the initial construction and ongoing operational phases of the proposed activities. Risk assessment of a proposed activity identifies a wide range of risks and potential impacts to relevant EVs as a potential result of carrying out the activity. This does not however mean all identified potential impacts will occur as a result of carrying out the activity.

Once initial unmitigated risks and potential impacts are identified as part of a risk assessment, appropriate control strategies are identified and implemented. Appropriately implemented control strategies will typically mitigate the likelihood of a potential impact occurring, and/or reduce the severity/consequences of the potential impact.

The risk assessment identifies initial (unmitigated) risks associated with the proposed activities for each relevant environmental value. Following identification of appropriate mitigation measures (control strategies), the residual (mitigated) risk posed to each environmental value has also been determined (refer to the risk assessment Table 33 in Appendix F for further detail). The risk assessment has been

undertaken in accordance with the Santos Management System (SMS) Risk Management Standard. The SMS Risk Management Standard is based on accepted principles and applicable Australian standards. Further detail on the Santos risk assessment process is provided in Appendix F.

The results of the risk assessment are summarised in the risk assessment Table 33 in Appendix F and discussed in Sections 4.1 to 4.6.2. The risk assessment identified a range of potential impacts and control strategies associated with the proposed activities. Following consideration of control strategies, a residual risk of 'Low' was assigned to all potential impacts to relevant EVs.

Potential impacts to MSES in context of the *Environmental Offset Act 2014* are discussed in Section 4.4.

4.1 Land Resources

Potential direct and indirect impacts to land resources will be predominantly short-term and associated with the initial limited clearing and construction phases of the project. The proposed activities would result in direct disturbance of land for the construction of well leases, access tracks, gathering infrastructure and other incidental petroleum activities as described in Section 2.2.

Proposed disturbance may temporarily reduce the availability of land for agriculture. However, these impacts would be offset by commercial agreements between Santos and relevant property owners.

Following completion of the construction phase, large sections of land will begin regenerating to achieve stability and groundcover similar to that of surrounding areas. For example, the majority of the gathering line / pipeline construction RoW will be rehabilitated following pipeline installation (with the exception of the retention of basic vehicle access to allow for mandatory routine inspections and maintenance via light vehicles i.e. a simple running track is required to be maintained for light vehicle access).

Disturbed areas no longer required for construction will be progressively rehabilitated / stabilised as construction progresses. Rehabilitation of disturbed areas following construction will typically include:

- contouring to match surrounding landforms;
- re-establishment of surface drainage lines;
- re-spreading of stockpiled topsoil and establishment of groundcover; and
- placement of cleared vegetation as required.

As discussed in Section 2.2 (and as displayed on Figure 2), proposed infrastructure has been predominantly located adjacent to existing landholder fence lines to minimise disturbance to remnant native vegetation, and disruption to existing land uses i.e. cropping and grazing land. Santos also proposes to utilise some multi-well leases to minimise disturbance, maximise gas recovery, and/or accommodate landholder requirements. Further, as discussed in Section 2.2, for the purposes of efficiency and to minimise land disturbance in the Project Area, gas and PW generated from the Project Area will utilise existing centralised water and gas processing facilities (including compression stations) located on adjoining RSGPA tenures (authorised under EA EPPG00898213).

More specifically, gas produced from the Project Area is planned to be transferred to an existing compressor station located on PL 314 via new and existing gas gathering infrastructure e.g. gas pipelines and trunklines. In future, gas from the Project Area may potentially be processed or sent elsewhere, subject to relevant approvals (refer to Figure 1 to Figure 2).

PW is proposed to be transferred to existing approved dams located on adjacent tenures. PW from these dams is then proposed to be transferred to existing approved water treatment facilities located on PL 314, where the water will be processed through a fines and sludge removal facility before being further processed, or bypassed around, the Roma Reverse Osmosis Plant (ROP) to meet re-use criteria in

accordance with *End of Waste Code Irrigation of Associated Water* (ENEW07546918, Version 1.07) (DETSI, 2025a). The Roma ROP is located approx. 25 km northwest of the Project Area. Adequate water and brine storage and treatment capacity has been assessed to be available on adjacent tenures to manage peak water and brine production from the Project.

Integration with the RSGPA activities will negate the requirement to locate gas compression or large water management facilities within the Project Area. Accordingly, this will result in less major infrastructure being required to be located in the Project Area, which will minimise disturbance to remnant native vegetation and assist in minimising disruption to existing land uses i.e. cropping and grazing land.

During construction and operational phases, there is a risk of minor accidental spills or leaks of fuels and chemicals, fuels, and PW to soils. This may have the potential to result in minor localised contamination of soil.

The proposed activities may result in direct and indirect impacts to land resources (as described in Section 3.1), primarily as a result of:

- infrastructure construction (earthworks activities, including grading and trenching);
- vehicle and plant movements;
- minor spills or leaks of fuels and chemicals from vehicles and equipment;
- loss of containment;
- bushfire and flood (natural event); and
- fire (ignition sources resulting from activities).

Santos aims to minimise the operational footprint and significant disturbance associated with its activities as far as reasonably practicable. However, potential direct and indirect impacts to land resource EVs resulting from the proposed activities may include:

- reduction in visual amenity;
- soil erosion, topsoil loss, inversion and compaction;
- disturbance to land use and suitability changes;
- reduction in agricultural productivity; and
- contamination of soil.

Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate the residual risk to land resource EVs as a result of the proposed activities is classified as ‘Low’.

4.2 REs, ESAs, and Flora and Fauna

The proposed activities may result in direct and indirect impacts to REs, ESAs, Flora and Fauna (as described in Sections 3.2 to 3.5) primarily as a result of:

- infrastructure construction (earthworks activities, including grading and trenching);
- entrapment in voids (trenches / bell holes / pits);
- vehicle and plant movements; and
- fire (ignition sources resulting from activities).

Santos aims to minimise the operational footprint and significant disturbance associated with its activities as far as reasonably practicable. However, potential direct and indirect impacts to REs / ESAs and Flora and Fauna resulting from the proposed activities may include:

- damage to and/or loss of native riparian vegetation and habitat;
- damage to and/or loss of high value flora;
- introduction and/or spread of weeds, pest plants, animals and pathogens;
- loss of species population, further endangerment and loss in species diversity; and
- disturbance, injury or loss of fauna.

As discussed in Section 2.2, significant pre-planning has been undertaken to locate existing and proposed infrastructure to minimise impacts to environmental and land resource values. Santos developed a PDF for the Project Area to locate proposed infrastructure to trial multiple iterations of proposed infrastructure locations to maximise avoidance and minimise disturbance to REs, ESAs, Flora and Fauna (and MNES, MNES) and other environmental and landholder values (refer to Figure 2). As can be seen in Figure 2 and Figure 4, the majority of existing and proposed disturbance has been located in non-remnant vegetation or previously cleared areas. Where disturbance to remnant and regrowth vegetation will be required, Santos has actively shifted or reduced disturbance widths and areas to mitigate disturbance to sensitivities wherever practicable. Santos also proposes to utilise some multi-well leases to minimise disturbance, maximise gas recovery, and/or accommodate landholder requirements.

More specifically, Santos is proposing to disturb 0.30 ha of remnant and regrowth RE 11.3.2, and 0.60 ha of general ephemeral wetland habitat (non-remnant) as part of the proposed development. No disturbance to TECs is proposed. Proposed disturbance to REs, ESAs and Primary Protection Zones (PPZs), and potential fauna habitat are detailed in Table 14 to Table 16, respectively.

As discussed in Section 3.5.1, no NCA or EPBC Act listed threatened flora species were detected during field surveys and no NCA or EPBC Act flora species are assessed to potentially or likely be present. Further, the Project Area does not fall within a High-Risk Area on the Protected Plants Flora Survey Trigger Map. Refer to Appendix D (Boobook, 2025) for further information.

As discussed in 3.5.2, several fauna species listed under the NCA and EPBC Act are considered to potentially or likely occur, or have potentially suitable habitat located in the Project Area. Potential habitat for these species was predicted and mapped by Boobook (2025) based on known vegetation and habitat feature associations for each species. Minor disturbance to small sections of potentially suitable habitat for relevant listed species is detailed in Table 16.

Proposed impacts to potentially suitable listed fauna habitat are minor i.e. a total of 0.90 ha of disturbance to potential habitat is proposed, and of this, 0.30 ha constitutes disturbance to remnant and regrowth vegetation.

Further, as discussed in Section 2.2, for the purposes of efficiency and to minimise land disturbance in the Project Area, gas and PW generated from the Project Area will utilise existing centralised water and gas processing facilities (including compression stations) located on adjoining RSGPA tenures (authorised under EA EPPG00898213). Integration with the RSGPA activities will negate the requirement to locate gas compression or large water management facilities within the Project Area. Accordingly, this will result in less major infrastructure being required in the Project Area, which will minimise disturbance to native vegetation and assist in minimising disruption to existing land uses.

The proposed activities would result in the direct disturbance of land for the construction of well leases, access tracks, gathering infrastructure and other incidental petroleum activities as described in Section

2.2. Following completion of the construction phase, large sections of land will immediately begin regenerating to achieve stability and groundcover similar to that of surrounding areas. For example, the majority of the gathering line / pipeline construction RoW will be rehabilitated following pipeline installation (with the exception of the retention of basic vehicle access to allow for mandatory routine inspections and maintenance via light vehicles i.e. a simple running track is required to be maintained for light vehicle access).

Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to REs / ESAs and Flora and Fauna EVs as a result of the proposed activities are classified as 'Low'.

Table 14: Proposed Disturbance to REs

RE	Remnant / Regrowth	RE Description	VM Act Status	BD Status	VMA Structural Category	Disturbance Area (ha)

Sharp-tailed Sandpiper (*Calidris acuminata*)	V	SL	General Habitat includes ground-truthed wetlands and dams	General: 0.60	General: 7.31
Latham's Snipe (*Gallinago hardwickii*)	V	SL	General Habitat includes ground-truthed wetlands and dams	General: 0.60	General: 7.31

Key to Status: CE/CR = Critically Endangered; E = Endangered; V = Vulnerable; NT = Near Threatened; SL = Special Least Concern; C = Least Concern.

[1] Identified habitat RE were classified as Primary or General Habitat as follows:

- **Primary habitat** - is an area containing resources that are considered essential for the maintenance of populations of the species (e.g. potential habitat for breeding, roosting, foraging, shelter, for either migratory or non-migratory species). 'Primary Habitat' is defined from known records and/or expert advice (including the findings of preclearance surveys).
- **General habitat** - consists of areas or locations that are used by transient individuals or where species have been recorded but there is insufficient information to assess the area as 'Primary Habitat'. 'General Habitat' may be defined from known records or habitat that is considered to potential support a species according to expert knowledge of habitat relationships, despite the absence of specimen backed records. 'General Habitat' may include areas of suboptimal habitat for species.

[2] Disturbance areas will be an overestimate of impacts due to overlap of potentially suitable habitat areas in the PDF.

4.3 Matters of State Environmental Significance

As discussed in Sections 3.2 and 3.6, Boobook undertook an ecological field survey and assessment of the Project Area. Following completion of the ecological field survey, Boobook compiled an EAR (attached as Appendix D) inclusive of a Significant Residual Impact (SRI) assessment of the proposed activities in accordance with the requirements of the DETSI SRI Guideline (DEHP, 2014).

As discussed in Section 3.6, the DETSI MSES report and EAR (Boobook, 2025) (both reports are attached as Appendix D) identified the following MSES to be present within the Project Area:

- Protected wildlife (fauna) habitat (an area of habitat (e.g. foraging, roosting, nesting or breeding habitat) for an animal that is endangered, vulnerable or a special least concern animal (section 6(4), EO Reg);
- Regulated Vegetation (prescribed REs that are Endangered and Of Concern); and
- Regulated Vegetation (prescribed REs to the extent the ecosystem is located within a defined distance from the defining banks of a relevant watercourse).

EVs analogous to MSES protected wildlife (fauna and flora habitat) (i.e. remnant REs) have been assessed for the Project Area by this risk assessment, and relevant control measures to mitigate potential risks and impacts to remnant REs are detailed in Table 33. The results of the risk assessment indicate that residual risks to MSES (where analogous to REs / ESAs and Flora and Fauna EVs) as a result of the proposed activities are classified as 'Low'.

Refer to Section 4.4 for further information on potential impacts to MSES in the context of assessment against the requirements of the *Environmental Offsets Act 2014 and* the DETSI SRI Guideline (DEHP, 2014).

4.4 Environmental Offsets Act 2014

As per Section 8 of the *Environmental Offsets Act 2014* (EO Act), a significant residual impact (SRI) is generally an adverse impact, whether direct or indirect, of a prescribed activity on all or part of a prescribed environmental matter (PEM) that:

a) remains, or will or is likely to remain, (whether temporarily or permanently) despite on-site avoidance and mitigation measures for the prescribed activity; and

b) is, or will or is likely to be, significant.

The proposed development would constitute a prescribed activity under s9 of the EO Act. In accordance with s207(1)(c) of the EP Act, the administering authority may impose an environmental offset condition on an EA. However, s14(2) of the EO Act states that an offset condition may only be imposed on an EA if the proposed activity will, or is likely to have a SRI on a PEM, and all reasonable on-site mitigation measures for the prescribed activity have been, or will be, undertaken.

The *Queensland Environmental Offsets Policy Significant Residual Impact Guideline* (SRI Guideline) (DEHP, 2014) has been developed to assist in deciding whether or not a prescribed activity will, or is likely to have a SRI on a PEM.

Boobook carried out an SRI assessment for PEMs-MSES potentially impacted by the project in accordance with the criteria provided in the SRI Guideline. The SRI assessment is detailed in the EAR (Boobook, 2025) (attached as Appendix D). The SRI assessment found that, after considering potential impacts, mitigation measures and the state SRI criteria, the proposed development will not have a SRI on any PEMs-MSES values (refer to SRI assessment contained in Table 17).

Table 17: Significant Residual Impact Summary Table (adapted from Boobook, 2025)

Prescribed environmental matter as per EOR	Presence in the Project Area	
Regulated vegetation: Endangered and Of Concern REs	☒	The Project Area does not contain areas of regulated vegetation that is a 'prescribed RE'. DEHP (2014) defines regulated vegetation to be a prescribed RE as per the EOR which does not include regrowth (Category C) vegetation. No remnant or Category B areas are present within the Project Area on the RVMM. As discussed in Section 3.6.2, regulated vegetation mapped within the Project Area on the RVMM consists entirely of three areas of Category C (RE 11.3.2/11.3.17/11.3.25, high value regrowth) vegetation. Therefore, the Project Area contains no prescribed RE or MSES PEM for the purposes of SRI assessment under the EOR and Significant Residual Impact Guideline (DEHP 2014). In conclusion, the proposed activities will not result in an SRI to Regulated Vegetation (Endangered and Of Concern RE).
Regulated vegetation: Prescribed REs within the defined distance of a watercourse	☒	The Project Area does not contain areas of regulated vegetation that is a 'prescribed RE' within the defined distance of a watercourse. DEHP (2014) defines regulated vegetation to be a prescribed RE as per the EOR which does not include regrowth (Category C) vegetation. No remnant or Category B areas are present within the Project Area on the RVMM (accessed 22/07/2025). As discussed in Section 3.6.2, regulated vegetation mapped within the Project Area on the RVMM consists entirely of three areas of Category C (RE 11.3.2/11.3.17/11.3.25, high value regrowth) vegetation. Portions of two Category C areas occur within the defined distance from the defining banks of a watercourse identified on the vegetation management watercourse map. As these areas are mapped as regrowth, they are not prescribed RE. Therefore, the Project Area contains no prescribed RE or MSES PEM for the purposes of SRI assessment under the EOR and Significant Residual Impact Guideline (DEHP 2014). In conclusion, the proposed activities will not result in an SRI to Regulated Vegetation (within the defined distance of a watercourse).
Connectivity areas	☑	The Landscape Fragmentation and Connectivity Tool was utilised to assess the proposed disturbances for potential impacts to Connectivity Areas. The Tool determined no SRI was triggered by the proposed activities. Refer to Section 4.4.1 for further information.
Wetlands and watercourses	☒	The following wetlands or watercourses are not present within the Project Area: • Wetlands in a wetland protection area as shown on the Map of referrable wetlands under schedule 12, part 2 of the *Environmental Protection Regulation 2019;* • Wetlands of high ecological significance (HES) as shown on the Map of referrable wetlands under schedule 12, part 2 of the *Environmental Protection Regulation 200*; or • Wetlands or watercourses in a high ecological value waters as identified under the *Environmental Protection (Water) Policy 2009*, schedule 2.

Prescribed environmental matter as per EOR	Presence in the Project Area	
Designated precinct in a strategic environmental area	☒	The Project Area is not located in a designated precinct in a strategic environmental area.
Protected wildlife habitat	☑	• Based on fauna habitat / RE associations, wildlife habitat for NCA listed species relevant to SRI assessment may be present within the Project Area (refer to Section 3.3.1 and Table 9). • No high-risk areas on the flora survey trigger map exist within the Project Area. Boobook undertook ecological impact assessment against the SRI criteria as per the SRI Guideline (DEHP, 2014) for relevant NCA listed species assessed as likely or potentially occur in the Project Area. No NCA listed flora species were assessed to likely or potentially occur in the Project Area (refer to Section 3.5 for further detail). Following detailed assessment against the NCA SRI criteria, Boobook (2025) concluded the proposed activities are not expected to result in an SRI to protected wildlife species (or their habitat) listed under the NCA. Refer to Section 4.4.2 for further information.
Protected areas	☒	There are no protected areas within the Project Area.
Highly protected zones of State marine parks	☒	The Project Area does not contain highly protected zones of a State marine park.
Fish habitat areas	☒	Areas declared under the *Fisheries Act 1994* to be a fish habitat area are not present within the Project Area.
Waterway providing for fish passage	☑	The Project Area contains watercourses providing potential fish passage, as detailed in Section 3.7. The proposed development would not have an SRI on this PEM because linear infrastructure construction activities located in waterways providing for fish passage would not: • reduce the extent, frequency, or duration of fish passage; • result in a substantial change to the hydrological regime of the watercourse; or • lead to significant changes in water quality parameters within the watercourse. Other measures to be carried out to reduce potential impacts on surface waters where required are detailed in Section 4.4 and Table 33. Proposed EA conditions relating to impacts to surface waters and wetlands are also detailed in the Schedule B EA conditions in Appendix A).
Marine plants	☒	Areas containing marine plants are not present in the Project Area.
Legally secured offset areas	☒	No legally secured offset areas are present within the Project Area.

4.4.1 Connectivity Areas

Boobook (2025) utilised the Landscape Fragmentation and Connectivity Tool to assess the proposed disturbances for potential impacts to Connectivity Areas. The Tool determined no SRI was triggered by the proposed activities. Connectivity areas are areas of remnant vegetation outside urban areas containing prescribed RE that are required for ecosystem functioning. As both test results were negative, the overall result is the impact will not be significant. Results of the connectivity tool are summarised in Table 18. Refer to Boobook (2025) for further information.

Table 18: Connectivity areas that are a RE (not in urban area) within the Project Area (adapted from Boobook, 2025)

Connectivity Test	Regional scale extent of core remnant RE pre-impact	Change threshold for local scale core remnant RE	Change in core local scale remnant RE post-impact	Number of core areas ≥1 ha pre-impact	Number of core areas ≥1 ha post-impact	Test Result
Change in core remnant RE extent at the local scale	4.4%	2%	0%			Not Significant
Loss / fragmentation of core remnant RE at the site (Disturbance Footprint) scale				0	0	Not Significant

4.4.2 Protected Wildlife Habitat

The SRI Guideline provides that a prescribed activity is likely to have a significant impact on protected wildlife habitat if:

- For endangered and vulnerable wildlife habitat (including an area of essential habitat as mapped on the *essential habitat map*), an action is likely to have a significant impact on endangered and vulnerable wildlife if the impact on the habitat is likely to:
  - lead to a long-term decrease in the size of a local population; or
  - reduce the extent of occurrence of the species; or
  - fragment an existing population; or
  - result in genetically distinct populations forming as a result of habitat isolation; or
  - result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat; or
  - introduce disease that may cause the population to decline, or
  - interfere with the recovery of the species; or
  - cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.

- For special least concern (non-migratory) animal wildlife habitat, an action is likely to have a significant impact on a special least concern (non-migratory) animal wildlife habitat if it is likely that it will result in:
  - a long-term decrease in the size of a local population; or
  - a reduced extent of occurrence of the species; or
  - fragmentation of an existing population; or
  - result in genetically distinct populations forming as a result of habitat isolation; or
  - disruption to ecologically significant locations (breeding, feeding or nesting sites) of a species.

As discussed in Section 3.5, Boobook undertook an ecological assessment of the Project Area to determine likelihood of occurrence and presence of potentially suitable habitat for EPBC Act and NCA listed flora and fauna (protected wildlife habitat) (for species relevant to SRI assessment under the EO Act)in the Project Area.

The Project Area may provide suitable habitat for a range of EPBC Act and NCA listed fauna species assessed as likely to or potentially to occur in the Project Area (refer to Table 9).

All species assessed as likely to or potentially to occur in the Project Area, with the exception of Short-beaked echidna (NCA: SL) and Woma (NCA: NT), are listed under both the EPBC Act and NCA.

Boobook (2025) have prepared an EAR to assess potential impacts posed by the proposed activities to relevant species, communities, and migratory species listed under the NCA and/or EPBC Act. The EAR has been compiled to support this application (for a new site-specific EA under the requirements of the EP Act), and to support a referral for the Project to the Department of Climate Change, Energy, the Environment and Water (DCCEEW) under the requirements of the EPBC Act.

Boobook undertook ecological impact assessment against the Significant Impact (SI) criteria as per the *Matters of National Environmental Significance - Significant Impact Guidelines 1.1 (DoE, 2013)* for EPBC Act listed species assessed as likely or potentially to occur in the Project Area.

Further, Boobook also undertook ecological impact assessment against the SRI criteria as per the SRI Guideline (DEHP, 2014) for relevant EPBC Act and NCA listed species assessed as likely or potentially occur in the Project Area. No EPBC Act or NCA listed flora species were assessed to likely or potentially occur in the Project Area (refer to Section 3.5 for further detail).

Following detailed assessment against the NCA SRI and EPBC Act SI criteria (as summarised in Table 19 and Table 20, respectively), Boobook (2025) concluded the proposed activities are not expected to result in an SI or SRI to relevant species (or their habitat) listed under the EPBC Act and NCA. Refer to the Boobook EAR (2025) for further information.

Table 19: Assessment of potential significant impacts upon NC Act-listed fauna species potentially present within the Project Area (adapted from Boobook, 2025).

Species	Significant Residual Impact Criteria (DEHP 2014)							Significant Residual Impact
	Lead to a long-term decrease in the size of a population.	Reduce the Extent of Occurrence (EoO) of the species.	Fragment an existing population / result in genetically distinct populations forming as a result of habitat isolation.	Cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.	Result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat.	Introduce disease that may cause the population to decline.	Interfere with the recovery of the species.	
Calyptorhynchus lathami Glossy Black-Cockatoo NC Act: Vulnerable	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat within remnant woodland. Feed trees occur nearby but are not present in the Disturbance Footprint. This small area would support few potential nesting/roost trees. The species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than a resident.	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat. No nest or roost trees were identified during surveys. This mobile and wide-ranging species is capable of traversing non-remnant areas between nest/roost trees and feed trees.	No: The disturbance will not affect dispersal of this species, which travels long distances between suitable foraging trees.	Unlikely: Loss of 0.30 ha of remnant woodland with potential nesting and roost trees. However, the species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than a resident.	None known	None known	Unlikely: Loss of 0.30 ha of remnant eucalypt woodland habitat. However, potential nest trees (large trees with large hollows) are in very low abundance.	No: There will be no decrease in foraging habitat. There may be minimal loss of potential nest sites with disturbance of 0.30 ha of remnant / regrowth potential habitat comprising RE 11.3.2.
Hirundapus caudacutus White-throated Needletail NC Act: Vulnerable	No: The species is an aerial feeding insectivore that forages over a wide range of intact and modified landscapes, with a general preference for wooded areas. It does not breed in Australia during its summer presence.	No: The proposed disturbance is not materially relevant to the species.	No: The proposed disturbance is not materially relevant to the species.	No: No impact on foraging resources is anticipated, no other critical locations are relevant to the species in Australia. The species roosts overnight in tall trees along scarps and is unlikely to roost in the Project Area.	None known	None known	No: The proposed disturbance will not reduce the extent of remnant woodland. The species does not breed in Australia.	No: The proposed disturbance is not materially relevant to the species.
Rostratula australis Australian Painted Snipe NC Act: Endangered	No: No potentially suitable habitat occurs within the Disturbance Footprint (i.e. the Disturbance Footprint lacks small ephemeral soaks in floodplain depressions and artificial wetlands such as farm dams).	No: There will be no disturbance to wetland habitat.	No: There will be no disturbance to wetland habitat. The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal in this species.	No: There will be no disturbance to wetland habitat and there is no habitat for this species within the Disturbance Footprint.	None known.	None known.	No: There will be no disturbance to wetland habitat and there is no habitat for this species within the Disturbance Footprint.	No: There will be no disturbance to wetland habitat and there is no habitat for this species within the Disturbance Footprint.
Phascolarctos cinereus Koala NC Act: Endangered	Unlikely: Potential loss of 0.30 ha of eucalypt woodland habitat will not lead to a decrease in size of the local population.	Unlikely: No sign of koala was detected within the Project Area. It is likely that the Project Area would be used by occasional transient individuals. The loss of 0.30 ha of potential habitat in the Disturbance Footprint is unlikely to affect the occurrence of Koala within the Project Area.	No: Koala are capable of crossing gaps between habitat patches and may use isolated paddock trees. The loss of several small areas of habitat, summing to 0.30 ha, will not disrupt habitat corridors through this area and will have negligible effect on Koala dispersal through the Project Area.	Unlikely: The loss of several small areas of eucalypt woodland habitat, summing to 0.30 ha, is unlikely to have measurable impacts on occasional Koala usage of the Project Area. All habitat within the Project Area is already fragmented and disturbed by thinning, grazing, weeds and edge effects. The Disturbance Footprint is a small proportion of this habitat.	None known	None known: chlamydia is present in the Koala population of southern inland Queensland, but this bacterial disease is unlikely to be exacerbated by the proposed development.	Unlikely: The loss of several small areas of potential habitat, totalling 0.30 ha will have minimal effect on the recovery of Koala in this area.	No: The proposed development will result in the loss of up to 0.30 ha of remnant and regrowth eucalypt woodland (RE 11.3.2) spread across several fragments. This small area is unlikely to reduce Koala numbers or to disrupt Koala movement through the area. No evidence of Koala was found within the Project Area and it is likely that Koala occurrence within the Project Area is occasional and transient. It is likely that the 0.30 ha of habitat proposed to be cleared involves the removal of <15 mature trees from the Disturbance Footprint.
Egernia rugosa Yakka Skink NC Act: Vulnerable	Unlikely: Removal of logs and accumulations of woody debris in 0.30 ha of habitat within the Disturbance Footprint could reduce some shelter and breeding habitat for this species. However, these features are scarce within the Project Area (BioCondition scores for woody debris averaged 20% of benchmark values) and low numbers of logs/log piles were recorded in microhabitat assessments.	Unlikely: Loss of 0.3 ha of woodland could potentially impact residents. However, few individuals would occupy this small area. The species was not detected within the Project Area and shelter habitat features were scarce. The disturbance will not affect the broader distribution of the species.	No: The disturbance does not pose a barrier to dispersal of this species.	Unlikely: Removal of logs and large woody debris may reduce shelter and breeding habitat. However, these habitat features are scarce in the Project Area.	None known.	None known.	Unlikely: Loss of 0.3 ha, across several habitat patches could potentially impact on any resident individuals but the disturbance is unlikely to affect overall abundance and occurrence within the region.	No: The presence pf this species was not confirmed within the Project Area. Loss of up to 0.30 ha of remnant and regrowth woodland habitat (RE 11.3.2) could impact on any resident individuals. However, this small area would hold few, if any, individuals and these impacts may be mitigated by preclearing of the route by a fauna spotter.
Hemiaspis damelii Grey Snake NC Act: Endangered	Unlikely: 0.30 ha of potential habitat occurs within the Project Area. Mapped habitat comprises fragmentary areas of riparian woodland.	Unlikely: The Project Area is peripheral to the species distribution. If the species occurs in this area, it is unlikely to be restricted to the mapped habitat.	No: The proposed development will not exacerbate existing fragmentation.	Unlikely: The 0.30 ha of mapped shelter, foraging, breeding and dispersal habitat comprises disturbed alluvial woodland fragments. Similar features occur in the vicinity and this habitat is unlikely to be limiting. Loss if 0.30 ha of habitat is unlikely to contribute to decline.	None known.	None known.	No: Only 0.30 ha of mapped habitat within the Project Area with similar habitat abundant in the vicinity.	No: Presence of this species within the Project Area was not confirmed during the field survey. The Project Area is peripheral to the species distribution and there are no records in the vicinity. Potentially suitable floodplain woodland and ephemeral wetland habitat (RE 11.3.2 and 11.3.25) occurs beyond the Disturbance Footprint.
Tachyglossus aculeatus Short-beaked Echidna NC Act: Special Least Concern	Unlikely: Loss of up to 0.30 ha of woodland habitat comprising regrowth and remnant. Removal of logs and accumulations of woody debris could reduce shelter and breeding habitat for this species. However, these features are scarce within the Project Area (BioCondition scores for woody debris averaged 20% of benchmark values. 1-5 logs with hollows in each 0.5 ha assessment site).	Unlikely: Loss of up to 0.30 ha of regrowth and remnant woodland habitat could potentially impact upon foraging or sheltering resident individuals. However, few individuals would occur in these small peripheral areas. The species was not detected within the Project Area and critical habitat features (e.g. log piles, large logs, rock crevices) were scarce or absent. The disturbance will not affect the broader distribution of the species.	No: The disturbance does not pose a barrier to dispersal of this species.	Unlikely: Removal of some logs and large woody debris may reduce shelter and breeding habitat. However, these habitat features are scarce in the Project Area. Available habitat in the Project Area is 144.72 ha	N/A	N/A	N/A	No: The species was not confirmed present within the Project Area. Loss of up to 0.30 ha of remnant and regrowth woodland habitat (RE 11.3.2) could impact on any resident individuals. However, this small area would hold few, if any, individuals and these impacts may be mitigated by preclearing of the route by a fauna spotter. The species is likely to have a patchy occurrence in the Project Area and suitable habitat features such as logs and woody debris were scarce within the Project Area.

Table 20: Assessment of potential significant impacts upon EPBC Act-listed fauna species within the Project Area (adapted from Boobook, 2025).

Species	Significant Impact Criteria (DoE 2013)									Significant Impact
	Lead to a long-term decrease in the size of a population	Reduce the Area of Occupancy (AoO) of the species	Fragment an existing population into two or more populations	Adversely affect habitat critical to the survival of a species	Disrupt the breeding cycle of a population	Modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is	Lead to a long-term decrease in the size of a population	Reduce the Area of Occupancy (AoO) of the species	Fragment an existing population into two or more populations	
Rostratula australis Australian Painted Snipe EPBC Act: Endangered	No. The species is a rare visitor in very low numbers to the region. There are no known important populations of the species in or near the Project Area.	No. The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal in this species.	No. Wetlands within the Project Area are very small and highly ephemeral. Although these wetlands may occasionally be used by transitory individuals they do not represent habitat critical to the surveyal of the species.	Unlikely: Breeding has been recorded in all months of the year in response to wetland conditions. The small and highly ephemeral nature of wetlands within the Project Area are unlikely to be attractive for breeding by this species.	No. Wetlands within the Project Area are very small and highly ephemeral. Disturbance will only occur to 0.60 ha of 7.31 ha available wetland habitat within the Project Area. Disturbance to this small area will not cause this species to decline.	None known.	None known.	No. The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.
Phascolarctos cinereus Koala Endangered	Unlikely: Potential loss of 0.30 ha of eucalypt woodland habitat will not lead to a decrease in size of the local population.	Unlikely: No sign of koala was detected within the Project Area. It is likely that this area would be used by occasional transient individuals. The loss of 0.30 ha of potential habitat in the Disturbance Footprint is unlikely to affect the occurrence of Koala within the Project Area.	No: Koala are capable of crossing gaps between habitat patches and may use isolated paddock trees. The loss of several small areas of habitat, summing to 0.30 ha, will not disrupt habitat corridors through this area and will have negligible effect on Koala dispersal through the Project Area.	Unlikely: The loss of several small areas of eucalypt woodland habitat, summing to 0.30 ha, is unlikely to have measurable impacts on occasional Koala usage of the Project Area.	No evidence of Koala was found within the Project Area and it is likely that Koala occurrence within the Project Area is occasional and transient. The breeding cycle is unlikely to be disrupted.	This small area is unlikely to reduce Koala numbers or to disrupt Koala movement through the Project Area. It is likely that the 0.30 ha of habitat proposed to be cleared involves the removal of <15 mature trees from the Disturbance Footprint.	None known	None known: chlamydia is present in the Koala population of southern inland Queensland, but this bacterial disease is unlikely to be exacerbated by the proposed development.	Unlikely: The loss of several small areas of potential habitat, totalling 0.30 ha will have minimal effect on the recovery of Koala in this area.	No: The proposed development will result in the loss of up to 0.30 ha of remnant and regrowth eucalypt woodland (RE 11.3.2) spread across several fragments.
Hemiaspis damelii Grey Snake EPBC Act: Endangered	Unlikely: 0.30 ha of potential habitat occurs within the Project Area. Mapped habitat comprises fragmentary areas of riparian woodland.	Unlikely: The 0.30 ha of mapped habitat includes already fragmented habitat patches.	No: The proposed development will not exacerbate existing fragmentation.	Unlikely: The 0.30 ha of mapped shelter, foraging, breeding and dispersal habitat comprises disturbed alluvial woodland fragments. Similar features occur in the vicinity and this habitat is unlikely to be limiting.	No: Only 0.30 ha of mapped habitat within the Project Area with similar habitat abundant in the vicinity.	Unlikely: The 0.30 ha of mapped shelter, foraging, breeding and dispersal habitat comprises disturbed alluvial woodland fragments. Similar features occur in the vicinity and this habitat is unlikely to be limiting. Loss if 0.30 ha of habitat is unlikely to contribute to decline.	None known.	None known.	No: Only 0.30 ha of mapped habitat within the Project Area with similar habitat abundant in the vicinity.	No: Presence of this species within the Project Area was not confirmed during the field survey. The Project Area is peripheral to the species distribution and there are no records in the vicinity. Potentially suitable floodplain woodland and ephemeral wetland habitat (RE 11.3.2 and 11.3.25) occurs beyond the Disturbance Footprint.
Calidris acuminata Sharp-tailed Sandpiper EPBC Act: Vulnerable	No. The species is an occasional visitor in low numbers to the region. There are no important populations of the species in or near the Project Area.	No. The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal of this species.	No. Wetlands within the Project Area are very small and highly ephemeral. Although these wetlands may occasionally be used by transitory individuals they do not represent habitat critical to the surveyal of the species.	No. The species does not breed within Australia. Breeding occurs between June and August in northern Siberia (DCCEEW 2024c).	No. Wetlands within the Project Area are very small and highly ephemeral. Disturbance will only occur to 0.60 ha of 7.31 ha available wetland habitat within the Project Area. Disturbance to this small area will not cause this species to decline.	None known.	None known.	No. The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.
Calyptorhynchus lathami lathami Glossy Black-Cockatoo EPBC Act: Vulnerable	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat within remnant woodland. Feed trees occur nearby but are not present in the Disturbance Footprint. This small area would support few potential nesting/roost trees. The species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than a resident.	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat. No nest or roost trees were identified during surveys. This mobile and wide-ranging species is capable of traversing non-remnant areas between nest/roost trees and feed trees.	No: The disturbance will not affect dispersal of this species, which travels long distances between suitable foraging trees.	Unlikely: Loss of 0.30 ha of remnant woodland with potential nesting and roost trees. However, the species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than a resident.	Unlikely: Loss of 0.30 ha of remnant woodland with potential nesting trees. However, the species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than a breeding resident.	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat within remnant woodland. Feed trees occur nearby but are not present in the Disturbance Footprint.	None known	None known	Unlikely: Loss of 0.30 ha of remnant eucalypt woodland habitat. However, potential nest trees (large trees with large hollows) are in very low abundance.	No: There will be no decrease in foraging habitat. There may be minimal loss of potential nest sites with disturbance of 0.30 ha of remnant / regrowth potential habitat comprising RE 11.3.2.
Gallinago hardwickii Latham's Snipe EPBC Act: Vulnerable	No. The species is an occasional visitor in low numbers to the region. There are no important populations of the species in or near the Project Area.	No. The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal of this species.	No. Wetlands within the Project Area are very small and highly ephemeral. Although these wetlands may occasionally be used by transitory individuals they do not represent habitat critical to the surveyal of the species.	No. The species does not breed within Australia. Breeding occurs between May and July in north-eastern Asia (Hansen *et al.* 2020).	No. Wetlands within the Project Area are very small and highly ephemeral. Disturbance will only occur to 0.60 ha of 7.31 ha available wetland habitat within the Project Area. Disturbance to this small area will not cause this species to decline.	None known.	None known.	No. The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.
Hirundapus caudacutus White-throated Needletail EPBC Act: Vulnerable	No: The species is an aerial feeding insectivore that forages over a wide range of intact and modified landscapes, with a general preference for wooded areas.	No: The proposed disturbance is not materially relevant to the species.	No: The proposed disturbance is not materially relevant to the species.	No: No impact on foraging resources is anticipated, no other critical locations are relevant to the species in Australia. The species roosts overnight in tall trees along scarps and is unlikely to roost in the Project Area.	No. It does not breed in Australia during its summer presence.	No: The proposed disturbance is not materially relevant to the species.	None known	None known	No: The proposed disturbance will not reduce the extent of remnant woodland. The species does not breed in Australia.	No: The proposed disturbance is not materially relevant to the species.
Egernia rugosa Yakka Skink EPBC Act: Vulnerable	Unlikely: Removal of logs and accumulations of woody debris in 0.3 ha of habitat within the Disturbance Footprint could reduce some shelter and breeding habitat for this species. However, these features are scarce within the Project Area (BioCondition scores for woody debris averaged 20% of benchmark values) and low numbers of logs/log piles were recorded in microhabitat assessments.	Unlikely: Loss of 0.3 ha of woodland could potentially impact residents. However, few individuals would occupy this small area. The species was not detected within the Project Area and shelter habitat features were scarce. The disturbance will not affect the broader distribution of the species.	No: The disturbance does not pose a barrier to dispersal of this species.	Unlikely: Removal of logs and large woody debris may reduce shelter and breeding habitat. However, these habitat features are scarce in the Project Area.	Unlikely. The species has a patchy occurrence in the region and suitable habitat features such as logs and woody debris were scarce within the Project Area.	Unlikely. The species has a patchy occurrence in the region and suitable habitat features such as logs and woody debris were scarce within the Project Area.	None known.	None known.	Unlikely: Loss of 0.30 ha, across several habitat patches could potentially impact on any resident individuals but the disturbance is unlikely to affect overall abundance and occurrence within the region.	No: The presence pf this species was not confirmed within the Project Area. Loss of up to 0.30 ha of remnant and regrowth woodland habitat (RE 11.3.2) could impact on any resident individuals. However, this small area would hold few, if any, individuals and these impacts may be mitigated by preclearing of the route by a fauna spotter.

4.5 Surface Water and Wetlands

The proposed activities have potential to result in direct and indirect impacts to surface water EVs (as described in Section 3.7) primarily as a result of:

- drilling and hydraulic stimulation / fracturing activities;
- production operations;
- infrastructure construction (earthworks activities including grading and trenching);
- vehicle and plant movements;
- minor spills or leaks of fuels and chemicals from vehicles and equipment;
- loss of containment; and
- flood (natural event).

Santos aims to minimise the operational footprint and significant disturbance associated with its activities as far as reasonably practicable. However, potential direct and indirect impacts to surface water values resulting from the proposed activities may include (adapted from KCB, 2025):

- disturbance to natural drainage patterns;
- degradation of downstream water quality from sediment releases / minor spills or leaks of fuels, chemicals or other fluids (PW / hydrotest water);
- damage to and/or loss of native riparian vegetation and habitat;
- reduction in groundwater quantity and/or availability for other users; and
- contamination of soil and/or watercourses.

As discussed in Section 3.7, Santos commissioned KCB to undertake a WRA (KCB, 2025) of proposed activities located in the Project Area (attached as Appendix E). The following summary is based on the findings of the report as they relate to surface water and wetlands. Refer to Appendix E for further information.

As discussed in Section 3.7, the PDF (linear infrastructure only) will cross mapped SO 1 watercourses at five locations, and will cross mapped SO 3 watercourses at two locations. Drainage features located in the Project Area are mapped as SO 1 to 4, and they are expected to be ephemeral, with streamflow only expected to occur following rainfall events. There is limited to no groundwater contribution from the regional groundwater system to watercourses (as baseflow) in the Project Area.

Further, there are no HES or GES wetlands, spring vents, spring complexes or watercourse springs recorded within or in the vicinity of the Project Area. Boobook (2025) did identify several small ephemeral wetland areas located in non-remnant vegetation (cleared paddocks) in the Project area. These areas are potential ephemeral habitat for wetland bird species such as Australian Painted Snipe (*Rostratula australis*) and Latham's Snipe (*Gallinago hardwickii*).

Proposed linear infrastructure construction activities will be undertaken in compliance with proposed EA conditions relating to impacts to surface waters and wetlands (refer to Schedule B EA conditions in Appendix A).

Further, to ensure no significant impacts to waterways providing for fish passage, linear infrastructure construction activities located in waterways providing for fish passage would not:

- reduce the extent, frequency, or duration of fish passage;
- result in a substantial change to the hydrological regime of the watercourse; or
- lead to significant changes in water quality parameters within the watercourse.

Appropriate erosion and sediment control (ESC) measures will also be implemented where required to mitigate potential sediment impacts to drainage features. The RoW will also be constructed ensure sufficient area is available to construct appropriate erosion and ESC structures (where required). These ESC structures will assist to minimise potential for sedimentation to waters.

Rehabilitation will commence as soon as reasonably practicable following completion of construction activities, including the restoration of natural landform contours to ensure natural surface water flows are maintained.

Other measures to be carried out to reduce impacts on surface waters include:

- watercourse crossings would be designed to ensure fish passage during periods of flow is maintained;
- construction of linear infrastructure within a water course would preferentially be carried out in periods of low or no flow;
- where it is necessary to carry out works in a watercourse during periods of flow, these would be carried out in accordance with the relevant Department of Agriculture, Fisheries and Forestry Waterway Barrier Works Code(s);
- watercourse crossings would be selected at locations where the least impact to riparian flora and fauna will occur (i.e. clearing of vegetation and at narrowest and shallowest locations) where practicable;
- construction or maintenance of linear infrastructure activities in watercourses will comply with the turbidity limit of relevant EA conditions, and water quality monitoring would be carried out downstream of watercourse crossing works where necessary to ensure compliance with water quality limits;
- santos will only construct in ephemeral wetland areas when they are dry, and linear infrastructure RoWs will be reinstated to their natural landform following construction;
- appropriate spill kits would be kept on site and in staff vehicles for use in the event of a spill or leak of hydrocarbons or chemicals; and
- chemicals, fuels or other hazardous substances would be stored and managed in accordance with relevant Australian Standards.

Groundwater impact modelling predicts some drawdown may occur in the Springbok Sandstone due to proposed CSG water extraction. There are no predicted impacts to water resources due to project related groundwater drawdown in the Springbok Sandstone because the Springbok Sandstone is overlain by several tight aquitards such as the Westbourne Formation, the Orallo Formation, and the Doncaster Member. Groundwater modelling demonstrates that drawdown from the Springbok Sandstone does not propagate through to surface formations. The Springbok Sandstone outcrops ~38km north of the Project Area, which is located outside the project's area of influence. Based on the lack of predicted drawdown for the geological units overlying the Springbok Sandstone and surficial Quaternary deposits, and the fact that the Springbok Sandstone outcrops well outside the project's area of lateral drawdown influence, there is no potential for impacts to the surficial hydrological systems as a result of the proposed activities. Refer to Appendix E (KCB, 2025) for further information.

Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to surface water EVs as a result of the proposed activities are classified as 'Low'.

4.6 Groundwater

As discussed in Section 3.7, Santos commissioned KCB to undertake a WRA (KCB, 2025) of proposed activities located in the Project Area (attached as Appendix E).

Predicted impacts to groundwater as a result of the Project were estimated using the OGIA groundwater model developed for predicting effects on groundwater due to CSG and coal mine development within the Surat Cumulative Management Area (CMA). Based on the information provided by Santos and for the purpose of assessing potential impact of CSG water extraction on groundwater resources, OGIA have modelled a Project only scenario, which includes only CSG water production from the Project, and a Cumulative scenario, which includes the simulation of all current and proposed CSG and coal mine developments within the Surat CMA.

Potential impacts to water-dependent assets have been considered with respect to the *Water Act 2000* trigger threshold for springs (0.2 m drawdown) and bores (5 m drawdown in consolidated aquifer; 2 m drawdown in unconsolidated aquifer) using the predicted drawdown for both the Project only and Cumulative scenarios:

- For the Project only scenario, the predicted long-term drawdown impacts associated with the Project are limited to the Springbok Sandstone, the WCM and the Durabilla Formation, located at depths greater than 500 mbgl in the Project Area.
- The Cumulative scenario drawdown results indicate drawdown within the Westbourne Formation, Springbok Sandstone, WCM and Durabilla Formation, located at depths greater than 470 mbgl in the Project Area.
- The Cumulative scenario predicts drawdown greater that 0.2 m in outcropping geological units (Bungil Formation, Mooga Sandstone and Orallo Formation) in an area more than 12 km geologically up-dip and to the north of the Project Area. This drawdown is not associated with the proposed Project but is rather associated with the water production from neighbouring CSG developments operating on tenures located closer to these outcropping units.

Given the abovementioned modelling results and assessment findings, the WRA concluded that exceedance of the *Water Act 2000* water level trigger (and Commonwealth Joint Industry Framework (JIF)) GDE risk thresholds is not anticipated for the proposed activities; and:

- Surficial deposits are not recognised to be connected to the Surat Basin units in the Project Area. There is no predicted Project only drawdown in these surficial deposits. The Project was assessed to not have a significant impact on GDEs.
- Bore triggers are not predicted to be exceeded as a result of the Project.
- Notable wetlands, spring vents or spring complexes are not predicted to be impacted. The Project only contribution to the predicted Cumulative scenario drawdown for watercourse springs is assessed to be negligible.
- Proposed activities do not include planned direct abstraction from, or discharges to, watercourses. Impacts on surface water users, EVs and spiritual values are not anticipated.

Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to groundwater EVs as a result of the proposed activities are classified as ‘Low’.

4.6.1 Hydraulic Fracture Stimulation

As discussed in Section 2.2, subject to trials and project planning, all wells to be located in the Project Area may be subject to stimulation (i.e. hydraulic fracturing). Hydraulic fracturing is necessary to properly assess the potential of the petroleum resource and inform decision making on future projects, as well as to increase the recovery of the resource.

Potential impacts to groundwater as a result of hydraulic fracture stimulation, and mitigation strategies, are discussed in Section 4.6 and summarised in Table 33, respectively. Moreover, Santos ensures the risk of environmental harm to groundwater formations is negligible by ensuring CSG wells are drilled and hydraulic fracturing processes are undertaken in accordance with the *Code of Practice for the*

construction and abandonment of petroleum wells and associated bores in Queensland Version 2 (Code of Practice) (DNRME, 2019). The purpose of this code is to ensure that all petroleum wells, CSG wells and associated bores are constructed, maintained and abandoned to a minimum acceptable standard resulting in long-term well integrity, containment of petroleum and the protection of groundwater resources.

Further, Santos uses best practice well logging, well design, well completion and well cementing methods to ensure well integrity prior to hydraulic fracturing. This would ensure fracture and production fluids are contained within the well and isolated from the aquifer units during the wells production life and following plugging and abandonment.

The Queensland Government's Gasfields Commission publishes data on well integrity. They have concluded that when such national and international codes are used then the likelihood, and therefore risk, of well integrity failure resulting in underground leakage is assessed to be low to near zero (Queensland Gasfield Commission, 2015). Santos' production wells will be designed to:

- prevent any interconnection between target hydrocarbon-bearing formations and aquifers;
- ensure that gas is contained within the well and associated pipework and equipment without leakage;
- ensure zonal isolation between different aquifers is achieved; and
- not introduce substances that may cause environmental harm.

Santos has prepared a Hydraulic Fracturing Risk Assessment (HFRA) (EHS Support 2021)) and Stimulation Impact Monitoring Program (SIMP) (Santos, 2021) for Santos' production operations throughout Eastern Queensland, including PL 1123. Further, Santos has developed a Chemical Risk Assessment Framework (CRAF) (Santos, 2025) for the Project.

The HFRA is attached to this document as Appendix H. The SIMP is attached as Appendix 4 to the WRA (KCB, 2025) (attached as Appendix E). The CRAF is available upon request by DETSI.

Monitoring of the hydraulic stimulation process (and stimulation fluids) is undertaken throughout the stimulation activities (prior- and post- activities) in accordance with the requirements of the SIMP.

The CRAF has been developed to guide the assessment of risk associated with chemicals used during CSG operations (drilling and completions, and hydraulic fracturing) for the Project. The CRAF incorporates best practice risk assessment methodology for the assessment of potential impacts associated with the use of chemicals to MNES and MSES. The CRAF is based on existing Santos approved chemical risk assessment frameworks and aligns with best practice methodologies.

Further, a Project specific Chemical Risk Assessment Register (CRAR) (EHS Support 2024) has been developed in accordance with the requirements of the CRAF to identify the potential risks and effects of chemicals used during CSG operations (drilling and completions, and hydraulic fracturing) specific to the Project. The CRAF / CRAR assessment process is designed to align with national guidance and other regulatory frameworks and assesses the full lifecycle of chemicals that are stored, transported, handled, used and / or disposed during or following drilling and completions, and hydraulic fracturing activities. The CRAR summarised the potential risks and effects of chemicals used during the life cycle of CSG extraction to MNES / MSES.

The abovementioned assessments indicate the risks associated with hydraulic fracturing operations are manageable.

4.6.2 Underground water rights requirements (s126A EP Act)

Section 126A of the EP Act has specific requirements for application that:

- are carried out on one or more resource tenures for which the relevant tenure is a petroleum lease; and

- involve the exercise of underground water rights or a change to the exercise of underground water rights.

The requirements for section 126A are addressed in Table 21.

Table 21: Exercising underground water rights

Requirement	Reference to Information
A statement that the applicant proposes to exercise underground water rights.	Santos proposed to exercise underground water rights within the Project Area (PL 1123) as authorised under the *Petroleum and Gas (Production and Safety) Act 2004.*
A description of the area/s in which underground water rights are proposed to be exercised.	The areas that may be developed comprise the full extent of the Project Area (PL 1123), notwithstanding specific land access, cultural heritage or environmental constraints that may influence development of certain petroleum activities within the Project Area.
A description of the aquifer/s affected or likely to be affected.	Refer to Sections 3.8.1 and the WRA (KCB, 2025) (attached as Appendix E).
An analysis of the movement of underground water to and from the affected or potentially affected aquifer/s.	Refer to Sections 3.8.2 to 3.8.4 and the WRA (KCB, 2025) (attached as Appendix E).
A description of the area of the aquifer where the water level is predicted to decline because of the exercise of underground water rights.	Refer to Section 3.8 and the WRA (KCB, 2025) (attached as Appendix E).
The predicted quantities of water to be taken or interfered with because of the exercise of underground water rights.	The total estimated groundwater abstraction volume for the duration of the Project (with an expected operational life of 30-50 years) is estimated to be 645 ML (KCB, 2025).
Information on predicted impacts to the quality of groundwater that will, or may, happen because of the exercise of underground water rights.	Refer to Section 4.6 and the WRA in detail (KCB, 2025) (attached as Appendix E). Provided that petroleum wells are designed and construction in accordance with the *Code of Practice for the construction and abandonment of petroleum wells and associated bores in Queensland Version 2* (DNRME, 2019) and measures identified in Section 4.6 and Table 33 are implemented, there is unlikely to be any impact on groundwater quality from the exercise of underground water rights. This is because well integrity measures will ensure that separated hydrostratigraphic units remain isolated. Further, potential impacts to water-dependent assets have been considered with respect to the *Water Act 2000* trigger threshold for springs (0.2 m drawdown) and bores (5 m drawdown in consolidated aquifer; 2 m drawdown in unconsolidated aquifer) using the predicted drawdown for both the Project only and Cumulative scenarios: • For the Project only scenario, the predicted long-term drawdown impacts associated with the Project are limited to the Springbok Sandstone, the WCM and the Durabilla

Requirement	Reference to Information
	Formation, located at depths greater than 500 mbgl in the Project Area. • The Cumulative scenario drawdown results indicate drawdown within the Westbourne Formation, Springbok Sandstone, WCM and Durabilla Formation, located at depths greater than 470 mbgl in the Project Area. • The Cumulative scenario predicts drawdown greater that 0.2 m in outcropping geological units (Bungil Formation, Mooga Sandstone and Orallo Formation) in an area more than 12 km geologically up-dip and to the north of the Project Area. This drawdown is not attributed to the proposed Project, but rather to groundwater extraction associated with neighbouring CSG developments operating on tenures located closer to these outcropping units. Given the abovementioned modelling results and assessment findings, the WRA (KCB, 2025) concluded that exceedance of the *Water Act 2000* water level trigger (and Commonwealth Joint Industry Framework (JIF)) and GDE risk thresholds is not anticipated for the proposed activities; and: • Surficial deposits are not recognised to be connected to the Surat Basin units in the Project Area. There is no predicted Project only drawdown in these surficial deposits. The Project was assessed to not have a significant impact on GDEs. • Bore triggers are not predicted to be exceeded as a result of the Project. • Notable wetlands, spring vents or spring complexes are not predicted to be impacted. The Project only contribution to the predicted Cumulative scenario drawdown for watercourse springs is assessed to be negligible. • Proposed activities do not include planned direct abstraction from, or discharges to, watercourses. Impacts on surface water users, EVs and spiritual values are not anticipated.
Information on the environmental values that will, or may, be affected by the exercise of underground water rights.	**Impact to Water Bores** Refer to Sections 3.8.6 and 4.6. For the Project only scenario, the maximum predicted drawdown in the target formations at the locations of the 368 (existing, abandoned but usable, proposed and potential) water supply bores, is 0.03 m. For the Cumulative scenario, assessment was undertaken using the same approach adopted for the Project only scenario (e.g. *Water Act 2000* trigger thresholds). No bores are indicated to exceed the trigger threshold within a 25 km buffer of the Project Area. The bore triggers are therefore not predicted to be exceeded as a result of Project only or Cumulative scenario activities and predicted impact on groundwater supply bores is assessed as negligible. The contribution of the Project does not result in any additional bores being triggered in the Cumulative scenario. Further, under the Queensland *Water Act 2000*, CSG proponents are required to undertake baseline assessments of water bores located within their petroleum tenures prior to

Requirement	Reference to Information
	commencement of production. Baseline assessments are undertaken in accordance with the *Baseline Assessment Guideline* (DES, 2017), to obtain information such as: bore status, type and purpose; information related to the construction of the bore, including depth installed, screen interval and source aquifer; groundwater level and quality and field gas measurement; and bore equipment including pump depth, pumping frequency and flow rate. There is one operational water bore located within the Project Area. This bore is attributed to the Mooga Sandstone. The baseline assessment was undertaken in 2009 for RN 123195 (refer to Table 13). Another groundwater bore (RN208460) was drilled on the tenement in June 2024. This new bore is indicated as "no longer used". Santos are in the process of revising their Baseline Assessment Plan, as required by the Queensland *Water Act*, with baseline assessment planned to occur in Q4 2025 (prior to commencement of the Project) if it is required. **Impact to GDEs** Refer to Section 3.8.5 and 4.6. No new springs and GDE areas are triggered due to drawdown contribution from the Project, and no material impacts on spring vents, complexes or watercourse springs as a result of Project development are identified. Further, it is considered unlikely that groundwater present in surficial units, that potentially support TGDEs, will be impacted by CSG related drawdown due to the Project. Refer to Appendix E (KCB, 2025) for further information. **Impact to Other Surface Waters** Refer to Sections 3.7 and 4.4. Based on the lack of predicted drawdown for the geological units overlying the Springbok Sandstone and surficial Quaternary deposits, and the fact that the Springbok Sandstone outcrops well outside the project's area of lateral drawdown influence, there is no potential for impacts to the surficial hydrological systems as a result of the proposed activities. Refer to Appendix E (KCB, 2025) for further information.
Information on strategies for avoiding, mitigating or managing the predicted impacts on the environmental values or predicted impacts on the quality of groundwater.	Refer to Section 4.6 and Table 33.

4.7 Air Quality and Noise

The proposed activities may result in impacts to air quality and noise values (as described in Section 3.9), respectively), primarily as a result of:

- infrastructure construction;
- vehicle and plant movements;
- fire (ignition sources resulting from activities); and
- minor exhaust emissions generated from vehicles, equipment and machinery.

Santos aims to minimise the operational footprint and significant disturbance associated with its activities as far as reasonably practicable. However, potential direct and indirect impacts to air quality and noise values resulting from the proposed activities may include:

- air pollution and localised reduction in air quality;
- nuisance caused by vibration, noise and dust generation; and
- disturbance to fauna and livestock.

The majority of these potential air and noise impacts would be temporary and limited to the initial construction period. The proposed activities (and potential noise and air quality impacts) are also consistent with those associated with existing petroleum activities authorised by the nearby Backbone EA (EPPG04323316), RSGPA (EPPG00898213) and RSGPAE (EPPG00662213) EAs, and existing land use (pastoral / grazing / cropping activities).

Construction activities associated with the proposed development would typically occur from 6am to 6pm, seven days per week for a relatively limited period of time i.e. limited to a number of weeks.

Background noise monitoring has not been undertaken for the proposed activities given that the development occurs within the existing operational GLNG-GFD tenure areas (RSGPA and RSGPAE EA tenure areas).

The deemed background noise levels as prescribed in Table 2 of the DETSI guideline *'Prescribing noise conditions for environmental authorities for petroleum activities*' (ESR/2016/1935, Version 2.05) (DETSI, 2025) are considered to be representative of the ambient acoustic environment. The deemed background levels are detailed in Table 22.

Table 22: Deemed Background Noise Levels

Time period	Deemed background noise level (dB(A))
7:00 am – 6:00 pm	35
6:00 pm – 10:00 pm	30
10:00 pm – 6:00 am	25
6:00 am – 7:00 am	30

The primary air pollutants generated during construction and operations would be minor dust and exhaust emissions from operating vehicles, plant and machinery. These sources will be predominately temporary, occurring only during the construction period. These relatively minor dust and exhaust emissions would remain local to the source, and are unlikely to affect air quality EVs of the broader Project Area provided that mitigation and management measures identified in Table 33 are implemented. There are eleven potential sensitive receptors, including five residences located within the Project Area, and six residences located within approximately 1km of the Project Area boundary.

Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to air quality and noise EVs as a result of the proposed activities are classified as 'Low'.

4.8 Waste

The proposed activities may result in impacts to EVs (as described in Section 3.9), respectively) due to the generation of waste, primarily as a result of the storage and disposal of:

- general waste;

- waste fuels;
- oils and other chemicals; and
- produced fluids and other process wastes.

Excessive waste generation from the inefficient use of resources, and improper management or storage of wastes generated by petroleum activities, has the potential to impact on EVs. Under Schedule 8, Part 3 of the *Environmental Protection Regulation 2019*, the environmental objective for activities with waste impacts is:

> *Any waste generated, transported, or received as part of carrying out the activity is managed in a way that protects all environmental values.*

Performance outcomes are:

a) waste generated, transported, or received, is managed in accordance with the waste and resource management hierarchy in the *Waste Reduction and Recycling Act 2011*; and

b) if waste is disposed of, it disposed of in a way that prevents or minimises adverse effects on environmental values.

Waste that would potentially be generated by the proposed activities may include the following:

- batteries and electrical – lead acid batteries, gel type batteries, nickel cadmium batteries and alkaline batteries generated from equipment, vehicles, generators and electronics;
- chemical waste and chemical containers – chemical wastes may include herbicides, pesticides, paints and solvents. Chemical containers are those containing any volume of free chemical that is a regulated waste and may include waste oil containers and aerosol cans containing solvent or paint;
- concrete / aggregate / asphalt – concrete, aggregate and asphalt materials removed from demolished infrastructure that are not suitable for recycling;
- contaminated soil – contaminated soils may be generated where localised spills of hydrocarbons and other contaminants occurs;
- cooking oil – waste cooking oil is generated from kitchen facilities at temporary mobile camps;
- drilling fluids and muds – waste drilling fluids, muds and cuttings are generated from the drilling process;
- effluent – treated effluent from the STP;
- general recycling – plastic bottles and food containers, glass bottles and jars, milk cartons, aluminium bottles and cans, metal lids from jars, tin cans, aluminium cans, plastic cups, cardboards and paper packaging, folders, envelopes, office paper, magazines, cereal boxes, clean paper towels, steel scraps;
- grease trap waste – grease trap waste is generated from kitchen facilities at temporary mobile camps;
- green waste – green waste produced from vegetation clearing activities;
- hydrostatic test water – spend water used in the hydrostatic testing of pipelines to test pipeline integrity;
- intermediate bulk containers (IBCs) – containers used for transport of fluids and bulk materials;
- oily filters, rags, and absorbents - Oily filters, rags, and absorbents are generated from routine equipment and vehicle servicing, repair and filter changes;
- oily water – oily water may be produced from servicing equipment, machinery and vehicles;
- pipeline tape wrap – pipeline tape wrap protects the pipeline against corrosion;

- plastic lines - waste plastic liners associated with sumps and turkeys nest dams;
- PW – also known as coal seam gas water, is released from the coal seam and brought to the surface during operation of wells;
- putrescible and other domestic waste – food scraps, food wrappers, packaging materials, textile materials, plastic wrapping film, plastic bags, facial tissues, ear plugs, pens and pencils, polystyrene, aluminium foil, waxy paper, cardboard, non-recyclable plastics, etc.;
- scrap steel and metal – scrap steel and metal may include steel piping, values and cabling;
- stimulation fluids and flowback water – this waste is generated when the fluids used in the stimulation process are brought back to the surface;
- timber – untreated timber derived from packaging and uses that cannot be reused or recycled;
- triethylene glycol (TEG) / glycol / coolant – is generated from equipment and vehicle fluid changes;
- tyres – tyres and tubes are generated from tyre changes on work and vehicle equipment;
- used spill kits – used spill kits are generated from spill clean-up of chemicals and hydrocarbons;
- waste oil – small quantities of waste oil are generated routinely from vehicle and equipment oil changes;
- wellhead separator waste (coal fines) – separators at wellheads separate gas and water and remove other materials; and
- wiring – electrical wiring and equipment not suitable for reuse.

Further, management of PW, residual drilling materials, hydraulic fracturing stimulation fluids and hydrostatic test water and water from LPDs are specifically discussed in Sections 4.8.1 to 4.8.5.

Impacts associated with the generation of waste, primarily as a result of the storage and disposal of waste, have the potential to impact on EVs including on land and biodiversity, visual amenity, soil and water quality and human health. Santos aims to minimise the operational footprint and significant disturbance associated with its activities as far as reasonably practicable. However, potential direct and indirect impacts to EVs resulting from the generation, storage and disposal of waste may include:

- reduction in visual amenity;
- disturbance, injury or loss of fauna and livestock (i.e. fauna/livestock access to waste/contaminants);
- contamination of soil and water resources (groundwater / surface water);
- disturbance to land use and land suitability changes; and
- reduction in agricultural productivity.

Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to EVs due to the generation, storage and disposal of waste as a result of the proposed activities are classified as ‘Low’

4.8.1 Produced Water Management

PW (generated as part of CSG production activities) would be managed in accordance with the Queensland Government’s *Coal Seam Water Management Policy 2012* (DETSI, 2025d).

As discussed in Section 2.2, the majority of PW generated from the Project Area will be transferred to existing approved water storages and treatment facilities located adjacent to the Project Area on PLs

314 and 315 via new and existing water gathering and storage infrastructure. Petroleum activities undertaken on PLs 314 and 315 are authorised under existing Santos EA EPPG00898213 (RSGPA).

Table 23 outlines the expected water quality for the Project, based on Myalla (PL 282: neighbours the Project Area diagonally to the northeast) and Washpool Creek (PL 318: neighbours the Project Area to the south) well data. PW quality is slightly alkaline with elevated chloride and sodium concentrations, which contribute to elevated TDS / EC levels (KCB, 2025).

Peak water production is predicted to occur in January 2028 at 0.24 ML/day (7.12 ML/month). The total volume of PW for the duration of the Project is estimated to be 645 ML (KCB, 2025). Adequate water and brine storage and treatment capacity has been assessed to be available on adjacent tenures to manage peak water and brine production from the Project.

Further, Santos have established procedures to prevent uncontrolled discharge of PW (i.e. restriction of production by “turning down” or “shutting-in” wells). Site water balances are undertaken for all project phases at these water management facilities to ensure adequate storage and treatment capacity is available, and this will include consideration of PW transferred from the Project Area.

PW stored within the Project Area will be limited to small volumes held in portable tanks. A proportion of PW stored in tanks on site will be used for on-site activities such as water supply for drilling and hydraulic fracturing purposes, and/or to provide a water source for dust suppression / construction activities (where the water use meets proposed EA conditions and criteria). Approximately 158 ML of water will be re-used in this way, and represents ~24% of estimated PW volume. Design and operation of portable tanks will follow Queensland regulatory conditions and guidelines.

Beneficial use of PW in the Project Area would be carried out to achieve the following outcomes:

- vegetation is not damaged;
- soil quality is not adversely impacted;
- there is no surface ponding or runoff beyond the designated release area;
- there are no aerosols or odours;
- deep drainage below the root zone of any vegetation is minimised; and
- the quality of shallow aquifers is not adversely affected.

Detailed management measures for each component of the PW management system, and measurable criteria for PW management and beneficial use, are outlined in Table 24 and Table 25, respectively.

Requirements for a site-specific application for CSG activities (s126 of the EP Act) are addressed in Section 1.2.2 (requirements for site specific applications). In the event that any management criteria are not complied with, works/operations that potentially cause the non-compliance would be assessed (and paused if appropriate) and an investigation would commence to identify why the non-compliance has occurred, the effectiveness of existing controls, new controls to be applied where appropriate and any remedial actions to be taken.

Produced water quality (Section126(1)(c) of the EP Act)

Material changes to the quality of PW are not reasonably expected to occur while the activity is being carried out. PW quality will be monitored in accordance with relevant EA conditions and the requirements of the SIMP. Further, as per the requirements outlined in the *Petroleum and Gas (Production and Safety) Act 2004*, the volume of PW will be monitored and recorded and provided to the DNRME in accordance with statutory obligations.

Further, to minimise impacts to shallow groundwater quality, as a result of beneficial use activities such as dust suppression and off tenement irrigation, water quality will be monitored to confirm compliance with water quality objectives in the *End of Waste Code Irrigation of Associated Water (including coal*

seam gas water) (ENEW07546918, Version 1.07) (DETSI, 2025a) and *End of Waste Code Associated Water (including coal seam gas water) (ENEW07547018, Version 1.06)* (DETSI, 2025b).

4.8.2 Prioritisation hierarchy for managing and using CSG water and managing saline waste

The objective of the *Coal Seam Water Management Policy 2012* (DETSI, 2025d) is to encourage the beneficial use of CSG water in a way that protects the environment and maximises its productive use as a valuable resource.

The objective of the policy is achieved when CSG water and saline waste is managed consistently with the prioritisation hierarchies and the management criteria as below:

Managing and using CSG water:

- **Priority 1** – CSG water is used for a purpose that is beneficial to one or more of the following: the environment, existing or new water users, and existing or new water-dependent industries.
- **Priority 2** – After feasible beneficial use options have been considered, treating and disposing CSG water in a way that firstly avoids, and then minimises and mitigates, impacts on EVs.

Managing saline/brine waste:

- **Priority 1** – Brine or salt residues are treated to create useable products wherever feasible.
- **Priority 2** – After assessing the feasibility of treating the brine or solid salt residues to create useable and saleable products, disposing of the brine and salt residues in accordance with strict standards that protect the environment.

To meet the objective of the policy, Santos has conducted a detailed assessment of the proposed water management methods to ensure the proposed management options are achievable and realistic.

Accordingly, Santos has adopted the management option, principle and criteria as outlined in Table 24 and Table 25. The proposed management principles align with the DETSI *Information Sheet: CSG water management: measurable criteria* (ESR/2016/1902) (Version 1.03), and the proposed conditions of the EA. Produced water may be used for dust suppression in alignment with proposed EA conditions.

Prioritisation hierarchy for managing saline/brine waste under the policy

CSG brine is the waste that is produced as a result of treating CSG water using RO technologies. Brine is generally unsuitable for release to the environment and must be appropriately managed in a dedicated CSG brine dam. The concentration and composition of salts and minerals in the brine depends on the characteristics of the CSG water and the treatment process.

The volume and concentrations of total dissolved solids (TDS) in CSG water vary significantly across individual fields. DETSI defines brine as water with a TDS concentration greater than 40,000 milligrams per litre which is a category 2 regulated waste.

In 2023, DETSI in collaboration with industry community groups and academia developed a long-term approach for the management of CSG brine 2023-2033 (the action plan). Under the action plan it is recognised that while the most feasible option is encapsulation of brine waste, research and investigation of alternative options for brine management must be continued in keeping with circular economy principles.

Brine will not be stored in the Project Area. As discussed in Section 2.2, the majority of PW (and resulting saline/brine waste) generated from the Project Area will be transferred to existing approved water storages and treatment facilities located adjacent to the Project Area on PLs 314 and 315 via new and existing water gathering and storage infrastructure. Petroleum activities undertaken on PLs 314 and 315 are authorised under existing Santos EA EPPG00898213 (RSGPA).

On PL 314, the water will be processed through a fines and sludge removal facility before being further processed, or bypassed around, the Roma Reverse Osmosis Plant (ROP) to meet re-use criteria in accordance with *End of Waste Code Irrigation of Associated Water (including coal seam gas water) (ENEW07546918, Version 1.07)* (DETSI, 2025a).

Table 23: PL 1123 Expected Water Quality (adapted from KCB, 2025)

Analyte	Dissolved or total	Limit of detection	Min.	P10	Median	P90	Max.	Sample count
Boron (mg/L)	Dissolved	0.05	<0.05	0.563	0.71	0.857	0.92	44

Table 24: Management of each component of produced water management system

PW management action	Management measures

Storage	• PW may be temporarily stored in portable tanks prior to beneficial use on site, treatment for beneficial use, or transfer off-tenure;
	• tanks would be located away from watercourses and sensitive areas to minimise risk of water reaching watercourses in the event of a release;
	• tanks would be designed in accordance with relevant standards;
	• tanks would be regularly monitored and inspected to ensure sufficient capacity and integrity;
	• in the event of a release, the following measures would be implemented:
	  ○ cause and release location would be identified and actions taken to rectify failure;
	  ○ sampling/monitoring of affected soil and/or water would be carried out where necessary to determine impacts to the receiving environment;
	  ○ soil and/or water would be remediated where necessary; and
	  ○ the administering authority would be notified in accordance with the requirements of the proposed EA conditions.

Transfer	• water gathering lines would be used to transfer PW from wells to tanks and/or trunk lines; and • water gathering lines would be designed and constructed in accordance with APGA *Code of Practice For Upstream Polyethylene Gathering Networks-CSG Industry – Version 6* (APGA, 2024).
Treatment to facilitate beneficial use	• in some cases, PW may be treated to achieve a water quality that is fit for purpose for an identified beneficial use; and • any chemicals used in water treatment processes would be stored, handled and managed in accordance with relevant Australian Standards.
Beneficial use such as: • dust suppression • construction and operational uses • irrigation; and • third party transfer.	• PW may be used for dust suppression, in construction and for operational purposes (i.e. drilling, compaction, etc.). • Criteria for beneficial use would be determined through the application of the *End of Waste Code Irrigation of Associated Water (including coal seam gas water) (ENEW07546918, Version 1.07)* (DETSI, 2025a) and *End of Waste Code Associated Water (including coal seam gas water) (ENEW07547018, Version 1.06)* (DETSI, 2025b) where applicable and/or proposed EA conditions; • dust suppression activities would not occur within or immediately adjacent to watercourses or wetlands, and in accordance with proposed EA conditions; and • the volume of PW applied to land for beneficial uses would be proportionate to the activity requirements and take account of the local conditions (i.e. surface materials, soil saturation and weather) and water quality. Application of water would be managed in accordance with proposed EA conditions.

Table 25: Produced water measurable criteria

Objective	Environmental values	Component	Measurable criteria
PW use	EVs, as defined in the *Environmental Protection (Water) Policy 2019*, potentially relevant to the use of PW within the Project Area include both aquatic	• dust suppression and construction; • irrigation; and	• compliance with EA conditions relating to PW use and storage, including: ○ Schedule B – Water; and

Objective	Environmental values	Component	Measurable criteria
	ecosystem and human use EVs as follows: • protection of slightly to moderately disturbed aquatic waters; • recreation and aesthetics (primary recreation with direct contact); • secondary recreation and visual appreciation with no contact; • suitability for drinking water supplies (only relevant to the Dawson River); • primary industries (irrigation, water for farm use, stock watering, and human consumption of wild or stocked fish or crustaceans); • industrial use; and • cultural and spiritual values.	• third party transfer.	○ Schedule D – Land. • criteria for beneficial use would be determined through the application of the *End of Waste Code Irrigation of Associated Water (including coal seam gas water) (ENEW07546918, Version 1.07)* (DETSI, 2025a) and *End of Waste Code Associated Water (including coal seam gas water) (ENEW07547018, Version 1.06)* (DETSI, 2025b) where applicable and/or proposed EA conditions; and • dust suppression activities would not occur within or immediately adjacent to watercourses or wetlands
PW storage		• tanks	• compliance with EA conditions relating to PW use and storage, including: ○ Schedule B – Water; ○ Schedule D – Land; and • tanks would be designed in accordance with relevant standards. Tanks would be regularly monitored and inspected to ensure sufficient capacity and integrity.

4.8.3 Residual Drilling Material

Residual drilling material (RDM) would be managed using the following measures to reduce the risk of environmental harm:

- RDM would only be disposed of on-site in accordance with proposed EA condition E6, i.e.:
  - by mix-bury-cover method if the residual drilling material meets the approved quality criteria; or
  - by an alternative method and/or quality that is certified by a suitably qualified third party as acceptable for disposal to land and that environmental harm will not result from the proposed disposal;
- cement returns may be stored in cement bins, allowed to harden and then crushed up for mix bury cover, disposal to landfill, or sent to landfill;
- drilling fluids may be permitted to evaporate, or treated and reused for drilling, or if tested and meets general waste conditions disposed of at a suitable facility; and
- sumps and pits would be temporary and small for safe containment of drilling fluids.

4.8.4 Hydraulic Fracturing Stimulation Fluids

Fluids used for hydraulic fracture stimulation would be stored in a fracture fluid tank and either reused during stimulation activities at other wells or removed for disposal by a licenced contractor.

4.8.5 Hydrostatic Test Water and Water from Low Point Drains

Hydrostatic test water from pipelines and water from LPDs may be released to Land in a manner that ensures:

- vegetation is not damaged;
- soil quality is not adversely impacted;
- there is no surface ponding or runoff beyond the designated release area;
- there is no aerosols or odours;
- deep drainage below the root zone of any vegetation is minimised; and
- the quality of shallow aquifers is not adversely affected.

4.9 Rehabilitation

The EVs of the existing environment and pre-disturbed land use of the Project Area are described in the preceding sections. Rehabilitation activities should seek to maintain or enhance, and protect the following EVs:

- the existing primary land use for agriculture
- ecosystem functioning including provision of wildlife habitat and connectivity, and ecosystem services like clean air and water; and
- visual amenity of the landscape.

Rehabilitation works would aim to meet Rehabilitation Acceptance Criteria under the proposed EA conditions. Rehabilitation and decommissioning of disturbed land areas would occur progressively in accordance with proposed EA conditions.

The objective of rehabilitation and decommissioning is to achieve a post development landform that is:

- safe for humans, native fauna and livestock
- non-polluting; and
- stable and able to sustain appropriate land use.

Disturbed areas such as pipeline RoWs would be stabilised post-construction to ensure the safe and effective operation of assets and to minimise the risk of erosion, soil loss and weed invasion. Stabilisation works would include:

- remediating areas of contaminated land resulting from petroleum activities
- re-establishing surface drainage lines and re-profiling contours for operational use
- establishing a safe landform for humans and livestock in areas of significant cut and fill
- reinstating top soil
- soil conditioning where required; and
- promoting the establishment of groundcover vegetation.

Once disturbed areas are no longer required for operations, these would be returned to an appropriate land use in accordance with landholder needs and applicable regulatory requirements. Agricultural land uses and natural areas comprising MSES, ESAs and other forms of vegetation are the two most common pre-disturbance land uses to be rehabilitated. Final rehabilitation of natural areas would be undertaken to achieve the final rehabilitation criteria specified conditions for the proposed EA.

Decommissioning of wells would occur on an ongoing basis as production within the Project Area is exhausted. Wells at the end of their lifecycle would initially be capped to enable future uses such as for other resource activities or monitoring. Only once it is determined that the well has no future use is it plugged and abandoned in accordance with regulatory requirements and the *Code of Practice for the construction and abandonment of petroleum wells and associated bores in Queensland* (DNRME, 2019).

5.0 Greenhouse Gas Emissions Inventory

This section has been compiled to address greenhouse gas (GHG) emission application requirements under the EP Act and in accordance with the DETSI guideline *Greenhouse gas emissions* (ESR/2024/6819, Version 1.01) (DETSI, 2025c).

This application for a new site-specific EA is required to include sufficient information to enable DETSI to consider the potential impacts of each relevant activity for the whole life of the project – which includes the construction, operations and decommissioning phases and ultimately surrender of the EA.

Estimated Scope 3 emissions are not required to be included in applications where projected Scope 1 and Scope 2 emissions are expected to be less than 25,000 tonnes of CO2-e per annum.

The process to address DETSI GHG emission application requirements consists of the following steps:

1. Identify the GHG emissions likely to be generated throughout the life of the project
2. Determine if the application meets the medium to high GHG emission category
3. Identify the management practices proposed to be implemented to prevent or minimise adverse impacts
4. Identify if a GHG abatement plan will be required to accompany the application; and
5. Describe the impacts of climate change on EVs and the risk and likely magnitude of such impacts based on the relative scale of the project's net GHG emissions.

5.1 Greenhouse Gas Emissions Category and Calculation Methodology

Scope 1 and 2 GHG emissions have been quantified for the following activities for the life of the Project – which includes the construction, operations and decommissioning phases and ultimately surrender of the EA.

Scope 1 emissions from the Project are considered direct emissions and are derived from:

- Fuel combustion – diesel use for stationary and transport-related activities
- Flaring – non-routine flaring during well completion and decommissioning activities and flaring associated with gas production,
- Venting – during hydraulic fracture stimulation and work-over activities; and
- Fugitive emissions – including from natural gas exploration, development and production activities, gas gathering pipelines and produced water.

Scope 2 emissions for a facility represent the 'indirect' emissions that are released outside the facility boundary to produce the electricity that is imported into the facility and used. The Scope 2 emissions for this Project relate to emissions associated with the purchase of electricity from the grid primarily during the Operational phase.

Scope 1 emissions (refer to Table 26) from the Project are expected to occur primarily through diesel fuel consumption (27%), flaring (11%), venting (19%) and fugitives (43%).

As per the NGER Determination, *Method 1* emission factors, which are default emission factors derived from the National Greenhouse Accounts methods and based on national average estimates, has been used to determine Scope 1 GHG emissions from the above activities.

Table 26: Scope 1 emissions for the Project

Scope 1 emissions source	Average annual emissions (tCO2e)	Total emissions during 50-year Project life (tCO2e)
Fuel use	178	8,891
Non-routine flaring	71	3,571
Venting	126	6,292
Fugitives	279	13,952
Total	**654**	**32,706**

Scope 2 emissions (refer to Table 27) arise from electricity purchased from the grid representing 100% of Scope 2 emissions.

Table 27: Scope 2 emissions for the Project

Scope 2 emissions source	Average annual emissions (tCO2e)	Total emissions during 50-year Project life (tCO2e)
Purchased electricity	1,282	61,547
Total	**1,282**	**61,547**

Scope 1 and 2 GHG emissions have been quantified for the potential life of the Project for a 50-year period. Emission factors for the above sources have been referenced from the *National Greenhouse and Energy Reporting (Measurement) Determination 2008, Compilation No: 19* (hereafter 'the NGER Determination') – a legislative instrument under the NGER scheme. Energy content factors for the fuel sources have also been referenced from the NGER Determination. Scope 1 emissions primarily arise from fugitive emissions and fuel use, Scope 2 from purchased electricity. Table 28 outlines total Scope 1 and 2 emissions from the Project over the 50-year lifespan.

Table 28: Total Scope 1 and 2 emissions for the life of the Project

Emissions category	Average annual emissions (tCO2)	Total emissions during 50-year Project life (tCO2e)
Scope 1	654	**32,706**
Scope 2	1,282	**61,547**
Total Scope 1 and 2	**1,936**	**94,253**

Table 29 outlines the sources of Scope 1 and 2 emissions for the life of the Project and the associated assumptions used for calculating emissions estimates.

Table 29: Greenhouse gas emissions sources and assumptions

Emissions Source	Description
Scope 1	
Fuel – liquid fuel combustion	Diesel fuel combustion for stationary and transport energy purposes. Energy content (GJ/kL), and emission factors for CO_2, CH_4 and N_2O expressed in kg CO2-e/GJ have been referenced from the NGER Determination.
Flare – Gas exploration and development	Flaring emission from gas exploration have been estimated using Method 1 as per Section 3.44 – Division 3.3.2 – Oil or gas exploration and development of the NGER Determination.
Flare – Gas development and production	Annual production-related flaring has been estimated from 2029 onwards. Gas production during the first two (2) years is expected to be minimal, and the likelihood of considerable flaring occurring during this period is very low. Accordingly, annual production flaring emissions have been estimated from 2029 for the remainder of the Project life. It is noted that production-related flaring emissions fall within the Project Area boundary and are therefore classified as Scope 1 emissions. For the purposes of this GHG assessment, it is assumed that the average quantity of gas flared for each well located in the Project Area is approximately 2.1 t CO_2-e per well per year. This assumption is based on historical emissions released from gas flared at the Roma Hub facility during processing activities.
Venting – well completion	Venting emissions associated with well completion activities were estimated using the Method 1 approach as per Section 3.46AB – Subdivision 3.3.2.3.1 – Fugitive emissions that result from deliberate releases from process vents, system upsets and accidents – well completions of the NGER Determination. CH_4 and CO_2 percentages in the unprocessed gas was based on referencing other similar CSG facilities. Assumption that all well completions would involve hydraulic fracturing and flaring, therefore, the corresponding venting emission factors specified in the NGER Determination were applied to estimate venting emissions from well completion events. Assumption that all 24-wells will be completed within the same year, and accordingly the emissions were estimated based on that assumption.
Venting – well workover	Venting emissions associated with well workovers were estimated using the Method 1 approach as per Section 3.85P – Subdivision 3.3.9A.8 – Natural gas production – emissions that are vented – well workovers of the NGER Determination.

Emissions Source	Description
	CH_4 and CO_2 percentages in the unprocessed gas was based on referencing other CSG facilities. Assumtion that well workovers will not involve any hydraulic fracturing and the relevant venting emission factors for non-hydraulic fracturing workovers specified in the NGER Determination were applied to estimate venting emissions from these activities. Assumption that workovers will occur once every five (5) years for each well and will happen during the same year, and accordingly the emissions were estimated.
Fugitives – gas production	Fugitive emissions from natural gas production were estimated using the Method 1 approach as per Section 3.73A – Subdivision 3.3.6A.1 – onshore natural gas production, other than emissions that are vented or flared – wellheads. CH_4 and CO_2 percentages in the unprocessed gas was based on referencing other similar CSG facilities.
Fugitives – produced water	Fugitive emissions from produced water were estimated using the Method 1 approach as per Section 3.73NA – Division 3.3.6D – produced water from oil and gas exploration and development, crude oil production, natural gas production or natural gas gathering and boosting (other than emissions that are vented or flared). CH_4 and CO_2 percentages in the unprocessed gas was based on referencing other similar CSG facilities.
Fugitives – gas gathering pipelines	Fugitive emissions from natural gas gathering other than emissions that are vented or flared were estimated using the Method 1 approach as per Section 3.73K – Division 3.3.6C – natural gas gathering and boosting (other than emissions that are vented or flared) CH_4 and CO_2 percentages in the unprocessed gas was based on referencing other CSG facilities.
Scope 2	
Purchased Electricity	Scope 2 emissions from electricity purchased from the grid annually for well operating activities at the Project Area were estimated using emission factors published by the Department of Climate Change, Energy, the Environment and Water in *Australia's emissions projections 2025.* Appendix D of the projections report provides annual Scope 2 emission factors for Australia's electricity grid under the baseline scenario for the period 2025–2040. For Queensland, the baseline scenario shows a gradual decrease in Scope 2 emission factors (t CO_2-e/MWhr) as a consequence of increased penetration of renewable energy sources. Queensland's grid emission factor is expected to reduce from 0.65 t CO_2-e/MWhr in 2025 to approximately 0.12 t CO_2-e/MWhr by 2036, after which it stabilises at around 0.10 t CO_2-e/MWhr

Emissions Source	Description
	through to 2040. This trajectory is consistent with Australia's proposed net-zero pathway, where residual emissions from electricity generation progressively decreases as renewable energy generation becomes the dominant source of energy supply. The trajectory published in Appendix D of the projection's guidebook has been used to estimate Scope 2 emissions from the well operating activities at the Project Area.

Emissions context

According to DCCEEW[1], Australia's national greenhouse gas emissions in 2023 (latest available data) were 453.4MtCO2e. Table 30 below compares the annual average Scope 1 and 2 emissions to this national volume.

Table 30: Project annual emissions in context to Australia's annual emissions

Emissions category	Average annual emissions (tCO2)	Project emissions contribution to Australia's annual emissions (%)
Scope 1	654	0.0001
Scope 2	1,282	0.0003
Total Scope 1 and 2	**1,885**	**0.0004**

The global GHG emissions for 2022 (latest year) were 49.3 GtCO2e[2]. Table 31 compares the annual average Scope 1 and 2 emissions to this global volume.

Table 31: Project annual emissions in context to global annual emissions

Emissions category	Average annual emissions (tCO2)	Project emissions contribution to the world's annual emissions (%)
Scope 1	654	0.000001
Scope 2	1,282	0.000003
Total Scope 1 and 2	**1,885**	**0.000004**

[1] Department of Climate Change, Energy, the Environment and Water (DCCEEW), n.d. Australia's National Greenhouse Accounts, *https://ageis.climatechange.gov.au/*, viewed November 2025.
[2] ClimateWatch, 2025. Historical GHG Emissions, https://www.climatewatchdata.org/ghg-emissions?end_year=2022&start_year=1990, viewed November 2025.

At 0.0004% of Australia's annual GHG emissions[1], and 0.000004% of global emissions[2], the net GHG emissions from the Project comprise a nominal amount in the overall scheme of the national and international GHG emissions and whilst these are theoretical calculations for indicative purposes only, will not materially or substantially contribute to Australia's or Queensland's GHG emissions or global emissions levels.

5.2 Proposed Mitigation and Management Practices

Given that only limited Scope 1 and 2 emissions are associated with the Project, the focus for the project is to optimise fuel use and enhance operational efficiency. The reduction initiatives for reducing emissions are outlined in Table 32.

Santos maintains all vehicles and plant to meet Original Equipment Manufacturer (OEM) specifications. This is done to optimise performance and reduce fuel consumption and emissions.

Further, Santos operates in accordance with the following State petroleum industry Codes of Practice:

- *Code of Practice For leak detection, management & reporting for petroleum operating plant Petroleum and Gas Inspectorate Version 6* (available here);
    - This Code of Practice outlines the requirement for Santos to have a leak management program in place to find, classify, report and repair leaks; and
- *Code of Practice For the construction and abandonment of petroleum wells and associated bores in Queensland Petroleum and Gas Inspectorate Version 2* (available here);
    - This Code of Practice outlines the requirement for Santos to construct and maintain petroleum wells in a manner so as to prevent leakage.

Santos also has a Climate Transition Action Plan (CTAP) in place which outlines how it plans to reduce GHG emissions through the energy transition by improving operational efficiency, offering carbon solutions and clean fuels, and by providing lower emission products across the supply chain. The CTAP meets the DETSI GHG abatement hierarchy of first to avoid, reduce, substitute and finally offset.

Table 32: Emissions reductions proposed

Reduction Initiatives	Emission Type	Initiatives Details
All vehicles and plant (internal combustion and electric) will be serviced and maintained in accordance with manufacturer's recommended service schedule.	Scope 1 and 2	Optimises fuel and electricity consumption associated with GHG emissions.
Plan proposed activities (excluding well operation) to reduce operating hours for the Project to as little as practicable.	Scope 1 and 2	Optimises and reduces fuel and electricity consumption associated with GHG emissions.

5.3 Risk Assessment of the likely magnitude of impacts on environmental values

According to the Queensland Government's Future Climate Dashboard, significant climatic changes are projected under the Representative Concentration Pathway (RCP) 4.5 scenario for the and Maranoa region (Appendix I). This moderate emissions scenario indicates that the region will experience notable increases in temperature and changes in precipitation patterns. Under RCP 4.5, the average temperature is expected to rise by 0.74 to 2.3°C by 2050 and 1.1 to 3.1°C by 2070, compared to 1986-2005 data (Queensland Government, 2024).

The region is also projected to see a decrease in average annual rainfall, with more pronounced variability and extended periods of drought, along with an increase in the number of extremely hot days as Australia's climate changes. These climatic changes will likely exacerbate heat stress on local ecosystems, reduce agricultural productivity, and strain water resources. Consequently, comprehensive risk assessments and adaptive strategies are crucial to mitigate these adverse impacts and enhance the region's resilience to climate change (CSIRO, 2024, BOM, 2024).

The Intergovernmental Panel on Climate Change (IPCC) has identified that continued GHG emissions will cause further warming and long-lasting changes on the global climate system in general. To assess the likely magnitude of impact of the project activities on EVs of the region, the Transient Climate Response to Cumulative Carbon Emissions (TCRE) metric has been applied as outlined in the IPCC's Climate Change 2023 Synthesis Report (IPCC, 2023).

The TCRE metric estimates that each trillion tonnes of carbon emitted as CO_2 results in approximately 0.45°C of global mean peak surface temperature change. Using this methodology, the projected emissions from the proposed project activities (total Scope 1 and 2 emissions during 50-year Project life) equate to an infinitesimal temperature increase of approximately 2.31481084E-10°C beyond natural climatic variability.

This rigorous assessment aligns with IPCC and national regulatory guidelines and underscores the negligible environmental impact from the proposed activities. This concludes that the projected impact is negligible and that it poses no threat on EVs, including MSES, or human safety. In summary, despite ongoing and projected climatic changes, impacts from the proposed activities on the climate are insignificant.

7.0 Appendices

Appendix A: Proposed EA Conditions

Due to varying joint venture and commercial arrangements, PL 1123 cannot be added to any of the existing adjacent EAs as an authorised tenure.

The holders of Santos operated petroleum tenures surrounding PL 1123 are different to those of PL 1123, and therefore PL 1123 cannot be added as an authorised tenure to their respective EAs.

Santos is therefore seeking a new site-specific EA to authorise petroleum production on PL 1123.

Given the proximity of the Project Area to the RSGPA and RSGPAE tenures, proposed development and operation of the Project Area will be carried out as a single integrated operation with existing authorised RSGPA and RSGPAE petroleum tenures and activities.

Gas and water generated from the Project Area will utilise existing centralised gas and water processing facilities (including compression stations) located on adjoining RSGPA tenures. Integration with these existing facilities will negate the requirement to locate gas compression and large water management facilities within the Project Area.

Further, due to the use and reliance on co-located infrastructure approved under the existing adjacent EAs, and to ensure consistent operational standards, compliance and reporting requirements across tenures, for the new EA, Santos is seeking EA conditions consistent with those of the RSGPA EA (EPPG00898213), which are predominately based on the Streamlined model conditions for petroleum activities (DETSI, 2024).

Due to the limited scope of activities proposed for PL 1123, there are several RSGPA EA conditions not required, and these conditions have been excluded from proposed EA conditions. Santos also requests addition of a small number of contemporary EA conditions recently approved by DETSI for use in the Santos Towrie (PL 1059) EA (P-EA-100130995).

Further, Santos requests the following prescribed Environmentally Relevant Activity (ERA) is authorised on the new EA (refer to Section 5.2 for further information on the requirement for this ERA):

Schedule 3 – 3 – A petroleum activity that is likely to have a significant impact on a category A or B Environmentally Sensitive Area.

The proposed EA conditions and ERA are deemed appropriate for development of PL 1123; and the proposed development and EA conditions are reflective of standard developments currently operating in the broader Roma region. The environmental values of the project are also similar to or the same as surrounding Roma tenures due to their close geographic proximity.

Further, the conditions of the RSGPA EA are a product of the outcome of a rigorous Environmental Impact Statement (EIS) based EPBC Act approval process, and the granted conditions of approval were designed to regulate impacts associated with more than 6100 CSG wells.

Refer to proposed EA conditions below.

Proposed EA Conditions

Environmentally relevant activity and location details

Proposed ERA	Justification
Schedule 3 – 3 A petroleum activity that is likely to have a significant impact on a category A or B environmentally sensitive area	Proposed activities will disturb 13.5 ha of a Category B ESA (that being the PPZ of Endangered REs 11.9.10 / 11.3.17). Refer to Section 5.2 and Table 13 for further information on the requirement for this ERA.

<tr><td>A7</td><td>All laboratory analyses and tests required must be undertaken by a laboratory that has NATA accreditation for such analyses and tests.</td><td></td></tr>
<tr><td>A8</td><td>Notwithstanding condition (A7), where there are no NATA accredited laboratories for a specific analyte or substance, then duplicate samples must be sent to at least two separate laboratories for independent testing or evaluation.</td><td></td></tr>
</table>

A9	Monitoring and sampling must be carried out in accordance with the requirements of the following documents (as relevant to the sampling being undertaken), as amended from time to time: (a) for waters and aquatic environments, the Queensland Government's Monitoring and Sampling Manual 2009 –Environmental Protection (Water) Policy 2009 (b) for groundwater, Groundwater Sampling and Analysis – A Field Guide and any applicable Australian Standard (c) for noise, the latest administering authority's Noise Measurement Manual and any applicable Australian Standard (d) for air, the Queensland Air Quality Sampling Manual and/or Australian Standard 4323.1:1995 Stationary source emissions method 1: Selection of sampling positions, as appropriate for the relevant measurement (e) for soil, the Guidelines for Surveying Soil and Land Resources, 2nd edition (McKenzie et al.2008), and/or the Australian Soil and Land Survey Handbook, 3rd edition (National Committee on Soil and Terrain, 2009) (f) for dust, Australian Standard AS3580.	
Contingency Procedures for Emergency Environmental Incidents		
A10	Petroleum activities involving significant disturbance to land cannot commence until the development of written contingency procedures for emergency environmental incidents which include, but are not necessarily limited to: (a) A clear definition of what constitutes an environmental emergency incident or near miss for the petroleum activity. (b) Consideration of the risks caused by the petroleum activity including the impact of flooding and other natural events on the petroleum activity. (c) Response procedures to be implemented to prevent or minimise the risks of environmental harm occurring. (d) The practices and procedures to be employed to restore the environment or mitigate any environmental harm caused. (e) Procedures to investigate causes and impacts including impact monitoring programs for releases to waters and/or land. (f) Training of staff to enable them to effectively respond. (g) Procedures to notify the administering authority, local government and any potentially impacted landholder.	
Maintenance of Plant and Equipment		
A11	All plant and equipment must be maintained and operated in their proper and effective condition.	
A12	The following infrastructure must be signed with a unique reference name or number in such a way that it is clearly observable: (a) regulated dams and low consequence dams (b) exploration, appraisal and development wells (c) water treatment facilities (d) sewage treatment facilities (e) specifically authorised discharge points to air and waters (f) any chemical storage facility associated with the environmentally relevant activity of chemical storage (g) field compressor stations (h) central compressor stations (i) gas processing facilities; and (j) pipeline compressor stations.	
A13	Measures to prevent fauna being harmed from entrapment must be implemented during the construction and operation of well infrastructure, dams and pipeline trenches.	
Documentation		

A14	A certification must be prepared by a suitably qualified person within 30 business days of completing every plan, procedure, program and report required to be developed under this environmental authority, which demonstrates that: (a) relevant material, including current published guidelines (where available) have been considered in the written document (b) the content of the written document is accurate and true; and (c) the document meets the requirements of the relevant conditions of the environmental authority.	
A15	All plans, procedures, programs, reports and methodologies required under this environmental authority must be written and implemented.	
A16	All documents required to be developed under this environmental authority must be kept for five (5) years.	
A17	All documents required to be prepared, held or kept under this environmental authority must be provided to the administering authority upon written request within the requested timeframe.	
A18	A record of all complaints must be kept including the date, complaint's details, source, reason for the complaint, description of investigations and actions undertaken in resolving the complaint.	
Third Party Audit		
A19	A third-party auditor, nominated by the holder of this environmental authority and accepted by the administering authority, must audit compliance with the conditions of this environmental authority at a minimum frequency of every three (3) years.	
A20	Notwithstanding condition A19, and prior to undertaking the third-party audit, the scope and content of the third-party audit can be negotiated with the administering authority.	
A21	An audit report must be prepared and certified by the third-party auditor presenting the findings of each audit carried out.	
A22	Any recommendations arising from the audit report must be acted upon by: (a) investigating any non-compliance issues identified; and (b) as soon as reasonably practicable, implementing measures or taking necessary action to ensure compliance with the requirements of this environmental authority.	
A23	A written response must be attached to the audit report detailing the actions taken on stated dates: (a) by the holder to ensure compliance with this environmental authority; and (b) to prevent a recurrence of any non-compliance issues identified.	
A24	The audit report required by condition A21 and the written response to the audit report required by condition A23 must be submitted with the subsequent annual return.	
Schedule B - Water		
Contaminant Release		
B1	Contaminants must not be directly or indirectly released to any waters except as permitted under this environmental authority.	
B2	The extraction of groundwater as part of the petroleum activities from underground aquifers must not directly or indirectly cause environmental harm to any watercourse or wetland.	
Works in Watercourses, Wetlands and Lakes		
B3	Only construction or maintenance of linear infrastructure is permitted in or within a general ecologically significant wetland or in a watercourse.	

B4	The construction and/or maintenance of linear infrastructure that will result in significant disturbance in or on the bed and banks of a watercourse or within a general ecologically significant wetland must be conducted in accordance with the following order of preference: (a) conducting works in times when there is no water present; (b) conducting works in times of no flow; (c) conducting works in times of flow but in a way that does not impede low flow.	
B5	The construction and maintenance of linear infrastructure authorised under condition B3 must comply with the water quality limits specified in *Schedule B, Table 1 Release Limits for Construction or Maintenance of Linear Infrastructure.* Refer to Schedule B, Table 1 in the RSGPA EA (EPPG00898213).	
B6	Monitoring must be undertaken at a reasonable frequency to ensure compliance with condition B5.	
B7	A register must be kept of all linear infrastructure construction and maintenance activities in a wetland of other environmental value and watercourses, which must include: (a) location of the activity (e.g., GPS coordinates (GDA94) and watercourse name) (b) estimated flow rate or surface water at the time of the activity (c) duration of work (d) results of impact monitoring carried out under condition B6.	
B8	Petroleum activities must occur outside a wetland of high ecological significance.	
B9	Petroleum activities must not negatively impact a wetland of high ecological significance.	
B10	Linear infrastructure activities, other than linear infrastructure construction and/or maintenance activities, must not change the existing surface water hydrological regime of any general ecologically significant wetland.	
B11	The construction and/or maintenance of linear infrastructure in any general ecologically significant wetland must not: (a) prohibit the flow of surface water in or out of the wetland; (b) impact surface water quality in the wetland unless specifically authorised by this environmental authority; (c) drain the wetland; (d) fill the wetland; (e) impact bank stability; or (f) result in the clearing of riparian vegetation outside of the required footprint.	
B12	Where the petroleum activity(ies) is carried out on floodplains petroleum activity(ies) must be carried out in a way that does not: (a) concentrate flood flows in a way that will or may cause or threaten an adverse environmental impact; or (b) divert flood flows from natural drainage paths and alter flow distribution; or (c) increase the local duration of floods; or (d) increase the risk of detaining flood flows.	
Erosion and Sediment Control		

B13	For activities involving significant disturbance to land, control measures that are commensurate to the site-specific risk of erosion, and risk of sediment release to waters must be implemented to: (a) preferentially divert stormwater around significantly disturbed land, or allow stormwater to pass through the site in a controlled manner and at non-erosive flow velocities; (b) minimise soil erosion resulting from wind, rain, and flowing water; (c) minimise the duration that disturbed soils are exposed to the erosive forces of wind, rain, and flowing water; (d) minimise work-related soil erosion and sediment runoff; and (e) minimise negative impacts to land or properties adjacent to the activities (including roads).	
Well Testing		
B14	Subject to conditions B15 and B16 the injection of CSG water or better quality groundwater is authorised in wells that are not exploration, appraisal or development wells, for the purposes of hydraulic testing, where such hydraulic tests are undertaken for no more than two (2) consecutive days.	
B15	The maximum volume of CSG water or better quality groundwater injected for the purposes of hydraulic testing identified in condition B14 must not exceed 1 ML per hydraulic test.	
B16	Written notification detailing the type and location (GPS coordinates) of any hydraulic testing undertaken in accordance with condition B14 must be provided to the administering authority at least 10 business days prior to the commencement of the hydraulic test.	
Schedule C – Land		
General		
C1	Contaminants must not be directly or indirectly released to land except as permitted under this environmental authority.	
Top Soil Management		
C2	Top soil must be managed in a manner that preserves its biological and chemical properties.	
Land Management		
C3	Land that has been significantly disturbed by the pipeline activities must be managed to ensure that gully erosion or subsidence do not occur on that land.	
Chemical Storage		
C4	Chemicals and fuels stored, must be effectively contained and where relevant, meet Australian Standards, where such a standard is applicable.	
Pipeline Operation and Maintenance		
C5	Contaminants authorised to be released to land under conditions C6, C8, C14 and C20 must be carried out in a manner that ensures: (a) vegetation is not damaged; (b) soil quality is not adversely impacted; (c) there is no surface ponding or runoff beyond the designated release area; (d) there is no aerosols or odours; (e) deep drainage below the root zone of any vegetation is minimised; (f) the quality of shallow aquifers is not adversely affected.	Requested for operational and compliance consistency with surrounding approved Santos operated tenures and infrastructure.
Pipeline Wastewater		

C6	Contaminants that are hydrostatic test water from pipelines and contaminants from low point drains may be released to land in accordance with condition C5.	Requested for operational and compliance consistency with surrounding approved Santos operated tenures and infrastructure. This also aligns with the basis of design for the flowlines.
C7	Produced water may be re-used in: (a) drilling and well hole activities; or (b) stimulation activities.	
C8	Produced water may be released to land for the following purposes: (a) dust suppression; (b) construction and operational purposes for the petroleum activity authorised by this environmental authority; and (c) irrigation.	
C9	Produced water irrigated to land must: (a) not exceed the release limits specified in *Schedule C, Table 1a Irrigation water quality monitoring*; and (b) be monitored at the frequency and for the quality characteristics at the monitoring point specified in *Schedule C, Table 1a - Irrigation water quality monitoring*; or (c) the process under C10 has been completed.	
C10	Produced water for irrigation which does not meet criteria in condition C10 (a) and (b) may be used for irrigation provided a report has been completed which: (a) determines soil structure, stability and productive capacity will be maintained or improved; (b) determines there are no toxic effects to crops; (c) determines yields and produce quality are maintained or improved; (d) states water quality criteria, which has been determined in accordance with the assessment procedures outlined *in Schedule C, Table 1b Assessment procedures for water quality criteria*; and (e) includes a water monitoring program to ensure that condition C10 (a), (b) and (c) are being achieved. Refer to Schedule C, Tables 1a and 1b in the RSGPA EA (EPPG00898213).	
C11	Produced water may be used for domestic, or stock purposes provided the water quality complies with the criteria specified in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC and ARMCANZ 2000).	
C12	Produced water may be transferred to a third-party to be used for the following purposes, subject to condition C13: (a) dust suppression; (b) construction and operational purposes; or (c) domestic or stock purposes provided the water quality complies with criteria specified in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC and ARMCANZ 2000).	

C13	If the responsibility of coal seam gas water is given or transferred to a third party in accordance with condition C12, the holder of the environmental authority must ensure that: (a) the responsibility of the coal seam gas water is given or transferred in accordance with a written agreement (the third-party agreement); and (b) the third party is made aware of the General Environmental Duty under section 319 of the *Environmental Protection Act 1994*.	
Sewage Treatment Works		
C14	Greywater or treated sewage effluent from a treatment system with a daily peak design capacity of up to 21 EP may be: (a) released to land by sub-surface or spray irrigation provided it is to a fenced and signed contaminant release area that is: i. a minimum distance of 50 metres from any watercourse, wetland or protected area; and ii. a minimum distance of 100 metres from any potable water supply or stock drinking water supply; and iii. kept vegetated with groundcover that is not a prohibited or restricted pest species; or (b) used for dust suppression, construction and operational purposes subject to condition C16.	Modified from RSGPA EA (EPPG00898213) to be limited to 21 EP and added "operational" to C14(b), but otherwise unchanged.
C15	When circumstances prevent the irrigation of treated sewage effluent to land, the contaminants must be directed to on-site storage or lawfully disposed of off-site.	
C16	Treated sewage effluent may only be used for dust suppression, construction and operational purposes provided that: (a) the treated sewage effluent has not been stored in a dam or tank prior to use; (b) on local government controlled roads, written approval from the relevant Local Government has been given to the holder of this environmental authority; and (c) the treated sewage effluent quality: (i) is monitored at the location and frequency specified in Schedule C, Table 2 – Treated Sewage Effluent Standards for Dust Suppression, Construction and Operational Purposes; and (ii) meets the release limits for each quality characteristic specified in Schedule C, Table 2 - Treated Sewage Effluent Standards for Dust Suppression, Construction and Operational Purposes. Refer to Schedule C, Table 2 in RSGPA EA (EPPG00898213).	
Schedule D – Biodiversity		
Confirming Biodiversity Values		
D1	Prior to undertaking activities that result in significant disturbance to land in areas of native vegetation, confirmation of on-the-ground environmentally sensitive areas and wetlands at that location must be undertaken by a suitably qualified person.	
D2	A suitably qualified person must develop and certify a methodology so that condition D1 can be complied with, and which is appropriate to confirm on-the-ground environmentally sensitive areas and wetlands.	
D3	Where areas mapped as environmentally sensitive areas and wetlands differ from those confirmed under conditions D1 and D2, petroleum activities may proceed in accordance with the conditions of the environmental authority based on the confirmed on-the-ground values.	
D4	All documentation survey information photographs, field data or any material associated with the field validation requirements in D1 must be maintained for the life of the environmental authority to demonstrate to the administering authority that surveys were conducted in a manner consistent with requirements contained in D2.	

<table>
<tr><td>D5</td><td>The location of the petroleum activity must be selected in accordance with the following site planning principles:
(a) maximise the use of areas of pre-existing disturbance
(b) in order of preference, avoid, minimise or mitigate any impacts, including cumulative impacts, on areas of native vegetation or other areas of ecological value
(c) minimise disturbance to land that may result in land degradation
(d) in order of preference, avoid then minimise isolation, fragmentation, edge effects or dissection of tracts of native vegetation; and
(e) in order of preference, avoid then minimise clearing of native mature trees.</td><td></td></tr>
<tr><td>D6</td><td>Petroleum activities must be carried out in accordance with Schedule D, Table 1 – Petroleum Activities in Environmentally Sensitive Areas, Schedule D, Table 2 – Authorised Petroleum Activities and Disturbance and any other relevant conditions of this environmental authority.

Refer to Schedule D, Table 1 in the RSGPA EA (EPPG00898213).

D7	Limited impact camps must not be located within a primary protection zone of Category C ESA (Essential Habitat) or Category C ESA (Nature Refuges).	
D8	Limited impact petroleum activities must not be located within areas that contain commercial species.	
D9	Despite condition D6 decommissioning petroleum activities are authorised within all ESAs other than Category A ESAs, and within all ESA protection zones when conducted in accordance with the land disturbance planning principles provided in condition D5.	
D10	Limited petroleum activities, limited impact camps or limited impact petroleum activities located within a primary protection zone or secondary protection zone of an environmentally sensitive area in accordance with *Schedule D, Table 1 – Petroleum Activities in Environmentally Sensitive Areas*, and activities listed in *Schedule D, Table 2 – Authorised Petroleum Activities and Disturbance* must not negatively affect the adjacent environmentally sensitive area.	
D11	Prior to carrying out limited petroleum activities or limited impact petroleum activities undertaken within environmentally sensitive areas in accordance with *Schedule D, Table 1 – Petroleum Activities in Environmentally Sensitive Areas*, it must be demonstrated, in the following order of preference that: (a) no reasonable or practicable alternative exists for carrying out the limited petroleum activities within the environmentally sensitive area; (b) the limited petroleum activities are preferentially located in pre-existing areas of clearing or significant disturbance; (c) clearance widths for linear infrastructure is minimised to the maximum extent possible, taking into account the following matters: (i) safe vehicle movement; (ii) drainage devices installed are of a type that is appropriate for the track type and location; (iii) erosion and sediment control measures installed are in accordance condition B13 and B3; and (iv) power line stays have been preferentially located within the pipeline right of way where possible. (d) the maximum clearance widths specified in *Schedule D, Table 3 - Authorised Disturbance for Linear Infrastructure* are not exceeded. Refer to Table 3 Authorised Disturbance for Linear Infrastructure in the RSGPA EA (EPPG00898213).	
D12	Significant residual impacts to prescribed environmental matters are not authorised under this environmental authority or the Environmental Offsets Act 2014 unless the impact is: (i) specified in Schedule B, Table 1 - Authorised impacts to MSES; or (ii) the impact(s) to the prescribed environmental matters, to the extent specified in Table 1 – Authorised impacts to MSES, has/have been assessed under the Environmental Protection Biodiversity Conservation Act 1999 (Cth).	Included based on outcome of SI/SRI assessments undertaken by Boobook (2025). Refer to Section 7.2 for further information.
Environmental Offsets

<tr><td colspan="3">Schedule E – Waste</td></tr>
<tr><td colspan="3">General Waste Management</td></tr>
<tr><td>E1</td><td>Measures must be implemented so that waste is managed in accordance with the waste and resource management hierarchy and the waste and resource management principles.</td><td></td></tr>
<tr><td>E2</td><td>All regulated waste must only be removed from the site by a person who holds a current authority to transport such waste under the provisions of the Environmental Protection Act 1994.</td><td></td></tr>
<tr><td>E3</td><td>Waste, including waste fluids, but excluding waste used in closed-loop systems, must be transported off-site for lawful re-use, remediation, recycling or disposal, unless the waste is specifically authorised by conditions C6, C8, C14 and E4, E7, E8 to be disposed of or used on site.</td><td></td></tr>
<tr><td>E4</td><td>Unless otherwise authorised by the conditions of this EA to be released to land, Waste fluids, other than flare precipitant stored in flare pits, or residual drilling material, or drilling fluids stored in sumps, must be contained in either:
(a) an above ground container; or
(b) a structure which contains the wetting front.</td><td></td></tr>
<tr><td>E5</td><td>Vegetation waste may be burned if it relates to a state forest, timber reserve or forest entitlement area administered by the Forestry Act 1959 and a permit has been obtained under the Fire and Rescue Service Act 1990.</td><td></td></tr>
<tr><td>E6</td><td>Following the completion of the petroleum activity(ies), any residual brine and / or solid salt present in any dam must be removed and transported to a facility that can lawfully reuse, recycle or dispose of such waste under the Environmental Protection Act 1994.</td><td></td></tr>
<tr><td colspan="3">Residual Drilling Materials</td></tr>
<tr><td>E7</td><td>If sumps are used to store residual drilling material or drilling fluids, they must only be used for the duration of drilling activities.</td><td></td></tr>
<tr><td>E8</td><td>Residual drilling material can only be disposed of on- site:
(a) by mix-bury-cover method if the residual drilling material meets the approved quality criteria; or
(b) if it is certified by a suitably qualified third-party as being of acceptable quality for disposal to land by the proposed method and that environmental harm will not result from the proposed disposal.</td><td></td></tr>
<tr><td>E9</td><td>Records must be kept to demonstrate compliance with conditions E7 and E8.</td><td></td></tr>
<tr><td colspan="3">Schedule F – Noise</td></tr>
<tr><td>F1</td><td>Petroleum activities must not cause environmental nuisance at a sensitive place, other than where an alternative arrangement is in place.</td><td></td></tr>
</table>

F2	Notwithstanding condition F1, emission of noise from the petroleum activity at levels less than those specified in Schedule F, Table 1 Noise nuisance limits are not considered to be environmental nuisance. Refer to Schedule F, Table 1 Noise nuisance limits in RSGPA EA (EPPG00898213).	
F3	If the noise subject to a valid complaint is tonal or impulsive, the adjustments detailed in *Schedule F, Table 2 Adjustments to be added to noise levels at sensitive receptors* are to be added to the measured noise level(s) to derive LAeq, adj, 15 min. Refer to Schedule F, Table 2 Adjustments to be added to noise levels at sensitive receptors in RSGPA EA (EPPG00898213).	
F4	Notwithstanding condition F2, emission of any low frequency noise must not exceed either F4(a) and F4(b), or F4(c) and F4(d) in the event of a valid complaint about low frequency noise being made to the administering authority: (a) 60 dB(C) measured outside the sensitive receptor; and (b) the difference between the external A-weighted and C-weighted noise levels is no greater than 20 dB; or (c) 50 dB(Z) measured inside the sensitive receptor; and (d) the difference between the internal A-weighted and Z-weighted (Max LpZ, 15 min) noise levels is no greater than 15 dB.	
Schedule G – Air		
G1	Unless venting is authorised under the *Petroleum and Gas (Production and Safety) Act 2004* or the *Petroleum Act 1923*, waste gas must be flared in a manner that complies with all of G1(a) and G1(b) and G3(c), or with G1(d): (a) an automatic ignition system is used, and (b) a flame is visible at all times while the waste gas is being flared, and (c) there are no visible smoke emissions other than for a total period of no more than 5 minutes in any 2 hours, or (d) it uses an enclosed flare.	
Schedule H – Regulated Structures		
Assessment of Consequence Category		
H1	Regulated Structures are not authorised by this environmental authority.	Inserted as Santos is not proposing any regulated structures in PL 1123.
Schedule I – Well Construction, Maintenance and Stimulation Activity		
Drilling Activities		
I1	Oil based or synthetic based drilling muds must not be used in the carrying out of the petroleum activity(ies).	
I2	Drilling activities must not result in the connection of the target gas producing formation and another aquifer.	
I3	Practices and procedures must be in place to detect, as soon as practicable, any fractures that have or may result in the connection of a target gas producing formation and another aquifer as a result of drilling activities.	
Simulation Activities		
I4	Polycyclic aromatic hydrocarbons or products that contain polycyclic aromatic hydrocarbons must not be used in stimulation fluids in concentrations above the reporting limit.	
I5	Stimulation activities must not negatively affect water quality, other than that within the stimulation impact zone of the target gas producing formation.	

I6	Stimulation activities must not cause the connection of the target gas producing formation and another aquifer.	
I7	The internal and external mechanical integrity of the well system prior to and during well stimulation must be ensured such that there is: (a) no significant leakage in the casing, tubing, or packer; and (b) there is no significant fluid movement into another aquifer through vertical channels adjacent to the well bore hole.	
I8	Practices and procedures must be in place to detect, as soon as practicable, any fractures that cause the connection of a target gas producing formation and another aquifer.	
Stimulation Risk Assessment		
I9	Prior to undertaking well stimulation activities, a risk assessment must be developed to ensure that stimulation activities are managed to prevent environmental harm.	
I10	The stimulation risk assessment required must be carried out for every well to be stimulated prior to stimulation activities being carried out at that well and address issues at a relevant geospatial scale such that changes to features and attributes are adequately described and must include, but not necessarily be limited to: (a) a process description of the stimulation activity to be applied, including equipment and a comparison to best international practice; (b) provide details of where, when and how often stimulation is to be undertaken on the tenures covered by this environmental authority; (c) a geological model of the field to be stimulated including geological names, descriptions and depths of the target gas producing formation(s); (d) naturally occurring geological faults; (e) seismic history of the region (e.g. earth tremors, earthquakes); (f) proximity of overlying and underlying aquifers; (g) description of the depths that aquifers with environmental values occur, both above and below the target gas producing formation. (h) identification and proximity of landholders' active groundwater bores in the area where stimulation activities are to be carried out; (i) the environmental values of groundwater in the area; (j) an assessment of the appropriate limits of reporting for all water quality indicators relevant to stimulation monitoring in order to accurately assess the risks to environmental values of groundwater; (k) description of overlying and underlying formations in respect of porosity, permeability, hydraulic conductivity, faulting and fracture propensity; (l) consideration of barriers or known direct connections between the target gas producing formation and the overlying and underlying aquifers; (m) a description of the well mechanical integrity testing program; (n) process control and assessment techniques to be applied for determining extent of stimulation activities (e.g. microseismic measurements, modelling etc); (o) practices and procedures to ensure that the stimulation activities are designed to be contained within the target gas producing formation; (p) groundwater transmissivity, flow rate, hydraulic conductivity and direction(s) of flow; (q) a description of the chemicals used in stimulation activities (including estimated total mass, estimated composition, chemical abstract service numbers and properties), their mixtures and the resultant compounds that are formed after stimulation; (r) a mass balance estimating the concentrations and absolute masses of chemicals that will be reacted, returned to the surface or left in the target gas producing formation subsequent to stimulation; (s) an environmental hazard assessment of the chemicals used including their	

	mixtures and the resultant chemicals that are formed after stimulation including: (i) toxicological and ecotoxicological information of chemicals used; (ii) information on the persistence and bioaccumulation potential of the chemicals used; (iii) identification of the stimulation fluid chemicals of potential concern derived from the risk assessment; (t) an environmental hazard assessment of use, formation of, and detection of polycyclic aromatic hydrocarbons in stimulation activities; (u) if used, identification and an environmental hazard assessment of using radioactive tracer beads in stimulation activities (v) an environmental hazard assessment of leaving stimulation chemicals in the target gas producing formation for extended periods subsequent to stimulation; (w) human health exposure pathways to operators and the regional population; (x) risk characterisation of environmental impacts based on the environmental hazard assessment; (y) potential impacts to landholder bores as a result of stimulation activities; (z) the determination of the likelihood of causing interconnectivity and/or negative water quality as a result of stimulation activities undertaken in close proximity or each other; and (aa) potential environmental or health impacts which may result from stimulation activities including but not limited to water quality, air quality (including suppression of dust and other airborne contaminants), noise and vibration.	
Water Quality Baseline Monitoring		
I11	Prior to undertaking any stimulation activity, a baseline bore assessment must be undertaken of the water quality of: (a) all landholders' active groundwater bores (subject to access being permitted by the landholder) that are spatially within a two (2) kilometre horizontal radius from the location of the stimulation initiation point within the target gas producing formation; and (b) all landholders' active groundwater bores (subject to access being permitted by the landholder) in any aquifer that is within 200 metres above or below the target gas producing formation and is spatially located with a two (2) kilometre radius from the location of the stimulation initiation point; and (c) any other bore that could potentially be adversely impacted by the stimulation activity(ies) in accordance with the findings of the risk assessment required by conditions I9 and I10.	
I12	Prior to undertaking stimulation activities at a well, there must have sufficient water quality data to accurately represent the water quality in the well to be stimulated. The data must include, as a minimum, the results of analyses for the parameters in condition I13.	
I13	Baseline bore and well assessments must include relevant analytes and physicochemical parameters to be monitored in order to establish baseline water quality and must include, but not necessarily be limited to: (a) pH (b) electrical conductivity [µS/m] (c) turbidity [NTU] (d) total dissolved solids [mg/L] (e) temperature [°C] (f) dissolved oxygen [mg/L] (g) dissolved gases (methane, chlorine, carbon dioxide, hydrogen sulfide) [mg/L] (h) alkalinity (bicarbonate, carbonate, hydroxide and total as CaCO3) [mg/L] (i) sodium adsorption ratio (SAR) (j) anions (bicarbonate, carbonate, hydroxide, chloride, sulphate) [mg/L]	

	(k) cations (aluminium, calcium, magnesium, potassium, sodium) [mg/L] (l) dissolved and total metals and metalloids (including but not necessarily being limited to: aluminium, arsenic, barium, borate (boron), cadmium, total chromium, copper, iron, fluoride, lead, manganese, mercury, nickel, selenium, silver, strontium, tin and zinc) [µg/L] (m) total petroleum hydrocarbons [µg/L] (n) BTEX (as benzene, toluene, ethylbenzene, ortho-xylene, para- and meta-xylene, and total xylene) [µg/L] (o) polycyclic aromatic hydrocarbons (including but not necessarily being limited to: naphthalene, phenanthrene, benzo[a]pyrene) [µg/L] (p) sodium hypochlorite [mg/L] (q) sodium hydroxide [mg/L] (r) formaldehyde [mg/L] (s) ethanol [mg/L]; and (t) gross alpha + gross beta or radionuclides by gamma spectroscopy [Bq/L].	
I14	Despite condition I13, baseline bore and well assessment undertaken prior to 07 December 2022 must include the minimum water quality analytes and physico-chemical parameters identified in the Baseline Assessment Guideline (EHP) and any restricted stimulation fluids as defined in the Environmental Protection Act 1994, as amended from time to time, in order to establish baseline water quality.	
Simulation Impact Monitoring Program		
I15	Stimulation Impact Monitoring Program must be developed prior to the carrying out of stimulation activities which must be able to detect adverse impacts to water quality from stimulation activities and must consider the findings of the risk assessment required by conditions (I9) and (I10) that relate to stimulation activities and must include, as a minimum, monitoring of: (a) the stimulation fluids to be used in stimulation activities at sufficient frequency and which sufficiently represents the quantity and quality of the fluids used; and (b) flow back waters from stimulation activities at sufficient frequency and which sufficiently represents the quality of that flow back water; and (c) flow back waters from stimulation activities at sufficient frequency and accuracy to demonstrate that 150 per cent of the volume used in stimulation activities has been extracted from the stimulated well; and (d) all bores in accordance with condition (I11) at the following minimum frequency: (i) monthly for the first six (6) months subsequent to the stimulation activities being undertaken; then (ii) annually for the first five (5) years subsequent to the stimulation activities being undertaken or until analytes and physico-chemical parameters listed in condition (I13) are not detected in concentrations above baseline bore monitoring data on two (2) consecutive monitoring occasions.	
I16	The Stimulation Impact Monitoring Program must provide for monitoring of: (a) analytes and physico-chemical parameters relevant to baseline bore and well assessments to enable data referencing and comparison including, but not necessarily being limited to the analytes and physico- chemical parameters in condition I13; and (b) any other analyte or physico-chemical parameters that will enable detection of adverse water quality impacts and the inter-connection with a non-target aquifer as a result of stimulation activities including chemical compounds that are actually or potentially formed by chemical reactions with each other or coal seam materials during stimulation activities.	
I17	The results of the Stimulation Impact Monitoring Program must be made available to any potentially affected landholders upon request by that landholder.	
Schedule J – Rehabilitation		
Rehabilitation Planning		

J1	A Rehabilitation Plan must be developed by a suitably qualified person and must include the: (a) rehabilitation goals; and (b) procedures to be undertaken for rehabilitation that will: (i) achieve the requirements of conditions (J2) to (J6) inclusive; and (ii) provide for appropriate monitoring and maintenance.	
Transitional Rehabilitation		
J2	Significantly disturbed areas that are no longer required for the on-going petroleum activities, must be rehabilitated within 12 months (unless an exceptional circumstance in the area to be rehabilitated (e.g. a flood event) prevents this timeframe being met) and be maintained to meet the following acceptance criteria: (a) contaminated land resulting from petroleum activities is remediated and rehabilitated; (b) the areas are: (i) non-polluting; (ii) a stable landform; (iii) re-profiled to contours consistent with the surrounding landform (c) surface drainage lines are re-established; (d) top soil is reinstated; and (e) either: (i) groundcover, that is not a prohibited or restricted pest species, is growing; or (ii) an alternative soil stabilisation methodology that achieves effective stabilisation is implemented and maintained.	
Remaining Dams		
J3	Where there is a dam, (including a low consequence dam) that is being or intended to be used by the landholder or overlapping tenure holder, the dam must be decommissioned to no longer accept inflow from the petroleum activity(ies) and the contained water must be of a quality suitable for the intended on- going uses(s) by the landholder or overlapping tenure holder.	
Pipeline Activities		
J4	Pipeline trenches must be backfilled and topsoils reinstated within three months after pipe laying.	
J5	Reinstatement and revegetation of the pipeline right of way must commence within 6 months after cessation of petroleum activities for the purpose of pipeline construction.	
J6	Backfilled, reinstated and revegetated pipeline trenches and right of ways must be: (a) a stable landform (b) re-profiled to a level consistent with surrounding soils (c) re-profiled to original contours and established drainage lines; and (d) vegetated with groundcover which is not a prohibited or restricted pest species, and which is established and growing.	
Final Rehabilitation Acceptance Criteria		
J7	All significantly disturbed areas caused by petroleum activities which are not being or intended to be utilised by the landholder or overlapping tenure holder, must be rehabilitated to meet the following final acceptance criteria measured either against the highest ecological value adjacent land use or the pre- disturbed land use: (a) greater than or equal to 70 per cent of native ground cover species richness (b) greater than or equal to the total per cent ground cover (c) less than or equal to the per cent species richness of prohibited or restricted pest species	

	(d) where the adjacent land use contains, or the pre-clearing land use contained, one or more regional ecosystem(s), then: (i) at least one Regional Ecosystem(s) from the same broad vegetation group, as demonstrated by the predominant species in the ecologically dominant layer, must be present; and, (ii) the Regional Ecosystem present in J7(d)(i) must possess an equivalent or higher conservation value (biodiversity status) than the Regional ecosystem(s) in either the adjacent land or pre-disturbed land.	
Final Rehabilitation Acceptance Criteria in Environmentally Sensitive Areas		
J8	Where significant disturbance to land has occurred in an environmentally sensitive area, the following final rehabilitation criteria as measured against the pre- disturbance biodiversity values assessment (required by conditions D1 and D3) must be met: (a) greater than or equal to 70% of native ground cover species richness (b) greater than or equal to the total per cent ground cover (c) less than or equal to the per cent species richness of Prohibited or restricted pest species (d) greater than or equal to 50% of organic litter cover (e) greater than or equal to 50% of total density of coarse woody material; and (f) all predominant species in the ecologically dominant layer, that define the pre-disturbance regional ecosystem(s) are present.	
Schedule K – Notification		
K1	The administering authority must be notified through the Pollution Hotline as soon as reasonably practicable, but within 48 hours after becoming aware of: (a) any unauthorised significant disturbance to land; or (b) any unauthorised release of contaminants greater than: (i) 200 L of hydrocarbons; or (ii) 200 L of stimulation additives; or (iii) 500 L of stimulation fluids; or (iv). (iv) 1,000 L of brine; or (v) 5,000 L of coal seam gas water; or (vi). (vi) 10,000 L of sewage effluent; (vii) 100,000 L of irrigation-quality coal seam gas water, released inside a designated irrigation area authorised by condition C8(c). (c) a potential or actual loss of structural or hydraulic integrity of a dam; or (d) when the level of the contents of any regulated dam reaches the mandatory reporting level; or (e) when a regulated dam will not have available storage to meet the design storage allowance on the 1 November of any year; or (f) any incident where there is a potential or actual loss of well integrity (e.g. when the annulus pressure during stimulation increases by more than 3.5 MPa from the pressure immediately preceding stimulation); or (g) any detection of restricted stimulation fluids from stimulation fluid monitoring; or (h) any analyses result from baseline bore, well or stimulation impact monitoring that exceeds a water quality objective for the protection of an environmental value of that water resource; or (i) any analyses result from groundwater monitoring that exceeds trigger action investigation levels, if provided in this environmental authority.	
K2	The notification of emergencies or incidents as required by condition K1 must include but not be limited to the following information: (a) the environmental authority number and name of the holder; (b) the tenure type and number where the emergency or incident occurred; (c) the name and telephone number of the designated contact person;	

	(d) the location of the emergency or incident (GDA94); (e) the date and time that the emergency or incident occurred; (f) the date and time the holder of this environmental authority became aware of the emergency or incident; (g) details of the nature of the event and the circumstances in which it occurred; (h) the estimated quantity and type of any contaminants involved in the incident; (i) the actual or potential suspected cause of the emergency or incident; (j) a description of the land use at the site of the emergency or incident (e.g. grazing, pasture, forest etc.) and/or the name of any relevant waters and other environmentally sensitive features; (k) a description of the possible impacts from the emergency or incident; (l) a description of whether stock and/or wildlife were exposed to any contaminants released and measures taken to prevent access for the duration of the emergency or incident; (m) any sampling conducted or proposed, relevant to the emergency or incident; (n) landholder details and details of landholder consultation; (o) immediate actions taken to control the impacts of the emergency or incident and how environmental harm was mitigated at the time of the emergency or incident; and (p) whether further examination/root cause analysis is required and if so, the expected date by when this examination will be completed and reported to the administering authority.	
K3	Within 10 business days following the initial notification under conditions K1 and K2 unless a longer time is agreed to by the administering authority, a written report must be provided to the administering authority, including the following (where relevant to the emergency or incident): (a) the root cause of the emergency or incident; (b) the confirmed quantities and types of any contaminants involved in the incident; (c) results and interpretation of any analysis of samples taken at the time of the emergency or incident (including the analysis results of any impact monitoring); (d) a final assessment of the impacts from the emergency or incident including any actual or potential environmental harm that has occurred or may occur in the longer term as a result of the release; (e) the success or otherwise of actions taken at the time of the incident to prevent or minimise environmental harm; (f) results and current status of landholder consultation, including commitment to resolve any outstanding issues/concerns; and (g) actions and/or procedural changes to prevent a recurrence of the emergency or incident.	

Definitions

Key terms and/or phrases used in this document are defined in this section. Where a term is not defined, the definition in the Environmental Protection Act 1994, its regulations or environmental protection policies must be used. If a word remains undefined it has its ordinary meaning.

Word or Phrase	Definitions
Adjacent Land Use(s)	means the ecosystem function adjacent to an area of significant disturbance, or where there is no ecosystem function, the use of the land. An adjacent land use does not include an adjacent area that shows evidence of edge effect.
Administering Authority	means:

<table>
<tr><td></td><td>a) for a matter, the administration and enforcement of which has been devolved to a local government under section 514 of the Environmental Protection Act 1994 the local government; or
b) for all other matters the Chief Executive of the Department of Environment, Science and Innovation; or
c) another State Government Department, Authority, Storage Operator, Board or Trust, whose role is to administer provisions under other enacted legislation.</td></tr>
<tr><td>Affected Person</td><td>is someone whose drinking water can potentially be impacted as a result of discharges from a dam or their life or property can be put at risk due to dwellings or workplaces being in the path of a dam break flood.</td></tr>
<tr><td>AHD</td><td>means Australian Height Datum and is the datum used for the determination of elevations in Australia. The determination uses a national network of benchmarks and tide gauges and sets mean sea level at zero elevation.</td></tr>
<tr><td>Alternative Arrangement</td><td>means a written agreement about the way in which a particular environmental nuisance impact will be dealt with at a sensitive place and may include an agreed period of time for which the arrangement is in place. An alternative arrangement may include, but is not limited to, a range of nuisance abatement measures to be installed at the sensitive place, or provision of alternative accommodation for the duration of the relevant nuisance impact.</td></tr>
<tr><td>Analogue Site</td><td>means an area of land which contains values and characteristics representative of an area to be rehabilitated prior to disturbance. Such values must encompass land use, topographic, soil, vegetation, vegetation community attributes and other ecological characteristics. Analogue sites can be the pre-disturbed site of interest where significant surveying effort has been undertaken to establish benchmark parameters.</td></tr>
<tr><td>Analytes</td><td>means a chemical parameter determined by either physical measurement in the field or by laboratory analysis.</td></tr>
<tr><td>Annual Exceedance Probability or AEP</td><td>the probability that at least one event in excess of a particular magnitude will occur in any given year.</td></tr>
<tr><td>Appraisal well</td><td>means a petroleum well to test the potential of one (1) or more natural underground reservoirs for producing or storing petroleum. For clarity, an appraisal well does not include an exploration well.</td></tr>
<tr><td>Approved quality criteria</td><td>for the purposes of residual drilling materials, means the residual drilling material meet the following quality standards:
Part A In all cases:
<table><tr><th>Parameter</th><th>Maximum concentration</th></tr><tr><td>pH</td><td>6-10.5 (range)</td></tr><tr><td>Electrical Conductivity</td><td>20 dS/m (20,000 µS/cm)</td></tr><tr><td>Chloride*</td><td>8000 mg/L</td></tr></table>
*Chloride analysis is only required if an additive containing chloride was used in the drilling process.
The limits in Part A must be measured in the clarified filtrate of oversaturated solids prior to mixing.
Part B If any of the following metals are a component of the drilling fluids, then for that metal:
<table><tr><th>Parameter</th><th>Maximum concentration</th></tr><tr><td>Arsenic</td><td>20 mg/kg</td></tr><tr><td>Selenium</td><td>5 mg/kg</td></tr><tr><td>Boron</td><td>100 mg/kg</td></tr><tr><td>Cadmium
Chromium</td><td>3 mg/kg
400 mg/kg</td></tr><tr><td>Copper</td><td>100 mg/kg</td></tr><tr><td>Lead</td><td>600 mg/kg</td></tr></table></td></tr>
</table>

<table>
<tr><td></td><td>The limits in Part B and Part C refer to the post soil/by-product mix. Part C If a hydrocarbon sheen is visible, the following hydrocarbon fractions:
<table>
<tr><th>TPH</th><th>Maximum concentration</th></tr>
<tr><td>C6 – C10</td><td>170 mg/kg</td></tr>
<tr><td>C10 – C16</td><td>150 mg/kg</td></tr>
<tr><td>C16 – C34</td><td>1300 mg/kg</td></tr>
<tr><td>C34 – C40</td><td>5600 mg/kg</td></tr>
<tr><td>Total Polycyclic Aromatic Hydrocarbons (PAHs)</td><td>20 mg/kg</td></tr>
<tr><td>Phenols (halogenated)</td><td>1 mg/kg</td></tr>
<tr><td>Phenols (non-halogenated)</td><td>60 mg/kg</td></tr>
<tr><td>Monocyclic aromatic hydrocarbons (Total sum of benzene, toluene, ethyl benzene, xylenes including otho, para and meta xylenes) and styrene)</td><td>7 mg/kg</td></tr>
<tr><td>Benzene</td><td>1 mg/kg</td></tr>
</table></td></tr>
<tr><td>Areas of Pre-existing Disturbance</td><td>means areas where environmental values have been negatively impacted as a result of anthropogenic activity and these impacts are still evident. Areas of pre-disturbance may include areas where legal clearing, logging, timber harvesting, or grazing activities have previously occurred, where high densities of weed or pest species are present which have inhibited re-colonisation of native regrowth, or where there is existing infrastructure (regardless of whether the infrastructure is associated with the authorised petroleum activities). The term ‘areas of pre-disturbance’ does not include areas that have been impacted by wildfire/s, controlled burning, flood or natural vegetation die-back.</td></tr>
<tr><td>Assessed or Assessment</td><td>by a suitably qualified and experienced person in relation to a consequence assessment of a dam, means that a statutory declaration has been made by that person and, when taken together with any attached or appended documents referenced in that declaration, all of the following aspects are addressed and are sufficient to allow an independent audit of the assessment:
a) exactly what has been assessed and the precise nature of that determination;
b) the relevant legislative, regulatory and technical criteria on which the assessment has been based;
c) the relevant data and facts on which the assessment has been based, the source of that material, and the efforts made to obtain all relevant data and facts; and
d) the reasoning on which the assessment has been based using the relevant data and facts, and the relevant criteria.</td></tr>
<tr><td>Associated Water</td><td>means underground water taken or interfered with, if the taking or interference happens during the course of, or results from, the carrying out of another authorised activity under a petroleum authority, such as a petroleum well, and includes waters also known as produced formation water. The term includes all contaminants suspended or dissolved within the water.</td></tr>
<tr><td>Associated works</td><td>in relation to a dam, means:
a) operations of any kind and all things constructed, erected or installed for that dam; and
b) any land used for those operations.</td></tr>
<tr><td>Australian Standard 2187</td><td>means Australian Standard 2187.0:1998 Explosives—Storage, transport and use, Part 0, Australian Standard 2187.1:1998 Explosives—Storage, transport and use Part 1 and Australian Standard 2187.2:2006 Explosives—Storage</td></tr>
</table>

	and use, Part 2 or any updated versions that becomes available from time to time.
Australian Standard 3580	means any of the following publications: • AS3580.10.1 Methods for sampling and analysis of ambient air - Determination of particulate matter - Deposited matter - Gravimetric method. • AS3580.9.6 Methods for sampling and analysis of ambient air Determination of suspended particulate matter PM10 high volume sampler with size-selective inlet Gravimetric method • AS3580.9.9 Methods for sampling and analysis of ambient air Determination of suspended particulate matter PM10 low volume sampler Gravimetric sampler.
Australian Standard 4323	means Australian Standard 4323.1:1995 Stationary source emissions method 1: Selection of sampling positions.
Authority	means an environmental authority.
Background noise level	means the sound pressure level, measured in the absence of the noise under investigation, as the L A90, T being the A-weighted sound pressure level exceeded for 90 per cent of the measurement time period T of not less than 15 minutes, using Fast response.
Bed and Banks	for a watercourse or wetland means land over which the water of the watercourse or wetland normally flows or that is normally covered by the water, whether permanently or intermittently; but does not include land adjoining or adjacent to the bed or banks that is from time to time covered by floodwater.
Being or intended to be utilised by the landholder or overlapping tenure holder	for significantly disturbed land, means there is a written agreement (e.g. land and compensation agreement) between the landholder or the overlapping tenure holder and the holder of the environmental authority identifying that the landholder or the overlapping tenure holder has a preferred use of the land such that rehabilitation standards for revegetation by the holder of the environmental authority are not required. For dams, means there is a written agreement (e.g. land and compensation agreement) between the landholder or the overlapping tenure holder and the environmental authority holder identifying that the landholder or the overlapping tenure holder has a preferred use for the dam such that rehabilitation standards for revegetation by the holder of the environmental authority are not required.
Beneficial use	means with respect to dams, that the current or proposed owner of the land on which a dam stands, has found a use for that dam that is: • of benefit to that owner in that it adds real value to their business or to the general community, • in accordance with relevant provisions of the Waste Reduction and Recycling Act 2011, • sustainable by virtue of written undertakings given by that owner to maintain that dam, and • the transfer and use have been approved or authorised under any relevant legislation. Or, with respect to coal seam gas water, refer to the Department of Environment and Heritage Protection's Guideline – Approval of Coal Seam Gas Water for Beneficial Use.
Bore	means a water observation bore or a water supply bore that is either sub artesian or artesian.
Brine	means saline water with a total dissolved solid concentration greater than 40 000 mg/l.
BTEX	means benzene, toluene, ethylbenzene, ortho-xylene, para-xylene, meta-xylene and total xylene.

Bund or bunded	in relation to spill containment systems for fabricated or manufactured tanks or containers designed to a recognised standard means an embankment or wall of brick, stone, concrete or other impervious material which may form part or all of the perimeter of a compound and provides a barrier to retain liquid. Since the bund is the main part of a spill containment system, the whole system (or bunded area) is sometimes colloquially referred to within industry as the bund. The bund is designed to contain spillages and leaks from liquids used, stored or processed above ground and to facilitate clean-up operations. As well as being used to prevent pollution of the receiving environment, bunds are also used for fire protection, product recovery and process isolation.
Business day	has the meaning in the Acts Interpretation Act 1954 and Environmental Protection Act 1994 and means a day that is not— • a Saturday or Sunday; or • a public holiday, special holiday or bank holiday in the place in which any relevant act is to be or may be done; or • a business day that occurs during the period starting on 20 December in a year and ending on 5 January in the following year.
Category A Environmentally Sensitive Area	means any area listed in Schedule 19, part 1, section 1 of the Environmental Protection Regulation 2019.
Category B Environmentally Sensitive Area	means any area listed in Schedule 19, part 1, section 2 of the Environmental Protection Regulation 2019.
Category C Environmentally Sensitive Area	means any of the following areas: • Nature Refuges as defined under the Nature Conservation Act 1992; • Koala Habitat Areas as defined under the Nature Conservation (Koala) Conservation Plan 2006; • State Forests or Timber Reserves as defined under the Forestry Act 1959; • Regional parks (resource use area) under the Nature Conservation Act 1992; • An area validated as “Essential Habitat” from ground-truthing surveys in accordance with the Vegetation Management Act 1999 for a species of wildlife listed as endangered or vulnerable under the Nature Conservation Act 1992; • Of Concern Regional Ecosystems that are remnant vegetation identified in the database called ‘RE description database’ containing Regional Ecosystem numbers and descriptions.
Certifying or Certify or Certified or Certification	in relation to a dam, means assessment and approval must be undertaken by a suitably qualified and experienced person in relation to any assessment or documentation required by this Manual, including design plans, ‘as constructed’ drawings and specifications, construction, operation or an annual report regarding regulated structures, undertaken in accordance with the Board of Professional Engineers of Queensland Policy Certification by RPEQs (ID:1.4 (2A))
Certifying or Certify or Certified or Certification	in relation to any matter other than a design plan, ‘as constructed’ drawings or an annual report regarding dams means, a Statutory Declaration by a suitably qualified person or suitably qualified third-party accompanying the written document stating: • The person’s qualifications and experience relevant to the function; • that the person has not knowingly included false, misleading or incomplete information in the document; • that the person has not knowingly failed to reveal any relevant information or document to the administering authority;

	• that the document addresses the relevant matters for the function and is factually correct; and • that the opinions expressed in the document are honestly and reasonably held.
Clearing	for vegetation: a) means remove, cut down, ringbark, push over, poison or destroy in any way including by burning, flooding or draining; but b) does not include destroying standing vegetation by stock or lopping a tree.
Closed-Loop Systems	means using waste on site in a way that does not release waste or contaminants in the waste to the environment.
Coal Seam Gas Water	means underground water brought to the surface of the earth, or moved underground in connection with exploring for, or producing coal seam gas.
Coal seam gas water concentrate	means the concentrated saline water waste stream from a water treatment process that does not exceed a total dissolved solid concentration of 40 000 mg/L.
Commercial species	means species as listed in parts 1, 2 and 3 of Schedule 6 of the Vegetation Management Regulation 2012, which are above the diameters / sizes specified in this Schedule for each listed species.
Consequence	in relation to a structure as defined, means the potential for environmental harm resulting from the collapse or failure of the structure to perform its primary purpose of containing, diverting or controlling flowable substances.
Consequence Category	means a category, either low, significant or high, into which a dam is assessed as a result of the application of tables and other criteria in the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933).
Construction or Constructed	in relation to a dam includes building a new dam and modifying or lifting an existing dam, but does not include investigations and testing necessary for the purpose of preparing a design plan.
Control Measure	has the meaning in section 31 of the Environmental Protection Regulation 2019 and means a device, equipment, structure, or management strategy used to prevent or control the release of a contaminant or waste to the environment.
Daily Peak Design Capacity	for sewage treatment works, has the meaning in Schedule 2, section 63(4) of the Environmental Protection Regulation 2019 as the higher equivalent person (EP) for the works calculated using each of the formulae found in the definition for EP.
Dam	means a land-based structure or a void that is designed to contains, diverts or controls flowable substances, and includes any substances that are thereby contained, diverted or controlled by that land-based structure or void and associated works. A dam does not mean a fabricated or manufactured tank or container, designed and constructed to an Australian Standard that deals with strength and structural integrity of that tank or container.
Design Plan	is a document setting out how all identified consequence scenarios are addressed in the planned design and operation of a regulated structure.
Design Storage Allowance or DSA	means an available volume, estimated in accordance with the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933) published by the administering authority, must be provided in a dam as at 1 November each year in order to prevent a discharge from that dam to an annual exceedance probability (AEP) specified in that Manual.
Development Well	means a petroleum well which produces or stores petroleum. For clarity, a development well does not include an appraisal well.
Discharge area	means:

	• that part of the land surface where groundwater discharge produces a net movement of water out of the groundwater; and • identified by an assessment process consistent with the document Salinity Management Handbook • Queensland Department of Natural Resources, 1997, as amended from time to time; or • identified by an approved salinity hazard map held by the administering authority.
Document	has the meaning in the Acts Interpretation Act 1954 and means: • any paper or other material on which there is writing; • any paper or other material on which there are marks; • figures, symbols or perforations having a meaning for a person qualified to interpret them; and • any disc, tape or other article or any material from which sounds, images, writings or messages are capable of being produced or reproduced (with or without the aid of another article or device).
Ecologically Dominant Layer	has the meaning in the Methodology for Surveying and Mapping of Regional Ecosystems and Vegetation Communities in Queensland (Version 3.2 August 2012) and means the layer making the greatest contribution to the overall biomass of the site and the vegetation community (NLWRA 2001). This is also referred to as the ecologically dominant stratum or the predominant canopy in woody ecosystems.
Ecosystem Function	means the interactions between and within living and nonliving components of an ecosystem and generally correlates with the size, shape and location of the vegetation community.
Enclosed Flare	means a device where the residual gas is burned in a cylindrical or rectangular enclosure that includes a burning system and a damper where air for the combustion reaction is admitted.
Environmental Harm	has the meaning in section 14 of the Environmental Protection Act 1994 and means any adverse effect, or potential adverse effect (whether temporary or permanent and of whatever magnitude, duration or frequency) on an environmental value, and includes environmental nuisance. Environmental harm may be caused by an activity a) whether the harm is a direct or indirect result of the activity; or b) whether the harm results from the activity alone or from the combined effects of the activity and other activities or factors.
Environmental Nuisance	has the meaning in section 15 of the Environmental Protection Act 1994 and means unreasonable interference or likely interference with an environmental value caused by a) aerosols, fumes, light, noise, odour, particles or smoke; or b) an unhealthy, offensive or unsightly condition because of contamination; or c) another way prescribed by regulation.
Equivalent Person or EP	has the meaning under section 3 of the Planning Guidelines For Water Supply and Sewerage, 2005, published by the Queensland Government. It is calculated in accordance with Schedule 2, Section 63(4) of the Environmental Protection Regulation 2019 where: • EP = V/200 where V is the volume, in litres, of the average dry weather flow of sewage that can be treated at the works in a day; or • EP = M/2.5 where M is the mass, in grams, of phosphorus in the influent that the works are designed to treat as the inlet load in a day.
Essential Habitat	essential habitat means section 20AC (2) of the Vegetation Management Act 1999 validated as 'protected wildlife habitat' from ground-truthing surveys for

	species of wildlife identified as critically endangered, endangered or vulnerable under the Nature Conservation Act 1992.
Evaporation dam	means an impoundment, enclosure or structure that is designed to be used to hold CSG water for evaporation.
Exploring for petroleum	means carrying out an activity for the purpose of finding petroleum or natural underground reservoirs as per section 14 of the Petroleum and Gas (Production and Safety) Act 2004 for example including: • conducting a geochemical, geological or geophysical survey; • drilling a well; • carrying out testing in relation to a well; • taking a sample for chemical or other analysis.
Exploration Well	means a petroleum well that is drilled to: • explore for the presence of petroleum or natural underground reservoirs suitable for storing petroleum; or • obtain stratigraphic information for the purpose of exploring for petroleum. For clarity, an exploration well does not include an appraisal or development well.
Fill	means any kind of material in solid form (whether or not naturally occurring) capable of being deposited at a place but does not include material that forms a part of, or is associated with, a structure constructed in a watercourse or wetland including a bridge, road, causeway, pipeline, rock revetment, drain outlet works, erosion prevention structure or fence.
Flare Pit	has the meaning in the Manual for Assessing Consequence Categories and Hydraulic Performance of Structures (ESR/2016/1933), and means containment area where any hydrocarbon that is discovered in an over-pressured reservoir during a drilling operation is diverted to, and combusted, The flare pit is only used during the drilling and work over process on a petroleum well.
Flare Precipitant	means waste fluids which result from the operation of a flare.
Floodplain	has the meaning in the Water Act 2000 and means an area of reasonably flat land adjacent to a watercourse that: • is covered from time to time by floodwater overflowing from the watercourse; and • does not, other than in an upper valley reach, confine floodwater to generally follow the path of the watercourse; and • has finer sediment deposits than the sediment deposits of any bench, bar or in-stream island in the watercourse.
Flowable substance	means matter or a mixture of materials which can flow under any conditions potentially affecting that substance. Constituents of a flowable substance can include water, other liquids fluids or solids, or a mixture that includes water and any other liquids fluids or solids either in solution or suspension.
Fuel burning or combustion equipment	means a permanent fuel burning or combustion equipment which is in isolation, or combined in operation, or which are interconnected, is, or is capable of burning more than 500 kg of fuel in an hour.
GDA	means Geocentric Datum of Australia.
Geophysical survey	means a systematic collection of geophysical data.
Great Artesian Basin (GAB) spring	means an area protected under the Environment Protection and Biodiversity Conservation Act 1999 because it is considered to be a Matter of National Environmental Significance and identified as a: • community of native species dependent on natural discharge of groundwater from the Great Artesian Basin; or

	• Great Artesian Basin spring; or • Great Artesian Basin discharge spring wetland. A GAB spring includes a spring vent, spring complex or watercourse spring and includes the land to which water rises naturally from below the ground and the land over which the water then flows. Note: The Australian Government's Protected Matters Search Tool should be used to get an indication of whether the area of interest may contain an MNES spring. Note: The GAB springs dataset can be requested from the Queensland Government Herbarium.
Greywater	means wastewater generated from domestic activities such as laundry, dishwashing, and bathing. Greywater does not include sewage.
Groundwater Dependent Ecosystems (GDE)	means ecosystems which require access to groundwater on a permanent or intermittent basis to meet all or some of their water requirements so as to maintain their communities of plants and animals, ecological processes and ecosystem services. For the purposes of the environmental authority, groundwater dependent ecosystems do not include those mapped as "unknown".
Growing	means to increase by natural development, as any living organism or part thereof by assimilation of nutriment; increase in size or substance.
High value regrowth	vegetation means vegetation located — (a) on freehold land, indigenous land, or land subject of a lease issued under the Land Act 1994 for agriculture or grazing purposes or an occupation licence under that Act; and (b) in an area that has not been cleared (other than for relevant clearing activities) for at least 15 years, if the area is — (i) an endangered regional ecosystem; or (ii) an of concern regional ecosystem; or (iii) a least concern regional ecosystem.
Holder	means any person who is the holder of, or is acting under, that environmental authority.
Hydraulic fracturing	means a technique used to create cracks in underground coal seams to increase the flow and recovery of gas or oil out of a well. It involves pumping a fluid, comprised largely of water and sand, under pressure, into a coal seam. This action fractures the coal seam which provides a pathway that increases the ability for gas to flow through the coal.
Hydraulic performance	means the capacity of a regulated dam to contain or safely pass flowable substances based on the design criteria specified for the relevant consequence category in the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933).
Hydraulic testing	means the testing of a geological formation to evaluate the hydrogeological characteristics of the formation.
Impulsive noise	means sound characterised by brief excursions of sound pressure (acoustic impulses) that significantly exceed the background sound pressure. The duration of a single impulsive sound is usually less than one second.
Incidental activity	for this environmental authority means an activity that is not a specified relevant activity and is necessary to carry out the activities listed in Schedule A, Table 1 – Scale and Intensity for the Activities.
Infrastructure	means plant or works including for example, communication systems, compressors, powerlines, pumping stations, reservoirs, roads and tracks, water storage dams, evaporation or storage ponds and tanks, equipment, buildings and other structures built for the purpose and duration of the conduct of the petroleum activity(ies) including temporary structures or

	structures of an industrial or technical nature, including, for example, mobile and temporary camps. Infrastructure does not include other facilities required for the long-term management of the impact of those petroleum activities or the protection of potential resources. Such other facilities include dams other than water storage dams (e.g. evaporation dams), pipelines and assets, that have been decommissioned, rehabilitated, and lawfully recognised as being subject to subsequent transfer with ownership of the land.
LAeq, adj, 15 mins	means the A-weighted sound pressure level of a continuous steady sound, adjusted for tonal character, that within any 15 minute period has the same square sound pressure as a sound level that varies with time.
LA 90, adj, 15 mins	means the A-weighted sound pressure level, adjusted for tonal character, that is equal to or exceeded for 90 per cent of any 15 minutes sample period equal, using Fast response.
Lake	means: • a lagoon, swamp or other natural collection of water, whether permanent or intermittent; and • the bed and banks and any other element confining or containing the water.
Land degradation	has the meaning in the Vegetation Management Act 1999 and means the following: • soil erosion • rising water tables • the expression of salinity • mass movement by gravity of soil or rock • stream bank instability • a process that results in declining water quality.
Landholders' Active Groundwater Bores	means bores that are able to continue to provide a reasonable yield of water in terms of quantity for the bores authorised purpose or use. This term does not include monitoring bores owned by the administering authority of the Water Act 2000.
Limited impact camps	mean accommodation camps that: • are temporary (no more than 6 months); • are located within pre-existing areas of clearing or significant disturbance; • are up to 2 ha or located within well sites; and • may involve sewage treatment works that are no release works or release works that involve an irrigation release within pre-existing areas of clearing or significant disturbance.
Limited Impact Petroleum Activities	means petroleum activities that are located within areas that are not a regional ecosystem and: • are single well sites (includes observation, pilot, injection and production wells) greater than 1 ha; or • are multi-well sites greater than 1 ha; and • may involve construction of new access tracks that are required as part of the construction or servicing a petroleum activity that can be lawfully carried out within an ESA or its protection zone; and • may involve upgrading or maintenance of existing roads or tracks; and • may include power and communication lines; and • may include gas gathering lines from a well site to the initial compression facility; and

	• may include water gathering lines from a well site to the initial water storage or dam.
Limited Petroleum Activities	mean any low impact petroleum activity, and: • single well sites (includes observation, pilot, injection and production wells) up to 1 ha and associated infrastructure (water pumps and generators, sumps, flare pits or dams) located on the well site or up to 1.25 ha if the well pad includes the use of a tank (minimum 1ML) for above ground fluid storage, • multi-well sites up to an additional (in addition to single well site above) 0.25 ha per additional well and associated infrastructure (water pumps and generators, sumps, flare pits, dams or tanks) located on the well site to a maximum of 3 ha, • construction of new access tracks that are required as part of the construction or servicing a petroleum activity that can be lawfully carried out within an ESA or its protection zone upgrading or maintenance of existing roads or tracks, • power and communication lines, • gas gathering lines from a well site to the initial compression facility, • water gathering lines from a well site to the initial water storage or dam, • camps within well site that may involve sewage treatment works that are a no release works. • activities necessary to achieve compliance with the conditions of the EA in relation to another limited petroleum activity (e.g. sediment and erosion control measures, rehabilitation), • geophysical, geotechnical, geological, topographic and cadastral surveys (including seismic, sample /test / geotechnical pits, core holes).
Linear infrastructure	means powerlines, communication, pipelines, roads and access tracks.
Long term noise event	is a noise exposure, when perceived at a sensitive receptor, persists for a period of greater than five (5) days, even when there are respite periods when the noise is inaudible within those five (5) days.
Lopping	a tree, means cutting or pruning its branches, but does not include — • removing its trunk; and • cutting or pruning its branches so severely that it is likely to die.
Low Consequence Dam	means any dam that is not a high or significant consequence category as assessed using the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933).
Low flow	means flow up to the one month average recurrence interval.
Low impact petroleum activities	means petroleum activities which do not result in the clearing of native vegetation, earthworks or excavation work that cause either, a significant disruption to the soil profile or permanent damage to vegetation that cannot be easily rehabilitated immediately after the activity is completed. Examples of such activities include but are not necessarily limited to: • chipholes • coreholes • geophysical surveys • seismic surveys • soil surveys • topographic surveys • cadastral surveys • ecological surveys

	• installation of environmental monitoring equipment (including surface water).
Map of Queensland wetland environmental values	means the statutory map under the Environmental Protection (Water and Wetland Biodiversity) Policy 2019. It identifies wetlands of high ecological significance (HES) and general ecological significance (GES) across the state.
Max LpZ, 15 min	means the maximum value of the Z-weighted sound pressure level measured over 15 minutes.
Max LpA, 15 min	means the absolute maximum instantaneous A-weighted sound pressure level, measured over 15 minutes.
Mandatory Reporting Level or MRL	means a warning and reporting level determined in accordance with the criteria in the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933) published by the administering authority.
Manual	in reference to dams means the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933) published by the administering authority, as amended from time to time.
Medium term noise event	is a noise exposure, when perceived at a sensitive receptor, persists for an aggregate period not greater than five (5) days and does not re-occur for a period of at least four (4) weeks. Re- occurrence is deemed to apply where a noise of comparable level is observed at the same receptor location for a period of one hour or more, even if it originates from a difference source or source location.
Methodology	means the science of method, especially dealing with the logical principles underlying the organization of the various special sciences, and the conduct of scientific inquiry.
Mix-bury-cover method	means the stabilisation of residual drilling solids in the bottom of a sump by mixing with subsoil and which occurs in accordance with the following methodology: • the base of the subsoil and residual solid mixture must be separated from the groundwater table by at least one metre of a continuous layer of impermeable subsoil material (kw = 10– 8 m/s) or subsoil with a clay content of greater than 20per cent; and • the residual solids is mixed with subsoil in the sump and cover; and • the subsoil and residual solids is mixed at least three parts subsoil to one part waste (v/v); and • a minimum of one metre of clean subsoil must be placed over the subsoil and residual solids mixture; and topsoil is replaced.
Month	has the meaning in the Acts Interpretation Act 1954 and means a calendar month and is a period starting at the beginning of any day of one (1) of the 12 named months and ending: • immediately before the beginning of the corresponding day of the next named month; or • if there is no such corresponding day—at the end of the next named month.
NATA accreditation	means accreditation by the National Association of Testing Authorities Australia.
Oil based drilling mud	means mud where the base fluid is a petroleum product such as diesel fuel.
Overburden pressure	means the pressure or stress imposed on a layer of soil or rock by the weight of overlying material. The overburden pressure at a depth z is given by p(z) = p0 + g ∫0≈ p(z) dz where p(z) is the density of the overlying rock at depth z

	and g is the acceleration due to gravity. p0 is the datum pressure, like the pressure at the surface.
Pipeline Waste Water	means hydrostatic testing water, flush water or water from low point drains.
Pre-disturbed land use	means the function or use of the land as documented prior to significant disturbance occurring at that location.
Predominant species	has the meaning in the Methodology for Surveying and Mapping of Regional Ecosystems and Vegetation Communities in Queensland (Version 3.2 August 2012) and means a species that contributes most to the overall above-ground biomass of a particular stratum.
Prescribed Environmental Matter	has the meaning in section 10 of the Environmental Offsets Act 2014.
Primary protection zone	means an area within a 200 metre buffer from the boundary of any Category A, B or C Environmentally Sensitive Area.
Produced Water	has the meaning in Section 15A of the Petroleum and Gas (Production and Safety) Act 2004 and means CSG water or associated water for a petroleum tenure.
Prohibited or Restricted Pest Species	means any pest that is: a) a plant or animal, other than a native species of plant or animal, that is i. invasive biosecurity matter under the Biosecurity Act 2014 (Qld); or Notes — 1 See the Biosecurity Act 2014, schedule 1, part 3 or 4 or schedule 2, part 2; and 2 See the note to the Biosecurity Act 2014, schedules 1 and 2. ii. controlled biosecurity matter or regulated biosecurity matter under the Biosecurity Act 2014 (Qld) iii. tramp ants listed in schedule 1 and schedule 2 of the Biosecurity Act 2014 (Qld) b) pest declared under a local law by the local government for the Land to be a pest because the pest is causing, or has the potential to cause, an adverse environmental, economic or social impact in all or part of the local government area.
Regional ecosystem(s)	has the meaning in the Methodology for Surveying and Mapping of Regional Ecosystems and Vegetation Communities in Queensland (Version 3.2 August 2012) and means a vegetation community in a bioregion that is consistently associated with a particular combination geology, landform and soil. Regional ecosystems of Queensland were originally described in Sattler and Williams (1999). The Regional Ecosystems Description Database (Queensland Herbarium 2013) is maintained by Queensland Herbarium and contains the current descriptions of regional ecosystems.
Regulated structure	means any structure in the significant or high consequence category as assessed using the Manual for assessing consequence categories and hydraulic performance of structures (ESR/2016/1933) published by the administering authority. A regulated structure does not include: • a fabricated or manufactured tank or container, designed and constructed to an Australian Standard that deals with strength and structural integrity of that tank or container; • a sump or earthen pit used to store residual drilling material and drilling fluid only for the duration of drilling and well completion activities; • a flare pit.
Rehabilitation or rehabilitated	means the process of reshaping and revegetating land to restore it to a stable landform and in accordance with the acceptance criteria and, where relevant, includes remediation of contaminated land. For the purposes of pipeline rehabilitation, rehabilitation includes reinstatement, revegetation and restoration.

Reinstate or reinstatement	for pipelines, means the process of bulk earth works and structural replacement of pre-existing conditions of a site (i.e. soil surface typography, watercourses, culverts, fences and gates and other landscape(d) features) and is detailed in the APGA Code of Environmental Practice: Onshore Pipelines Revision 4 (2017).
Remnant vegetation	means vegetation, part of which forms the predominant canopy of the vegetation — • covering more than 50 per cent of the undisturbed predominant canopy; and • averaging more than 70 per cent of the vegetation's undisturbed height; and • composed of species characteristic of the vegetation's undisturbed predominant canopy cover.
Reporting limit	means the lowest concentration that can be reliably measured within specified limits of precision and accuracy during routine laboratory operating conditions. For many analytes, the reporting limit is selected as the lowest non-zero standard in the calibration curve. Results that fall below the reporting limit will be reported as "less than" the value of the reporting limit. The reporting limit is also referred to as the practical quantitation limit or the limit of quantitation. For polycyclic aromatic hydrocarbons, the reporting limit must be based on superultra trace methods and, depending on the specific polycyclic aromatic hydrocarbon, will range between 0.005 ug/L – 0.02 ug/L.
Residual drilling material	means waste drilling materials including muds and cuttings or cement returns from well holes and which have been left behind after the drilling fluids are pumped out.
Resource activity(ies)	has the meaning in section 107(d) of the Environmental Protection Act 1994.
Restoration	means the replacement of structural habitat complexity, ecosystem processes, services and function from a disturbed or degraded site to that of a predetermined or analogue site. For the purposes of pipelines, restoration applies to final rehabilitations after pipeline decommissioning.
Restricted stimulation fluids	means fluids used for the purpose of stimulation, including fracturing, that contain the following chemicals in more than the maximum amounts prescribed under section 70 of the Environmental Protection Regulation 2019: • petroleum hydrocarbons containing benzene, ethylbenzene, toluene or xylene; or • chemicals that produce, or are likely to produce, benzene, ethylbenzene, toluene or xylene as the chemical breaks down in the environment. The amount of any chemical is not measured in relation to water included in the restricted stimulation fluid. For clarity, the term restricted stimulation fluids only applies to fluids injected down well post-perforation.
Revegetation or revegetating or revegetate	means to actively re-establish vegetation through seeding or planting techniques in accordance with site specific management plans.
Secondary Protection Zone	in relation to a Category A or Category B ESA means an area within 100 metres from the boundary of the primary protection zone.
Sensitive Place	means: • a dwelling (including residential allotment, mobile home or caravan park, residential marina or other residential premises, motel, hotel or hostel); • a library, childcare centre, kindergarten, school, university or other educational institution;

	• a medical centre, surgery or hospital; • a protected area; • a public park or garden that is open to the public (whether or not on payment of money) for use other than for sport or organised entertainment; • a work place used as an office or for business or commercial purposes, which is not part of the petroleum activity(ies) and does not include employees accommodation or public roads; and • for noise, a place defined as a sensitive receptor for the purposes of the Environmental Protection (Noise) Policy 2019.
Sensitive receptor	is defined in Schedule 2 of the Environmental Protection (Noise) Policy 2019, and means an area or place where noise is measured.
Short term noise event	is a noise exposure, when perceived at a sensitive receptor, persists for an aggregate period not greater than eight hours and does not re-occur for a period of at least seven (7) days. Re- occurrence is deemed to apply where a noise of comparable level is observed at the same receptor location for a period of one hour or more, even if it originates from a different source or source location.
Significantly disturbed or significant disturbance or significant disturbance to land or areas	has the meaning in Schedule 12, section 4 of the Environmental Protection Regulation 2008. Land is significantly disturbed if – a) it is contaminated land; or b) it has been disturbed and human intervention is needed to rehabilitate it: i. to a condition required under the relevant environmental authority; or ii. if the environmental authority does not require the land to a particular conditions – to the condition it was in immediately before the disturbance
Site	means the relevant petroleum activity(ies) to which the environmental authority relates.
Specified relevant activities	for this environmental activity means an activity that: a) but for being carried out as a resource activity, would otherwise be an activity prescribed under section 19 of the Environmental Protection Act 1994 as an environmentally relevant activity; or b) stimulation activities; or c) extracting material other than by dredging.
Spillway	means a weir, channel, conduit, tunnel, gate or other structure designed to permit discharges from the dam, normally under flood conditions or in anticipation of flood conditions.
Stable	has the meaning in Schedule 8 of the Environmental Protection Regulation 2019 and for a site, means the rehabilitation and restoration of the site is enduring or permanent so that the site is unlikely to collapse, erode or subside.
Stimulation	means a technique used to increase the permeability of a natural underground reservoir, including for example, hydraulic fracturing/hydrofracking, fracture acidizing and the use of proppant treatments.
Stimulation fluid	means the fluid injected into an aquifer to increase the permeability of a natural underground reservoir. For clarity, the term stimulation fluid only applies to fluids injected down well post- perforation.
Stimulation impact zone	means a 100 metre maximum radial distance from the stimulation target location within a gas producing formation.
Structure	for the purposes of Schedule H means a dam or levee.

Suitably qualified person	means a person who has professional qualifications, training, skills or experience relevant to the nominated subject matter and can give authoritative assessment, advice and analysis to performance relative to the subject matters using the relevant protocols, standards, methods or literature.
Suitably Qualified and Experienced Person	in relation to regulated structures means a person who is a Registered Professional Engineer of Queensland (RPEQ) under the provisions of the Professional Engineers Act 2002, and has demonstrated competency and relevant experience: • for regulated dams, an RPEQ who is a civil engineer with the required qualifications in dam safety and dam design • for regulated levees, an RPEQ who is a civil engineer with the required qualifications in the design of flood protection embankments. Note: It is permissible that a suitably qualified and experienced person obtain subsidiary certification from an RPEQ who has demonstrated competence and relevant experience in either geomechanics, hydraulic design or engineering hydrology.
Suitably qualified third-party	means a person who: a) has qualifications and experience relevant to performing the function including but not limited to: i. a bachelor's degree in science or engineering; and ii. 3 years' experience in undertaking soil contamination assessments; and b) is a member of at least one organisation prescribed in Schedule 14 of the Environmental Protection Regulation 2019; and not be an employee of, nor have a financial interest or any involvement which would lead to a conflict of interest with the holder(s) of the environmental authority.
Sump	means a pit in which waste residual drilling material or drilling fluids are stored only for the duration of drilling activities.
Synthetic based drilling mud	means a mud where the base fluid is a synthetic oil, consisting of chemical compounds which are artificially made or synthesised by chemically modifying petroleum components or other raw materials rather than the whole crude oil.
Third party auditor	means a suitably qualified person who is either a certified third-party auditor or an internal auditor employed by the holder of the environmental authority and the person is independent of the day to day management and operation of the petroleum activity(ies) covered by this environmental authority.
Topsoil	means the surface (top) layer of a soil profile, which is more fertile, darker in colour, better structured and supports greater biological activity than underlying layers. The surface layer may vary in depth depending on soil forming factors, including parent material, location and slope, but generally is not greater than about 300 mm in depth from the natural surface.
Total density of coarse woody material	means the total length of logs on the ground greater than or equal to 10 cm diameter per hectare and number of logs on the ground greater than or equal to 10cm diameter per hectare.
Transmissivity	means the rate of flow of water through a vertical strip of aquifer which is one unit wide and which extends the full saturated depth of the aquifer.
Valid complaint	means a complaint the administering authority considers is not frivolous, nor vexatious, nor based on mistaken belief.
Vegetation Management Act 1999 (VM Act) Class	has the meaning provided in Division 7A of the Vegetation Management Act 1999. The VM Act class for each Regional Ecosystem is provided in the Vegetation Management Regulation 2012.
Void	means any constructed, open excavation in the ground.

Waste and Resource Management Hierarchy	has the meaning provided in section 9 of the Waste Reduction and Recycling Act 2011 and is the following precepts, listed in the preferred order in which waste and resource management options should be considered: a) AVOID unnecessary resource consumption; b) REDUCE waste generation and disposal c) RE-USE waste resources without further manufacturing d) RECYCLE waste resources to make the same or different products e) RECOVER waste resources, including the recovery of energy f) TREAT waste before disposal, including reducing the hazardous nature of waste g) DISPOSE of waste only if there is no viable alternative.
Waste and Resource Management Principles	has the meaning provided in section 4(2)(b) of the Waste Reduction and Recycling Act 2011 and means the: a) polluter pays principle b) user pays principle c) proximity principle d) product stewardship principle.
Waste Fluids	has the meaning in section 13 of the Environmental Protection Act 1994 in conjunction with the common meaning of “fluid” which is “a substance which is capable of flowing and offers no permanent resistance to changes of shape”. Accordingly, to be a waste fluid, the waste must be a substance which is capable of flowing and offers no permanent resistance to changes of shape.
Watercourse	has the meaning in Schedule 4 of the Environmental Protection Act 1994 and means: 1) a river, creek or stream in which water flows permanently or intermittently a) in a natural channel, whether artificially improved or not; or b) in an artificial channel that has changed the course of the watercourse. 2) Watercourse includes the bed and banks and any other element of a river, creek or stream confining or containing water.
Waters	includes all or any part of a creek, river, stream, lake, lagoon, swamp, wetland, unconfined surface water, unconfined water in natural or artificial watercourses, bed and bank of any waters, non-tidal or tidal waters (including the sea), stormwater channel, stormwater drain, roadside gutter, stormwater run-off, and underground water.
Well Integrity	means the ability of a well to contain the substances flowing through it.
Well infrastructure	means infrastructure required for the construction and completion of a well including but not limited to cellar pits, dams and drill sumps.
Well site	means a maximum area of land disturbance for the purposes of constructing, installing and operating an exploration, appraisal or development well or such wells as part of a multi-well arrangement and includes well lease infrastructure.
Wetland	for the purpose of this environmental authority, wetland means: • areas shown on the Map of Queensland wetland environmental values, which is a state-wide statutory map under the Environmental Protection (Water and Wetland Biodiversity) Policy 2019; and • areas defined under the Queensland Wetlands Program as permanent or periodic / intermittent inundation, with water that is static or flowing fresh, brackish or salt, including areas of marine water, the depth of which at low tide does not exceed six (6) metres, and possess one or more of the following attributes:

	○ at least periodically, the land supports plants or animals that are adapted to and dependent on living in wet conditions for at least part of their life cycle, or ○ the substratum is predominantly undrained soils that are saturated, flooded or ponded long enough to develop anaerobic conditions in the upper layers, or ○ the substratum is not soil and is saturated with water, or covered by water at some time. The term wetland includes riverine, lacustrine, estuarine, marine and palustrine wetlands; and it does not include a Great Artesian Basin Spring or a subterranean wetland that is a cave or aquifer.
Wetlands of General Ecological Significance	"Wetlands of General Ecological Significance" or general ecologically significant wetland" is a wetland that meets the definition of a wetland and that is shown as a wetland of 'general ecological significance' on the Map of Queensland wetland environmental values.
Wetland of High Ecological Significance	otherwise known as "high conservation value wetland" is a wetland that meets the definition of a wetland and that is shown as a High Ecological Significance wetland on the Map of Queensland wetland environmental values.
Year	means a period of 12 months.
80th percentile	in relation to release limits means that not more than one (1) of the measured values is to exceed the stated release limit for any five (5) consecutive samples where: • the consecutive samples are taken over a five (5) month period; and • the consecutive samples are taken at approximately equal periods.
95th percentile	in relation to release limits means calculating the 95th percentile of all samples recorded over each 24 hour period for the duration of the release the result of which cannot exceed limits.

END OF ENVIRONMENTAL AUTHORITY

Appendix B: Detailed Description of Proposed Activities

Description of Proposed Activities

The following sections describe the proposed activities and infrastructure to be located and operated in the Project Area, respectively.

Seismic Surveys

Seismic acquisition is a method of investigating subsurface geological structures to identify locations to conduct drilling activities. Seismic data is collected by recording acoustic (sound) waves that are reflected from geological interfaces at depths of up to several thousand metres below surface. Seismic survey data is collected via use of “geophones” or “nodes” placed at regular intervals along “seismic lines”. Seismic lines are regularly ‘offset’ and ‘weaved’ around obstacles to:

(a) avoid the need to disturb terrain and long-lived perennial vegetation or other sensitivities such as watercourses; and

(b) reduce the ‘linearity’ and visual impact of seismic lines.

Seismic line preparation generally involves ‘walking’ a bulldozer with its front blade in the up position along seismic lines to gently flatten terrain and ground vegetation. Minor vegetation slashing can sometimes also be required. However, a range of methods can be utilised depending on the nature of data to be collected and sensitivity of the land to be surveyed. No seismic line preparation is typically undertaken in sensitive land systems.

Petroleum Exploration, Appraisal and Production wells

Well Lease Establishment

All CSG wells would be constructed on a prepared lease area which would accommodate the necessary drilling and well completion equipment and support infrastructure.

Single well leases will typically be no more than 1.25 hectares (ha) in size. Where additional area is needed to accommodate infrastructure such as a water balance tank or cut and fill lease construction, single well leases may be up to 1.5 ha in size. As discussed in Sections 2.1 and 2.2, Santos also proposes to utilise some multi-well leases to minimise disturbance, maximise gas recovery, and/or accommodate landholder requirements. Multi-well leases would be up to 2.5-3 ha in size, resulting in a larger footprint per lease area, but a reduced overall footprint per well given fewer single well leases would be required.

Where practicable, minimum disturbance leases would be used. These consist of the use of matting placed directly onto slashed vegetation to form a temporary hardstand surface (as opposed to a traditional lease, which involves clearing all vegetation and compacting / preparing the soil to form a hardstand surface).

More specifically, where a traditional lease is required, lease establishment involves:

- surveying and pegging the pad boundary
- constructing a diversion bund if required due to slope or proximity to watercourses
- clearing vegetation that is unable to be avoided
- removing and stockpiling topsoil
- levelling the pad by cutting and filling using material from borrow pit if required
- excavating and capping the rig hardstand
- capping and compacting the lease footprint
- excavating sump pit if required

- installing fencing and gate
- installing cellar and conductor on well centre
- installing pads for ancillary equipment and infrastructure (such a tanks and flowlines); and
- setting up drill rig and associated equipment.

Key equipment required on the lease during drilling includes:

- drill rig and associated equipment
- gas generator
- chemical and fuel storage
- mud pit or tank for drilling fluids
- flare and flare sump for disposal of gas during drilling and appraisal; and
- water storage (tank or small dam) for initial water supply and storage of PW during construction.

Drilling, Casing, and Cementing

There is potential for up to 24 wells to be constructed within the Project Area. All wells will be constructed in accordance with the *Code of Practice for the construction and abandonment of petroleum wells and associated bores in Queensland Version 2* (DNRME, 2019).

Drilling would occur on a 24-hour basis for approximately 1-3 weeks per well. The time to complete each well depends on the depth of the well, the geology of the area and the type of rig being used.

A variety of rotary and air drilling techniques are used to drill the well. Drilling fluids are continuously circulated down the drill pipe to lubricate and cool the drill bit and remove drill cuttings from the bore. Drilling fluid and cuttings are collected in surface tanks or in pits and removed from the well lease area for reuse, recycling or authorised disposal.

Through multiple cycles of drilling, installing casing and cementing casing, the well is isolated from surrounding formations. Santos would test and prove the integrity of the well prior to commencing gas extraction. The well casing within the coal seam is perforated to allow material from the coal seam to enter the well and go to surface. The wellhead is installed and completed with a pump and surface facilities.

Hydraulic Fracture Stimulation

Subject to trials and project planning, all wells to be located in the Project Area may be subject to stimulation (i.e. hydraulic fracturing) subject to trials to determine suitability of the process at the expected depth range. Hydraulic fracturing is necessary to properly assess the potential of the petroleum resource and inform decision making on future projects, as well as to increase the recovery of the resource.

Hydraulic fracturing involves pumping a fluid under pressure into the reservoir to open and connect fractures within the reservoir rock, thereby increasing the opportunity for the resource to move within the reservoir rock and flow toward the well. A proppant within the fluids holds the fractures open after the activity ceases. Approximately 99.5% of the material pumped into the well is water and sand. The remaining 0.5% is made up of minor quantities of additives used to:

- enhance fracture initiation
- help lubricate the flow of proppant (i.e., sand) into the fractures
- prevent microbial or chemical reactions following introduction of the fluids; and

- prevent formation of scale deposits that may affect the well or pumps.

Santos does not propose to use any restricted stimulation fluids as defined by proposed EA conditions and Section 206 of the EP Act and Section 70 of the EP Reg.

After the fracture process is completed and fluids that return to surface when the pressure is released are captured in tanks or lined pits for reuse, recycling or are transported to a licenced water management facility for treatment and/or disposal.

Hydraulic fracturing is a predominantly physical process in which hydraulic pressure is applied to a fluid to increase the effective permeability of the formation rock. The process creates narrow pathways (fractures) in the target formation to improve its ability to transmit gas back to and then out of the well.

After a pre-fracturing assessment and hydraulic fracturing design, onsite activities include site setup, perforation of the well casing and cement into discrete targeted sections of the cased bore (to access most viable gas bearing formation), injection of hydraulic fracturing fluid and flowback of the injected fluid. These processes are described in the following sections.

Pre-fracturing Assessment and Design

Operators investigate the subsurface conditions, including hydrogeological and mechanical properties of the target and surrounding geological units, to design the hydraulic fracturing program to strategically identify and reduce the possible risks involved (IESC, 2014).

To understand the geological formation and priorities for the hydraulic fracturing program, key aspects of subsurface characterisation (Beckwith, 2010) include:

- describing all geological units
- assessing target formation permeability
- analysing subsurface distribution of stresses and faults; and
- assessing fluid loss characteristics.

The hydraulic fracturing program is designed after the subsurface characterisation is complete. Part of this design is the prediction of fracture growth within the target zone. Specific hydraulic fracture simulation software is used to predict the geometry of fractures (fracture length, conductivity, and height), while the orientation is determined from the in-situ stress field (IESC, 2014). Typical inputs to numerical models include volume and properties of the fluid and proppant, closure stress, pressures within pores, permeability, mechanical properties, and layer geometry.

Several considerations influence the final design for each stimulation treatment, including:

- depth and thickness of the formation target
- lithology of formation target and bounding layers
- minimum and maximum horizontal stress across all layers (target and bounding)
- thickness of the seals above and below the target reservoir formation
- porosity and permeability of the formation
- pore fluid saturations (percentage of formation pore volume occupied by oil, gas, or water)
- pore fluid properties (e.g., density, water salinity)
- well performance data, including flow rates, formation pressure and produced fluid properties
- formation boundaries (as identified from seismic data)

- bulk rock density, elastic properties, and compressibility
- natural fracture networks; and
- stress field analysis to determine the maximum principal stress direction and the minimum principal stress direction.

Site Set Up

The well lease provides a stable working platform suitable for safely undertaking hydraulic fracturing operations. The lease area provides adequate space for the hydraulic fracturing vehicles and equipment, generators, fuel and chemical storage, casing and pipe storage and associated portable buildings. The well lease area generally incorporates the following standard features:

- a compacted and stable hard stand area
- an access road or track with clear entry and exit points for vehicles
- mobile wastewater treatment systems for the disposal of ablutions waste from well site offices and accommodation
- water storage tanks or ponds for hydraulic fracturing make up water and flowback fluid; and
- proppant and chemical storage for drilling and/or hydraulic fracturing operations.

Well Perforation

Holes are created in the well casing pipe at locations, which align to the centre of the coal seams targeted for gas production (these are referred to as 'perforations'). A section of the casing pipe typically less than one metre long is selected for perforation to allow the well to discretely access the coal seam. They are generally aligned slightly below the midpoint of the coal seam being fractured to accommodate the tendency for upward propagation of the fracture (in the direction of least stress).

The perforations, or holes, are created by blasting a jet of water or fine sand/water mix at high pressure at the pipe wall or using small explosives. The perforations penetrate the steel casing and the cement grout layer, and into the coal seam by up to half a metre.

Acid Injection

If the coal seam cleats are found to be naturally filled with calcite mineral (calcium carbonate) then a dilute acid mix is injected through the perforation holes into the coal seam to dissolve the calcite away prior to hydraulic fracturing. This is found to be necessary for less than 10% of gas wells only. It is carried out after completion of the well casing and directly prior to hydraulic fracturing operations, typically completed by the fracturing spread.

The selected coal seam can be pressurised with a 15% solution of hydrochloric acid (with preservatives), with typical volumes pumped of approximate $1m^3$. Hydraulic fracturing can then be carried out.

Hydraulic Fracturing Fluid

Hydraulic fracturing fluid generally consists of three parts: base fluid (the largest constituent by volume), additives and proppant. Base fluid (water) and proppant (sand) make up around 99% of the hydraulic fracturing fluid, with additives making up the remaining 1%. The purpose of the proppant is to keep the fractures open once the pump pressure is released which improves the productive potential of the well.

Each chemical additive serves a specific, engineered purpose such as:

- viscosity: gelling agents and crosslinkers are added to the water to provide viscosity to enable the proppant material such as sand or ceramic beads to be transported down the well and into the created fractures

- breakers: added to reduce the viscosity of the fluid when flowing back the well, enhancing recovery of fracturing fluid and additives to surface
- friction reduction: to reduce the force required to pump the fluid, friction reducers are added, making the fluid more 'slippery' and easier to pump at the high pressures and rates required to create the fracture network
- biocide: biocides or disinfectants are added to reduce the amount of naturally occurring microbes or organisms present in the water which can impact fluid stability and to ensure they will not enter and contaminate the reservoir
- scale and corrosion: scale and corrosion inhibitors are added to prevent deposition of mineral scales and to prevent corrosion of the steel casing or tubing; and
- surface tension: surfactants or surface tension modifiers are added to assist the back flow of fluids from the formation.

Stimulation Process

Several steps are involved in the hydraulic stimulation process to pump the designed fracture treatment. These include:

- diagnostic Fracture Injection Test to validate and update the proposed stimulation design. This involves injecting a small volume of water, shutting down the surface pumps and monitoring pressure decline to evaluate near wellbore entry friction, fracture gradient, fluid leak off, and minimum horizontal stress. This stage is typically only performed in the exploratory / appraisal stages of development, or until localised fracture characteristics are defined
- drift run to check there are no obstructions in the wellbore
- in the case of Plug and Perforation stimulation conveyance method, perforation of stimulation stage one (deepest stage) to gain access to the reservoir from the wellbore
- in the case of coiled tubing stimulation conveyance method, all stimulation stages are perforated before the fracturing crew and equipment arrive at the wellsite
- main stimulation treatment consisting of pad volume injection, slurry stage injection(s) with increasing proppant concentrations, and flush stage to displace last slurry stage through the perforations and into the fracture
- mechanical isolation of the completed fracture stimulation stage
- perforate the next stage to be hydraulically stimulated and repeat the processes above until the final fracture stimulation stage is completed
- remove all mechanical isolation devices by milling out the mechanical isolations; and
- flowback well to clean up fracture stimulation fluids and monitor hydrocarbon production.

A CSG well typically takes 1 to 2 days to complete hydraulic stimulation operations. Hydraulic fracture stimulation initial fluid flowback may occur for a period of 1 to 30 days, depending on the reservoir and clean up profile before the well is connected into the gathering network.

Injection and Isolation of Hydraulic Fracturing Fluid

Once the well has been perforated in the depth interval that is to be hydraulically fractured, fluid injection is performed.

Hydraulic fracturing fluid is injected into the well at the surface through the wellhead. The perforation zones are isolated by either a coiled tubing unit with packers, a bridge or frac plug set by a wireline operator, or by a baffle and ball-drop system.

Following isolation of the perforated zone, injection of fluid commences. The hydraulic fracturing fluid is forced into fractures and remains within the target reservoir. The bore design and construction, comprising multiple physical barriers such as cement and steel casing, ensure that the hydraulic fracturing fluid does not encounter overlying strata, including aquifers. The integrity of these barriers is tested before hydraulic fracturing activities are undertaken.

The injection pressure, injection rates, slurry volumes, fluid viscosity, additive concentrations and proppant concentration are monitored in real-time during each injection. Downhole pressure information is also recorded and reviewed during the hydraulic fracture stimulation operation. Down-hole pressures are calculated based on wellhead pressure, fluid density, casing diameter and the depth to the target formation. When a coiled tubing unit is used as part of the operation pressure is monitored: inside the casing above the top packer of the tool, inside the coiled tubing delivering the fluid and inside the wellhead at surface.

Once the entire hydraulic fracturing operation is complete for a well, completions rig or coiled tubing unit will generally mill out the bridge plugs or baffles that were installed for the hydraulic fracturing operation, to clear them from the well.

Return of Injected Fluid and Water (Flowback Fluid)

Once the injection process is complete, the internal pressure of the rock formation typically causes fluid to return or ‘flowback’ to the surface through the gas well. Flowback fluid contains the dissociation or broken-down products of the injected chemicals plus naturally occurring geogenic compounds.

The volume of the injected fluids which is recovered as flowback is variable depending on the formation, treatment execution, and fluid type used. Immediately after stimulation, typically a range of 0 - 20% of the stimulation volume is recovered within a few days of the completion of the fracturing operation. The well then continues to flowback once connected into the gathering network, where 100% of the stimulation volume is commonly recovered. The flowback water is typically temporarily stored tanks before treatment for reuse or disposal.

Flowback Fluid Management

The recovered fluid, or flowback, may be treated and stored for reuse in the next hydraulic fracturing event. Flowback fluid unable to be reused would be disposed of at a licensed facility or transferred to one of Santos’ engineered wastewater treatment facilities for treatment and management under existing approvals for those facilities.

Well Workover Operations

Maintenance activities termed ‘well workover operations’ are performed periodically to maintain or increase productivity. Workover operations are carried out on production wells by re-entering the well to perform pump repairs, well deepening, isolation of intervals or re-perforation.

Decommissioning and Rehabilitation

Decommissioning of wells would occur on an ongoing basis as production within the Project Area is exhausted. Wells at the end of their lifecycle would initially be capped to enable future uses such as for other resource activities or monitoring. Only once it is determined that the well has no future use is it plugged and abandoned in accordance with regulatory requirements and the *Code of Practice for the construction and abandonment of petroleum wells and associated bores in Queensland* (DNRME, 2019).

Gathering Lines

Santos would construct gas and water gathering lines (i.e. flowlines and pipelines) to transport produced gas and water from the production wells to gas compression and water management facilities located on adjoining Santos operated tenures. Gathering infrastructure would typically be constructed in 20-35 m wide Right of Way (RoW) corridors, and linear infrastructure would be co-located to reduce disturbance wherever feasible. The width of RoWs is influenced by the number of linear services co-located and the nature of the topography (and other considerations such as the size of areas needed to install erosion-sediment controls).

Gathering lines are typically constructed of high-density polyethylene (HDPE). Low point drains (LPDs) and high point vents (HPVs) would be installed at intervals along the gathering lines to allow drainage of condensate from gas, and the release of minor entrained gas from PW as required.

Gathering lines would be designed and constructed to comply with *Australian Standards AS2885 – Pipelines Gas and Liquid Petroleum* and the Australian Pipelines and Gas Association (APGA) *Code of Practice For Upstream Polyethylene Gathering Networks-CSG Industry – Version 6* (APGA, 2024).

Gathering lines would be constructed using a combination of conventional earthmoving equipment and specialist pipeline trenching and lifting equipment. Gathering lines are constructed using a standard construction methodology including:

- clearing and grading
- trenching and padding
- pipe stringing, laying, and welding
- backfilling and reinstating natural ground level; and
- installing marker signs as required.

Once installed, the construction RoW corridor would be rehabilitated back to the minimum width required for operations. Groundcover would be re-established along the operational RoW.

Access Tracks

Roads and access tracks would be required for construction and operational activities. Access tracks would have a typical disturbance width of 10-15m, and linear infrastructure would be co-located to reduce disturbance wherever feasible. The width of roads and co-located RoWs is influenced by the number of linear services co-located and the nature of the topography (and other considerations such as the size of areas needed to install erosion-sediment controls).

Access tracks would be built to allow servicing of well leases and access to other infrastructure (e.g. mobile camps). Wherever practicable, Santos would use existing access tracks and upgrade these if required. Where new access tracks are needed, Santos would aim to co-locate these with gathering lines and/or in already disturbed areas, where practicable to reduce clearing impacts.

- construction activities associated with roads and access tracks include:
- upgrading and/or widening of existing roads
- excavation and filling
- preparation of sub grade; and
- installation of drainage.

Other Incidental Petroleum Activities

Ancillary infrastructure and incidental petroleum activities would be required to support construction and operation activities. These include, but are not limited to:

- laydown, stockpile, storage, and vehicle cleaning areas
- a temporary workers camp including an STP and associated irrigation (<21 EP)
- low hazard dams and storage tanks
- power and communication lines
- borrow pits
- fencing
- environmental monitoring equipment and management controls
- geophysical, geotechnical, geological, topographic, cadastral, and ecological surveys; and
- supporting infrastructure, such as energy supply, water supply and communications.

Appendix C: Project Area Description

Project Area Description and Context

The Project Area is located approximately 43 km east of the town of Roma and 3 km east of the town of Wallumbilla in southern inland Queensland (refer to Figure 1). Further, the Project Area is located in the Maranoa Regional Council Local Government Area (LGA).

The Project Area covers a total area of approximately 1229 ha and will wholly replace all existing blocks of ATP 2053 (as detailed in Table 1 and Figure 1).

The Project Area is bounded by the RSGPA and RSGPAE and shares its boundaries with existing Santos operated PLs 281, 282, 315, 318 and 1020 (as shown in Figure 1).

Table 1: Graticular Block Summary

Block Name	Block Number	Sub-Block
CHAR	2295	E
CHAR	2295	D
CHAR	2295	K
CHAR	2295	J

Further, the Project Area overlaps the following property lot and plans:

- 105 WV68
- 109 RP189184
- 120 WAL53367
- 121 WAL53367
- 122 WAL53367

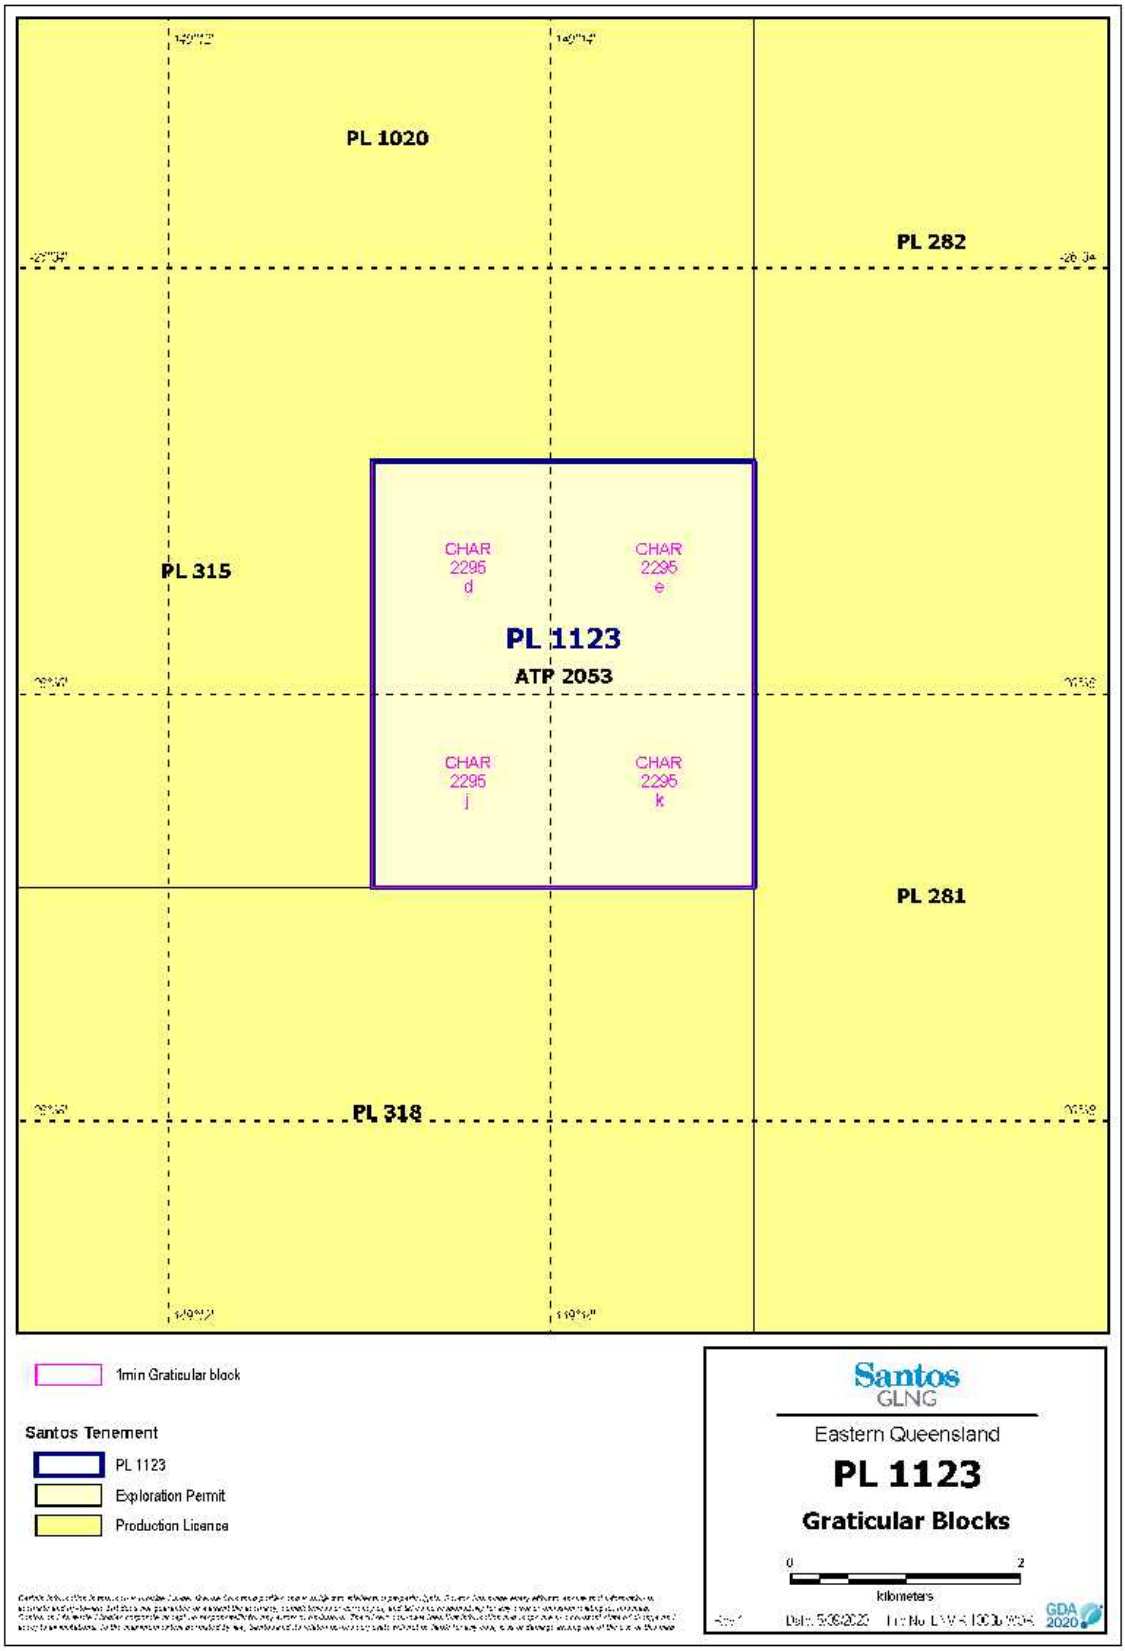

Figure 1: PL 1123 – Graticular Blocks

Land Use

Land within and surrounding the Project Area is predominantly used for agriculture (livestock grazing). The dominant land use is production from relatively natural environments specifically grazing native vegetation (94%). Grazing modified pastures and cropping is also undertaken in ~ 4% of the Project Area, with intensive land uses only constituting 0.8% (State of Queensland, 2025).

The land has been subject to intensive agricultural activities over an extended period of time, and this is reflected in the fragmented nature of remnant vegetation, and large areas of non-remnant vegetation present in the Project Area.

The proposed activities will not significantly impede land use for pastoral purposes (or future resource exploration purposes), and all landholders will be consulted prior to construction commencing.

Key industries within the wider region include agriculture, forestry, recreation and tourism, coal exploration and mining, and oil and gas exploration and production. The traditional industry base for the region has been agricultural, however in more recent times the oil and gas industry has become a more significant contributor to the region's economy.

The Project Area is intersected by the Warrego Highway and an associated stock route that follows the course of the highway (refer to Figure 1).

Further, the Project Area is wholly overlapped by 2 resource exploration permits – those being:

- EPG 2034 – Exploration Permit Geothermal with Within Energy Pty Ltd; and
- EPC 1763 – Exploration Permit Coal with Wanbei Coal Electricity International Mining (Australia) Pty Ltd.

Climate

Wallumbilla Post Office and Roma Airport (Bureau of Meteorology (BoM) site numbers 43038, 43091, respectively) are the closest active BoM weather stations (with rainfall and temperature data) to the Project Area. Monthly climate statistics from these weather stations indicate that Wallumbilla has a warm, sub-tropical environment receiving an average of 576 millimetres of rain per year, with the majority of this rainfall occurring during the summer period from October to March (BoM, 2025). Mean minimum and maximum temperatures range from 8.6–29.7 °C in July, and 20.7–45.8 °C in January.

Executive Summary

This report summarises ecological assessments of Authority to Prospect (ATP) 2053 ('the Project Area') undertaken for Santos between 2020 and 2024. The Project Area is proposed to be developed as part of the Roma Phase 7-7B-SD20 project and will involve the conversion of ATP 2053 to new Petroleum Lease (PL) 1123 to authorise commencement of Coal Seam Gas (CSG) production activities. Proposed activities within the Project Area would include CSG production, exploration and appraisal activities.

The Project Area is located approximately five km east of Wallumbilla, southern inland Queensland. The assessment includes surveys conducted by Boobook in March 2022, September 2023 and April 2024, covering parts of the Project Area south of the Warrego Highway, along with surveys by other contractors covering the remainder of ATP 2053.

Field surveys for this assessment included identification and mapping of remnant and regrowth regional ecosystems (RE) and Threatened Ecological Communities (TEC) across the Project Area. BioCondition assessments of vegetation condition were made at locations representing major vegetation types within the Project Area. Quaternary level vegetation structure assessments and faunal habitat assessments were made at representative locations across the Project Area.

Santos has developed a preliminary disturbance footprint (hereafter referred to as the Disturbance Footprint) for the project to locate infrastructure to avoid disturbance to Matters of National Environmental Significance (MNES), Matters of State Environmental Significance (MSES) and other environmental values. The Disturbance Footprint is defined as those parts of the Project Area that will be impacted by Project development activities. The Disturbance Footprint is displayed in Appendix A. Potential future changes to the Disturbance Footprint will be managed in accordance with the *Santos Roma Phase 7-7B-SD20 Development Environmental Protocol for Constraints Planning and Field Development Constraints Protocol* (Santos 2025).

Five RE types were recorded within the Project Area, these being:

- 11.3.2: *Eucalyptus populnea* woodland on alluvial plains (VM Act: Of Concern; Biodiversity status: Of Concern).
- 11.3.17: *Eucalyptus populnea* woodland with *Acacia harpophylla* and/or *Casuarina cristata* on alluvial plains (VM Act: Of Concern; Biodiversity status: Endangered).
- 11.3.25: *Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines (VM Act: Least Concern; Biodiversity status: Of Concern).
- 11.9.7: *Eucalyptus populnea*, *Eremophila mitchellii* shrubby woodland on fine-grained sedimentary rocks (VM Act: Of Concern; Biodiversity status: Of Concern).
- 11.9.10: *Eucalyptus populnea* open forest with a secondary tree layer of *Acacia harpophylla* and sometimes *Casuarina cristata* on fine-grained sedimentary rocks.

One RE occurs within the Disturbance Footprint:

- 11.3.2: *Eucalyptus populnea* woodland on alluvial plains (VM Act: Of Concern; Biodiversity status: Of Concern).

Two Threatened Ecological Communities (TEC) were present within the Project Area these being:

- Poplar Box grassy woodland on alluvial plains.
- Weeping Myall woodlands.

No TEC is present within the Disturbance Footprint.

No threatened flora species, listed under the Commonwealth *Environment Protection and Biodiversity Conservation Act 1999* (EPBC Act) or the Queensland *Nature Conservation Act 1992* (NC Act) were considered likely to occur within the Project Area based on desktop assessments. Suitable habitat was present in the Project Area for one flora species listed under the EPBC Act and two flora species listed under the NC Act. Field survey of flora species was limited to incidental observations and active searches for threatened plants around vegetation structure points. No EPBC Act or NC Act threatened flora species were found.

No comprehensive fauna surveys were performed under this Scope of Works. Fauna surveys were limited to incidental observations and active searches at BioCondition and other vegetation and habitat quality assessment sites. No

threatened fauna species listed under the EPBC Act and/or the NC Act were detected during the field survey. Nine threatened fauna species, including seven species listed under the EPBC Act and nine species listed under the NC Act, were considered potentially present within the Project Area. Suitable habitat was present in the Project Area for one SLC fauna species listed under the NC Act. Potential habitat for these species was predicted and mapped based on known vegetation and habitat feature associations.

Multiple migratory and/or marine species listed under the EPBC Act were assessed as potentially present within the Project Area. These are all widespread and mobile species occurring in habitats that are common in this landscape. These species do not depend on specific resources within the Project Area.

Several mapped watercourses, varying from first to third order intermittently flowing drainage lines, occur within the Project Area. No referable wetlands, lakes or springs occur within the Project Area. Several wetlands of general ecological significance were ground-truthed as being present within the Project Area and Disturbance Footprint. These wetlands may provide temporary habitat for MNES/MSES fauna.

The following Category B ESA are present within the Project Area:

- areas of ground-truthed Endangered RE (biodiversity status): 11.3.17 and 11.9.10.

The following Category C ESA are present within the Project Area:

- areas of ground-truthed Of Concern RE (biodiversity status): 11.3.2, 11.3.25 and 11.9.7.
- an area validated from ground-truthing surveys as 'protected wildlife habitat' that is category A, B or C on the Remnant Vegetation Management Map, in accordance with section 20A of the *Vegetation Management Act 1999*, for a species of wildlife listed as critically endangered, endangered or vulnerable under the NC Act as follows:
    - ground-truthed protected wildlife habitat: Glossy Black-Cockatoo (*Calyptorhynchus lathami lathami*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.3.25, 11.9.10.
    - ground-truthed protected wildlife habitat: White-throated Needletail (*Hirundapus caudacutus*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.3.25, 11.9.10.
    - ground-truthed protected wildlife habitat: Koala (*Phascolarctos cinereus*) - NC Act: Endangered: remnant and regrowth REs 11.3.2, 11.3.25, 11.9.10.
    - ground-truthed protected wildlife habitat: Yakka Skink (*Egernia rugosa*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.9.10.
    - ground-truthed protected wildlife habitat: Grey Snake (*Hemiaspis damelii*) - NC Act: Endangered: remnant and regrowth REs 11.3.2, 11.3.25.

The proposed CSG development would result in the following disturbance areas to remnant/regrowth RE and MNES/MSES fauna habitat:

- 11.3.2 remnant: 0.15 ha;
- 11.3.2 regrowth: 0.15 ha;
- MNES/MSES fauna wetland habitat: 0.6 ha.

No significant impact will occur as part of the proposed development for the following MNES:

- TEC;
- EPBC Act threatened flora populations/habitat;
- EPBC Act threatened and/or migratory fauna populations/habitat; and
- Wetlands of International or National Significance.

No significant residual impact will occur as part of the proposed development for the following MSES:

- Regulated vegetation;
- Connectivity areas;
- NC Act threatened flora populations/habitat;
- NC Act threatened and SLC fauna populations/habitat;
- Wetlands in a wetland protection area and wetlands of high ecological significance as shown on the Map of referrable wetlands under schedule 12, part 2 of the *Environmental Protection Regulation 2008*;
- Wetlands or watercourses in a high ecological value waters as identified under the *Environmental Protection (Water) Policy 2009*, schedule 2.Wetlands and watercourses;
- Designated precinct in a strategic environmental area;

- Protected wildlife habitat;
- Protected areas;
- Highly protected zones of State marine parks;
- Fish habitat areas;
- Waterway providing for fish passage because linear infrastructure construction activities located in waterways providing for fish passage would not:
    - reduce the extent, frequency, or duration of fish passage;
    - result in a substantial change to the hydrological regime of the watercourse; or
    - lead to significant changes in water quality parameters within the watercourse.
- Marine plants; and
- Legally secured offset areas.

Conclusions drawn in this report are based on available information at the time of writing. Any additional information may alter such conclusions and the author reserves the right to do so if such information becomes available. This report has been made as at the date of the report and is not to be used after six (6) months and not if there are any material changes meanwhile. In either event it should be referred back for review. To the extent permitted by law BOOBOOK does not accept liability for any loss or damage which any person may suffer arising from any negligence or breach of contract on its part. This report was prepared for the benefit of the party to whom it is directed only and for the purpose identified within. BOOBOOK does not accept responsibility to any other person for the contents of the report.

1. Introduction

1.1. Purpose and Scope

Santos proposes to construct and operate infrastructure associated with coal seam gas (CSG) extraction including a total of 24 CSG wells and associated gas and water pipelines (flowlines), laydown areas and access tracks for the Roma Phase 7-7B-SD20 (the Project), located near Wallumbilla, southern inland Queensland. This report summarises an ecological assessment undertaken for Santos (the Client) within ATP 2053 (hereafter referred to as 'the Project Area') including the associated proposed Disturbance Footprint (Appendix A).

Santos (the Client) required the following services in relation to identifying ecological values and potential constraints within the Project Area:

- Ground-truthed Regional Ecosystem (RE) and high value regrowth (HVR) vegetation mapping;
- Verification and mapping of any Threatened Ecological Communities (TEC);
- Matters of National Significance (MNES)/ Matters of State Significance (MSES) flora assessment plus incidental threatened flora observations;
- MNES/MSES fauna habitat assessment as per agreed habitat descriptions plus incidental threatened fauna observations; and
- BioCondition surveys of vegetation within the Project Area.

The results of the ecological assessment are based on an initial desktop assessment followed by field surveys to confirm vegetation communities within the Project Area. Additional field surveys, including BioCondition assessments and records of notable flora/fauna species and habitat values within the Project Area were restricted to an area south of the Warrego Highway comprising parts of Washpool, Lyndale and Ruby Farm. The primary purpose of this report is to provide a summary of potential MNES/MSES ecological constraints and values within the Project Area.

1.2. Survey Team

An ecological field survey covering parts of the Project Area south of the Warrego Highway was conducted for this assessment by Michael Cunningham (Senior Ecologist, Boobook) and Courtney Andrew (Graduate Ecologist, Boobook) on the 2nd – 4th March 2022. A further survey of vegetation in the road and railway reserve south of the Warrego Highway was conducted by Michael Cunningham and Rosamund Aisthorpe (Senior Ecologist/Botanist, Boobook) on 16th September 2023. Additional surveys of areas within the proposed Disturbance Footprint were conducted by Michael Cunningham and Weston Campbell (Field Technician, Boobook) on 19th April 2024. Vegetation survey data covering other parts of the Project Area north of the Warrego Highway were provided by Santos (O2 Ecology 2016; spatial data provided via email from Alex Clarke 6th September 2023).

The project supervisor (Craig Eddie) was approved by the Department of Climate Change, Energy, the Environment and Water (DCCEEW), as the Commonwealth Department of Sustainability, Environment, Water, Population and Communities (DSEWPaC), in writing on the 28th of January 2011 for the purpose of undertaking ecological assessment works for the Gladstone Liquefied Natural Gas (GLNG) project. All aspects of the project including field survey and reporting were conducted under the supervision of Craig Eddie.

1.3. Site Description

1.3.1. Location

The Project Area is located approximately 5 km east of Wallumbilla, south-central Queensland, within the Maranoa Regional Council area. It is accessed via the Warrego Highway, Seawrights Road and Scotts Road. The Project Area is shown within Appendix A.

1.3.2. Bioregion

The Project Area is entirely within Subregion 26 (Southern Downs) of the Brigalow Belt bioregion (Sattler and Williams 1999).

1.3.3. Vegetation

Much of the Project Area has been cleared of native vegetation to form non-remnant derived grassland dominated by introduced pasture grasses with occasional native trees and shrubs. Areas of remnant and regrowth native vegetation occur as irregular, discontinuous corridors along streamlines or as small, isolated fragments. River Red Gum (*Eucalyptus camaldulensis*) dominates riparian woodland along the banks of larger streams, while Poplar Box (*E. populnea*) dominates floodplain woodlands. Brigalow (*Acacia harpophylla*) and/or Belah (*Casuarina cristata*) are prominent in areas of heavy soil and patches of Weeping Myall (*A. pendula*) occur on floodplains. Some low-lying areas have groundcover dominated by characteristic wetland fringe plants including sedges, Nardoo (*Marsilea* spp.), forbs and grasses. These floodplain wetlands include areas of non-remnant vegetation and modified drainage structures such as channels and overflow areas around dams.

1.3.4. Geology, Topography & Soils

This is a landscape of low relief comprising a broad floodplain with meandering streamlines flanked by slightly elevated areas. Beyond the Project Area, to the east, an abrupt north-south trending plateau rises up to 50 m above the surrounds. There is no outcropping rock within the Project Area and the surface geology consists of Quaternary alluvial sediments (Qa) with an area of unconsolidated colluvial sediments derived from early Cretaceous mudstones of the Doncaster Member (Qs>Kud) in the east associated with the adjacent plateau (DoR 2024a). Soils vary from dark brown clay-loam and sandy clay-loams across much of the Project Area, to reddish clay-loam in the east.

1.3.5. Watercourses

The Project Area is drained by Washpool Creek and its minor tributaries which drain into Wallumbilla Creek, part of the Balonne River catchment, within the Murray-Darling Basin.

1.3.6. Current Land Use

The primary land use within the Project Area is livestock grazing.

1.3.7. Existing project related disturbances

Prior disturbances associated with gas exploration activities undertaken by Santos within ATP 2053 include the drilling of five CSG appraisal wells (RM23-21-1, RM23-43-1, RM23-42-1, RM23-41-1 and RM23-46-1) and construction of associated supporting infrastructure in 2022-2024.

2. Methodology

2.1. Desktop Assessment

A desktop assessment was performed prior to the field survey which included interrogation of the following datasets:

- EPBC Act Protected Matters Search Tool (PMST) (DCCEEW 2024a) (Appendix B);
- WildNet Queensland fauna and flora records (DESI 2024a,b);
- Atlas of Living Australia fauna and flora records (ALA 2024);
- Protected Plants Flora Survey Trigger Map (DESI 2024c);
- Referable Wetlands mapping (DESI 2024d);
- Environmentally Sensitive Area mapping (DESI 2024e);
- Matters of State Environmental Significance (DESI 2024f);
- State terrestrial biodiversity and aquatic conservation values (DESI 2024g);
- Regulated vegetation mapping as per the *Vegetation Management Act 1999* (VMA) (DoR 2024b);
- Remnant RE – biodiversity status (DESI 2024h);
- Mature Regrowth mapping (DESI 2024i);

- Essential Habitat mapping (DES 2022); and
- Ordered stream mapping (DoR 2024c).

The searches were conducted using online spatial layers and database searches, using land parcel (lot on plan) codes or central coordinates (26.60632°S, 149.23120°E, datum GDA94) as a geographic reference, and including a 10 km buffer. These datasets provided a baseline for subsequent field assessment.

2.2. Field Survey

In-field verification of desktop findings and additional findings of significance were undertaken in general accordance with the following:

- *Methodology for Survey and Mapping of Regional Ecosystems and Vegetation Communities in Queensland* (Neldner *et al.* 2022);
- *Methodology for Conducting Ecological Assessments* – GLNG Areas Rev 4.1 (Santos 2014); and
- *Functional Thresholds for Assessing Regional Ecosystem Functionality* (Santos 2015).

Formal survey sites were established in representative locations within each vegetation type, based on vegetation structure, floristics and condition. At each site quaternary vegetation structure and floristics, and fauna habitat assessments were conducted concurrently. Methodologies that were employed for each element of the field survey are further described in the following sections.

2.2.1. RE & TEC Assessment

RE and TEC assessment was informed by both desktop review and by ground-truthing during field assessment. Ground-truthing (and confidence level scoring) of the RE designation was undertaken using the quaternary level of data collection as described by Neldner *et al.* (2022).

Assessments were undertaken within 50 m x 20 m plots for the purpose of typifying the vegetation community under assessment. Plots were chosen within representative areas of each vegetation type encountered. Locations of quaternary assessment sites are shown in Appendix AC.

Vegetation community polygons were verified in accordance with Queensland RE description and biodiversity status as per the Regional Ecosystem Description Database (REDD) (Queensland Herbarium 2023a) and classified as remnant RE, vegetation consistent with RE (regrowth) or non-remnant vegetation (Santos 2014). For each area of potential TEC an assessment of vegetation survey data was made against TEC threshold criteria (e.g. TSSC 2013).

Vegetation community data was captured in the field and entered into Santos-specific data fields within spatial databases via GPS enabled Zebra tablet devices. Representative photographs were taken via a digital camera at each vegetation survey site and at other points as supporting evidence of the subject vegetation community. Capture and delineation of RE and TEC boundaries was undertaken using a combination of mobile GIS devices, GPS and/or delineation from imagery. A minimum mappable width of 25 m for linear vegetation corridors was applied. Patches were mapped to their full extent within the Project Area within practical limits (including land access constraints).

For any identified regrowth (i.e. vegetation floristically equivalent to a RE but not meeting structural thresholds of remnant RE) an ecosystem functionality assessment was conducted. This assessed selected vegetation characteristics against the parameters described in Santos (2015).

Plant names used within this document conform to those given in Bean (2024).

2.2.2. BioCondition Survey

BioCondition assessments were used to evaluate ecological functionality of vegetation in the Project Area. These assessments applied the methodologies described by Eyre *et al.* (2011, 2015). This involved the establishment of a 100 m x 50 m plot for measurements relating to canopy layer structure and diversity, a 100 m transect to measure canopy cover, a 50 m x 10 m subplot for measuring plant richness in shrub and ground layers, a 50 m x 20 m subplot for measuring coarse woody debris, and five 1 x 1 m quadrats to estimate ecological components of ground cover within the assessment area. These values were used as indicators of ecosystem function relative to minimally disturbed benchmark sites (Queensland Herbarium 2023b) within the same Assessment Unit (AU). Using the principle of streamlining (DES 2020), as requested by the client, two BioCondition assessments were considered sufficient

representation for each AU. BioCondition assessments were restricted to parts of the Project Area south of the Warrego Highway in Washpool, Lyndale and Ruby Farm.

For AU with very limited extent (< 10 ha) a single BioCondition assessment was considered sufficient representation. Where needed, additional quaternary vegetation assessments were made within each AU within the Project Area, as evidence of comparable vegetation condition.

The following information was recorded at each BioCondition site:

- Date;
- Observers;
- Description of location (bioregion, general description, co-ordinates for plot origin and centre, plot bearing and alignment);
- General habitat description and RE type;
- Median height for canopy, emergent and sub-canopy strata;
- Slope position/slope degree and slope aspect;
- Tree species richness (within 100 m x 50 m plot);
- Native plant species richness (within 50 m x 10 m plot);
- Non-native plant cover (within 50 m x 10 m plot);
- Total length of coarse woody debris (length >10 cm diameter and >0.5 m long within 50 m x 20 m plot);
- Number and average diameter at breast height (DBH) of large eucalypt and non-eucalypt trees (within 100 m x 50 m plot);
- Recruitment of canopy species (within the 100 m x 50 m plot);
- Tree and shrub canopy cover (within 100 m transect);
- Ground cover within 1 m x 1 m plots (native perennial grass and organic litter cover in the ground layer);
- Disturbances (severity, last event and observation type).

Large tree DBH thresholds for each RE were used where published benchmarks were available, otherwise the default ≥30 cm DBH for eucalypts and ≥20 cm DBH for non-eucalypts was applied.

Site photographs were taken using a digital camera in accordance with Eyre *et al.* (2015) (i.e. one photograph at plot origin and north, east, south and west photographs at the plot centre). Photograph numbers were recorded. Locations of BioCondition sites were determined using a handheld Global Positioning System (GPS) (Garmin GPSmap 78S) and BioCondition assessment data was captured by mobile GIS devices (Motion F5T tablet device).

This survey did not mark the origin and centre point of BioCondition plots with steel fence posts, as suggested in Eyre *et al.* (2015), due to current and proposed land use (grazing and coal seam gas development).

Scores for BioCondition sites were calculated in accordance with Eyre *et al.* (2015) which compares the values obtained at each survey site with values in the benchmark document for that particular RE (Queensland Herbarium 2023b). Subscores are awarded to each site are totalled and divided by the maximum possible score for that RE. This provides a numeric index along a continuum of biodiversity condition, where scores close to 0 indicate sites that are ecologically 'dysfunctional' and scores closer to 1 indicate increasing ecological integrity.

2.2.3. Fauna Habitat Assessment

An assessment of fauna habitat was completed at each quaternary vegetation assessment site and each BioCondition Site. Presence/absence, abundance or density of habitat features was recorded within a 50 m x 20 m plot at each survey site including:

- embedded and loose rocks and boulders (estimated % cover);
- logs (abundance);
- trees >18m height (abundance);

- logs with hollows (abundance);
- trees with hollows (abundance);
- trees and/or logs with loose bark (abundance);
- burrows, sinkholes and tunnel erosion (abundance);
- fallen bark (estimated % cover);
- shrub layer (estimated % cover);
- ground cover (estimated % cover);
- leaf litter (estimated % cover);
- termite mounds (abundance);
- mistletoe (abundance);
- rock structures (caves, overhangs and crevices);
- cliffs, escarpments and steep rocky slopes within 5km (presence);
- watercourses with permanent water, pools and riffles and abundant woody/rock cover (presence);
- cracking clays soils (presence);
- gilgai and ephemeral wetlands (presence); and
- canopy dominated by Myrtaceae species (presence).

In addition, representative fauna habitat features were recorded elsewhere, to indicate their type and occurrence throughout the Project Area, including non-remnant areas. Mapping of habitat features was not comprehensive. In general, fauna habitat features are expected to be most abundant in remnant and regrowth vegetation and these areas were addressed by assessment plots. The results of these assessments, combined with published information and suitably qualified ecologist knowledge of fauna distribution and habitat use in the region, were used to predict habitat suitability for nominated listed threatened fauna.

Results from fauna habitat assessments conducted within the Project Area and other records of fauna habitat features are included in spatial data provided to Santos. The location of mapped fauna habitat assessment sites is shown in Appendix C.

2.2.4. Threatened Flora Survey

Targeted surveys for threat-listed flora were informed by the desktop search results and local experience of Boobook ecologists. Searches for threat-listed flora under the EPBC and/or NC Act were carried out at vegetation assessment sites and in random meanders in targeted habitat types, including remnant and non-remnant vegetation. The results of these surveys and vegetation assessments, combined with published information and suitably qualified ecologist knowledge of flora distribution and habitat in the region, were used to predict habitat suitability for nominated listed threatened flora.

If detected, counts and extent of each population of threat-listed flora were made as well as structural characteristics and representative photographs taken. Data were recorded using the Santos-specific Notable Species - Flora Point or Region data capture layer.

2.2.5. Incidental Threatened Fauna Records

No comprehensive fauna surveys, using trapping, acoustic or other techniques, were undertaken under this Scope of Works. Incidental records of any threatened fauna obtained during field survey were fully documented including species name, location (with site co-ordinates or area of extent), habitat and number detected. Vegetation and habitat assessments were conducted at locations where threatened species were detected.

2.2.6. Survey Limitations

Individual mapped vegetation polygons have been assigned a confidence level (high, moderate, low) for both boundary accuracy and vegetation attributes within the polygon as per Neldner *et al.* (2022). All vegetation within the

Project Area was inspected in the field (ground-truthed) so that mapped polygons have a high confidence for boundary accuracy and vegetation attributes. Where Endangered or Of Concern RE types were encountered the full extent of the patch was mapped where this was physically practicable.

In some instances, vegetation communities may not be readily assigned to a RE, even when ground-truthed, as their floristics and structure reflect historical disturbance patterns such as clearing, thinning and fire history. In these cases, RE were allocated on the basis of 'best fit' with current RE descriptions.

Field surveys of Washpool, Lyndale and Ruby Farm were conducted in March 2022, during a warm, dry spell following a mild, wet late spring – early summer in late 2021. There was dense growth of grasses, which may have reduced detectability of some forb species. Conditions during the survey were suitable for identification of flowering forbs and grasses and identification of woody plant species based on vegetative features.

3. Results & Discussion

3.1. Matters of National Environmental Significance

3.1.1. Threatened Ecological Communities

PMST search results (DCCEEW 2024a) indicated the potential presence of five TEC within the Project Area these being:

- Brigalow (*Acacia harpophylla* dominant and co-dominant);
- Coolibah – Black Box woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions;
- Poplar Box grassy woodland on alluvial plains;
- Semi-evergreen vine thickets of the Brigalow Belt (North and South) and Nandewar Bioregions; and
- Weeping Myall woodlands.

Several areas of TEC were identified within the Project Area during field surveys including several small patches of Poplar Box Grassy Woodlands on Alluvial Plains TEC (Poplar Box TEC) and Weeping Myall Woodlands TEC (Weeping Myall TEC). All areas of TEC within the Project Area are disturbed by grazing and edge effects such as tree death and encroachment by introduced pasture grasses and other weeds. All Poplar Box TEC within the Project Area was assessed as Moderate Quality (Category C) with low native cover but retaining diverse native understorey plants and more than 10 mature trees per hectare (TSSC 2019). No TEC is present within the Disturbance Footprint. Mapped areas of TEC within the Project Area are shown in Appendix C. The extent of TEC within the Project Area is summarised in Table 1.

Table 1: Description and ground-truthed extent of TEC within the Project Area.

TEC Description	RE Code	Extent of TEC within the Project Area (ha)	Extent of TEC within the Disturbance Footprint (ha)
Poplar Box grassy woodland on alluvial plains	11.3.2	46.71	0.0
Weeping Myall Woodlands	11.3.2	7.61	0.0

3.1.2. Threatened Flora

3.1.2.1. Likelihood of Occurrence Assessment

PMST search results (DCCEEW 2024a, Appendix B) indicated the potential occurrence of four EPBC Act-listed threatened flora species within the Project Area, these being: Ooline (*Cadellia pentastylis*), a Bluegrass (*Dichanthium setosum*), Winged Pepper-cress (*Lepidium monoplocoides*) and Slender Tylophora (*Vincetoxicum forsteri*).

Desktop assessment (ALA 2024, DESI 2024a) did not produce any records of threatened flora species within 10 km of the Project Area.

A likelihood of occurrence assessment for EPBC Act-listed threatened flora potentially occurring within the Project Area is presented within Table 2.

Table 2: Assessment of likelihood of occurrence for EPBC Act-listed threatened flora within the Project Area.

Key to Status: E = Endangered; V = Vulnerable; NT = Near Threatened; C = Least Concern.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence
Apocynaceae	*Vincetoxicum forsteri* listed as *Tylophora linearis* Slender Tylophora	E	E	A cryptic twining vine, occurring in dry woodland along the western slopes of the Great Dividing Range, from Temora in southern NSW north to around Miles in southern Queensland (ALA 2024, DCCEEW 2024b, Boobook unpubl. data). The species is associated with shrubby woodland dominated by Ironbarks (*Eucalyptus crebra*, *E. fibrosa* or *E. sideroxylon*), Grey Box (*E. microcarpa*, *E. woollsiana*) or White Cypress Pine (*Callitris glaucophylla*) with a subcanopy of *Acacia* spp., *Melaleuca* spp., *Callitris* spp. and/or Bull Oak (*Allocasuarina luehmannii*) (Forster *et al.* 2004). These habitats occur on low fertility soils found on sandy plains, ironstone jump-ups and metamorphic substrates (land zones 5, 7 and 11). Aerial twines grow from a perennial rootstock after summer rains and wither in dry periods (Forster *et al.* 2004), during which the species may not be detectable.	None within the Project Area.	**Unlikely to be present.** There is no suitable habitat (i.e. dry shrubby woodland on land zones 5, 7 or 11) within the Project Area. This species does not occur in the vegetation types and landforms within the Project Area (i.e. grassy woodland on floodplains and low rises, land zones 3 and 9). The closest recorded occurrence is from Glenmorgan, 77 km south-southeast of the Project Area (ALA 2024).
Brassicaceae	*Lepidium monoplocoides* Winged Pepper-cress	V	C	A small forb occurring on semi-arid inland plains of the Murray-Darling Basin. It occurs in open, sparsely vegetated areas on heavy clay soils that are seasonally flooded (Mavromihalis 2010). This ephemeral species is found in floodplain woodlands dominated by Coolibah (*Eucalyptus coolabah*) and/or Black Box (*E. largiflorens*) as well as chenopod shrublands and halophytic wetlands. The species has a wide historic distribution through inland NSW and Victoria. The sole records from Queensland are from an area of natural saline scalds around Yelarbon, near the state border with NSW (ALA 2024). The Yelarbon population was recently described as a distinct species (Al-Shebaz 2023).	None within the Project Area.	**Unlikely to be present.** There are no suitable semi-arid, sparsely vegetated areas on heavy clay soils within the Project Area. There are no areas dominated by chenopods, halophytes or Coolibah/Black Box woodland in the Project Area. The Project Area is outside the known range of this species, being over 260 km from the closest records around Yelarbon (ALA 2024).
Poaceae	*Dichanthium setosum* A bluegrass	V	C	Occurs on basalt tablelands from southern NSW to Toowoomba in Queensland with disjunct populations in the central highlands, Einasleigh uplands and north-western highlands (ALA 2024; TSSC 2008). Found in eucalypt or Brigalow woodland on black clays and hard-setting red-brown loams (DESI 2024b; TSSC 2008). Occurs in some moderately disturbed areas such grassy roadside remnants and areas cleared for grazing (TSSC 2008).	None within the Project Area.	**Unlikely to be present.** There is no suitable habitat (i.e. basalt derived heavy clay soils – areas associated with landzone 8) within the Project Area or the vicinity. There are no records of the species within 200km of the Project Area (ALA 2024).

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence
Surianaceae	*Cadellia pentastylis* Ooline	V	V	This tree species occurs in northern NSW and southern Queensland (DCCEEW 2024b). Within Queensland it occurs in patches throughout the southern Brigalow Belt, from the NSW border to Rockhampton and Blackall (ALA 2024). It grows to a large and conspicuous tree occurring on undulating plains, valley slopes, hillsides and scarps, often in association with Brigalow and SEVT communities (DCCEEW 2024b, Santos 2012).	None within the Project Area.	**Unlikely to be present.** The Project Area does not include suitable habitat areas of SEVT (RE 11.9.4) or Brigalow dominated woodland on rises, hills and scarps (RE 11.7.1, 11.9.5). The closest specimen records are from around 50 km north of the Project Area (ALA 2024).

3.1.2.2. Field Survey Results

No EPBC Act-listed threatened flora was detected during field surveys within the Project Area.

3.1.3. Weeds of National Significance

Weeds of National Significance (WoNS) detected within the Project Area are listed in Table 3. Representative locations of these species are shown within Appendix C.

Table 3: WoNS recorded within the Project Area.

Family	Scientific Name	Common Name	Comments
Cactaceae	*Opuntia stricta*	Common Pest Pear	Occurs throughout the Project Area at very low densities.
Cactaceae	*Opuntia sulphurea*	Sulphur Pear	Scattered occurrences across the Project Area.
Cactaceae	*Opuntia tomentosa*	Velvety Tree Pear	Occurs throughout the Project Area at low densities.
Solanaceae	*Lycium ferocissimum*	African Boxthorn	Scattered occurrences in riparian vegetation across the Project Area.

3.1.4. Threatened Fauna

3.1.4.1. Likelihood of Occurrence Assessment

PMST search results (DCCEEW 2024b, Appendix B) predicted twenty-four EPBC Act-listed threatened fauna species that might occur within the buffered desktop search area. Wildlife Online and ALA searches (DESI 2024a, ALA 2024) produced records of one EPBC Act-listed threatened fauna species within the buffered desktop search area this being Koala (*Phascolarctos cinereus*). A likelihood of occurrence assessment for EPBC-listed threatened fauna within the Project Area is presented in Table 4.

Table 4: Assessment of likelihood of occurrence for EPBC Act-listed threatened fauna within the Project Area.

Key to Status: CE/CR = Critically Endangered; E = Endangered; V = Vulnerable; C = Least concern (NC Act).

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Aphelocephala leucopsis* Southern Whiteface	V	V	A sedentary or locally nomadic species occurring in sparsely treed open woodlands and shrublands across southern inland Australia (TSSC 2023a). Often observed in semi-arid *Acacia* low open woodland, particularly Mulga (*Acacia aneura*), and chenopod shrublands (Higgins and Peter 2002). In Queensland the species is largely restricted to southern border areas in the Mulga Lands, Channel Country, Nandewar and Darling Riverine Plains Bioregions (ALA 2024). Sporadic reports from elsewhere in the southern Brigalow Belt probably reflect vagrancy at the edge of the species range (Higgins and Peter 2002). The specific habitat needs of this species and causes of population declines over recent decades are not understood (Ehmke *et al.* 2021).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** The Project Area is outside the range of this largely sedentary species. Vagrant individuals may occasionally reach this area but there are no established populations known from the Southern Brigalow Belt, beyond the border rivers area. The closest record to the Project Area is an unvalidated 2016 sighting from Judd's Lagoon, 15 km to the east (Birdlife Australia 2024). This may be a vagrant or a misidentification. There are no other sightings at that location despite over 64 subsequent surveys (eBird 2024). There are no other post-2000 records of the species within 100 km of the Project Area.
Birds	*Calidris acuminata* Sharp-tailed Sandpiper	V	V	A non-breeding migratory wader species occurring on coastal and inland wetlands (Clemens *et al.* 2021a). Population monitoring within Australia suggests that this species has declined by around 45% over the past two decades (Clemens *et al.* 2021a). Individuals and flocks are regularly recorded across inland Queensland, especially in October and April during migration (ALA 2024; Birdlife Australia 2024; eBird 2024). Breeds in northern Siberia (DCCEEW 2024c) between June and August (Higgins and Davies 1996).	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Passage migrants are periodically reported from the area. Generally recorded around larger wetlands. However, suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Calidris ferruginea* Curlew Sandpiper	CE	CR	A non-breeding migratory wader species usually encountered on coastal and near-coastal saline and freshwater tidal and palustrine wetlands (Clemens *et al.* 2021b; DCCEEW 2024b). The Australian population has declined by 50-80% over the past two decades (Clemens *et al.* 2021b). Passage migrants are occasionally present on inland wetlands, and the species is sparsely recorded across inland Queensland (ALA 2024; Birdlife Australia 2024; eBird 2024).	None. Wetlands within the Project are not of sufficient size and quality to attract this species.	**Unlikely to be present.** Inland records are of sporadic passage migrants transiting during wet years but these are generally from larger wetlands.
Birds	*Calyptorhynchus lathami lathami* Glossy Black-Cockatoo (southeastern subspecies)	V	V	This subspecies occurs in subcoastal ranges from eastern Victoria north to central Queensland with sparse occurrences inland to the Carnarvon Range and along rivers of the Murray-Darling basin (ALA 2024; Cameron *et al.* 2021). The species occurs periodically around Roma, Surat, Glenmorgan, Jackson, Condamine and Chinchilla (BOOBOOK, unpubl.; ALA 2024). This is a specialised feeder dependent on the seeds of several species of *Allocasuarina* and *Casuarina*. It occurs in a variety of forest and woodland types where these food trees are present (Cameron *et al.* 2021; Menkhorst *et al.* 2020; Pizzey *et al.* 2012). It also uses isolated feed trees and small habitat patches within fragmented landscapes (Pavey *et al.* 2016; Holmes 2012). The species roves widely with some evidence of seasonal movements following maturation of She-oak fruits (Stock and Wild 2005; Hourigan 2012). Nesting habitat is in large, hollow-bearing live or dead trees usually in proximity to feed trees and water sources (Higgins 1999).	Primary feeding habitat - Remnant and regrowth: RE 11.3.17, 11.9.10 Sparse feed trees may occur in other remnant and regrowth vegetation and other non-remnant areas. Roosting and nesting habitat-remnant only: RE 11.3.2, 11.3.25, 11.9.7	**Potentially present.** Belah (*Casuarina cristata*) is moderately abundant within the Project Area. No other She-Oak tree species were observed. Potential nest trees (large trees with hollows near food and water sources) occur sparsely in remnant woodland within the Project Area. No evidence of Glossy Black-Cockatoo (chewed cones) was found within the Project Area but occasional visitors could occur.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Climacteris picumnus victoriae* Brown Treecreeper (south-eastern)	V	V	This sedentary, cooperative breeding, insectivorous bird occurs broadly around the Great Dividing Range, from the Grampians of Victoria to the Bunya Mountains in Queensland (Ford *et al.* 2021; Menkhorst *et al.* 2020). Along the inland and northern side of this range is a broad intergradation zone with *C. p. picumnus*, which is not EPBC Act-listed (Ford *et al.* 2021; Menkhorst *et al.* 2020; TSSC 2023b). *C. p. victoriae* occurs in eucalypt dominated open forest and woodland, often in periodically inundated areas, where there are abundant tree hollows and hollow logs and high invertebrate biomass associated with woody debris and leaf litter (Ford *et al.* 2021). This species lives in pairs and small family groups, roosting and nesting in tree hollows and foraging on the ground and on trees (Bennett *et al.* 2012; TSSC 2023b). Older siblings contribute to predator vigilance and feeding young, resulting in breeding success increasing with group size (Doerr and Doerr 2007). The species has limited ability to disperse across pastoral lands, rarely crossing gaps larger than 100 m (Doerr *et al*. 2011), and dispersing individuals are vulnerable to predators (Bennet *et al.* 2012). The major threats to the species are habitat loss and fragmentation (Ford *et al.* 2021). It is also sensitive to habitat degradation from grazing pressure, weeds and insufficient or excessive fire, resulting in increased exposure to predation and harassment by Noisy Miners (*Manorina melanocephala*), particularly in small woodland fragments (Bennett *et al.* 2012; TSSC 2023b; Ford *et al.* 2021).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** Woodland within the Project Area consists of small, predominantly linear patches with sparse woody debris and very few log hollows or tree hollows. The landscape around the Project Area is overwhelmingly transformed with no larger areas of woodland within 5 km. Such small, isolated, disturbed patches within a largely cleared landscape are unlikely to support this fragmentation sensitive species. This vocal, group living species is readily detectable but it was not observed during field surveys of the Project Area. There are no records in the vicinity of the Project Area, despite moderate survey effort in the Wallumbilla area (Birdlife Australia 2024; eBird 2024). The closest records are from remnant riparian woodland at Beranga Lagoon around 50 km south of the Project Area (Birdlife Australia 2024; eBird 2024).

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Erythrotriorchis radiatus* Red Goshawk	E	E	A sparsely distributed raptorial bird that is now restricted to tropical Australia (MacColl *et al.* 2021). The species inhabits extensively wooded areas with permanent water sources and avoids extensively cleared landscapes (Czechura *et al.* 2010). This highly mobile bird has a large home range and is capable of long-distance dispersal (MacColl *et al.* 2021). It roosts and nests in tall forest along major drainage lines, especially around waterholes, where there is high avian prey diversity. Foraging birds could potentially disperse far from these areas (Marchant and Higgins 1993). Red Goshawk is sensitive to landscape level clearing and has declined to extinction in southern and central Queensland (DERM 2012; Seaton 2014). The Brigalow Belt Bioregion is now considered to be outside the species extent of occurrence (MacColl *et al*. 2021).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** The Project Area is in a transformed landscape of derived grassland with only small, linear patches of native vegetation remaining. This extensively cleared landscape offers insufficient foraging and shelter resources for this species. There are no known records of the species within 100 km of the Project Area. Furthermore, the species is now considered extinct throughout southern and central Queensland (MacColl *et al*. 2021).
Birds	*Falco hypoleucos* Grey Falcon	V	V	A rarely seen species, occurring at low densities throughout the arid and semi-arid interior of Australia (TSSC 2020; Schoenjahn *et al.* 2021). In Queensland the species is largely restricted to the southwestern Mulga Lands and Channel Country Bioregions. This is a pursuit predator that feeds almost exclusively on birds, which it hunts on open woodland plains and around water sources (Schoenjahn *et al* 2022). The species nests in large trees along streamlines (TSSC 2020). The species is partially nomadic and itinerant individuals are occasionally recorded in more mesic areas such as the Brigalow Belt (ALA 2024).	None	**Unlikely to be present.** The Project Area does not include the species preferred habitat *Acacia* shrubland plains traversed by tree-lined watercourses (TSSC 2020). The Project Area is outside the species breeding range, which is restricted to arid inland areas.
Birds	*Gallinago hardwickii* Latham's Snipe	V	V	A spring-summer migrant to Australia from breeding grounds on islands and mainland north-eastern Asia (Hansen *et al*. 2020). Declines of 30-50% in the Japanese breeding population, over the past decade, are attributed to drought and habitat change in Australia. The species follows a migration pathway through New Guinea to north-eastern Queensland, dispersing throughout eastern Australia as far as Tasmania (Hansen *et al*. 2020). This cryptic species favours wet pastures and boggy margins of vegetated wetlands (Pizzey *et al*. 2012) including artificial and ephemeral swamps, close to inundated areas (Hansen *et al*. 2020). Individuals and small groups are regularly reported from inland southern and central Queensland, particularly after rainy periods.	None. Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Migrating individuals could potentially occur within the Project Area during wet periods. Suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Geophaps scripta scripta* Squatter Pigeon (southern subspecies)	V	V	This is a ground-feeding, ground-nesting pigeon occurring in Queensland from Texas, on the NSW border, through to Cape York. The southern subspecies has undergone long-standing decline, becoming extinct in NSW and rare in southern Queensland (Ward *et al*. 2021). The species inhabits woodland with a low, open ground layer, usually within a few kilometres of a water source (Higgins and Davies 1996). It feeds on seeds of legumes, forbs and some grasses (Higgins and Davies 1996; Ward *et al*. 2021). The species is largely terrestrial, preferring to crouch and freeze when disturbed, although birds will fly to safety on closer approach and birds roost in trees at night (Higgins and Davies 1996). Ongoing declines, particularly in the south of the range, have been attributed to intensive grazing, land clearing, predation by foxes and cats, and encroachment of foraging habitat by introduced pasture grasses, especially Buffel Grass (*Cenchrus ciliaris*) (Ward *et al*. 2021). Squatter Pigeon occurs in small, sedentary flocks and is readily detected as it preferentially forages in sparsely vegetated areas, including disturbed sites along roads, dams and stockyards. The species is regularly encountered in the upper Dawson catchment but appears to be near extinct in the heavily cleared landscape between Roma and Miles (Boobook 2015). Occasional sight records from the past two decades suggest the possibility of a small remnant population in forested areas around the Balonne River (ALA 2024; Birdlife Australia 2024). However, sightings require validation as Common Bronzewing (*Phaps chalcoptera*), a pigeon of similar size and markings may be confused with Squatter Pigeon.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** There is potentially suitable grassy woodland habitat within the Project Area. However, the Project Area is in a heavily cleared and severely fragmented landscape where this species appears to be extinct (Boobook 2015). There are no records in the vicinity of the Project Area, despite moderate bird survey effort in the Wallumbilla area, e.g. 44 Birdata surveys and 18 eBird checklists within 10 km of the Project Area (Birdlife Australia 2024; eBird 2024). The closest recent record is a 2021 sighting of three individuals at Brucedale State Forest, 38 km to the southwest.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Grantiella picta* Painted Honeyeater	V	V	An enigmatic, rarely encountered and dispersive species found in woodlands of inland eastern Australia, following fruiting of *Amyema* mistletoe food plants, on which it is dependent (Higgins *et al.* 2001; Watson 2012). Breeding in Box-Ironbark, Brigalow, Belah and Weeping Myall woodlands with abundant mistletoe, on the western slopes of the Great Dividing Range, from the Grampians in western Victoria north to around Chinchilla in Queensland (Watson *et al.* 2021). Dispersed records from further northwest in Queensland and the Northern Territory represent seasonal and nomadic movements across the winter range (Watson *et al.* 2021; ALA 2024). Historical declines occurred in heavily cleared areas in the south of the breeding range (Higgins *et al.* 2001). However, recent analyses suggest that the species population is larger than previously thought with no significant decline in the past decade (Watson *et al*. 2021).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.9.10	**Unlikely to be present.** The species is observed periodically in the region and nesting has been recorded from the Roma area. The species was recorded in 2023 from Brigalow woodland around Roma (eBird 2024). However, this species is closely associated with *Amyema* mistletoes, which are rare within the Project Area.
Birds	*Hirundapus caudacutus* White-throated Needletail	V	V	An aerial insectivore present in eastern Australia as a spring/summer non-breeding migrant from Asia (Tarburton 2021). Occurs over all habitat types, including disturbed areas, but with most sightings over wooded areas (Tarburton and Garnett 2021). Individuals roost on trunks and upper branches of tall trees at forest edges or trees on ridgelines, arriving and leaving roosts in the dark (Tarburton 2021). During cold conditions, birds may roost in tree hollows for a period of days, in a torpid state (Tarburton 2021). Migrating birds fly at high altitude and at night (Tarburton 2021). The species has few predators in Australia but predation of roosting birds by owls and, rarely, capture of birds in flight by Peregrine Falcon, have been recorded (Tarburton 2021). Ongoing declines appear largely due to loss of breeding sites (large trees with hollows) in northeast Asia (Tarburton and Garnett 2021). However, deaths from collision with wind turbines, in Australia and elsewhere, at night and in daylight, is an increasing threat for this bird (Tarburton 2021).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area).	**Likely to be present.** The species occurs in the region and is likely to overfly the Project Area occasionally between September and April, following storm fronts. There are no hills within the Project Area and few large trees and therefore the species is unlikely to roost here. There are no specific habitat features that would attract the species to this Site.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Birds	*Rostratula australis* Australian Painted Snipe	E	E	A secretive nomadic wader that forages and breeds in variably inundated wetlands with features such as complex shorelines, areas of shallow water, dense low vegetation and exposed wet mud (DEE 2019; Rogers *et al*. 2021). Uses both artificial and natural ephemeral and permanent wetlands (Marchant and Higgins 1993). Forages at shallow edges and adjacent vegetated margins of wetlands (DCCEEW 2024b) for seeds and invertebrates (Rogers *et al*. 2021). Recorded over much of Australia other than the driest interior, but most frequently recorded within the Murray-Darling Basin (ALA 2024). Partially migratory, with birds in south-eastern Australia moving in autumn-winter to coastal areas of central and northern Queensland, where it occurs year-round (Rogers *et al*. 2021). The species is unpredictable in occurrence and difficult to detect. Total numbers are estimated at below 2500 individuals (DEE 2019).	None. Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Migrating individuals could potentially occur within the Project Area during wet periods. Suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.
Birds	*Stagonopleura guttata* Diamond Firetail	V	V	An inobtrusive small ground-feeding finch that occurs in grassy woodlands and forests on tablelands and inland slopes of the Great Dividing Range across south-eastern Australia (Menkhorst *et al*. 2020). In Queensland the species range formerly extended throughout upland areas of the Brigalow Belt but is now largely confined to the New England Tableland Bioregion (ALA 2024; Hodder *et al*. 2021). Declines are attributed to woodland clearing and fragmentation with replacement of perennial indigenous grasses by introduced annual grasses (Hodder *et al*. 2021). Occasional recent records from the Expedition Range and Gurulmundi-Barakula areas may represent dispersing vagrants or small extant populations in rugged, forested uplands which are rarely surveyed (ALA 2024).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** Woodland in and around the Project Area consists of small, disturbed fragments encroached by pasture grasses. The species is intolerant of fragmentation and dependent on abundant native grass seeds for food in winter. Very occasional records from the Southern Brigalow Belt Bioregion over the past two decades are confined to extensively forested areas (ALA 2024; Birdlife Australia 2024; eBird 2024). The closest recent record is from Gurulmundi State Forest on the Great Dividing Range, around 80 km to the northeast of the Project Area.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Fish	*Maccullochella peelii* Murray Cod	V	-	A long-lived species, capable of surviving in impoundments and smaller intermittently connected waterholes. This species prefers slow flowing river channels with abundant instream wood and overhanging vegetation over steep banks (Koehn 2012). In Queensland naturally occurring populations of this species are confined to permanent water in riverine environments in the Condamine, Maranoa-Balonne, Weir, Moonie and Macintyre River catchments (Lintermans 2007).	None	**Unlikely to be present.** No suitable riverine habitat with permanent waterholes exists within the Project Area.
Mammals	*Chalinolobus dwyeri* Large-eared Pied Bat	E	E	This communally roosting insectivorous bat species extends across coastal ranges and inland around the Great Dividing Range, from Ulladulla in southern NSW to Shoalwater Bay in Queensland (ALA 2024; TSSC 2023c). The species inhabits forested rocky uplands within several kilometres of roost sites comprising caves, fissures and sheltered overhangs in cliffs and rocky outcrops (TSSC 2023c; Williams and Thompson 2018). Foraging habitat comprises the outer foliage of canopy trees including along forest edges and streamlines (Williams and Thompson 2018). In southern Queensland the species occurs in the Main Range east of Warwick, in forested areas around Stanthorpe and Western Creek, and in the Expedition and Carnarvon Ranges (ALA 2024).	None	**Unlikely to be present.** There is no suitable forest habitat within the Project Area. There is no suitable shelter habitat (rocky cliffs with deep crevices and caves) within 5 km of the Project Area. The closest records of the species are over 130 km to the north, in the rugged and extensively forested Expedition Range.
Mammals	*Dasyurus hallucatus* Northern Quoll	E	C	The historical distribution of this species in eastern Australia comprised extensively forested subcoastal ranges north from around Toowoomba through to Cape York, extending inland through the Fitzroy Basin (ALA 2024). However, the species has declined markedly and is now confined to rugged and remote areas throughout its distribution (Burnett 2012). Rugged forested uplands with abundant rock outcrops and boulder piles are required to support the species (Oakwood 2008). Post-2000 records in the Southern Brigalow Belt are from the Carnarvon Range and Kroombit Tops, near Biloela (ALA 2024).	None	**Unlikely to be present.** There are no extensively wooded areas within the Project Area. The landscape around the Project Area is largely cleared. There is no suitable shelter and denning habitat (rocky outcrops and boulder piles with crevices and caves) in the vicinity of the Project Area. There are no recent records of the species within 200 km of the Project Area.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Mammals	*Nyctophilus corbeni* South-eastern Long-eared Bat	V	V	This poorly known species has a patchy occurrence across the inland Murray-Darling basin and southern FitzRoy basin (Churchill 2008; Reardon 2012; ALA 2024). The species inhabits a variety of dry shrubby woodland and open forest types, particularly Box/Ironbark/Cypress Pine vegetation with a dense cluttered understory (Reardon 2012; TSSC 2015). Foraging individuals use temporary daytime roosts in tree hollows and crevices or under loose bark (Reardon 2012; TSSC 2015). Maternity colonies of up to 20 individuals roost in tree hollows, often in stags (TSSC 2015). Validated records of the species are known from sites in Expedition National Park, in the Carnarvon Ranges, Barakula State Forest and the Dawson River near Precipice National Park (ALA 2024).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** The species is generally restricted to the vicinity of extensively wooded areas. The landscape around the Project Area is largely cleared. Woodland within the Project Area is disturbed and open without a complex understorey.
Mammals	*Petauroides volans volans* Southern Greater Glider	E	E	The listed form occurs in south and central Queensland, extending inland beyond the western slopes of the Great Dividing Range (ALA 2024; TSSC 2022). This exclusively arboreal species is sensitive to fragmentation, being restricted to large habitat patches and highly connected corridors of riparian woodland with abundant hollow-bearing roost trees (TSSC 2022). Populations in this region are considered a distinct species, Central Greater Glider, *Petauroides armillatus*, by some authors (McGregor *et al*. 2020).	Remnant only: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10.	**Unlikely to be present.** Woodland in the Project Area consists of small, disconnected fragments that are distant from larger areas of remnant vegetation. There are no continuous riparian corridors within the Project Area and few large trees with hollows (none or 1-5 tree hollows recorded in 50 x 20 m plots in each vegetation type). The closest known occurrences are from the well-developed riparian corridor along Tchanning Creek, over 30 km to the east (Boobook, unpubl. data).

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Mammals	*Phascolarctos cinereus* Koala	E	E	Found in coastal and inland areas throughout eastern Australia. Inland areas, such as the southern Brigalow Belt, support a sparse and mobile population (Davies *et al.* 2013). Koalas require woodland and forest habitat with suitable food trees (mainly *Eucalyptus spp.*) (DAWE 2022). Eucalypts in riparian/alluvial areas are particularly favoured, including *E. tereticornis*, *E. camaldulensis* and in some areas *E. populnea* (Wu *et al.* 2012; Smith *et al.* 2013; Melzer *et al.* 2014). Other common food trees in the southern Brigalow Belt include Coolibah (*E. coolabah*), Ironbarks (*E. crebra, E. fibrosa*, *E. melanophloia*), Grey gums (*E. major*), Grey Box (*E. moluccana*, *E. microcarpa*) and Spotted Gum (*Corymbia citriodora*) (Youngentob *et al.* 2021). Koalas outside riparian habitat in inland Queensland also require access to water sources within 1 km, especially during dry periods (Davies *et al.* 2013). The species is sensitive to habitat fragmentation (McAlpine *et al.* 2015; DAWE 2022). Koalas are capable of traversing gaps between habitat patches and may feed in scattered paddock trees, but dispersing individuals in open habitats are at greater risk of predation and vehicle collision (Youngentob *et al.* 2021; DAWE 2022). The species generally occurs at lower density in fragmented landscapes and depends on larger areas of primary habitat as source populations and as refuges in drought (Smith *et al.* 2013; McAlpine *et al.* 2015).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Potentially present.** Riparian remnant and regrowth woodland dominated by *E. camaldulensis* and *E. populnea* provides suitable habitat for transient individuals to move through the Project Area. The landscape is heavily fragmented, however Koala are capable of dispersing over land using scattered paddock trees and corridors along streams. Koala are sparsely distributed in this area but there is a record from similar habitat within 10 km of the Project Area (ALA 2024). No scratches or other evidence of Koala were observed during field surveys.
Reptiles	*Anomalopus mackayi* Long-legged Worm-skink	V	E	A reduced limb burrowing skink found in grassland and grassy woodland on heavy black soil cracking-clay plains (Wilson 2022). Occurs on the Darling Downs of southern Queensland and the Darling River floodplains of northern inland NSW (ALA 2024; Wilson 2022). Australian government modelling of the species distribution predicts that the species may occur between Warwick and Condamine and between Goondiwindi, Narrabri and Walgett, NSW (DCCEEW 2023).	None	**Unlikely to be present.** There is no suitable habitat (heavy black cracking clay soils) for this species within the Project Area. The Project Area is outside the modelled potential distribution of the species (DCCEEW 2023). The closest records of the species are from Jimbour on the Darling Downs, around 190 km away.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Reptiles	*Delma torquata* Collared Delma	V	V	This flapfooted lizard ranges from around Ipswich in South-east Queensland through the Southern Brigalow Belt, although occupancy appears extremely localised and patchy (DCCEEW 2023; ALA 2024). Lives under surface rock or large woody debris in eucalypt woodlands and open forests (Peck 2012, Wilson 2022). The species has been recorded from some roadside corridor areas but is not known from small, isolated patches (ALA 2024). The species is rarely encountered, difficult to detect and search effort in this region is low.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** It is unlikely that this species could persist in such small, isolated and disturbed vegetation patches. The closest publicly accessible records are from the Hodgson area around 65 km to the west (ALA 2024).
Reptiles	*Egernia rugosa* Yakka Skink	V	V	The range of this large, communal-living skink extends throughout the Brigalow Belt and adjacent areas (ALA 2024). It inhabits woodland and open forests dominated by *Eucalyptus*, *Acacia* and *Callitris* spp. and may also occur in grassland areas with regrowth trees (DCCEEW 2023). The species requires loamy soils for burrows or shelters in sinkholes, abandoned rabbit warrens or piles of woody debris (Wilson 2022; Ferguson and Mathieson 2014; Eddie 2012). The species is rarely encountered, difficult to detect and search effort in this region is low.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.9.7, 11.9.10	**Potentially present.** Possible shelter habitat features within the Project Area, such as logs, were present but not abundant. The species is known to occur in some areas of disturbed habitat where suitable shelter sites are present. The species has been recorded from similarly fragmented vegetation around 21 km north of the Project Area.
Reptiles	*Furina dunmalli* Dunmall's Snake	V	V	A rarely encountered snake occurring in scattered patches of woodland and open forest throughout the Southern Brigalow Belt and adjacent parts of South-east Queensland (ALA 2024, DCCEEW 2023). This species requires abundant leaf litter and woody debris for shelter and prey (Hobson 2012a). Feeds nocturnally on small lizards such as skinks and geckos (Shine 1981). Occurs on heavy soils (Wilson 2022), often with soil cracks and/or gilgais. Most known sites are in large woodland patches and the species is not known to occur in heavily fragmented landscapes. The species is rarely encountered, difficult to detect and search effort in this region is low.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** It is unlikely that this species could persist in such small, isolated and disturbed vegetation patches. The species has been recorded from Yuleba State Forest, around 28 km east-northeast of the Project Area (ALA 2024).

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Reptiles	*Hemiaspis damelii*	E	E	A small to medium sized snake generally found on flood-prone soils including floodplains and gilgai-forming clay plains (Wilson 2022). Shelters in soil cracks and under debris, forages mainly nocturnally, feeding on frogs. Associated with ephemeral waterbodies in woodlands and open forests on heavy cracking clays, where it shelters in soil cracks (Hobson 2012b). It is also known to use cleared areas with suitable shelter and foraging habitat, such as gilgais with sedges and rushes.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25 and mapped wetland areas within the Project Area.	**Potentially present** The Project Area is peripheral to the species distribution, with the closest records from the Glenmorgan area, 85 km southeast (ALA 2024). However, the species is difficult to detect and the Project Area includes some floodplain wetland habitat with cracking clay soils.

3.1.4.2. Field Survey Results

No threatened fauna were recorded during field surveys of the Project Area; however, no intensive fauna surveys were undertaken.

3.1.4.3. Predictive Habitat Mapping

Microhabitat assessments and other field-based habitat observations were conducted within the Project Area as described in Section 2.2.3. The results of these assessments were then combined with ecologist knowledge to develop RE-based predictive habitat mapping for EPBC and NC Act-listed threatened fauna species confirmed, likely or potentially present within the Project Area.

Identified habitat RE were classified as Primary or General Habitat as follows:

Primary habitat - is an area containing resources that are considered essential for the maintenance of populations of the species (e.g. potential habitat for breeding, roosting, foraging, shelter, for either migratory or non-migratory species). 'Primary Habitat' is defined from known records and/or expert advice (including the findings of preclearance surveys).

General habitat - consists of areas or locations that are used by transient individuals or where species have been recorded but there is insufficient information to assess the area as 'Primary Habitat'. 'General Habitat' may be defined from known records or habitat that is considered to potential support a species according to expert knowledge of habitat relationships, despite the absence of specimen backed records. 'General Habitat' may include areas of suboptimal habitat for species.

Habitat mapping rules and the estimated total of General and Primary Habitat for each species within the Project Area and Disturbance Footprint are summarised in Table 5. Predictive habitat maps for threatened fauna are shown in Appendix D.

Table 5: Potentially suitable REs and estimated extent of Primary and General Habitat for EPBC Act-listed threatened fauna species assessed as likely to occur or potentially present within the Project Area and Disturbance Footprint.

Class	Species Name	Potentially Suitable REs within the Project Area	Mapped Extent of Habitat (ha) within the Project Area	Mapped Extent of Habitat (ha) within the Disturbance Footprint	Habitat Mapping Rules/Notes
Birds	*Calidris acuminata* Sharp-tailed Sandpiper	N/A. No ground-truthed RE are wetland REs.	General: 7.31	General: 0.60	No ground-truthed RE are wetland REs. Mapped General Habitat includes any ground-truthed wetlands and dams.
Birds	*Calyptorhynchus lathami lathami* Glossy Black-Cockatoo	Primary: 11.3.17, 11.9.10 General: 11.3.2, 11.3.25, 11.9.7 Remnant and regrowth of all REs.	Primary: 10.71 General: 68.81	Primary: 0.0 General: 0.30	This species requires suitable *Casuarina* or *Allocasuarina* feed trees and large hollow-bearing eucalypts for nesting and roost sites. Primary Habitat includes remnant and regrowth RE with moderate to high abundance of food trees being *Casuarina* and/or *Allocasuarina* spp. Mapped General Habitat includes remnant and regrowth RE that may contain suitable nesting features and/or a lower abundance of food trees and/or presence lesser utilised food trees.

Class	Species Name	Potentially Suitable REs within the Project Area	Mapped Extent of Habitat (ha) within the Project Area	Mapped Extent of Habitat (ha) within the Disturbance Footprint	Habitat Mapping Rules/Notes
Birds	*Gallinago hardwickii* Latham's Snipe	N/A. No ground-truthed RE are wetland REs.	General: 7.31	General: 0.60	No ground-truthed RE are wetland REs. Mapped General Habitat includes any ground-truthed wetlands and dams.
Birds	*Hirundapus caudacutus* White-throated Needletail	Primary: N/A General: 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 Remnant and regrowth of all REs.	Primary: 0.00 ha General: 79.52	Primary: 0.0 General: 0.30	This species feeds aerially over all habitat types. Mapped General Habitat includes all remnant and regrowth RE.
Birds	*Rostratula australis* Australian Painted Snipe	N/A. No ground-truthed RE are wetland REs.	General: 7.31	General: 0.60	No ground-truthed RE are wetland REs. Mapped General Habitat includes any ground-truthed wetlands and dams.
Mammals	*Phascolarctos cinereus* Koala	Primary: 11.3.2, 11.3.25, 11.9.7 General: 11.3.17, 11.9.10 Remnant and regrowth of all REs.	Primary: 68.81 General: 10.71	Primary: 0.30 General: 0.0	Mapped Primary Habitat includes all remnant and regrowth of RE dominated by Myrtaceae species containing known food trees e.g. *Eucalyptus populnea*, *E. camaldulensis*. General Habitat comprises other RE that may contain a lower abundance of food trees or less preferred food species within the family Myrtaceae.
Reptiles	*Egernia rugosa* Yakka Skink	Primary: 11.3.2 General: 11.3.17, 11.9.10 Remnant and regrowth of all REs.	Primary: 67.51 General: 10.71	Primary: 0.30 General: 0.00	Mapped Primary Habitat is based on known records within the nominated RE and includes all remnant and regrowth of the nominated RE. Mapped General Habitat includes all remnant vegetation and regrowth of the nominated RE. This may include sub-optimal habitat.
Reptiles	*Hemiaspis damelii* Grey Snake	Primary: N/A General: 11.3.2, 11.3.17, 11.3.25 Remnant and regrowth of all REs.	Primary: 0.00 General: 67.51	Primary: 0.0 General: 0.30	Mapped General Habitat includes all remnant and regrowth of the nominated RE.

The suitability of areas of vegetation as fauna habitat is determined by the presence and abundance of microhabitat features relevant to the needs of individual species or groups of species (e.g. terrestrial reptiles). In general, mature vegetation (remnant or regrowth) is more likely to support appropriate levels of these microhabitat features, while their presence in younger regrowth and clearings is less likely.

This is particularly the case where clearing for agriculture or other purposes has involved the destruction of fallen timber and coarse woody debris, such that where young regrowth is present it lacks necessary microhabitat for ground-dwelling fauna. It is acknowledged that some areas of young regrowth may contain suitable habitat for some species (e.g. log piles used by reptiles). However, such areas were rare within the Project Area which has a largely intact native vegetation cover. For the purposes of this report, Primary and/or General Habitat is assumed to be present only in remnant and regrowth vegetation.

3.1.5. Migratory and Marine Fauna

PMST search results (DCCEEW 2024a) indicated nine EPBC Act-listed migratory and 14 EPBC Act-listed marine fauna species that may occur within the buffered desktop search area. All EPBC Act-listed migratory and marine fauna species that may possibly occur within the Project Area are birds. A likelihood of occurrence assessment for EPBC Act-listed migratory and marine fauna is presented in Table 6.

Table 6: Assessment of likelihood of occurrence for EPBC Act-listed migratory and marine fauna within the Project Area.

Key to Status: CE/CR = Critically Endangered; E = Endangered; V = Vulnerable; NT = Near Threatened; SL = Special Least Concern; C = Least Concern; M = Migratory; Ma = Marine.

Scientific Name	Common Name	EPBC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE/habitat within the Project Area	Likelihood of Occurrence within the Project Area
Actitis hypoleucos	Common Sandpiper	M, Ma	Spring-summer migrant to Australia usually found in coastal environments (muddy, sandy or rocky stream banks, mangrove margins) but occasionally recorded from inland freshwater or saline wetlands during passage, including artificial habitats (Pizzey *et al.* 2012). There are no recent records from the Maranoa region (ALA 2024).	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area	**Potentially present.** Passage migrants are periodically reported from the area. Generally recorded around larger wetlands. However, suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.
Apus pacificus	Fork-tailed Swift	M, Ma	Seasonal migrant to Australia present October – April. An aerial species, commonly travelling in large flocks ahead of low-pressure cells in pursuit of insects which it takes on the wing (Menkhorst *et al.* 2020; Pizzey *et al.* 2012). Present over most habitat types including disturbed areas (ALA 2024; DoE 2015; DCCEEW 2024b). Most common in drier areas with large flocks roving over inland plains (DoE 2015; Tarburton 2015). In contrast to White-throated Needletail, populations of this species appear to be relatively stable (Tarburton 2015).	All vegetated and non-remnant areas.	**Likely to be present.** The species is periodically recorded in the region. Likely to overfly and feed above the Project Area in Spring and Summer.
Bubulcus ibis (as *Ardea ibis*)	Cattle Egret	Ma	Widely distributed in northern and eastern Australia, also south-west Australia. Inhabits a wide range of dryland and wetland habitats including pastoral areas and notably associates with livestock (Menkhorst *et al.* 2020, Pizzey *et al.* 2012). Nests colonially in flooded or swamp forests. An uncommon visitor to southern inland Queensland (ALA 2024).	All non-remnant areas.	**Potentially present.** The species could occasionally occur as a casual visitor within any cleared part of the Project Area.
Calidris acuminata	Sharp-tailed Sandpiper	V, M, Ma	A widespread spring-summer migrant to Australia, utilizing both inland and coastal wetlands such as tidal mudflats, saltmarshes and saline and freshwater inland swamps (Pizzey *et al.* 2012). There are numerous records in inland southern Queensland (ALA 2024).	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Passage migrants are periodically reported from the area. Generally recorded around larger wetlands. However, suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.

Scientific Name	Common Name	EPBC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE/habitat within the Project Area	Likelihood of Occurrence within the Project Area
Calidris ferruginea	Curlew Sandpiper	CE, M, Ma	A migratory species usually encountered on coastal and near-coastal saline and freshwater tidal and palustrine wetlands (DCCEEW 2024b). Passage migrants are occasionally present on inland wetlands, and the species is sparsely recorded across inland Queensland (ALA 2024).	No suitable wetland habitat is present for this species within the Disturbance Footprint.	**Unlikely to be present.** Inland records are of sporadic passage migrants transiting during wet years but these are generally from larger wetlands.
Calidris melanotos	Pectoral Sandpiper	M, Ma	Spring-summer migrant preferring freshwater wetlands, both inland and sub-coastally (Menkhorst *et al.* 2020, Pizzey *et al.* 2012). Much less common than the related Sharp-tailed Sandpiper in Australia, there are few records in inland southern Queensland (ALA 2024).	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area	**Potentially present.** Passage migrants are very rarely reported from the area. Generally recorded around larger wetlands. However, suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.
Chalcites osculans (as *Chrysococcyx osculans*)	Black-eared Cuckoo	Ma	Breeding migrant to inland Australia, inhabiting dry woodlands and shrublands (Menkhorst *et al.* 2020, Pizzey *et al.* 2012). The species is common in southern inland Queensland (ALA 2024).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area). Also uses non-remnant areas for foraging, shelter and breeding.	**Likely to be present.** Suitable habitat is present within remnant and non-remnant woodland and paddock trees. The species has been recorded from the broader region.
Cuculus optatus (including *C. saturatus*)	Oriental Cuckoo	M, Ma	Migrant to coastal and near-inland northern and eastern Australia, inhabiting denser forest types but may occur in other habitats on passage (Pizzey *et al.* 2012). There are scattered inland southern Queensland records (ALA 2024), however most are from woodland on or closer to the Great Dividing Range and/or in large forest blocks.	11.3.25	**Unlikely to be present.** The highly fragmented and disturbed vegetation present within the Project Area is unlikely to be utilised by this forest-dwelling species.
Gallinago hardwickii	Latham's Snipe	V, M, Ma	Spring-summer migrant, preferring wet pastures, boggy margins of vegetated wetlands and similar habitat at a range of elevations (Pizzey *et al.* 2012). Occasional records from the region.	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Migrating individuals could potentially occur within the Project Area during wet periods. Suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.
Haliaeetus leucogaster	White-bellied Sea-Eagle	Ma	Occurs around the entire Australian coast but also penetrates far inland on larger rivers (Menkhorst *et al.* 2020, Pizzey *et al.* 2012). Feeds on a variety of vertebrates and will take carrion.	11.3.25	**Unlikely to be present.** Transient individuals may overfly the Project Area, however there is no suitable lacustrine or riverine habitat within the Project Area.

Scientific Name	Common Name	EPBC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE/habitat within the Project Area	Likelihood of Occurrence within the Project Area
Hirundapus caudacutus	White-throated Needletail	V, M, Ma	Summer visitor in small to very large flocks that travel with weather fronts, occurring mainly in eastern Australia (Pizzey *et al.* 2012, ALA 2024). It feeds aerially over all natural and artificial environments.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area).	**Likely to be present.** The Project Area is within the known range of the species and it may forage aerially over all habitat types.
Merops ornatus	Rainbow Bee-eater	Ma	A widespread and abundant species that is a breeding migrant in this region. It arrives from the north in September, returning in April (Menkhorst *et al.* 2020, Pizzey *et al.* 2012). It feeds on bees and other invertebrates, aerially, sallying from a perch, or on the ground. It is a summer breeder in the region but requires open areas of loamy soil for nesting tunnels.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area). Also uses non-remnant areas for foraging, shelter and breeding.	**Likely to be present.** This species is regularly observed throughout the region in Spring – Summer.
Motacilla tschutschensis (as *Motacilla flava*)	Eastern Yellow Wagtail	M, Ma	Summer migrant in small numbers to coastal northern Australia with vagrants to southern Australia. It prefers open grassed areas such as wetland margins, short pasture and parks (Pizzey *et al.* 2012). There are no records for southern inland Queensland (ALA 2024).	None	**Unlikely to be present.** There are no existing records of this species from southern inland Queensland (ALA 2024).
Myiagra cyanoleuca	Satin Flycatcher	M, Ma	A passage migrant in southern Queensland, with birds recorded in a variety of woodland types as well as parks and gardens, but breeding in south-east Australia in more closed forest types (Pizzey *et al.* 2012). There are no records from the region (ALA 2024).	None	**Unlikely to be present.** The Project Area is on the inland periphery of the known range of this species (ALA 2024). Occasional passage migrants occur within the region, however the disturbed and highly fragmented woodland patches are unlikely to be utilised by this species.
Rostratula australis (as *Rostratula benghalensis*)	Australian Painted Snipe	E, Ma	Recorded over much of Australia other than the driest interior, but most frequently recorded within the Murray-Darling Basin (ALA 2024). Forages at shallow edges and adjacent vegetated margins of freshwater wetlands (DCCEEW 2024b) and is able to use both artificial and natural ephemeral and permanent wetlands (Marchant and Higgins 1993). Occasional records from the region (ALA 2024).	Potential habitat comprises mapped wetland areas and artificial wetlands such as dams within the Project Area.	**Potentially present.** Migrating individuals could potentially occur within the Project Area during wet periods. Suitable habitat for short-term visitors exists around dams and floodplain soaks within the Project Area.

3.1.6. Internationally & Nationally Important Wetlands

No internationally or nationally significant wetlands are present within or in close proximity to the Project Area. All Wetlands of International Significance identified within the PMST search are greater than 300-400 km downstream from the Project Area.

3.2. Matters of State Environmental Significance

3.2.1. Regional Ecosystems

State government mapped remnant RE (biodiversity status), regulated vegetation as per VMA and mature regrowth (DESI 2024h, DESI 2024i, DoR 2024b) is shown in Appendix A. No remnant (Category B) vegetation is mapped within the Project Area. Three areas within the Project Area are mapped as Category C regrowth containing Of Concern vegetation equivalent to the mixed RE 11.3.2/11.3.17/11.3.25 (70/20/10).

Ground-truthing identified five RE types within the Project Area, including those that are regrowth shown in government mapping (Appendix A). Vegetation in the southern part of the Project Area is on land zone 3 (Quaternary alluvium) associated with streamlines and alluvial plains. Vegetation in the northern part of the Project Area includes areas on land zone 9 (fine-grained sediments). Remnant vegetation occurs as disturbed, irregular and discontinuous corridors along streams, road easements and fence line corridors. Regrowth vegetation comprises Poplar Box (*Eucalyptus populnea*) woodland in riparian corridors, on narrow floodplains and on gently undulating terrain. Summary data for remnant and regrowth RE within the Project Area is presented within Table 7. Mapping of ground-truthed RE from field surveys is presented in Appendix C.

Table 7: Summary of extent of individual mapped REs from ground-truthing and imagery analysis within the Project Area and Disturbance Footprint.

RE Code	VM Act Class	Biodiversity Status	Short Description	Extent in the Project Area – remnant (ha)	Extent in the Project Area – regrowth (ha)	Extent in the Disturbance Footprint – remnant (ha)	Extent in the Disturbance Footprint – regrowth (ha)
11.3.2	OC	OC	*Eucalyptus populnea* woodland on alluvial plains	19.41	65.38	0.15	0.15
11.3.17	OC	E	*Eucalyptus populnea* woodland with *Acacia harpophylla* and/or *Casuarina cristata* on alluvial plains	10.81	0.00	0.00	0.00
11.3.25	LC	OC	*Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines	20.94	0.00	0.00	0.00
11.9.7	OC	OC	*Eucalyptus populnea*, *Eremophila mitchellii* shrubby woodland on fine-grained sedimentary rocks	0.61	1.30	0.00	0.00
11.9.10	OC	E	*Eucalyptus populne*a open forest with a secondary tree layer of *Acacia harpophylla* and sometimes *Casuarina cristata* on fine-grained sedimentary rocks	23.96	2.34	0.00	0.00

E = Endangered; OC = Of Concern; LC = Least Concern; NCAP = No Concern at Present

3.2.2. BioCondition Assessment

Vegetation condition was assessed using the BioCondition methodology of Eyre *et al.* (2015). Assessments were completed at 7 locations in the Project Area (Appendix AC), these being representative samples of four AU (i.e. remnant and regrowth RE) described in Table 7. Raw data for BioCondition assessment sheets have been provided separately to this report. BioCondition site characteristics and scores are summarised in Table 8.

Table 8: Summary of BioCondition assessment sites and results within the Project Area.

AU	RE	Structural condition	Assessment sites	Averaged BioCondition score
1	11.3.2	remnant	863-B03, 863-B05	0.60
2	11.3.2	regrowth	863-B01, 863-B02	0.53
3	11.3.17	remnant	863-B04, 863-B07	0.47
4	11.3.25	remnant	863-B06	0.47

All AU received moderate BioCondition scores (0.47 – 0.60) which indicate significant disturbance and consequent loss of ecosystem integrity relative to intact areas of each RE. These scores also reflect landscape level fragmentation of native vegetation, which is in small patch size, low connectivity among AU and a low proportion of remnant and regrowth vegetation in the surrounding landscape.

3.2.3. Threatened Flora & Essential Habitat

Desktop assessment (ALA 2024, DESI 2024a) did not produce any records of threatened flora species within 10 km of the Project Area. A likelihood assessment for NC Act-listed threatened flora that are also EPBC Act-listed species is included within Table 2 within section 3.1.2 of this report. A likelihood of occurrence assessment for NC Act-listed threatened flora which are not EPBC Act-listed species is included in Table 9.

Table 9: Assessment of likelihood of occurrence for NC Act-listed threatened flora within the Project Area.

Key to Status: E = Endangered; V = Vulnerable; NT = Near Threatened; C = Least Concern.

Class	Scientific & Common Name	EPBC Act Status	NC Act Status	Distribution and Known Habitat Use	Likelihood of Occurrence
Asteraceae	*Picris barbarorum* Plains Picris	-	V	An erect annual daisy occurring in grassy woodlands on floodplains, riverbanks and grasslands on heavy cracking clay soils (DESI 2024b). A record (ALA 2024) exists in roadside vegetation near Roma (ALA 2024).	**Unlikely to be present.** Habitat at the known sites is native grassland associated with heavy cracking clay soils. This habitat type is absent from the Project Area.

No NC Act-listed threatened flora was detected during field surveys of the Project Area.

The Project Area is not located within a High-Risk Area as shown on a Protected Plants Flora Survey Trigger Map (DESI 2024c). There is no state government mapped Essential Habitat for NC Act-listed threatened flora (DES 2022).

3.2.4. Special Least Concern Flora

No Special Least Concern (SLC) flora was detected within the Project Area.

3.2.5. Biosecurity Act Weeds & Other Weeds of Management Concern

Records of African Boxthorn (*Lycium ferocissimum*) and Sulphur Cactus (*Opuntia sulphurea*) were returned by desktop searches within 5 km of the Project Area centre point (DESI 2024a, ALA 2024). Four species of weeds (invasive plants) prescribed under the Queensland *Biosecurity Act 2014* were detected within the Project Area. These are Sulphur Cactus which is listed as a prohibited invasive plant, along with Velvety Tree Pear (*Opuntia tomentosa*), Common Pest Pear (*O. stricta*) and African Boxthorn which are listed as Category 3 restricted matter. These four species are also WoNS as described at Section 3.1.3.

3.2.6. Threatened Fauna

3.2.6.1. Likelihood of Occurrence Assessment

Desktop searches of public databases (DESI 2024a, ALA 2024) contained records of Koala (NC Act: Endangered), Woma (*Aspidites ramsayi*) (NC Act: Near Threatened) and Common Death Adder (*Acanthophis antarcticus*) (NC Act: Vulnerable) within 10 km of the Project Area.

A likelihood of occurrence assessment for NC Act-listed threatened fauna that are also EPBC Act-listed species is included within Table 4 (refer to section 3.1.4 of this report). A likelihood of occurrence assessment for NC Act-listed threatened fauna which are not also EPBC Act-listed is shown in Table 10.

Table 10: Likelihood of occurrence assessment for NC Act-listed threatened fauna (additional to EPBC Act-listed species) within the Project Area.

Class	Scientific & Common Name	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Insects	*Jalmenus eubulus* Pale Imperial Hairstreak (butterfly)	V	This butterfly is essentially limited to the Brigalow Belt: its range extends from inland of Eungella, central Qld southward to the Carnarvon Range and Darling Downs, extending into far northern NSW (ALA 2024). Usually associated with mature Brigalow (*Acacia harpophylla*) open forests and woodlands (Eastwood *et al.* 2008; Valentine and Johnson 2012). The species has a naturally fragmented habitat and is capable of dispersal over moderate distances, with vagrant individuals found far from patches of Brigalow habitat (Eastwood *et al.* 2008).	Remnant: 11.3.17, 11.9.10	**Unlikely to be present.** There is no Brigalow dominated woodland or other suitable habitat within the Project Area. Brigalow trees associated with RE 11.3.17 and 11.9.10 within the Project Area are in very low density and therefore unlikely to attract this species.
Reptiles	*Acanthophis antarcticus* Common Death Adder	V	A widespread but patchily distributed snake species with several historical records from the region (ALA 2024, DESI 2024b). Lives in woodlands, open forests and heathlands; requires abundant shelter/ambush predation cover e.g. low shrubs, rocks, logs and dense leaf litter (Wilson 2022).	Remnant: 11.9.10	**Unlikely to be present.** There are historical records of this species from around Wallumbilla. However, woodland within the Project Area is disturbed and open, containing few of the required microhabitat features for this species (i.e. there is a low density/abundance of low shrubs, rocks, dense leaf litter and/or rocks).
Reptiles	*Aspidites ramsayi* Woma	NT	A snake recorded from a variety of woodland and shrubland habitats in sub-humid to arid Australia (Wilson 2022). Shelters in hollow logs and abandoned animal burrows (e.g. rabbit warrens). It preys on reptiles and small mammals.	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Potentially present.** There are several records of this species from the vicinity of the Project Area. The species can persist in disturbed and fragmented habitats providing prey and shelter sites are present.

Class	Scientific & Common Name	NC Act Status	Distribution and Known Habitat Use	Potentially Suitable RE within the Project Area	Likelihood of Occurrence within the Project Area
Reptiles	*Strophurus taenicauda* Golden-tailed Gecko	NT	This gecko is endemic to inland southern and central Queensland, where it inhabits a variety of dry woodland and open forest habitats in the Brigalow Belt (DESI 2024b). Within these habitats it lives in tree hollows and splits, and under loose bark on live and dead trees (DESI 2024b, Wilson 2022).	Remnant and regrowth: RE 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10 (i.e. all mapped vegetation within the Project Area)	**Unlikely to be present.** The species has been recorded from nearby areas within large forest tracts. Potentially suitable habitat (dry woodland and open forest) occurs within the Project Area, however woodland within the Project Area is fragmented, disturbed and open, containing few of the required microhabitat features for this species (i.e. there is a low density/abundance of loose bark) and likely high levels of competition between Dubious Dtella (*Gehyra dubia*).

3.2.6.1. Field Survey Results

No NC Act-listed threatened species were found during the field survey; however, no intensive fauna surveys were undertaken.

3.2.6.2. Essential Habitat

There is no State government mapped Essential Habitat (DES 2022) for NC Act-listed threatened fauna within the Project Area.

3.2.6.3. Predictive Habitat Mapping

Predictive habitat mapping was developed for EPBC and NC Act-listed threatened fauna species confirmed, likely or potentially present within the Project Area as described in Section 3.1.4.3. These results were informed by likelihood of occurrence assessments listed within Table 4 and Table 10 for EPBC and/or NC Act-listed threatened fauna that may potentially occur within the Project Area. Predictive habitat mapping for NC Act-listed fauna potentially occurring within the Disturbance Footprint is shown in Appendix D. Species listed as Near Threatened under the NC Act that could potentially occur within the Project Area (e.g. Woma) do not constitute a MSES and are excluded from predictive habitat mapping.

3.2.7. Special Least Concern Fauna

3.2.7.1. Likelihood of Occurrence Assessment

Wildlife Online and ALA searches (DESI 2024a, ALA 2024) produced records of one SLC fauna species within the buffered desktop search area this being Short-beaked Echidna (*Tachyglossus aculeatus*). A likelihood of occurrence assessment for SLC fauna within the Project Area is presented in Table 11.

Table 11: Assessment of likelihood of occurrence for SLC fauna within the Project Area.

Key to Status: SLC = Special Least Concern

Class	Scientific and Common Name	EPBC Act Status	NC Act Status	General Habitat Requirements	Potentially Suitable RE within the Project Area	Likelihood of Occurrence
Mammals	Short-beaked Echidna *Tachyglossus aculeatus*	-	SLC	A ubiquitous inhabitant of a wide variety of landforms and climatic regimes across Australia (Augee 2008) where it digs in soil and litter for ants, termites and their larvae and eggs. It is commonly found in a variety of woodland types as well as cleared pastoral and farming lands with suitable microhabitat and food sources.	11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10	**Potentially present.** Recorded within the desktop search area (ALA 2024, DESI 2024a). The species is likely to have a patchy occurrence in the Project Area. Suitable habitat features such as logs and woody debris were scarce within the Project Area.
Mammals	Platypus *Ornithorhynchus anatinus*	-	SLC	Widespread species in eastern Australia but confined to permanent freshwater rivers and streams. It is patchily distributed in inland Queensland and is regularly reported from the Dawson River and its major tributaries (ALA 2024).	11.3.25	**Unlikely to be present.** The nearest records of this species are located over 100 km to the east and north of the Project Area. The areas of RE 11.3.25 within the Project Area do not include permanent aquatic habitat.

Migratory fauna that are SLC are addressed within section 3.1.5 of this report.

3.2.7.2. Field Survey Results

No SLC fauna species were recorded within the Project Area during the field survey, however no intensive fauna surveys were undertaken.

3.2.7.1. Predictive Habitat Mapping

Mapping rules and the estimated extent of potentially suitable habitat for SLC fauna species likely to occur within the Project Area are given in Table 12. Refer to Table 11 (Section 3.2.7.1) for a summary of habitat requirements for SLC species.

Table 12: Potentially suitable REs and estimated extent of habitat for SLC fauna species within the Project Area and Disturbance Footprint.

Class	Scientific and Common Name	Potentially Suitable REs within the Project Area	Mapped Extent of Habitat within the Project Area	Mapped Extent of Habitat (ha) within the Disturbance Footprint (ha)	Habitat Mapping Rules/Notes
Mammals	Short-beaked Echidna *Tachyglossus aculeatus*	Primary: N/A General: 11.3.2, 11.3.17, 11.3.25, 11.9.7, 11.9.10	Primary: 0.0 General: 153.08	Primary: 0.0 General: 0.30	Mapped General Habitat includes remnant and regrowth areas of the nominated RE.

3.2.8. Fauna Habitat Features & Potential Breeding Places

The results of fauna habitat assessments conducted within the Project Area are included within associated spatial data. Fauna habitat features present within the Project Area included hollow-bearing trees (dead and alive), hollow-bearing logs and piles of pushed timber. Location of fauna habitat assessment sites are shown in Appendix C.

3.2.9. Wetlands, Lakes & Springs

No springs or lakes were mapped as present within the Project Area. No wetlands of High Ecological Significance or wetlands of General Ecological Significance, as shown on a Map of Referable Wetlands (DESI 2024d), were mapped as present within the Project Area. No mapped wetlands in high ecological value waters, as identified under the *Environmental Protection (Water) Policy 2009,* occur within the Project Area.

No springs or lakes were detected during the field survey. Several areas of habitat which meet the criteria for wetlands (DERM 2011) were detected within the Project Area. These are wetlands of general ecological significance and their location and extent is shown within Appendix C. Representative images are shown in Figure 4a-b in Section 8.

3.2.10. Watercourses & Drainage Features

Several mapped streams occur within the Project Area including Washpool Creek. No stream assessments were undertaken within this scope of works. No mapped watercourses in high ecological value waters, as identified under the *Environmental Protection (Water) Policy 2009,* occur within the Project Area.

3.2.10.1. Waterways Providing for Fish Passage

The Queensland waterways for waterway barrier works mapping helps identify waterways as defined by the *Fisheries Act 1994* and the fisheries interest in waterways providing fish passage (a MSES under the *Environmental Offsets Act 2014*). In total, three waterways with a fish passage attribute 1 (green); one waterway with a fish passage attribute 2 (amber); and two waterways with a fish passage attribute 3 (red) occur within the Project Area. Each of these waterways, except one green and one amber, are intersected by the proposed Disturbance Footprint.

3.2.11. Environmentally Sensitive Areas

The following Category B ESA are present within the Project Area:

- areas of ground-truthed Endangered RE (biodiversity status): 11.3.17 and 11.9.10.

The following Category C ESA are present within the Project Area:

- areas of ground-truthed Of Concern RE (biodiversity status): 11.3.2, 11.3.25 and 11.9.7.
- an area validated from ground-truthing surveys as 'protected wildlife habitat' that is category A, B or C on the Remnant Vegetation Management Map, in accordance with section 20A of the *VMA*, for a species of wildlife listed as critically endangered, endangered or vulnerable under the NC Act as follows:
    - ground-truthed protected wildlife habitat: Glossy Black-Cockatoo (*Calyptorhynchus lathami lathami*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.3.25, 11.9.10.
    - ground-truthed protected wildlife habitat: White-throated Needletail (*Hirundapus caudacutus*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.3.25, 11.9.10.
    - ground-truthed protected wildlife habitat: Koala (*Phascolarctos cinereus*) - NC Act: Endangered: remnant and regrowth REs 11.3.2, 11.3.25, 11.9.10.
    - ground-truthed protected wildlife habitat: Yakka Skink (*Egernia rugosa*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.9.10.
    - ground-truthed protected wildlife habitat: Grey Snake (*Hemiaspis damelii*) - NC Act: Endangered: remnant and regrowth REs 11.3.2, 11.3.25.

Ground-truthed regional ecosystems comprising Category B and C ESA are shown in Appendix E1. Category C ESA comprising protected wildlife habitat as per the VMA regulated vegetation map (Appendix A2) are shown in Appendix E2.

3.2.12. Connectivity Areas

Connectivity areas are areas of remnant vegetation outside urban areas containing prescribed RE that are required for ecosystem functioning. As both test results were negative, the overall result is the impact will not be significant. Results of the connectivity tool are summarised in Table 13.

Table 13: Connectivity areas that are a RE (not in urban area) within the Project Area.

Connectivity Test	Regional scale[i] extent of core remnant RE pre-impact	Change threshold for local scale[ii] core remnant RE	Change in core local scale remnant RE post-impact	Number of core areas ≥1 ha pre-impact	Number of core areas ≥1 ha post-impact	Test Result
Change in core remnant RE extent at the local scale	4.4%	2%	0%			Not Significant
Loss/ fragmentation of core remnant RE at the site (Disturbance Footprint) scale				0	0	Not Significant

[i] Regional scale is an area within a 20 km buffer of the Disturbance Footprint
[ii] Local scale is an area within a 5 km buffer of the Disturbance Footprint

4. Potential Impacts

4.1. Predicted Impacts within the Project Area

The following assessment of potential impacts is based on the proposed Disturbance Footprint provided by Santos.

4.1.1. Matters of National Environmental Significance

4.1.1.1. Threatened Ecological Communities

No TEC occurs within the Disturbance Footprint within the Project Area therefore there will be no impact on TEC.

4.1.1.2. Threatened Flora

EPBC Act-listed threatened plant species that may potentially occur within the Project Area are given in Table 2 (section 3.1.2). No threatened plant species were detected during field surveys of the proposed disturbance area. No threatened flora species are expected to occur within the Project Area. The Project is therefore unlikely to impact on any threatened flora species and no impact assessment is required.

4.1.1.3. Threatened Fauna

EPBC Act-listed threatened fauna species that are likely to occur or may potentially occur within the Project Area are listed within Table 4 (section 3.1.4.1). Predicted mapping of threatened species habitat is shown in Appendix D. Potential impacts on species identified as likely to occur or potentially present within the Project Area are assessed below in Table 11, following the EPBC Act guidelines for Significant Impacts on Matters of National Environmental Significance (DoE 2013).

Potential impacts on EPBC Act-listed endangered fauna assessed as likely to occur or potentially occurring within the Project Area are summarised below in Table 11, following the EPBC Act *Guidelines for Significant Impacts on Matters of National Environmental Significance* (DoE 2013).

Table 14: Assessment of potential significant impacts (as per Significant Impact criteria within DoE 2013) upon EPBC Act-listed endangered fauna species within the Project Area.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of a population	**Reduce the Area of Occupancy (AoO) of the species**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of a population**	**Modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a critically endangered or endangered species becoming established in the critically endangered or endangered threatened species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Birds	*Rostratula australis* Australian Painted Snipe	No: The species is a rare visitor in very low numbers to the region. There are no known important populations of the species in or near the Project Area.	No: The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal in this species.	No: Wetlands within the Project Area are very small and highly ephemeral. Although these wetlands may occasionally be used by transitory individuals, they do not represent habitat critical to the surveyal of the species.	Unlikely: Breeding has been recorded in all months of the year in response to wetland conditions. The small and highly ephemeral nature of wetlands within the Project Area are unlikely to be attractive for breeding by this species.	No: Wetlands within the Project Area are very small and highly ephemeral. Disturbance will only occur to 0.60 ha of 7.31 ha available wetland habitat within the Project Area. Disturbance to this small area will not cause this species to decline.	None known.	None known.	No: The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of a population	**Reduce the Area of Occupancy (AoO) of the species**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of a population**	**Modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a critically endangered or endangered species becoming established in the critically endangered or endangered threatened species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Mammals	*Phascolarctos cinereus* Koala	Unlikely: Loss of 0.30 ha of eucalypt woodland will not lead to a decrease in size of the local population.	Unlikely: No sign of Koala was detected within the Project Area. It is likely that this area would be used by occasional transient individuals. The loss of 0.30 ha of potential habitat in the Disturbance Footprint is unlikely to affect the occurrence of Koala within the Project Area.	No: Koala are capable of crossing gaps between habitat patches and may use isolated paddock trees. The loss of several small areas of potential habitat, summing to 0.30 ha, will not disrupt habitat corridors through this area and will have negligible effect on Koala dispersal through the Project Area.	Unlikely: The loss of several small areas of potential habitat, summing to 0.30 ha, is unlikely to have measurable impacts on occasional Koala usage of the Project Area.	No: No evidence of Koala was found within the Project Area and it is likely that Koala occurrence within the Project Area is occasional and transient. The breeding cycle is unlikely to be disrupted.	No: This small area is unlikely to reduce Koala numbers or to disrupt Koala movement through the Project Area. It is likely that the 0.30 ha of potential habitat proposed to be cleared involves the removal of <15 mature trees from the Disturbance Footprint.	None known	None known: chlamydia is present in the Koala population of southern inland Queensland but this bacterial disease is unlikely to be exacerbated by the proposed development.	Unlikely: The loss of several small areas of potential habitat, totalling 0.30 ha will have minimal effect on the recovery of Koala in this area.	No: The proposed development will result in the loss of up to 0.30 ha of potential habitat (RE 11.3.2) spread across several fragments. This small area is unlikely to reduce Koala numbers or to disrupt Koala movement through the area. No evidence of Koala was found within the Project Area and it is likely that Koala occurrence within the Project Area is occasional and transient.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of a population	**Reduce the Area of Occupancy (AoO) of the species**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of a population**	**Modify, destroy, remove, isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a critically endangered or endangered species becoming established in the critically endangered or endangered threatened species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Reptiles	*Hemiaspis damelii* Grey Snake	Unlikely: 0.30 ha of potential habitat occurs within the Disturbance Footprint. Mapped habitat comprises fragmented patches of riparian or floodplain woodland.	Unlikely: The 0.30 ha of mapped habitat includes already fragmented habitat patches.	No: The proposed development will not exacerbate existing fragmentation.	Unlikely: The 0.30 ha of mapped shelter, foraging, breeding and dispersal habitat comprises disturbed alluvial woodland fragments. Similar features occur in the vicinity and this habitat is unlikely to be limiting.	No: Only 0.30 ha of mapped habitat within the Disturbance Footprint with similar habitat abundant in the vicinity.	Unlikely: The 0.30 ha of mapped shelter, foraging, breeding and dispersal habitat comprises disturbed alluvial woodland fragments. Similar features occur in the vicinity and this habitat is unlikely to be limiting. Loss of 0.30 ha of habitat is unlikely to contribute to a decline in the species.	None known.	None known.	No: Only 0.30 ha of mapped habitat within the Disturbance Footprint with similar habitat abundant in the vicinity.	No: Presence of this species within the Project Area was not confirmed during the field survey. The Project Area is peripheral to the species distribution and there are no records in the vicinity. Potentially suitable floodplain woodland and ephemeral wetland habitat (RE 11.3.2) is widespread beyond the Disturbance Footprint.

Potential impacts on EPBC Act-listed vulnerable fauna assessed as likely to occur or potentially occurring within the Project Area are summarised below in Table 12, following the EPBC Act *Guidelines for Significant Impacts on Matters of National Environmental Significance* (DoE 2013).

Table 15: Assessment of potential significant impacts (as per Significant Impact criteria within DoE 2013) upon EPBC Act-listed vulnerable fauna species within the Project Area.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of an important population of a species	**Reduce the Area of Occupancy (AoO) of an important population**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of an important population**	**Modify, destroy, remove or isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat.**	**Introduce disease that may cause the species to decline.**	**Interfere substantially with the recovery of the species.**	
Birds	*Calidris acuminata* Sharp-tailed Sandpiper	No: The species is an occasional visitor in low numbers to the region. There are no important populations of the species in or near the Project Area.	No: The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal of this species.	No: Wetlands within the Project Area are very small and highly ephemeral. Although these wetlands may occasionally be used by transitory individuals, they do not represent habitat critical to the surveyal of the species.	No: The species does not breed within Australia. Breeding occurs between June and August in northern Siberia (DCCEEW 2024c).	No: Wetlands within the Project Area are very small and highly ephemeral. Disturbance will only occur to 0.60 ha of 7.31 ha available wetland habitat within the Project Area. Disturbance to this small area will not cause this species to decline.	None known.	None known.	No: The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of an important population of a species	**Reduce the Area of Occupancy (AoO) of an important population**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of an important population**	**Modify, destroy, remove or isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat.**	**Introduce disease that may cause the species to decline.**	**Interfere substantially with the recovery of the species.**	
Birds	*Calyptorhynchus lathami lathami* Glossy Black-Cockatoo	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat. Feed trees occur nearby but are not present in the Disturbance Footprint. This small area supports few potential nest/roost trees. The species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than being a resident.	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat. No nest or roost trees were identified during surveys. This mobile and wide-ranging species is capable of traversing non-remnant areas between nest/roost trees and feed trees.	No: The disturbance will not affect dispersal of this species, which travels long distances between suitable foraging trees.	Unlikely: Loss of 0.30 ha of potential habitat is unlikely to affect habitat critical to the survival of the species.	Unlikely: Loss of 0.30 ha of potential habitat with no known nesting trees is unlikely to disrupt the breeding cycle of this species. However, the species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than being a breeding resident.	Unlikely: Loss of 0.30ha of potential habitat is unlikely to cause the species to decline. Feed trees occur nearby but are not present in the Disturbance Footprint.	None known	None known	Unlikely: Loss of 0.30 ha of potential habitat will not substantially interfere with the recovery of the species.	No: There will be no significant loss of habitat for this species within the Disturbance Footprint.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of an important population of a species	**Reduce the Area of Occupancy (AoO) of an important population**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of an important population**	**Modify, destroy, remove or isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat.**	**Introduce disease that may cause the species to decline.**	**Interfere substantially with the recovery of the species.**	
Birds	*Gallinago hardwickii* Latham's Snipe	No: The species is an occasional visitor in low numbers to the region. There are no important populations of the species in or near the Project Area.	No; The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal of this species.	No: Wetlands within the Project Area are very small and highly ephemeral. Although these wetlands may occasionally be used by transitory individuals they do not represent habitat critical to the surveyal of the species.	No: The species does not breed within Australia. Breeding occurs between May and July in north-eastern Asia (Hansen *et al*. 2020).	No: Wetlands within the Project Area are very small and highly ephemeral. Disturbance will only occur to 0.60 ha of 7.31 ha available wetland habitat within the Project Area. Disturbance to this small area will not cause this species to decline.	None known.	None known.	No: The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of an important population of a species	**Reduce the Area of Occupancy (AoO) of an important population**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of an important population**	**Modify, destroy, remove or isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat.**	**Introduce disease that may cause the species to decline.**	**Interfere substantially with the recovery of the species.**	
Birds	*Hirundapus caudacutus* White-throated Needletail	No: The species is an aerial feeding insectivore that forages over a wide range of intact and modified landscapes, with a general preference for wooded areas.	No: The proposed disturbance is not materially relevant to the species.	No: The proposed disturbance is not materially relevant to the species.	No: No impact on foraging resources is anticipated, no other critical locations are relevant to the species in Australia. The species roosts overnight in tall trees along scarps and is unlikely to roost in the Project Area.	No: the species does not breed in Australia during its summer presence.	No: The proposed disturbance is not materially relevant to the species.	None known	None known	No: The proposed disturbance will not reduce the extent of remnant woodland. The species does not breed in Australia.	No: The proposed disturbance is not materially relevant to the species.

Class	Species	Significant Impact Criteria (DoE 2013)									Significant Impact
		Lead to a long-term decrease in the size of an important population of a species	**Reduce the Area of Occupancy (AoO) of an important population**	**Fragment an existing population into two or more populations**	**Adversely affect habitat critical to the survival of a species**	**Disrupt the breeding cycle of an important population**	**Modify, destroy, remove or isolate or decrease the availability or quality of habitat to the extent that the species is likely to decline**	**Result in invasive species that are harmful to a vulnerable species becoming established in the vulnerable species' habitat.**	**Introduce disease that may cause the species to decline.**	**Interfere substantially with the recovery of the species.**	
Reptiles	*Egernia rugosa* Yakka Skink	Unlikely: Removal of logs and accumulations of woody debris in 0.30 ha of potential habitat within the Disturbance Footprint could reduce some shelter and breeding habitat for this species. However, these features are scarce within the Project Area and Disturbance Footprint (BioCondition scores for woody debris averaged 20% of benchmark values) and low numbers of logs/log piles were recorded in microhabitat assessments.	Unlikely: Loss of 0.30 ha of potential habitat could potentially impact any resident individuals. However, few individuals would occupy this small area. The species was not detected within the Project Area and shelter habitat features were scarce. The disturbance will not affect the broader distribution of the species.	No: The species is mobile and the proposed disturbance does not pose a barrier to dispersal of this species.	Unlikely: Removal of logs and large woody debris may reduce shelter and breeding habitat. However, these habitat features are scarce in the Project Area and within the Disturbance Footprint.	Unlikely: The species has a patchy occurrence in the region and potentially suitable habitat features such as logs and woody debris were scarce within the Project Area.	Unlikely: The species has a patchy occurrence in the region and potentially suitable habitat features such as logs and woody debris were scarce within the Project Area.	None known.	None known.	Unlikely: Loss of 0.30 ha, across several habitat patches could potentially impact on any resident individuals but the disturbance is unlikely to affect overall abundance and occurrence within the region.	No: The presence of this species was not confirmed within the Project Area. Loss of up to 0.30 ha of potential habitat (RE 11.3.2) could impact on any resident individuals. However, this small area would hold few, if any, individuals and these impacts may be mitigated by preclearing of the route by a fauna spotter.

4.1.1.4. Migratory Fauna

DoE (2013) identifies criteria for identifying significant impacts on EPBC-listed migratory species. An action is likely to have a significant impact on a listed migratory species if it results in:

- Isolation, modification or destruction of important habitat for this species.
- Establishment of a harmful invasive species in an area of important habitat.
- Disruption to breeding, feeding, migration, resting behaviour or life-expectancy of an ecologically significant proportion of the population of a listed species.

Government guidelines for assessing the significance of impacts refer to the linked concepts of 'important habitat' and an 'ecologically significant proportion' of a listed species' population (DoE 2013). The definition of these terms vary across species ecology, range, population size and circumstances (DoE 2013; DoE 2015). DoEE (2017) defines important habitat for migratory shorebirds that aggregate in flocks as an area:

- that has been identified as internationally important for shorebirds; or
- that supports at least 0.1 per cent of the East Asian-Australasian flyway population; or,
- that supports at least 2000 migratory shorebirds; or
- that supports at least 15 migratory shorebird species.

For Latham's Snipe, which has a more dispersed occurrence, important habitat is defined as an area that supports at least 18 individuals of this species (DoEE 2017). Guidelines for other listed migratory species suggest upper and lower thresholds of 1% and 0.1% of species populations as ecologically significant proportions at an international and national level, respectively (DoE 2015). Estimates of the lower threshold vary from 10 individuals of White-throated Needletail and 100 Fork-tailed Swift.

Wetland migratory species potentially occurring within the Project Area include Australian Painted Snipe, Latham's Snipe, Common Sandpiper, Sharp-tailed Sandpiper and Pectoral Sandpiper. None of these species will be significantly impacted by the proposed project as there will be minor disturbance to wetland habitat (0.60 ha out of 7.31 ha of available habitat in the Project Area).

For the other migratory species, these being White-throated Needletail and Fork-tailed Swift, these are both aerial species which will not be impacted upon by the Project as this development is not materially relevant to them.

The Project Area is unlikely to harbour an ecologically significant proportion of any listed migratory species' population. The proposed action is unlikely to reduce the geographic range of any of these species and the Project Area does not otherwise contain or constitute important habitat for these species. Therefore, the proposed action is unlikely to result in significant impacts on any listed migratory species.

4.1.1.5. Internationally and Nationally Important Wetlands

No internationally or nationally important wetlands occur at or near the Project Area. The Project will therefore not impact upon any internationally or nationally important wetlands.

4.1.2. Matters of State Environmental Significance

A summary of MSES prescribed environmental matters (PEM) potentially within the Project Area is below in Table 16.

Table 16: Summary of Significant Residual Impacts assessed within the Project Area.

Prescribed environmental matter (PEM) as per EOR	Presence in the Project Area	
Regulated vegetation: Endangered and Of Concern REs	☒	The Project Area does not contain areas of regulated vegetation that is a 'prescribed RE'. DEHP (2014) defines regulated vegetation to be a prescribed RE as per the *Environmental Offsets Regulation 2014* (EOR) which does not include regrowth (Category C) vegetation. No remnant or Category B areas are present within the Project Area on the '*Regulated Vegetation Management Map'*. As discussed in Section 3.2.1, regulated vegetation mapped within the Project Area on the *Regulated Vegetation Management Map* consists entirely of three areas of Category C (RE 11.3.2/11.3.17/11.3.25, high value regrowth) vegetation. Therefore, the Project Area contains no prescribed RE or MSES PEM for the purposes of SRI assessment under the EOR and *Significant Residual Impact Guideline* (DEHP 2014). In conclusion, the proposed activities will not result in an SRI to *Regulated Vegetation* (Endangered and Of Concern RE).
Regulated vegetation: Prescribed RE within the defined distance of a watercourse	☒	The Project Area does not contain areas of regulated vegetation that is a 'prescribed RE' within the defined distance of a watercourse. DEHP (2014) defines regulated vegetation to be a prescribed RE as per the *Environmental Offsets Regulation 2014* (EOR) which does not include regrowth (Category C) vegetation. No remnant or Category B areas are present within the Project Area on the '*Regulated Vegetation Management Map'*. As discussed in Section 3.2.1, regulated vegetation mapped within the Project Area on the *Regulated Vegetation Management Map* consists entirely of three areas of Category C (RE 11.3.2/11.3.17/11.3.25, high value regrowth) vegetation. Portions of two Category C areas occur within the defined distance from the defining banks of a watercourse identified on the vegetation management watercourse map. As these areas are mapped as regrowth, they are not prescribed RE. Therefore, the Project Area contains no prescribed RE or MSES PEM for the purposes of SRI assessment under the EOR and *Significant Residual Impact Guideline* (DEHP 2014). In conclusion, the proposed activities will not result in an SRI to *Regulated Vegetation* (within the defined distance of a watercourse).
Connectivity areas	☑	The Landscape Fragmentation and Connectivity Tool was utilised to assess the proposed disturbances for potential impacts to Connectivity Areas. The Tool determined no SRI was triggered by the proposed activities. Refer to Section 3.2.12 for further information.
Wetlands and watercourses	☒	The following wetlands or watercourses are not present within the Project Area: • Wetlands in a wetland protection area as shown on the Map of referrable wetlands under schedule 12, part 2 of the *Environmental Protection Regulation 2008*; • Wetlands of high ecological significance as shown on the Map of referrable wetlands under schedule 12, part 2 of the *Environmental Protection Regulation 2008*; or • Wetlands or watercourses in a high ecological value waters as identified under the *Environmental Protection (Water) Policy 2009*, schedule 2.
Designated precinct in a strategic environmental area	☒	The Project Area is not located in a designated precinct in a strategic environmental area.
Protected wildlife habitat	☑	• Based on fauna habitat / RE associations, wildlife habitat for NC Act listed species relevant to SRI assessment may be present within the Project Area (refer Sections 3.2.11 and 4.1.2.5 for further information). • No high-risk areas on the flora survey trigger map exist within the Project Area.
Protected areas	☒	There are no protected areas within the Project Area.
Highly protected zones of State marine parks	☒	The Project Area does not contain highly protected zones of a State marine park.
Fish habitat areas	☒	Areas declared under the *Fisheries Act 1994* to be a fish habitat area are not present within the Project Area.
Waterway providing for fish passage	☑	The Project Area contains watercourses providing potential fish passage, as detailed in Section 3.2.10.1. The proposed development would not have an SRI on this PEM because linear infrastructure construction activities located in waterways providing for fish passage would not: • reduce the extent, frequency, or duration of fish passage; • result in a substantial change to the hydrological regime of the watercourse; or • lead to significant changes in water quality parameters within the watercourse.
Marine plants	☒	Areas containing marine plants are not present in the Project Area.
Legally secured offset areas	☒	No legally secured offset areas are present within the Project Area.

4.1.2.1. Regional Ecosystems

The proposed development will not impact on any Endangered RE.

A total of .18 ha of OC RE (11.3.2) occurs within the Disturbance Footprint (refer to Table 7: section 3.2.1). The Project Area is in a largely cleared landscape. These disturbance areas are a small fraction of each vegetation assessment unit within the Project Area and are largely on the margins of vegetation fragments. The proposed development will have minimal effect on the extent and connectivity of these ecosystems within the Project Area.

The proposed development will not impact on any No Concern at Present RE.

4.1.2.2. Threatened flora

NC Act-listed threatened plant species that may potentially occur within the Project Area are given in Table 9 (Section 3.2.3). No NC Act-listed threatened plant species were detected during field surveys and none are expected to occur within the Project Area. Therefore, the Project is unlikely to impact on any NC Act-listed threatened flora species.

4.1.2.3. Threatened fauna

NC Act-listed threatened fauna that may potentially occur within the Project Area are listed within Table 4 and Table 10. Predictive habitat mapping for NC Act-listed fauna potentially occurring within the Disturbance Footprint is shown in Appendix D. Potential impacts on endangered and vulnerable fauna species that are NC Act-listed are assessed in Table 13. Other NC Act-listed species that could potentially occur within the Project Area (e.g. Woma) are excluded from impact assessment as Near Threatened species do not constitute MSES. This assessment is consistent with the Significant Residual Impact criteria from Section 5 of the *Significant Residual Impact Guideline* (DEHP 2014). This assessment is also consistent with the MNES significant impact assessment as per section 4.1.1.3 (Tables 11 and 12). In summary, no significant impact is expected on any NC Act-listed MSES fauna.

Table 17: Assessment of potential significant residual impacts (as per SRI criteria within DEHP (2014) upon NC Act-listed endangered and vulnerable fauna species potentially present within the Project Area.

Class	Species	Significant Residual Impact Criteria (DEHP 2014)							Significant Residual Impact
		Lead to a long-term decrease in the size of a population.	**Reduce the Extent of Occurrence (EoO) of the species.**	**Fragment an existing population / result in genetically distinct populations forming as a result of habitat isolation.**	**Cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.**	**Result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Birds	*Calidris acuminata* Sharp-tailed Sandpiper NC Act: Vulnerable	No: The species is an occasional visitor in low numbers to the region. There are no important populations of the species in or near the Project Area.	No: The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only. This is a trans-continental species therefore there will be no reduction in EoO as a result of Project activities.	No: The species is mobile and wide-ranging and occurs only seasonally in the region. The proposed development is unlikely to restrict dispersal in this species, nor result in the formation of genetically distinct populations.	No: The Project Area is not an ecologically significant location for the species. Similar areas used for foraging, migration and/or resting are abundant in the surrounding landscape. The species does not breed within Australia.	None known	None known	No: The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.
Birds	*Calyptorhynchus lathami* Glossy Black-Cockatoo NC Act: Vulnerable	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat. This small area supports few potential nest/roost trees. The species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than being a resident.	Unlikely: Loss of 0.30 ha of potential shelter and breeding habitat. No nest or roost trees were identified during surveys. This mobile and wide-ranging species is capable of traversing non-remnant areas between nest/roost trees and feed trees.	No: The disturbance will not affect dispersal of this species, which travels long distances between suitable foraging trees.	Unlikely: Loss of 0.30 ha of potential habitat is unlikely to cause disruption to any ecological significant locations for breeding, feeding or nesting. The species has not been recorded in the Project Area and is likely to occur as an occasional visitor, rather than being a resident.	None known	None known	Unlikely: Loss of 0.30 ha of potential habitat will not substantially interfere with recovery of the species.	No: there will be no significant loss of habitat for this species within the Disturbance Footprint.

Class	Species	Significant Residual Impact Criteria (DEHP 2014)							Significant Residual Impact
		Lead to a long-term decrease in the size of a population.	**Reduce the Extent of Occurrence (EoO) of the species.**	**Fragment an existing population / result in genetically distinct populations forming as a result of habitat isolation.**	**Cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.**	**Result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Birds	*Gallinago hardwickii* Latham's Snipe NC Act: Vulnerable	No: The species is an occasional visitor in low numbers to the region. There are no important populations of the species in or near the Project Area.	No. The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only. This is a trans-continental species therefore there will be no reduction in EoO as a result of Project activities.	No: The species is mobile and wide-ranging and occurs only seasonally in the region. The proposed development is unlikely to restrict dispersal in this species, nor result in the formation of genetically distinct populations.	No: The Project Area is not an ecologically significant location for the species. Similar areas used for foraging, migration and/or resting are abundant in the surrounding landscape. The species does not breed within Australia.	None known	None known	No: The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.
Birds	*Hirundapus caudacutus* White-throated Needletail NC Act: Vulnerable	No: The species is an aerial feeding insectivore that forages over a wide range of intact and modified landscapes, with a general preference for wooded areas. It does not breed in Australia during its summer presence.	No: The proposed disturbance is not materially relevant to the species.	No: The proposed disturbance is not materially relevant to the species.	No: No impact on foraging resources is anticipated, no other critical locations are relevant to the species in Australia. The species roosts overnight in tall trees along scarps and is unlikely to roost in the Project Area.	None known	None known	No: The proposed disturbance will not reduce the extent of remnant woodland. The species does not breed in Australia.	No: The proposed disturbance is not materially relevant to the species.

Class	Species	Significant Residual Impact Criteria (DEHP 2014)							Significant Residual Impact
		Lead to a long-term decrease in the size of a population.	**Reduce the Extent of Occurrence (EoO) of the species.**	**Fragment an existing population / result in genetically distinct populations forming as a result of habitat isolation.**	**Cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.**	**Result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Birds	*Rostratula australis* Australian Painted Snipe NC Act: Endangered	No: The species is a rare visitor in very low numbers to the region. There are no known important populations of the species in or near the Project Area.	No: The available wetland habitat within the Project Area (0.60 ha) is likely to support only a few individuals during favourable conditions in spring-summer only. The disturbance will not affect the broader distribution of the species which is extensive across Australia.	No: The species is mobile and wide-ranging and occurs only sporadically in the region. The proposed development is unlikely to restrict dispersal in this species, nor result in the formation of genetically distinct populations.	No: The Project Area is not an ecologically significant location for the species. Similar areas used for foraging, migration and/or resting are abundant in the surrounding landscape. Breeding has been recorded in all months of the year in response to wetland conditions. The small and highly ephemeral nature of wetlands within the Project Area are unlikely to be attractive for breeding by this species.	None known.	None known.	No: The Project is unlikely to cause harm to any individuals and is therefore unlikely to interfere with recovery of the species.	No: There will be no substantial decrease in available foraging habitat within the Project Area i.e. there will be disturbance to only 0.60 ha of mapped wetland habitat. Total available mapped wetland habitat available within the Project Area is 7.31 ha. There will be no loss if individuals as a result of Project activities.

Class	Species	Significant Residual Impact Criteria (DEHP 2014)							Significant Residual Impact
		Lead to a long-term decrease in the size of a population.	**Reduce the Extent of Occurrence (EoO) of the species.**	**Fragment an existing population / result in genetically distinct populations forming as a result of habitat isolation.**	**Cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.**	**Result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Mammals	*Phascolarctos cinereus* Koala NC Act: Endangered	Unlikely: Potential loss of 0.30 ha of potential habitat will not lead to a decrease in size of the local population.	Unlikely: No sign of Koala was detected within the Project Area. It is likely that the Project Area would be used by occasional transient individuals. The loss of 0.30 ha of potential habitat in the Disturbance Footprint is unlikely to affect the occurrence of Koala within the Project Area.	No: Koala are capable of crossing gaps between habitat patches and may use isolated paddock trees. The loss of several small areas of potential habitat, summing to 0.30 ha, will not disrupt habitat corridors through this area and will have negligible effect on Koala dispersal through the Project Area.	Unlikely: The loss of several small areas of potential habitat, summing to 0.30 ha, is unlikely to have measurable impacts on occasional Koala usage of the Project Area. All habitat within the Project Area is already fragmented and disturbed by thinning, grazing, weeds and edge effects. The Disturbance Footprint is a small proportion of this habitat and would require the potential removal of <15 mature trees.	None known	None known: chlamydia is present in the Koala population of southern inland Queensland but this bacterial disease is unlikely to be exacerbated by the proposed development.	Unlikely: The loss of several small areas of potential habitat, totalling 0.30 ha will have minimal effect on the recovery of Koala in this area.	No: The proposed development will result in the loss of up to 0.30 ha of potential habitat (RE 11.3.2) spread across several fragments. This small area is unlikely to reduce Koala numbers or to disrupt Koala movement through the area. No evidence of Koala was found within the Project Area and it is likely that Koala occurrence within the Project Area is occasional and transient.

Class	Species	Significant Residual Impact Criteria (DEHP 2014)							Significant Residual Impact
		Lead to a long-term decrease in the size of a population.	**Reduce the Extent of Occurrence (EoO) of the species.**	**Fragment an existing population / result in genetically distinct populations forming as a result of habitat isolation.**	**Cause disruption to ecologically significant locations (breeding, feeding, nesting, migration or resting sites) of a species.**	**Result in invasive species that are harmful to an endangered or vulnerable species becoming established in the endangered or vulnerable species' habitat.**	**Introduce disease that may cause the population to decline.**	**Interfere with the recovery of the species.**	
Reptiles	*Egernia rugosa* Yakka Skink NC Act: Vulnerable	Unlikely: Removal of logs and accumulations of woody debris in 0.30 ha of potential habitat within the Disturbance Footprint could reduce some shelter and breeding habitat for this species. However, these features are scarce within the Project Area (BioCondition scores for woody debris averaged 20% of benchmark values) and low numbers of logs/log piles were recorded in microhabitat assessments.	Unlikely: Loss of 0.30 ha of potential habitat could potentially impact any resident individuals. However, few individuals would occupy this small area. The species was not detected within the Project Area and shelter habitat features were scarce. The disturbance will not affect the broader distribution of the species.	No: The species is mobile and the proposed disturbance does not pose a barrier to dispersal of this species.	Unlikely: Removal of logs and large woody debris may reduce shelter and breeding habitat. However, these habitat features are scarce in the Project Area and within the Disturbance Footprint.	None known.	None known.	Unlikely: Loss of 0.30 ha, across several habitat patches could potentially impact on any resident individuals but the disturbance is unlikely to affect overall abundance and occurrence within the region.	No: The presence of this species was not confirmed within the Project Area. Loss of up to 0.30 ha of potential habitat (RE 11.3.2) could impact on any resident individuals. However, this small area would hold few, if any, individuals and these impacts may be mitigated by preclearing of the route by a fauna spotter.
Reptiles	*Hemiaspis damelii* Grey Snake NC Act: Endangered	Unlikely: 0.30 ha of potential habitat occurs within the Disturbance Footprint. Mapped habitat comprises fragmented patches of riparian or floodplain woodland.	Unlikely: The Project Area is peripheral to the species distribution. If the species occurs in this area, it is unlikely to be restricted to the mapped habitat.	No: The proposed development will not exacerbate existing fragmentation.	Unlikely: The 0.30 ha of mapped shelter, foraging, breeding and dispersal habitat comprises disturbed alluvial woodland fragments. Similar features occur in the vicinity and this habitat is unlikely to be limiting. Loss if 0.30 ha of potential habitat is unlikely to contribute to a decline in the species.	None known.	None known.	No: Only 0.30 ha of mapped habitat is within the Disturbance Footprint with similar habitat abundant in the vicinity.	No: Presence of this species within the Project Area was not confirmed during the field survey. The Project Area is peripheral to the species distribution and there are no records in the vicinity. Potentially suitable floodplain woodland and ephemeral wetland habitat (RE 11.3.2) occurs beyond the Disturbance Footprint.

4.1.2.4. SLC fauna

SLC fauna (other than those that are also migratory species) that may potentially occur within the Project Area are discussed in section 3.2.7. Predictive habitat for SLC fauna potentially occurring within the Disturbance Footprint is shown in Appendix D. Potential impacts on SLC species are assessed in Table 14.

Table 18: Assessment of potential significant residual impacts (as per SRI criteria within DEHP (2014) upon NC Act-listed SLC (non-migratory) fauna species potentially present within the Project Area.

Class	Species	Significant Residual Impact (DEHP 2014)					
		Lead to a long-term decrease in the size of a local population.	**Reduce the Extent of Occurrence (EoO) of the species.**	**Fragmentation of an existing population.**	**Result in genetically distinct populations forming as a result of habitat isolation.**	**Disruption to ecologically significant locations (breeding, feeding or nesting sites) of a species.**	**Significant Residual Impact**
Mammals	*Tachyglossus aculeatus* Short-beaked Echidna	Unlikely: Loss of up to 0.30 ha of potential habitat comprising regrowth and remnant. Removal of logs and accumulations of woody debris could reduce shelter and breeding habitat for this species. However, these features are scarce within the Project Area and Disturbance Footprint (BioCondition scores for woody debris averaged 20% of benchmark values. 1-5 logs with hollows in each 0.5 ha assessment site).	Unlikely: Loss of up to 0.30 ha of potential habitat could potentially impact upon foraging or sheltering resident individuals. However, few individuals would occur in these small peripheral areas. The species was not detected within the Project Area and critical habitat features (e.g. log piles, large logs, rock crevices) were scarce or absent. The disturbance will not affect the broader distribution of the species.	No: The disturbance does not pose a barrier to dispersal of this mobile species.	No: The disturbance does not pose a barrier to dispersal of this species.	Unlikely: Removal of some logs and large woody debris may reduce shelter and breeding habitat. However, these habitat features are scarce in the Project Area and Disturbance Footprint. Available habitat in the Project Area is 153.08 ha	No: The species was not confirmed present within the Project Area. Loss of up to 0.30 ha of potential habitat (RE 11.3.2) could impact on any resident individuals. However, this small area would hold few, if any, individuals and these impacts may be mitigated by preclearing of the route by a fauna spotter. The species is likely to have a patchy occurrence in the Project Area and suitable habitat features such as logs and woody debris were scarce within the Project Area.

4.1.2.5. Environmentally Sensitive Areas

The Disturbance Footprint includes a total of 0.30 ha of ESA category C, comprising one Of Concern regional ecosystem (RE 11.3.2). Impacts on these areas are addressed in section 4.1.2.1 (Regional Ecosystems).

The following Category C ESA is present within the Disturbance Footprint:

- ground-truthed protected wildlife habitat: Glossy Black-Cockatoo (*Calyptorhynchus lathami lathami*) - NC Act: Vulnerable: remnant and regrowth RE 11.3.2 (0.30 ha).
- ground-truthed protected wildlife habitat: White-throated Needletail (*Hirundapus caudacutus*) - NC Act: Vulnerable: remnant and regrowth RE 11.3.2 (0.30 ha).
- ground-truthed protected wildlife habitat: Koala (*Phascolarctos cinereus*) - NC Act: Endangered: remnant and regrowth RE 11.3.2 (0.30 ha).
- ground-truthed protected wildlife habitat: Yakka Skink (*Egernia rugosa*) - NC Act: Vulnerable: remnant and regrowth RE 11.3.2 (0.30 ha).
- ground-truthed protected wildlife habitat: Grey Snake (*Hemiaspis damelii*) - NC Act: Endangered: remnant and regrowth RE 11.3.2 (0.30 ha).

4.1.2.6. Watercourses, Wetlands & Springs

The Project Area includes crossing points on mapped streams, comprising first to third order intermittent streams. No assessment of stream impacts was conducted within this scope of works. There are no state government mapped wetlands or springs within the Project Area. The Project will potentially impact on 0.6 ha of ground-truthed wetland which may provide temporary habitat for MNES/MSES wetland fauna species.

5. Conclusions

An ecological assessment within the Project Area identified the following ecological values/potential constraints:

Matters of National Environmental Significance:

- Two TEC were detected within the Project Area:
  - Poplar Box grassy woodland on alluvial plains; and
  - Weeping Myall woodlands.
- No EPBC Act-listed threatened flora species were detected within the Project Area and no suitable habitat is present for species identified within desktop searches.
- Four species of WoNS were detected within the Project Area, namely:
  - Common Pest Pear (*Opuntia stricta*);
  - Sulphur Cactus (*O. sulphurea*);
  - Velvety Tree Pear (*O. tomentosa*); and
  - African Boxthorn (*Lycium ferocissimum*).
- No EPBC Act-listed threatened fauna species were detected within the Project Area:
- Potential habitat for the following EPBC Act-listed threatened fauna species was present within the Project Area:
  - Sharp-tailed Sandpiper (*Calidris acuminata*) – Vulnerable;
  - Glossy Black-Cockatoo (*Calyptorhynchus lathami lathami*) – Vulnerable;
  - Latham's Snipe (*Gallinago hardwickii*) – Vulnerable;
  - White-throated Needletail (*Hirundapus caudacutus*) – Vulnerable;
  - Australian Painted Snipe (*Rostratula australis*) – Endangered;
  - Koala (*Phascolarctos cinereus*) – Endangered;
  - Yakka Skink (*Egernia rugosa*) – Vulnerable; and

- Grey Snake (*Hemiaspis damelii*) – Endangered.

- Potential habitat for the following EPBC Act-listed threatened fauna species is present within the Disturbance Footprint:
  - Sharp-tailed Sandpiper – 0.60 ha;
  - Glossy Black-Cockatoo – 0.30 ha;
  - Latham's Snipe – 0.60 ha;
  - White-throated Needletail – 0.30 ha;
  - Australian Painted Snipe – 0.60 ha;
  - Koala – 0.30 ha;
  - Yakka Skink – 0.30 ha; and
  - Grey Snake – 0.30 ha.
- Potential habitat for multiple EPBC Act-listed migratory fauna species is present within the Project Area.
- No Wetlands of International or National Significance occur within the Project Area.

Significant Impacts

- No TEC is present within the Disturbance Footprint and therefore no significant impact to TEC will occur as part of the proposed development.
- No significant impact to MNES flora will occur as part of the proposed development.
- No significant impact to MNES wetlands will occur as part of the proposed development.
- No significant impact to MNES threatened and/or migratory fauna populations/habitat is expected as a result of the proposed development. This is due to existing severe fragmentation of vegetation/habitat, generally poor habitat quality, the very small and localised disturbance area relative to surrounding habitat patches and citing of infrastructure to largely avoid disturbance to vegetation.

Matters of State Environmental Significance and/or potential constraints:

- Two Endangered RE are present within the Project Area these being:
  - 11.3.17: *Eucalyptus populnea* woodland with *Acacia harpophylla* and/or *Casuarina cristata* on alluvial plains; and
  - 11.9.10: *Eucalyptus populne*a open forest with a secondary tree layer of *Acacia harpophylla* and sometimes *Casuarina cristata* on fine-grained sedimentary rocks.
- Three Of Concern RE are present within the Project Area these being:
  - 11.3.2: *Eucalyptus populnea* woodland on alluvial plains;
  - 11.3.25: *Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage lines; and
  - 11.9.7: *Eucalyptus populnea*, *Eremophila mitchellii* shrubby woodland on fine-grained sedimentary rocks.
- One Of Concern RE is present within the Disturbance Footprint:
  - 11.3.2: *Eucalyptus populnea* woodland on alluvial plains.
- BioCondition scores for regrowth and remnant vegetation within the Project Area varied from 0.47 to 0.60 indicating significant disturbance and loss of ecological integrity relative to benchmark sites.
- No NC Act-listed threatened flora species were detected within the Project Area and no suitable habitat is present for these species.
- Four Biosecurity Act Category 3 Restricted Matter invasive plants were present within the Project Area, these being the three WoNS species (above): Velvety Tree Pear (*Opuntia tomentosa*), Sulphur Cactus (*O. sulphurea*), Common Pest Pear (*O. stricta*) and African Boxthorn (*Lycium ferocissimum*).

- No NC Act-listed threatened fauna species were detected within the Project Area.
- Potentially suitable habitat is present for multiple NC Act-listed threatened fauna species, including the EPBC Act-listed species (above), and additionally:
    - Woma (*Aspidites ramsayi*) (NC Act - Near Threatened).
- Potentially suitable habitat is present for one NC Act-listed SLC fauna species, this being:
    - Short-beaked Echidna (*Tachyglossus aculeatus*).
- The Project Area includes scarce potential fauna breeding and/or shelter places (e.g. fallen timber and wood piles, logs, decorticating trees, hollow-bearing live or dead trees and small ephemeral wetlands).
- No mapped referable wetlands occur within the Project Area. Several wetlands were ground-truthed as being present within the Project Area and Disturbance Footprint.
- No lakes or springs occur within the Project Area.
- Several mapped streams occur within the Project Area varying from Order 1 to 3 intermittent drainage lines.
- The following Category B ESA are present within the Project Area:
    - areas of ground-truthed Endangered RE (biodiversity status): 11.3.17 and 11.9.10.
- The following Category C ESA are present within the Project Area:
    - areas of ground-truthed Of Concern RE (biodiversity status): 11.3.2, 11.3.25 and 11.9.7.
    - an area validated from ground-truthing surveys as 'protected wildlife habitat' that is category A, B or C on the Remnant Vegetation Management Map, in accordance with section 20A of the VMA, for a species of wildlife listed as critically endangered, endangered or vulnerable under the NC Act as follows:
        - ground-truthed protected wildlife habitat: Glossy Black-Cockatoo (*Calyptorhynchus lathami lathami*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.3.25, 11.9.10.
        - ground-truthed protected wildlife habitat: White-throated Needletail (*Hirundapus caudacutus*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.3.25, 11.9.10.
        - ground-truthed protected wildlife habitat: Koala (*Phascolarctos cinereus*) - NC Act: Endangered: remnant and regrowth REs 11.3.2, 11.3.25, 11.9.10.
        - ground-truthed protected wildlife habitat: Yakka Skink (*Egernia rugosa*) - NC Act: Vulnerable: remnant and regrowth: RE 11.3.2, 11.9.10.
        - ground-truthed protected wildlife habitat: Grey Snake (*Hemiaspis damelii*) - NC Act: Endangered: remnant and regrowth REs 11.3.2, 11.3.25.

Significant Residual Impacts

- No significant residual impact to MSES flora will occur as part of the proposed development.
- No areas mapped as Category B (remnant) occur within the regulated vegetation management map and therefore no significant residual impact to MSES regulated vegetation will occur as part of the proposed development.
- No significant residual impact to MSES connectivity areas will occur as part of the proposed development.
- No significant residual impact to MSES threatened and SLC fauna populations/habitat is expected as a result of the proposed development. This is due to existing severe fragmentation of vegetation/habitat, generally poor habitat quality, the very small and localised disturbance area relative to surrounding habitat patches and citing of infrastructure to largely avoid disturbance to vegetation.
- No MSES wetlands occur within the Project Area and therefore no significant residual impact will occur as part of the proposed development.
- No MSES watercourses occur within the Project Area and therefore no significant residual impact will occur as part of the proposed development.

6. Recommendations

It is recommended that the findings in this report are considered during detailed project planning such that disturbance to the ecological values within the Project Area may be avoided wherever practical.

Where disturbance is unavoidable, the following impact mitigation measures should be implemented in accordance with the approved site environmental management plan and regulatory approval conditions:

- Briefing of Project personnel on habitat values, species, possible impacts and procedural responses.
- As the Project Area is already fragmented and flora/fauna habitat is limited, disturbance to remaining regrowth and remnant vegetation should be avoided wherever possible and practical.
- Utilise existing roads where possible for access tracks including any existing crossings of watercourses and through vegetation strips.
- Fauna spotter to be present on-site to move fauna and habitat features prior to and during any clearing within identified regrowth and/or remnant vegetation and in identified wetland areas.
- Implement weed hygiene measures for vehicles and machinery entering the Project Area;
- Implement weed control measures for Sulphur Cactus (*Opuntia sulphurea*), a Prohibited weed under the Biosecurity Act, within the Project Area prior to any disturbance.

EPBC Act Protected Matters Report

This report provides general guidance on matters of national environmental significance and other matters protected by the EPBC Act in the area you have selected. Please see the caveat for interpretation of information provided here.

Report created: 23-Oct-2024

Summary

Details

- Matters of NES
- Other Matters Protected by the EPBC Act
- Extra Information

Summary

Matters of National Environment Significance

This part of the report summarises the matters of national environmental significance that may occur in, or may relate to, the area you nominated. Further information is available in the detail part of the report, which can be accessed by scrolling or following the links below. If you are proposing to undertake an activity that may have a significant impact on one or more matters of national environmental significance then you should consider the Administrative Guidelines on Significance.

World Heritage Properties:	None
National Heritage Places:	None
Wetlands of International Importance (Ramsar	4
Great Barrier Reef Marine Park:	None
Commonwealth Marine Area:	None
Listed Threatened Ecological Communities:	5
Listed Threatened Species:	28
Listed Migratory Species:	9

Other Matters Protected by the EPBC Act

This part of the report summarises other matters protected under the Act that may relate to the area you nominated. Approval may be required for a proposed activity that significantly affects the environment on Commonwealth land, when the action is outside the Commonwealth land, or the environment anywhere when the action is taken on Commonwealth land. Approval may also be required for the Commonwealth or Commonwealth agencies proposing to take an action that is likely to have a significant impact on the environment anywhere.

The EPBC Act protects the environment on Commonwealth land, the environment from the actions taken on Commonwealth land, and the environment from actions taken by Commonwealth agencies. As heritage values of a place are part of the 'environment', these aspects of the EPBC Act protect the Commonwealth Heritage values of a Commonwealth Heritage place. Information on the new heritage laws can be found at https://www.dcceew.gov.au/parks-heritage/heritage

A permit may be required for activities in or on a Commonwealth area that may affect a member of a listed threatened species or ecological community, a member of a listed migratory species, whales and other cetaceans, or a member of a listed marine species.

Commonwealth Lands:	None
Commonwealth Heritage Places:	None
Listed Marine Species:	14
Whales and Other Cetaceans:	None
Critical Habitats:	None
Commonwealth Reserves Terrestrial:	None
Australian Marine Parks:	None
Habitat Critical to the Survival of Marine Turtles:	None

Extra Information

This part of the report provides information that may also be relevant to the area you have

State and Territory Reserves:	None
Regional Forest Agreements:	None
Nationally Important Wetlands:	None
EPBC Act Referrals:	10
Key Ecological Features (Marine):	None
Biologically Important Areas:	None
Bioregional Assessments:	1
Geological and Bioregional Assessments:	None

Details

Matters of National Environmental Significance

Wetlands of International Importance (Ramsar Wetlands) [Resource Information]

Ramsar Site Name	Proximity	Buffer Status
Banrock station wetland complex	1100 - 1200km upstream from Ramsar site	In feature area
Narran lake nature reserve	300 - 400km upstream from Ramsar site	In feature area
Riverland	1100 - 1200km upstream from Ramsar site	In feature area
The coorong, and lakes alexandrina and albert wetland	1300 - 1400km upstream from Ramsar site	In feature area

Listed Threatened Ecological Communities [Resource Information]

For threatened ecological communities where the distribution is well known, maps are derived from recovery plans, State vegetation maps, remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.
Status of Vulnerable, Disallowed and Ineligible are not MNES under the EPBC Act.

Community Name	Threatened Category	Presence Text	Buffer Status
Brigalow (Acacia harpophylla dominant and co-dominant)	Endangered	Community known to occur within area	In buffer area only
Coolibah - Black Box Woodlands of the Darling Riverine Plains and the Brigalow Belt South Bioregions	Endangered	Community may occur within area	In feature area
Poplar Box Grassy Woodland on Alluvial Plains	Endangered	Community likely to occur within area	In feature area
Semi-evergreen vine thickets of the Brigalow Belt (North and South) and Nandewar Bioregions	Endangered	Community likely to occur within area	In buffer area only
Weeping Myall Woodlands	Endangered	Community likely to occur within area	In feature area

Listed Threatened Species [Resource Information]

Status of Conservation Dependent and Extinct are not MNES under the EPBC Act.
Number is the current name ID.

Scientific Name	Threatened Category	Presence Text	Buffer Status

Scientific Name	Threatened Category	Presence Text	Buffer Status
BIRD			
Aphelocephala leucopsis Southern Whiteface [529]	Vulnerable	Species or species habitat may occur within area	In feature area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area	In feature area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area	In feature area
Calyptorhynchus lathami lathami South-eastern Glossy Black-Cockatoo [67036]	Vulnerable	Species or species habitat may occur within area	In feature area
Climacteris picumnus victoriae Brown Treecreeper (south-eastern) [67062]	Vulnerable	Species or species habitat may occur within area	In buffer area only
Erythrotriorchis radiatus Red Goshawk [942]	Endangered	Species or species habitat may occur within area	In feature area
Falco hypoleucos Grey Falcon [929]	Vulnerable	Species or species habitat likely to occur within area	In feature area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]	Vulnerable	Species or species habitat may occur within area	In feature area
Geophaps scripta scripta Squatter Pigeon (southern) [64440]	Vulnerable	Species or species habitat may occur within area	In feature area
Grantiella picta Painted Honeyeater [470]	Vulnerable	Species or species habitat likely to occur within area	In feature area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat may occur within area	In feature area

Scientific Name	Threatened Category	Presence Text	Buffer Status
Rostratula australis			
Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area	In feature area
Stagonopleura guttata			
Diamond Firetail [59398]	Vulnerable	Species or species habitat may occur within area	In feature area
FISH			
Maccullochella peelii			
Murray Cod [66633]	Vulnerable	Species or species habitat may occur within area	In buffer area only
MAMMAL			
Chalinolobus dwyeri			
Large-eared Pied Bat, Large Pied Bat [183]	Endangered	Species or species habitat may occur within area	In buffer area only
Dasyurus hallucatus			
Northern Quoll, Digul [Gogo-Yimidir], Wijingadda [Dambimangari], Wiminji [Martu] [331]	Endangered	Species or species habitat may occur within area	In feature area
Nyctophilus corbeni			
Corben's Long-eared Bat, South-eastern Long-eared Bat [83395]	Vulnerable	Species or species habitat may occur within area	In feature area
Petauroides volans			
Greater Glider (southern and central) [254]	Endangered	Species or species habitat likely to occur within area	In feature area
Phascolarctos cinereus (combined populations of Qld, NSW and the ACT)			
Koala (combined populations of Queensland, New South Wales and the Australian Capital Territory) [85104]	Endangered	Species or species habitat likely to occur within area	In feature area
PLANT			
Cadellia pentastylis			
Ooline [9828]	Vulnerable	Species or species habitat likely to occur within area	In feature area
Dichanthium setosum			
bluegrass [14159]	Vulnerable	Species or species habitat likely to occur within area	In feature area

Scientific Name	Threatened Category	Presence Text	Buffer Status
Lepidium monoplocoides			
Winged Pepper-cress [9190]	Endangered	Species or species habitat may occur within area	In feature area
Vincetoxicum forsteri listed as Tylophora linearis			
[92384]	Endangered	Species or species habitat may occur within area	In buffer area only
REPTILE			
Anomalopus mackayi			
Five-clawed Worm-skink, Long-legged Worm-skink [25934]	Vulnerable	Species or species habitat may occur within area	In feature area
Delma torquata			
Adorned Delma, Collared Delma [1656]	Vulnerable	Species or species habitat may occur within area	In feature area
Egernia rugosa			
Yakka Skink [1420]	Vulnerable	Species or species habitat may occur within area	In feature area
Furina dunmalli			
Dunmall's Snake [59254]	Vulnerable	Species or species habitat may occur within area	In feature area
Hemiaspis damelii			
Grey Snake [1179]	Endangered	Species or species habitat likely to occur within area	In feature area

Listed Migratory Species		[Resource Information]	
Scientific Name	Threatened Category	Presence Text	Buffer Status
Migratory Marine Birds			
Apus pacificus			
Fork-tailed Swift [678]		Species or species habitat likely to occur within area	In feature area
Migratory Terrestrial Species			
Cuculus optatus			
Oriental Cuckoo, Horsfield's Cuckoo [86651]		Species or species habitat may occur within area	In feature area
Hirundapus caudacutus			
White-throated Needletail [682]	Vulnerable	Species or species habitat may occur within area	In feature area

Scientific Name	Threatened Category	Presence Text	Buffer Status
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area	In feature area
Migratory Wetlands Species			
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area	In feature area
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area	In feature area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area	In feature area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area	In feature area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]	Vulnerable	Species or species habitat may occur within area	In feature area

Other Matters Protected by the EPBC Act

Listed Marine Species		[Resource Information]	
Scientific Name	Threatened Category	Presence Text	Buffer Status
Bird			
Actitis hypoleucos Common Sandpiper [59309]		Species or species habitat may occur within area	In feature area
Apus pacificus Fork-tailed Swift [678]		Species or species habitat likely to occur within area overfly marine area	In feature area
Bubulcus ibis as Ardea ibis Cattle Egret [66521]		Species or species habitat may occur within area overfly marine area	In feature area

Scientific Name	Threatened Category	Presence Text	Buffer Status
Calidris acuminata Sharp-tailed Sandpiper [874]	Vulnerable	Species or species habitat may occur within area	In feature area
Calidris ferruginea Curlew Sandpiper [856]	Critically Endangered	Species or species habitat may occur within area overfly marine area	In feature area
Calidris melanotos Pectoral Sandpiper [858]		Species or species habitat may occur within area overfly marine area	In feature area
Chalcites osculans as Chrysococcyx osculans Black-eared Cuckoo [83425]		Species or species habitat likely to occur within area overfly marine area	In feature area
Gallinago hardwickii Latham's Snipe, Japanese Snipe [863]	Vulnerable	Species or species habitat may occur within area overfly marine area	In feature area
Haliaeetus leucogaster White-bellied Sea-Eagle [943]		Species or species habitat may occur within area	In feature area
Hirundapus caudacutus White-throated Needletail [682]	Vulnerable	Species or species habitat may occur within area overfly marine area	In feature area
Merops ornatus Rainbow Bee-eater [670]		Species or species habitat may occur within area overfly marine area	In feature area
Motacilla flava Yellow Wagtail [644]		Species or species habitat may occur within area overfly marine area	In feature area
Myiagra cyanoleuca Satin Flycatcher [612]		Species or species habitat may occur within area overfly marine area	In feature area

Scientific Name	Threatened Category	Presence Text	Buffer Status
Rostratula australis as Rostratula benghalensis (sensu lato)			
Australian Painted Snipe [77037]	Endangered	Species or species habitat likely to occur within area overfly marine area	In feature area

Extra Information

EPBC Act Referrals				[Resource Information]
Title of referral	Reference	Referral Outcome	Assessment Status	Buffer Status
Coal Seam Gas Field Development for Natural Gas Liquefaction Park, Curtis Island	2008/4059		Post-Approval	In buffer area only
Controlled action				
Expansion of Coal Seam Gas Fields	2009/4974	Controlled Action	Post-Approval	In feature area
Queensland Hunter Gas Pipeline, approximately 825 km in length	2008/4483	Controlled Action	Completed	In buffer area only
Santos GLNG Gas Field Development Project, QLD	2012/6615	Controlled Action	Post-Approval	In feature area
Not controlled action				
Comet Ridge to Wallumbilla natural gas pipeline	2006/2604	Not Controlled Action	Completed	In buffer area only
Construct and operate 112km long underground gas transmission pipeline	2008/4358	Not Controlled Action	Completed	In buffer area only
Improving rabbit biocontrol: releasing another strain of RHDV, sthrn two thirds of Australia	2015/7522	Not Controlled Action	Completed	In feature area
QSN3 Project, expand 935km gas pipeline and supporting infrastructure	2009/5072	Not Controlled Action	Completed	In buffer area only
Queensland Hunter Gas Pipeline, approximately 833 km in length	2008/4620	Not Controlled Action	Completed	In buffer area only
Reedy Creek to Wallumbilla gas transmission pipeline, sthrn Qld	2017/7888	Not Controlled Action	Completed	In buffer area only

Caveat

1 PURPOSE

This report is designed to assist in identifying the location of matters of national environmental significance (MNES) and other matters protected by the Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act) which may be relevant in determining obligations and requirements under the EPBC Act.

The report contains the mapped locations of:

- World and National Heritage properties;
- Wetlands of International and National Importance;
- Commonwealth and State/Territory reserves;
- distribution of listed threatened, migratory and marine species;
- listed threatened ecological communities; and
- other information that may be useful as an indicator of potential habitat value.

2 DISCLAIMER

This report is not intended to be exhaustive and should only be relied upon as a general guide as mapped data is not available for all species or ecological communities listed under the EPBC Act (see below). Persons seeking to use the information contained in this report to inform the referral of a proposed action under the EPBC Act should consider the limitations noted below and whether additional information is required to determine the existence and location of MNES and other protected matters.

Where data are available to inform the mapping of protected species, the presence type (e.g. known, likely or may occur) that can be determined from the data is indicated in general terms. It is the responsibility of any person using or relying on the information in this report to ensure that it is suitable for the circumstances of any proposed use. The Commonwealth cannot accept responsibility for the consequences of any use of the report or any part thereof. To the maximum extent allowed under governing law, the Commonwealth will not be liable for any loss or damage that may be occasioned directly or indirectly through the use of, or reliance

3 DATA SOURCES

Threatened ecological communities

For threatened ecological communities where the distribution is well known, maps are generated based on information contained in recovery plans, State vegetation maps and remote sensing imagery and other sources. Where threatened ecological community distributions are less well known, existing vegetation maps and point location data are used to produce indicative distribution maps.

Threatened, migratory and marine species

Threatened, migratory and marine species distributions have been discerned through a variety of methods. Where distributions are well known and if time permits, distributions are inferred from either thematic spatial data (i.e. vegetation, soils, geology, elevation, aspect, terrain, etc.) together with point locations and described habitat; or modelled (MAXENT or BIOCLIM habitat modelling) using

Where little information is available for a species or large number of maps are required in a short time-frame, maps are derived either from 0.04 or 0.02 decimal degree cells; by an automated process using polygon capture techniques (static two kilometre grid cells, alpha-hull and convex hull); or captured manually or by using topographic features (national park boundaries, islands, etc.).

In the early stages of the distribution mapping process (1999-early 2000s) distributions were defined by degree blocks, 100K or 250K map sheets to rapidly create distribution maps. More detailed distribution mapping methods are used to update these distributions

4 LIMITATIONS

The following species and ecological communities have not been mapped and do not appear in this report:

- threatened species listed as extinct or considered vagrants;
- some recently listed species and ecological communities;
- some listed migratory and listed marine species, which are not listed as threatened species; and
- migratory species that are very widespread, vagrant, or only occur in Australia in small numbers.

The following groups have been mapped, but may not cover the complete distribution of the species:

- listed migratory and/or listed marine seabirds, which are not listed as threatened, have only been mapped for recorded
- seals which have only been mapped for breeding sites near the Australian continent

The breeding sites may be important for the protection of the Commonwealth Marine environment.

Refer to the metadata for the feature group (using the Resource Information link) for the currency of the information.

Environmental Reports

Matters of State Environmental Significance

For the selected area of interest

ATP: 2053

Environmental Reports - General Information

The Environmental Reports portal provides for the assessment of selected matters of interest relevant to a user specified location, or area of interest (AOI). All area and derivative figures are relevant to the extent of matters of interest contained within the AOI unless otherwise stated. Please note, if a user selects an AOI via the "central coordinates" option, the resulting assessment area encompasses an area extending for a 2km radius from the point of interest.

All area and area derived figures included in this report have been calculated via reprojecting relevant spatial features to Albers equal-area conic projection (central meridian = 146, datum Geocentric Datum of Australia 2020). As a result, area figures may differ slightly if calculated for the same features using a different co-ordinate system.

Figures in tables may be affected by rounding.

The matters of interest reported on in this document are based upon available state mapped datasets. Where the report indicates that a matter of interest is not present within the AOI (e.g. where area related calculations are equal to zero, or no values are listed), this may be due either to the fact that state mapping has not been undertaken for the AOI, that state mapping is incomplete for the AOI, or that no values have been identified within the site.

The information presented in this report should be considered as a guide only and a field survey may be required to validate values on the ground.

Please direct queries about these reports to: Planning.Support@detsi.qld.gov.au

Disclaimer

Whilst every care is taken to ensure the accuracy of the information provided in this report, the Queensland Government makes no representations or warranties about its accuracy, reliability, completeness, or suitability, for any particular purpose and disclaims all responsibility and all liability (including without limitation, liability in negligence) for all expenses, losses, damages (including indirect or consequential damage) and costs which the user may incur as a consequence of the information being inaccurate or incomplete in any way and for any reason.

Matters of State Environmental Significance (MSES)

MSES Categories

Queensland's State Planning Policy (SPP) includes a biodiversity State interest that states:

'The sustainable, long-term conservation of biodiversity is supported. Significant impacts on matters of national or state environmental significance are avoided, or where this cannot be reasonably achieved; impacts are minimised and residual impacts offset.'

The MSES mapping product is a guide to assist implementation of the SPP biodiversity policy. While it supports the SPP, the mapping does not replace the regulatory mapping or environmental values specifically called up under other laws or regulations.

The SPP defines matters of state environmental significance as:

- Protected areas (including all classes of protected area except coordinated conservation areas) under the *Nature Conservation Act 1992;*

- Marine parks and land within a 'marine national park', 'conservation park', 'scientific research', 'preservation' or 'buffer' zone under the Marine Parks Act 2004 ;

- Areas within declared fish habitat areas that are management A areas or management B areas under the Fisheries Regulation 2008;

- *Threatened wildlife under the Nature Conservation Act 1992* and special least concern animals under the Nature Conservation (Wildlife) Regulation 2006;

- Regulated vegetation under the *Vegetation Management Act 1999* that is:

  - Category B areas on the regulated vegetation management map, that are 'endangered' or 'of concern' regional ecosystems;
  - Category C areas on the regulated vegetation management map that are 'endangered' or 'of concern' regional ecosystems;
  - Category R areas on the regulated vegetation management map;
  - Regional ecosystems that intersect with watercourses identified on the vegetation management watercourse and drainage feature map;
  - Regional ecosystems that intersect with wetlands identified on the vegetation management wetlands map;

- Strategic Environmental Areas under the *Regional Planning Interests Act 2014* ;

- Wetlands in a wetland protection area of wetlands of high ecological significance shown on the Map of Queensland Wetland Environmental Values under the Environment Protection Regulation 2019;

- Wetlands and watercourses in high ecological value waters defined in the Environmental Protection (Water) Policy 2009, schedule 2;
- Legally secured offset areas.

MSES Values Present

The MSES values that are present in the area of interest are summarised in the table below:

Table 2: Summary of MSES present within the AOI

1a Protected Areas- estates	0 ha	0.0%
1b Protected Areas- nature refuges	0 ha	0.0%
1c Protected Areas- special wildlife reserves	0 ha	0.0%
2 State Marine Parks- highly protected zones	0 ha	0.0%
3 Fish habitat areas (A and B areas)	0 ha	0.0%
4 Strategic Environmental Areas (SEA)	0 ha	0.0%
5 High Ecological Significance wetlands on the Map of Queensland Wetland Environmental Values	0 ha	0.0%
6a High Ecological Value (HEV) wetlands	0 ha	
6b High Ecological Value (HEV) waterways	0 km	Not applicable
7a Threatened (endangered or vulnerable) wildlife	0 ha	0.0%
7b Special least concern animals	0 ha	0.0%
7c i Koala habitat area - core (SEQ)	0 ha	0.0%
7c ii Koala habitat area - locally refined (SEQ)	0 ha	0.0%
7d Sea turtle nesting areas	0 km	Not applicable
8a Regulated Vegetation - Endangered/Of concern in Category B (remnant)	0 ha	0.0%
8b Regulated Vegetation - Endangered/Of concern in Category C (regrowth)	45.17 ha	3.7%

MSES mapping of sea turtle nesting areas identifies beaches where the recorded number of turtle nests are over 1% of the turtle species or genetic stock. The linework is also deliberately extended along nearby rocky coastlines and headlands to recognise that significant numbers of nesting adults and hatchlings can become disoriented by light pollution from development on rocky coastlines and headlands while navigating offshore from nesting beaches.

Map 5 - MSES - Offset Areas

Appendices

Appendix 1 - Matters of State Environmental Significance (MSES) methodology

MSES mapping is a regional-scale representation of the definition for MSES under the State Planning Policy (SPP). Its primary purpose is to support implementation of the SPP biodiversity policy.

MSES mapping does not replace the regulatory mapping or environmental values specifically called up under other laws or regulations.

MSES mapping does not determine whether state or local development assessment is required. For state assessment triggers refer to the Development Assessment Mapping System (DAMS). For local assessment triggers, refer to the relevant local planning scheme.

The Queensland Government's "Method for mapping - matters of state environmental significance can be downloaded from:

http://www.ehp.qld.gov.au/land/natural-resource/method-mapping-mses.html .

Appendix 2 - Source Data

The datasets listed below are available on request from:

http://qldspatial.information.qld.gov.au/catalogue/custom/index.page

- Matters of State environmental significance

Note: MSES mapping is not based on new or unique data. The primary mapping product draws data from a number of underlying environment databases and geo-referenced information sources. MSES mapping is a versioned product that is updated generally on a twice-yearly basis to incorporate the changes to underlying data sources. Several components of MSES mapping made for the current version may differ from the current underlying data sources. To ensure accuracy, or proper representation of MSES values, it is strongly recommended that users refer to the underlying data sources and review the current definition of MSES in the State Planning Policy, before applying the MSES mapping.

Individual MSES layers can be attributed to the following source data available at QSpatial:

Senior Environmental Advisor

Dear Mr. Clarke:

Santos Roma Phase 7-7B-SD20 (ATP 2053) Water Resources Impact Assessment to support Environmental Authority Application
Final Rev00a

KCB Australia Pty Ltd (KCB) is pleased to provide this Final Water Assessment Report to Santos to support the Environmental Authority application to convert ATP 2053 to a Petroleum Lease (PL). Should you have any queries regarding this document, please do not hesitate to contact the undersigned on SLabuschagne@klohn.com or +61 7 3004 0237.

Yours truly,

KCB AUSTRALIA PTY LTD.

Simone Labuschagne M.Sc Pr.Sci.Nat
Senior Hydrogeologist

EXECUTIVE SUMMARY

Santos and its joint venture partners are proposing a new gas field development located in central-eastern Queensland to supply natural gas to commercial markets. The proposed development will be known as the 'Santos Roma Phase 7-7B-SD20 Development' (hereafter referred to as the Project).

The Project will involve the progressive construction, operation, decommissioning and rehabilitation of up to 24 coal seam gas (CSG) wells, gas and water gathering flowlines and access track infrastructure in petroleum exploration tenure Authority to Prospect (ATP) 2053 (hereafter referred to as the Project Area).

Petroleum exploration activities undertaken by Santos in the Project Area to date include drilling and completion of 5 CSG appraisal wells and construction of associated infrastructure in 2022-2024. These activities are authorised under existing approved Environmental Authority (EA) 0002052. The Project will include the construction/operation of up to 24 CSG wells and their connection to existing approved gas and water gathering lines. The existing 5 wells form part of the proposed 24 CSG wells. Santos is seeking a new EA under the *Environmental Protection Act 1994* (State of Queensland 2024d) to convert the Project Area from an ATP to a new Petroleum Lease (PL) to authorise commercial gas production activities.

In support of the EA application, a water assessment for the Project has been completed and the outcomes of the assessment are presented in this report. The key findings from the assessment are summarised below.

Description of the Project

The Project Area covers approximately 13 km^2 of land located approximately 5 km east of the regional township of Wallumbilla. The project is wholly surrounded by Santos operated Petroleum Leases (PLs) 281, 282, 315, 318 and 1020, authorised under existing *Environment Protection and Biodiversity Conservation Act* (EPBC Act) approvals (EPBC Numbers 2008/4059 and 2012/6615, respectively) and EAs (EPPG00898213 and EPPG00662213), in which Santos is approved to construct/operate up to 4,401 CSG wells.

The Project will include the construction/operation of up to 24 CSG wells and their connection to gas and water gathering lines. CSG and water produced from the Project Area will be sent to existing approved centralised gas and water storage / processing and gas compression facilities located on adjacent Santos owned and operated petroleum tenures. Petroleum activities undertaken on adjacent tenures are authorised under existing EPBC Act approvals and Queensland EAs (as stated above).

Site Conceptualisation

Surface Water Context

The Project Area is located in the upper reaches of the Balonne River sub-basin, which is part of the wider Condamine-Balonne Basin). Key watercourses within the Project Area include Washpool Creek and Middle Creek which are tributaries of Wallumbilla Creek. Watercourse flows in the Project Area are characteristically ephemeral and typically only flow during and immediately following significant rainfall events.

This is a consequence of the Project Area being in the uppermost reaches of the catchment, with limited runoff area. There are no identified third-party surface water users in the vicinity of the Project.

Groundwater Context and Groundwater Dependent Assets

The gas target formation for the Project is the Walloon Coal Measures (WCM) of the Surat Basin. The WCM occur locally at depths greater than 650 meters below ground level (mbGL). The Surat Basin forms part of the Great Artesian Basin (GAB), which comprises several aquifers and aquitards.

Groundwater use in the vicinity (25 km) of the Project is predominately associated with the Mooga Sandstone and the Orallo Formation, followed by the Gubberamunda Sandstone. Most are used for stock and domestic purposes, with 368 water supply bores identified within 25 km of the Project Area. Potential Groundwater Dependent Ecosystems (GDEs) within the Project Area include potential terrestrial GDEs and ephemeral wetlands associated with the surficial deposits (alluvium and Tertiary deposits). There are no spring vents or complexes within 25 km of the Project Area.

Connectivity Between the Alluvium and Underlying Surat Basin Units

Surficial deposits are not recognised to be connected to the Surat Basin units in the Project Area. Surficial deposits in the Project Area are immediately underlain by a tight aquitard (the Doncaster Member of the Wallumbilla Formation) and are vertically separated from the GAB aquifers by thick sequences of several other tight aquitards and partial aquifers. The Mooga Sandstone, the uppermost regional aquifer in the Project Area, is situated at a depth greater than 120 mbGL in the vicinity of the Project. The presence of thick sequences of aquitards further serves to limit the propagation of drawdown from the WCM into the overlying and underlying aquifers.

Potential impacts that may result from Project activities to the hydrological system are summarised below.

Impact Assessment

The Project is located within the Surat Cumulative Management Area (CMA), which was declared in 2011. The Office of Groundwater Impact Assessment (OGIA) was established under the *Water Act 2000* and is responsible for predicting regional impacts on water pressures in aquifers, developing water monitoring and spring management strategies; and assigning responsibility to individual petroleum tenure holders for implementing specific parts of the strategies within the Surat CMA. These predictions, strategies and responsibilities are set out in the Surat CMA Underground Water Impact Report (UWIR), prepared, refined, and maintained by OGIA.

Outputs from the Surat CMA numerical model have been used to predict drawdown impacts to groundwater as a result of the Project. Based on the information provided by Santos and for the purpose of assessing potential impact of CSG water extraction on groundwater resources, OGIA have modelled a Project only scenario, which includes only CSG water production from the Project, and a Cumulative scenario, which includes the simulation of all current and proposed developments (including reasonably foreseeable Santos developments ATPs 1187 and 2052).

Potential impacts to water-dependent assets have been considered with respect to the Queensland Water Act 2000 trigger threshold for springs (0.2 m drawdown) and bores (5 m drawdown in consolidated aquifer; 2 m drawdown in unconsolidated aquifer) using the predicted drawdown for both the Project only and Cumulative scenarios:

- For the Project only scenario, the predicted long-term drawdown impacts associated with the Project are limited to the Springbok Sandstone, the WCM and the Durabilla Formation, located at depths greater than 500 mbGL in the Project Area.
- The Cumulative scenario drawdown results indicate drawdown within the Westbourne Formation, Springbok Sandstone, WCM and Durabilla Formation, located at depths greater than 470 mbGL in the Project Area.
- The Cumulative scenario predicts drawdown greater that 0.2 m in outcropping geological units (Bungil Formation, Mooga Sandstone and Orallo Formation) in an area more than 12 km geologically up-dip and to the north of the Project Area. This drawdown is not associated with the proposed Project but is rather associated with the water production from neighbouring CSG developments operating on tenures located closer to these outcropping units.

This water assessment shows that exceedance of the Water Act 2000 water level trigger / Joint Industry Framework (JIF) GDE risk thresholds is not anticipated for this Project:

- Surficial deposits are not recognised to be connected to the Surat Basin units in the Project Area. There is no predicted Project only drawdown in these surficial deposits. The Project was assessed to not have a significant impact on GDEs.
- Bore triggers are not predicted to be exceeded as a result of the Project only or Cumulative scenario activities.
- Notable wetlands, spring vents or spring complexes are not predicted to be impacted. The Project only contribution to the predicted Cumulative scenario drawdown for watercourse springs is assessed to be negligible.
- Proposed activities do not include planned direct abstraction from, or discharges to, watercourses. Impacts on surface water users, environmental values and spiritual values are not anticipated.
- The use of chemicals poses a low to insignificant risk following adoption of the appropriate standards and implementation of avoidance, mitigation, management and monitoring measures as proposed by Santos.

Avoidance, Mitigation and Management

Santos will adhere to any relevant EA conditions as well as mandatory requirements and guidelines, including the '*Code of Practice for the construction and abandonment of petroleum wells, and associated bores in Queensland Version 2'* (State of Queensland 2019a) applicable Australian Standards for storing and handling applicable materials, *'Manual for Assessing Consequence Categories and Hydraulic Performance of Structures'* (DESI 2024), and *'Streamlined Model Conditions for Petroleum Activities'* (State of Queensland 2024k).

In additional, Santos have developed a comprehensive set of management documents, including an Environmental Management Plan (EMP) (Santos 2024a), with the objective to achieve ongoing environmental compliance with regulatory requirements and to facilitate implementation of best practice environmental management strategies. The EMP includes a set of supporting Environmental Control Plans (ECPs) that detail management actions, responsibility and timing relating to potential impacts.

CSG development on tenures surrounding the Project comprises up to 4,401 CSG wells, which are authorised under existing EPBC Act and EA approvals. These Projects are conditional to the JIF framework (Australian Government 2021). The application of the JIF framework to surrounding development provides comfort that defined environmental outcomes for groundwater (as defined in the JIF) will be achieved.

Monitoring and Reporting

Groundwater monitoring will be undertaken in accordance with the requirements provided as part of the UWIR Water Monitoring Strategy (WMS) (OGIA 2021a), and Santos's Eastern Queensland *Stimulation Impact Monitoring Program* (SIMP) (Santos 2021) and any relevant EA conditions. Sixteen (16) nested WMS UWIR monitoring bores are present within 25 km of the Project Area. The SIMP provides procedures for baseline groundwater bore assessment, stimulation fluid and flowback monitoring, and post-stimulation groundwater bore monitoring.

The EMP for the Project includes ECP 3, which details management actions, responsibility and timing relating to activities that have the potential to impact water resources.

Produced water will be monitored in accordance with any relevant EA conditions, the SIMP and the EMP (Santos 2024a).

Santos will undertake all reporting in accordance with relevant State and Commonwealth legislation and approval conditions, including OGIA as part of the UWIR requirements.

CLARIFICATIONS REGARDING THIS REPORT

This report is an instrument of service of Klohn Crippen Berger (KCB). The report has been prepared for the use of Santos (Client) for the specific application to support the Environmental Authority application for Roma Phase 7-7B-SD20 (ATP 2053), and it may not be relied upon by any other party without KCB's written consent.

KCB has prepared this report in a manner consistent with the level of care, skill and diligence ordinarily provided by members of the same profession for projects of a similar nature at the time and place the services were rendered; however, the use of this report will be at the user's sole risk absolutely and in all respects, and KCB makes no warranty, express or implied.

Use of or reliance upon this instrument of service by the Client is subject to the following conditions:

1. The report is to be read in full, with sections or parts of the report relied upon in the context of the whole report.
2. The Executive Summary is a selection of key elements of the report. It does not include details needed for the proper application of the findings and recommendations in the report.
3. The observations, findings and conclusions in this report are based on observed factual data and conditions that existed at the time of the work and should not be relied upon to precisely represent conditions at any other time.
4. The report is based on information provided to KCB by the Client or by other parties on behalf of the client (Client-supplied information). KCB has not verified the correctness or accuracy of such information and makes no representations regarding its correctness or accuracy. KCB shall not be responsible to the Client for the consequences of any error or omission contained in Client-supplied information.
5. KCB should be consulted regarding the interpretation or application of the findings and recommendations in the report.
6. This report is electronically signed and sealed and its electronic form is considered the original. A printed version of the original can be relied upon as a true copy when supplied by the author or when printed from its original electronic file.

1 INTRODUCTION

Santos and its joint venture partners are proposing a new gas field development located in central-eastern Queensland to supply natural gas to commercial markets. The proposed development will be known as the 'Santos Roma Phase 7-7B-SD20 Development' (hereafter referred to as the Project).

The Project will involve the progressive construction, operation, decommissioning and rehabilitation of up to 24 coal seam gas (CSG) wells, gas and water gathering flowlines and access track infrastructure in petroleum exploration tenure Authority to Prospect (ATP) 2053 (hereafter referred to as the Project Area).

KCB Australia Pty Ltd (KCB) has been commissioned by Santos to undertake an assessment of potential water-related impacts of proposed coal seam gas (CSG) production associated with the Project.

1.1 Project Background

The Project is located approximately 45 km east of the township of Roma in the central part of the Surat Basin, Queensland as shown in Figure 1.1. The Project Area is surrounded on all sides by the existing Santos 'Roma' gas field, which includes Petroleum Leases (PLs) 1020, 281, 282, 315, 318.

The Santos Roma gas field and abovementioned PLs are owned and operated by Santos as part of the existing approved Gladstone Liquified Natural Gas Field Development Project (GLNG GFD) (EPBC Numbers 2008/4059 and 2012/6615 and Queensland Environmental Authority (EAs) (EPPG00898213 and EPPG00662213). The Santos GLNG GFD Project consists of 35 petroleum tenures and an authorisation to produce gas from up to 4,401 CSG wells. The Project Area was not included in the scope of the Santos GLNG GFD Project because Santos did not own the tenure at the time of GLNG GFD project application in 2012. ATP 2053 was granted to Santos in 2020. The intent of the Project is to integrate it with existing Santos Roma / GLNG GFD Project gas and water processing infrastructure. Santos is the authorised holder and operator of the Project Area.

Petroleum exploration activities undertaken by Santos in the Project Area to date include drilling and completion of 5 CSG appraisal wells and construction of associated infrastructure in 2022-2024. These activities are authorised under existing approved EA 0002052. The Project will include the construction/operation of up to 24 CSG wells and their connection to existing approved gas and water gathering lines. The existing 5 wells form part of the proposed 24 CSG wells. Santos is seeking a new EA under the *Environmental Protection Act 1994* (EP Act) (State of Queensland 2024d) to convert the Project Area from an ATP to a PL and to authorise commercial gas production activities.

To enable commercial gas production activities within the Project Area, Santos will apply for new PL, granted under Chapter 2 of the *Petroleum and Gas (Production and Safety) Act 2004* (P&G Act) (State of Queensland 2020j) to replace the existing ATP. Further, to authorise petroleum production activities on the new PL, Santos will also need to apply for a new EA under the EP Act.

Further detail on project infrastructure is provided in Section 3.

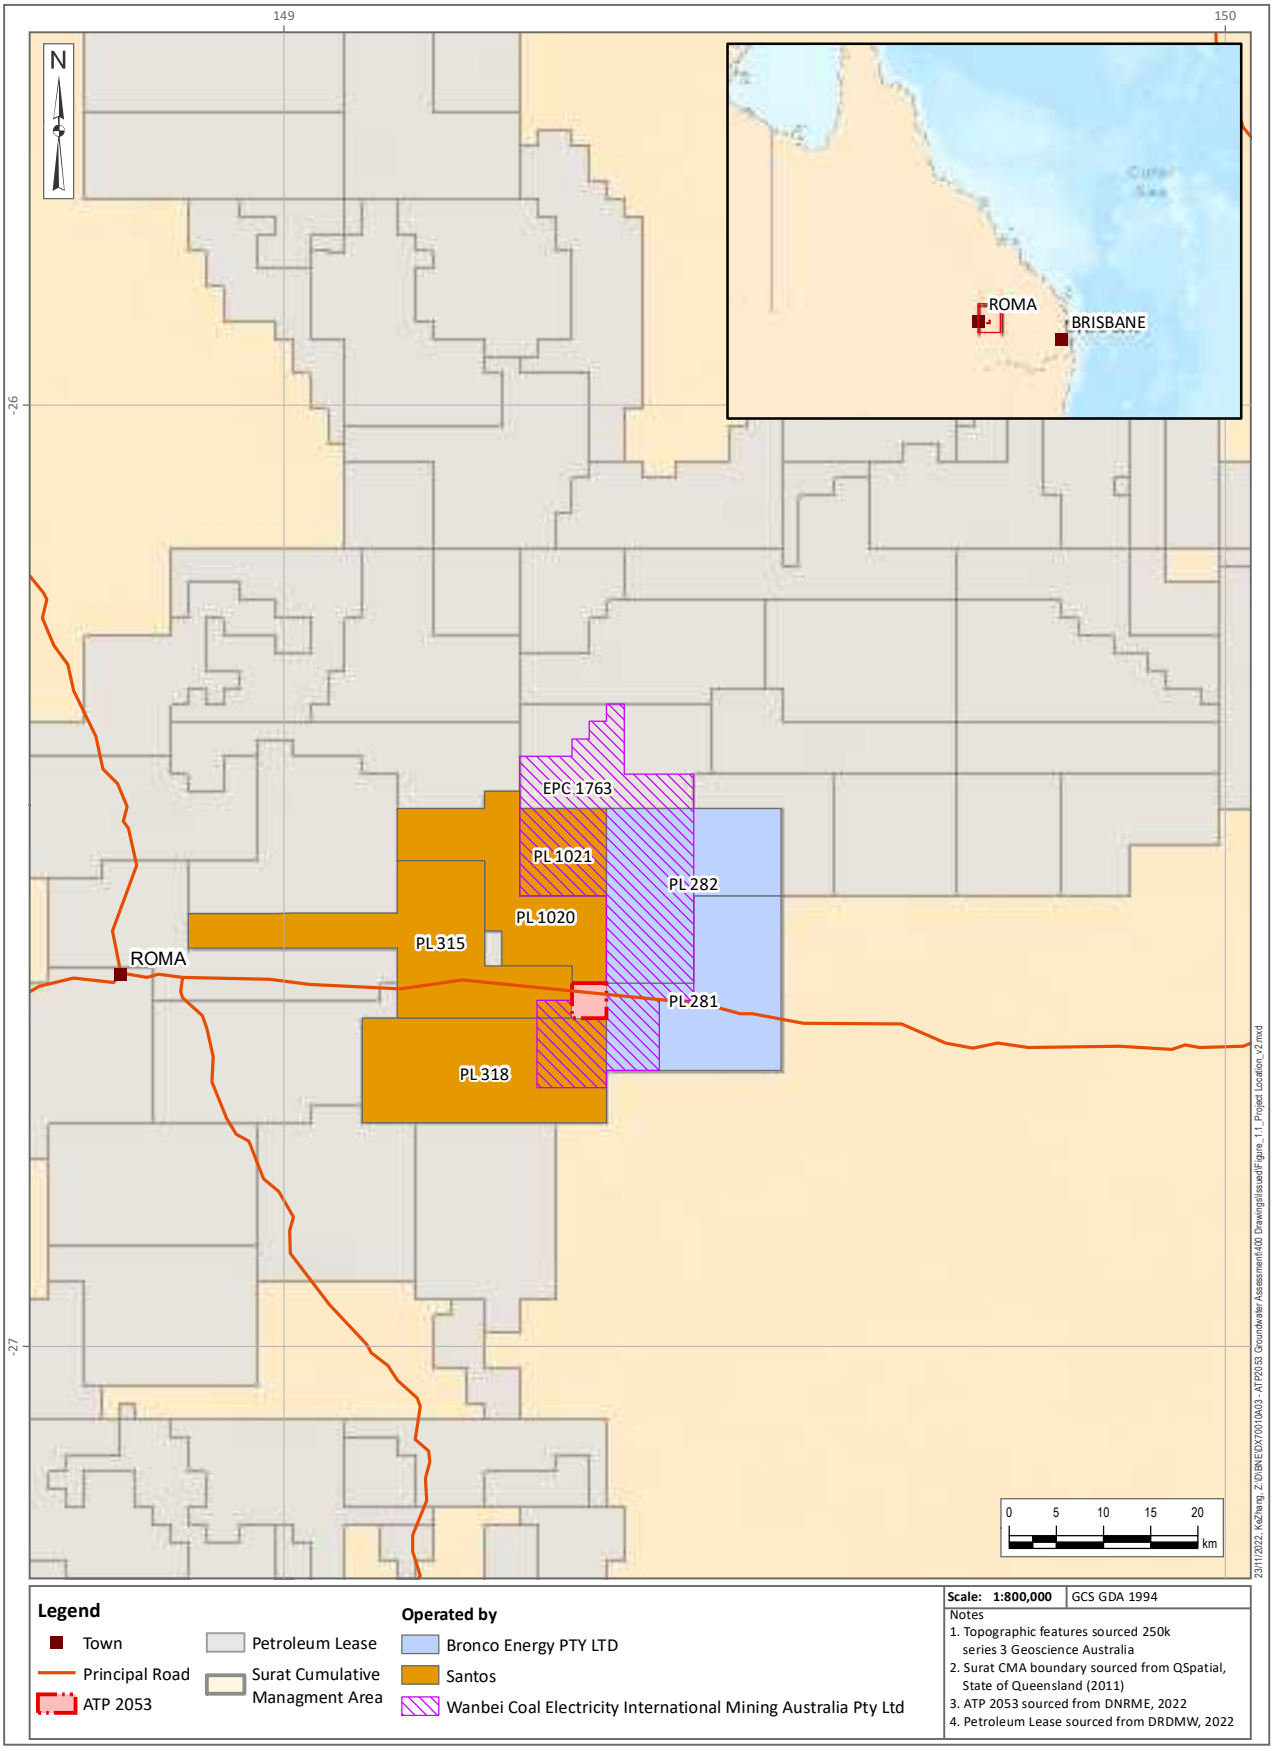

Figure 1.1 Project Location

1.2 Report Structure

This report has been prepared to accompany the EA application to the Queensland Department of Environment, Tourism, Science, and Innovation (DETSI) and is provided as supporting information with content related to groundwater and surface water, including description of baseline conditions and impact assessments, which has been undertaken in accordance with relevant legislation and guidelines (Section 2).

Section 1: Introduction to the Project, report purpose, and structure.

Section 2: Regulatory Framework, including an overview of the relevant Queensland and Commonwealth legislation related to water and CSG development / production.

Section 3: Project Description.

Section 4: Methodology for the assessment of the existing environment and environmental values; and impact assessment approach.

Section 5: Existing Environment, including a review of the topography, climate, land use.

Section 6: Hydrological setting and summary of surface water receptors and users.

Section 7: Hydrogeological setting and summary of groundwater receptors and users.

Section 8: Numerical Groundwater Modelling, including predicted extent of groundwater drawdown.

Section 9: Impact Assessment, which includes both Project only and Cumulative impacts.

Section 10: Mitigation, Management, and Monitoring.

2 REGULATORY FRAMEWORK

This water report has been prepared with consideration to key policies and legislation from the Commonwealth of Australia and the State of Queensland. This section provides an overview of applicable legislation / policies to this assessment.

2.1 Commonwealth Legislation

2.1.1 Environment Protection and Conservation Act 1999

The EPBC Act (Commonwealth of Australia 2024) is the central piece of environmental legislation at the Commonwealth level. It provides for the protection of environmental values, including matters of national environmental significance (MNES). Actions that are likely to have a significant impact on MNES are subject to the assessment and approval process under this Act. Water resources in relation to large coal mining and CSG development projects are a MNES. The Project constitutes a CSG development under the EPBC Act, and as such is being referred to the DCCEEW.

The regulatory guideline relevant to the Project, developed from the amendment to the EPBC Act identifying water resources as being a MNES, is the *Significant impact guidelines 1.3: Coal seam gas and large coal mining developments – impacts on water resources* (SI CSG Guideline 1.3) (Commonwealth of Australia 2022).

2.2 State Legislation

2.2.1 Petroleum and Gas (Production and Safety) Act 2004

The *Petroleum and Gas (Production and Safety) Act 2004* (P&G Act) (State of Queensland 2020j) is an Act relevant to exploring for, recovering and transporting by pipeline, petroleum and fuel gas, and ensuring the safe and efficient undertaking of those activities. The key purpose of this Act is to facilitate and regulate the undertaking of responsible petroleum activities and the development of a safe, efficient, and viable petroleum and fuel gas industry.

The P&G Act identifies underground water rights for petroleum tenures, and states that the holder of a petroleum tenure may take or interfere with underground water in the area of the tenure if the taking or interference happens during the course of, or results from, the carrying out of another authorised activity for the tenure.

The P&G Act prescribes mandatory compliance with the Queensland Department of Natural Resources, Mines, and Energy's (DNRME) *Code of Practice for the construction and abandonment* of petroleum wells, and associated bores in Queensland Version 2 (Code of Practice) (State of Queensland 2019a). The purpose of this code is to ensure that all petroleum wells, CSG wells and associated bores are constructed, maintained and abandoned to a minimum acceptable standard resulting in long-term well integrity, containment of petroleum and gas (P&G) and the protection of groundwater resources.

2.2.2 Water Act 2000

General Purpose of the Water Act

The Water Act 2000 (State of Queensland 2024m) is an Act to provide for the sustainable management of water and the management of impacts on underground water, among other purposes. This Act provides a framework for:

- The sustainable management of Queensland's water resources by establishing a system for the planning, allocation, and use of water;
- The sustainable and secure water supply and demand management for designated regions;
- The management of impacts on underground water caused by the exercise of underground water rights by the resource sector; and
- The effective operation of water authorities.

This Act covers water in a watercourse, lake or spring, underground water (or groundwater), overland flow water, or water that has been collected in a dam.

Water Act and Petroleum and Gas Activities

The Water Act 2000 provides for the management of the impacts on underground water caused by the exercise of underground water rights by resource tenure holders, which are regulated under the P&G Act 2004. The Act also outlines the requirements for make good agreements, associated with the impacts to underground water.

Chapter 3 of the Water Act 2000 has a stated purpose to provide for the management of impacts on underground water caused by the exercise of underground water rights by resource tenure holders, which includes petroleum tenure holders. To achieve the stated purpose, a regulatory framework is provided which requires:

- Resource tenure holders to monitor and assess the impacts of the exercise of underground water rights on water bores and to enter into make good agreements with the owners of the groundwater bores as necessary;
- The preparation of Underground Water Impact Reports (UWIR) that establish underground water obligations, including obligations to monitor and manage impacts on aquifers and springs; and
- Managing the cumulative impacts of the activities of two or more resource tenure holders' underground water rights on underground water.

Under this regulatory framework, where there is an area of concentrated development, a CMA can be declared. The Project Area is located within the Surat CMA, which was declared by the Queensland Government in 2011. The Office of Groundwater Impact Assessment (OGIA) was established under the Water Act 2000 and is responsible for predicting regional impacts on water pressures in aquifers; developing water monitoring and spring management strategies; and, assigning responsibility to individual petroleum tenure holders for implementing specific parts of the strategies within CMAs. These predictions, strategies and responsibilities are set out in the Surat CMA UWIR, prepared, and maintained by OGIA.

The Surat CMA UWIR was first published by Queensland Water Commission (QWC) in 2012 (QWC 2012a) to assess the cumulative impacts to the Surat and southern Bowen Basin, as a result of the expansion of CSG production by multiple, adjacent developers. A second and third UWIR was published by OGIA in 2016 (OGIA 2016c) and 2019 (OGIA 2019a), with the most recent coming into effect in May 2022 (OGIA 2021g).

OGIA also provide tenure holders with their obligations to comply with the Surat CMA UWIR Water Monitoring Strategy (WMS) (OGIA 2021a). The WMS includes:

- Installation, maintenance and collection of data from the groundwater monitoring network including water pressure and water chemistry;
- Monitoring of associated water volumes;
- A program for baseline assessment; and
- Tenure holder reporting of the data and activities relating to the above components.

OGIA has also provided Santos with groundwater modelling outputs from the 2021 UWIR numerical model to inform this assessment, which is further detailed in Section 8.

Trigger Thresholds

Under Section 362 of the Water Act 2000, a bore trigger threshold, for a consolidated aquifer, of 5 m applies (2 m for an unconsolidated aquifer). The 5 m threshold represents the maximum allowable groundwater level decline in a groundwater bore, due to petroleum tenure holders' activities, prior to triggering an investigation into the water level decline.

Under Section 379 of the Water Act 2000 a spring trigger threshold for an aquifer applies. This includes vent springs / complexes and watercourse spring (i.e., gaining streams). The threshold value is 0.2 m and represents the maximum allowable decline in the water level of an aquifer in connection with a spring, at the spring location, prior to triggering an investigation into the water level decline. The threshold value may change for an area if a regulation or prescribed threshold exists.

The Joint Industry Framework[1] (JIF) (Australian Government 2021) defines the threshold for aquatic and terrestrial DGEs as consistent with the spring trigger threshold, i.e., a drawdown exceeding 0.2 m at the location of the GDE that is caused by CSG development.

2.2.3 Environmental Protection Act 1994

The Environmental Protection Act 1994 (EP Act) (State of Queensland 2024d) is an Act with the objective to protect Queensland's environment while allowing for development that improves the total quality of life, both now and in the future, in a way that maintains the ecological processes on which life depends (ecologically sustainable development).

The EP Act states that 'to carry out an environmentally relevant activity (ERA) an environmental authority (EA) is required'. A resource activity, specifically a petroleum activity, is defined as an ERA.

[1] The purpose of the JIF is to establish a consistent post-approval framework for the management of impacts on groundwater caused by CSG developments within the Surat Cumulative Management Area (CMA) that are subject to approvals under the EPBC Act.

Environmental Authority

The Project approval status is discussed in Section 1.1 and 3.3. Santos is seeking a new EA under the *Environmental Protection Act 1994* to convert the Project Area from an ATP to a PL and to authorise commercial gas production activities.

The application must include the following items as detailed in Section 125 (Requirements for application generally) of the Act:

- Include an assessment of the likely impact of each relevant activity on the environmental values, including:
  - A description of the environmental values likely to be affected by each relevant activity;
  - Details of any emissions or releases likely to be generated by each relevant activity;
  - A description of the risk and likely magnitude of impacts on the environmental values;
  - Details of the management practices proposed to be implemented to prevent or minimise adverse impacts; and
  - Details of how the land, the subject of the application, will be rehabilitated after each relevant activity ceases.

Under the *Environmental Protection Act 1994*, streamlined model conditions for petroleum activities have been developed for incorporation into EA's (State of Queensland 2024l). The streamlined conditions are based on acceptable management approaches and constraints to protect environmental values.

2.2.3.1 Regulations and Policies Under the EP Act

Environmental Protection Regulation 2019

The *Environmental Protection Regulation 2019* (EP Reg)(State of Queensland 2023) is a subordinate legislation which supports the operation of the EP Act and prescribes the detail for the processes contained in the Act.

Section 28 of the EP Reg is relevant to this application and includes the documents prescribed for an application for an EA for a CSG activity.

Environmental Protection (Water and Wetland Biodiversity) Policy 2019

The purpose of the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* (State of Queensland 2019d) is to achieve the object of the EP Act in relation to waters and wetlands; protecting Queensland's water environment while allowing for development that is ecologically sustainable.

Coal Seam Gas Water Management Policy 2012

The primary objective of the *Coal Seam Gas Water Management Policy 2012* (State of Queensland 2012) relates to the management and use of CSG water under the EP Act. The role of the policy is to:

- Clearly state the government's position on the management and use of CSG water;

- Guide CSG operators in managing CSG water under their EA; and
- Ensure community understanding about the government's preferred approach to managing CSG water.

The *End of Waste Code Irrigation of Associated Water* (including coal seam gas water) (State of Queensland 2019c) and *End of Waste Code Associated Water* (including coal seam gas water) (State of Queensland 2024b) support the objective of the *Coal Seam Gas Water Management Policy 2012*, by specifying the standards required to be met where associated water is to be used for beneficial purposes.

2.2.4 Water Supply (Safety and Reliability) Act 2008

The *Water Supply (Safety and Reliability) Act 2008* (State of Queensland 2017c) is an Act that provides for the safety and reliability of water supply. The purpose of this Act is achieved primarily by providing:

- A regulatory framework for providing water and sewerage services in the State, including functions and powers of service providers;
- A regulatory framework for providing recycled water and drinking water quality, primarily for protecting public health;
- The regulation of referable dams;
- Flood mitigation responsibilities; and
- The protection of the interests of customers of service providers.

The key component of the Act relevant to the Project relates to the regulation of referable dams.

2.2.5 Sustainable Planning Act 2009

The *Sustainable Planning Act 2009* (State of Queensland 2017a) has a purpose to achieve ecological sustainability by managing the process by which development takes place, including ensuring the process is accountable, effective and efficient and delivers sustainable outcomes; managing the effects of development on the environment, including managing the use of premises; and continuing the coordination and integration of planning at the local, regional and State levels.

This act is relevant to the Project in terms of the proposed infrastructure associated with CSG production.

2.3 Environmental Values and Water Resource Management

2.3.1 Overview

The EP Act defines an Environmental Value (EV) as:

- A quality or physical characteristic of the environment that is conducive to ecological health or public amenity or safety; or
- Another quality of the environment identified and declared to be an environmental value under an environmental protection policy or regulation.

Under the EP Act, the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* (EP Policy) is established as subordinate legislation to achieve the objective of the Act in relation to Queensland waters. The purpose of the EP Policy is achieved by:

- Identifying EVs and management goals for Queensland waters;
- Stating water quality guidelines and water quality objectives to enhance or protect the environmental values;
- Providing a framework for making consistent, equitable and informed decisions about Queensland waters; and
- Monitoring and reporting on the condition of Queensland waters.

2.3.2 Surface and Groundwater Environmental Values

The EP Policy for the Maranoa-Balonne Rivers Basin (State of Queensland 2020a) provides defined EVs and water quality objectives (WQOs) for surface and groundwater under Schedule 1 of the policy. The Project Area is located within Maranoa-Balonne Rivers sub-basin in the Queensland Murray-Darling and Bulloo Basins. EVs for the Maranoa-Balonne Rivers sub-basin are presented in Table 2.1.

Table 2.1 Environmental Values for the Maranoa-Balonne Rivers Basin Surface Waters within the vicinity of the Project Area (State of Queensland 2020a)

Water	Sub-catchment	Environmental Values											
		Aquatic Ecosystem	Irrigation	Farm Supply / Use	Stock Water	Aquaculture	Human Consumer	Primary Recreation	Secondary Recreation	Visual Recreation	Drinking Water	Industrial Use	Cultural, Spiritual, And Ceremonial Values

Surface Water	Bungil Creek	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓
	Yuleba Creek	✓	✓	✓	✓		✓	✓	✓	✓	✓		✓

✓ means the EV is selected for protection. Blank indicates that the EV is not chosen for protection.

EVs have also been prepared for the Maranoa-Balonne River Basin groundwater systems (State of Queensland 2020a). The EVs have been developed for alluvial and fractured rock systems, and the deposits overlying the Great Artesian Basin (GAB). Units underlying the GAB are also considered.

Table 2.2 presents the draft groundwater EVs for each of the categories outlined in the policy (State of Queensland 2020b; 2020c; 2020d; 2020e; 2020f; 2020g; 2020h; 2020i).

Table 2.2 Environmental Values for the Maranoa-Balonne Rivers Basin Groundwater Within the Vicinity of the Project Area

Water	Environmental Values

Bowen Basin (continued)	✓			✓								✓

✓ denotes the EV is selected for protection. Blank indicates that the EV is not chosen for protection.

2.3.3 Water Quality Objectives – Groundwater and Surface Water

Water Quality Objectives (WQO) to protect the EVs are defined in *The Environmental Protection (Water and Wetland Biodiversity) Policy 2019 - Maranoa-Balonne Rivers Basin Environmental Values and Water Quality Objectives* (State of Queensland 2020a) and *The Environmental Protection (Water and Wetland Biodiversity) Policy 2019 - Queensland Murray-Darling and Bulloo Rivers Basins Groundwater Environmental Values and Water Quality Objectives* (State of Queensland 2020a). A summary of the WQOs in the Maranoa-Balonne Rivers Basin are provided below:

- Groundwater:
  - WQOs for aquatic ecosystems applicable to groundwater where groundwater interacts with surface water, the groundwater quality should not compromise identified EVs and WQOs for those waters.
- Surface Water:
  - Where the aquatic ecosystem has high ecological value the WQO is to maintain the existing water quality, habitat, biota, flow and riparian areas.
  - For Yuleba Creek (gauge 422219A) sub-basin waters the aquatic ecosystem is described as having high ecological value and described as moderately disturbed, and specific water quality guidelines have been produced (Table 3 of State of Queensland 2020).
  - For the protection for human consumption, objectives as per the Australian drinking water guidelines (ADWG) (NHMRC 2011) and Australia New Zealand Food Standards Code.
  - For suitability for industrial use there are no WQOs as water quality requirements vary within the industry.
  - For aquaculture, WQOs are provided (Tables 11-13 of State of Queensland 2020) and should be followed with the ADWG and Australia New Zealand Food Standards Code.
  - For secondary contact and visual recreation, objectives as per NHMRC (2011).
- Surface waters and groundwater:
  - For drinking water, local WQOs exist which relate to before and after water treatment and are based on a number of guidelines / legislation including the ADWG (NHMRC 2011).
  - WQOs to protect or restore indigenous and non-indigenous cultural heritage should be consistent with relevant policies and plans.
  - For irrigation, WQOs exist for metals, pathogens and other indicators in the Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZECC & ARMCANZ 2000).
  - For stock watering, objectives exist for faecal coliforms, total dissolved solids, metals, and other objectives based on guidelines presented in ANZECC & ARMCANZ (2000).
  - For farm use / supply, objectives are as per the guidelines in ANZECC & ARMCANZ (2000).

- For primary contact recreation objectives as per NHMRC (2011) and for freshwater objectives exist for cynobacteria / algae.

2.3.4 Water Resource and Resource Operations Plans

Water Plan (Great Artesian and Other Regional Aquifers) 2017

Groundwater in the Great Artesian Basin is managed within the *Water Plan (Great Artesian Basin and Other Regional Aquifers) 2017* (State of Queensland 2017b), under the Water Act 2000. The purpose of the plan is:

- To define the availability of water in the plan area;
- To provide a framework for sustainably managing water and the taking of water; and
- To identify priorities and mechanisms for dealing with future water requirements.

Water Plan (Condamine and Balonne) 2019

The surface water resource of the Maranoa-Balonne Sub-Basin is managed under the *Queensland Water Resource Plan* framework as part of the Water Plan *(Condamine and Balonne)* (State of Queensland 2019f). The purpose of the plan is to provide a framework for the allocation and sustainable management of surface and overland flow water in the plan area and to meet future water requirements including the protection of natural ecosystems and security of supply to water users as required by the Water Act 2000.

Condamine and Balonne Water Resources Plan 2019

The Project Area falls within the Condamine and Balonne Tributaries Water Management Area and is managed under the *Queensland Water Resource Plan* framework as part of the *Condamine-Balonne Water Resources Plan 2019* (State of Queensland 2019b). The *Queensland Water Resource Plan* was accredited by the Australian Government minister as being consistent with the Basin Plan and commenced on 21 September 2019. The key function of the *Queensland Water Resource Plan* is to provide the operating and environmental management rules and monitoring requirements to resource operations licence holders.

2.4 Application Requirements – Water

Environment Protection Act 1994

Section 126 and 126A of the EP Act outlines the application requirements related to CSG activities.

The requirements of Section 126 relate to the management of CSG water. These are addressed in the Roma Phase 7-7B-SD20 Proposed Produced Water Management Plan (WMP) (WRM 2024).

Section 126A outlines the requirements for applications involving the exercise of underground water requirements. These requirements are outlined in Table 2.3 and include reference to sections of the report where these items are addressed.

Table 2.3 Key *Environmental Protection Act 1994* Statutory Requirements

EP Act Section	Requirement	Reference
126A(2) (a)	The application must also state the following- any proposed exercise of underground water rights during the period in which resource activities will be carried out under the relevant tenure	Section 3
126A(2) (b)	The areas in which underground water rights are proposed to be exercised	Section 3
126A(2) (c)	For each aquifer affected, or likely to be affected, by the exercise of underground rights- ▪ A description of the aquifer; ▪ An analysis of the movement of underground water to and from the aquifer, including how the aquifer interacts with other aquifers and surface water; ▪ A description of the area of the aquifer where the water level is predicted to decline because of the exercise of underground water rights; and ▪ The predicted quantities of water to be taken or interfered with because of the exercise of underground water rights during the period in which resource activities were carried out.	Section 7 Section 3
126A(2) (d)	The environmental values that will, or may, be affected by the exercise of underground water rights and the nature and extent of the impacts on the environmental values;	Section 2, 6, 7 and 9
126A(2) (e)	Any impacts on the quality of groundwater that will, or may, happen because of the exercise of underground water rights during or after the period in which resource activities are carried out;	Section 9
126A(2) (f)	Strategies for avoiding, mitigating or managing the predicted impacts on the environmental values stated for paragraph (d) or the impacts on the quality of groundwater mentioned in paragraph (e).	Section 10

Application Requirements – Guideline

The State of Queensland have published a guideline under the Act for 'Application Requirements for Activities with Impacts to Water' (State of Queensland 2024g), which outlines the information to be provided to support an EA application for activities with impacts to water. The requirements of this guideline have been considered and addressed as part of this assessment.

3 PROJECT DESCRIPTION

3.1 Project Location and Regional Overview

The Project Area covers approximately 13 km^2 of land located 45 km east of the township of Roma and 5 km east of the regional township Wallumbilla, in southeast Queensland. The Project location is provided in Figure 1.1.

A summary of the regional Project setting is provided below, with further details included in the remainder of the report.

- The gas producing targets for the Project are within the Walloon Coal Measures (WCM), of the Middle Jurassic.
- The Project Area is located in the Balonne River sub-basin (within the wider the Condamine-Balonne Basin), and within the Condamine and Balonne Tributaries sub-catchment, which forms part of the larger Queensland Murray-Darling and Bulloo Basins (Section 6).
- Surficial potential groundwater systems within the vicinity of the Project Area include Quaternary deposits associated with Wallumbilla Creek and its tributaries, as well as other unconsolidated Quaternary sediments. Within the Project Area, Cretaceous units are also present at surface (Section 7.1.1).
- Water-dependent assets identified in the Project Area include third-party groundwater bores and potential terrestrial groundwater dependent ecosystems (GDEs) (Section 7.11 and 7.107.11).

Other Developments

The Project Area is located in the vicinity of the other petroleum projects and resource tenures, including:

- Santos owns and operates PLs 281, 282, 315, 318 and 1020 which surround the Project Area on all sides. As discussed in Section 1.1, these PLs are part of the existing Santos Roma gas field and are authorised under existing EPBC Act approvals (EPBC Numbers 2008/4059 and 2012/6615), and Queensland EAs (EPPG00898213 and EPPG00662213). The intent of the Project is to integrate it with existing Santos gas and water processing infrastructure. Santos is the authorised holder and operator of the Project Area.
- Coal exploration (EPC 1763), operated by Wanbei Coal Electricity International Mining Australia Pty Ltd since 2009 is located within the Project and to the northeast and south.
- Other reasonably foreseeable developments further afield and to the east of the Project include Santos owned and operated ATPs 1187, 2052 and 2054.

3.2 Project Components

The Project will involve the progressive construction, operation, decommissioning and rehabilitation of up to 24 CSG wells and associated petroleum activities and infrastructure. Hydraulic fracture stimulation may be used to complete wells as required. Single and multi-well leases are proposed. Construction and commercial gas production is expected to occur from mid-2025. Well development will be phased to optimise gas production.

CSG and water produced from the Project Area will be sent to existing approved centralised gas and water storage / processing and gas compression facilities located on adjacent Santos owned and operated petroleum tenures. As discussed in Section 1.1 and 3.1, petroleum activities on adjacent tenures are authorised under existing EPBC Act approvals and EAs. The Project will include the following components (but not limited to):

- Well leases (single and multi-well leases).
- Water / gas gathering lines, trunklines and pipelines.
- Roads and access tracks.
- Other supporting infrastructure:
  - Temporary water storage tanks;
  - Temporary workers camps;
  - Power and communications lines; and
  - Other incidental and ancillary petroleum activities.

3.3 Project Approval Status

As discussed in Section 1.1, petroleum exploration activities undertaken by Santos in the Project Area to date include drilling and completion of 5 CSG appraisal wells (RM23-21-1, RM23-43-1, RM23-42-1, RM23-41-1 and RM23-46-1) and construction of associated infrastructure in 2022-2024. These activities are authorised under existing approved EA 0002052. The existing 5 wells form part of the proposed 24 CSG wells.

To enable commercial gas production activities within the Project Area, Santos will apply for new PL, granted under Chapter 2 of the P&G Act (State of Queensland 2020j) to replace the existing ATP. Further, to authorise petroleum production activities on the new PL, Santos will also need to apply for a new EA under the EP Act (State of Queensland 2024d).

3.4 Project Activities and Infrastructure

An detailed overview of Project activities is provided in the Roma Phase 7-7B-SD20 Environmental Management Plan (EMP)(Santos 2024a)(Appendix V). Due to the characteristics of the geological formations located within the Project Area, all proposed CSG wells may require hydraulic fracturing to produce commercially viable gas volumes / rates.

3.4.1 CSG Production Wells and Water Production

Groundwater abstraction is required as part of the CSG production process. Groundwater is abstracted (pumped) from production wells to depressurise the target production coal seams. Depressurisation generates gas flow and sustains groundwater flow from the well to maintain the target producing operational pressure for each production well. A summary of the proposed production wells is provided in the following:

- CSG production wells will be drilled and constructed in accordance with the Code of Practice (State of Queensland 2019a). The purpose of this code is to ensure that all petroleum wells, CSG wells and associated bores are constructed, maintained and

abandoned to a minimum acceptable standard resulting in long-term well integrity, containment of petroleum and the protection of groundwater resources.

- A total of 24 wells (two wells are multi-wells comprising two wells each) are proposed to be developed. All wells are anticipated to be commissioned over a period of four months (6 wells per month) (subject to drill rig availability and logistical requirements).
- Hydraulic fracture stimulation will be used to complete wells as required. This will be conducted in accordance with the Code of Practice.
- A risk assessment of chemicals proposed to be used in CSG operations (drilling and completions, and hydraulic fracturing) has been completed for the Project. Refer to the *Chemical Risk Assessment - Santos Roma Phase 7B-SD20 Development* (EHS Support 2024a).
- Subject to relevant approvals, gas production and its associated water extraction will commence from mid-2025.
- The operating life of individual CSG production wells is anticipated to be approximately 30-50 years.

The management of produced water is described in the *Roma Phase 7-7B-SD20 proposed produced water management* (WMP) (WRM 2024) and summarised in this section.

The majority of produced water generated from the Project will be transferred to existing approved Roma gas field water storage (Pickanjinnie and / or Raslie Dams) and treatment facilities located adjacent to the Project Area on PLs 314 and 315 via new and existing water gathering infrastructure.

The Santos Roma gas field, including the abovementioned PLs 314 and 315, and existing water storage and treatment facilities, are owned and operated by Santos as part of the existing approved projects. In future, produced water from the Project Area may potentially be processed elsewhere, subject to environmental approvals.

Site water balances are undertaken for all Project phases at these water management facilities to ensure adequate storage and treatment capacity is available, and this will include consideration of produced water transferred from the Project.

Produced water volumes and rates are predicted using a stochastic reservoir modelling tool which produces probabilistic distributions applied to several key reservoir parameters (i.e. permeability, porosity and net coal). The model predictions generate production profiles (type curves).

These production profiles are used in field development planning to provide a water forecast. Type curves are updated during the life of the Project as more information (e.g. further and refined key reservoir parameters) becomes available.

Figure 3.1 presents the predicted 50th percentile (P50) water production forecast for the Project. Peak water production is predicted to occur in January 2028 at 0.24 ML/day (7.12 ML/month). The total volume of produced water for the duration of the Project is estimated to be 645 ML.

The combined P50 Roma Phase 7-7B-SD20 water production forecast and Roma field water production forecast indicate a peak in December 2027 at 12.43 ML/day (368 ML/month) as shown in Figure 3.2.

Anticipated climate change trends (refer to Section 5.1.1) indicate decreased annual rainfall and increased annual evaporation over time for low and high emissions scenarios. These scenarios would result in smaller volumes in all water storages; therefore, not adopting these climate change forecasts is considered to be conservative to forecast future storage volumes, and capacities using the water balance model.

Water balance simulations for P15 and P85 historic rainfall years were run to coincide with the year in which the Phase 7-7B-SD20 Stage 2 peak flow within the Roma total flow occurred. These simulations represent minimum and maximum historical rainfall years. There were no water balance model simulations that predicted dam or tank overflows.

Table 3.1 outlines the expected water quality for the Project, based on Myalla (PL 282: neighbours the Project diagonally to the northeast) and Washpool Creek (PL 318: neighbours the Project to the south) well data. Produced water quality is slightly alkaline with elevated chloride and sodium concentrations, which contribute to elevated TDS / EC levels.

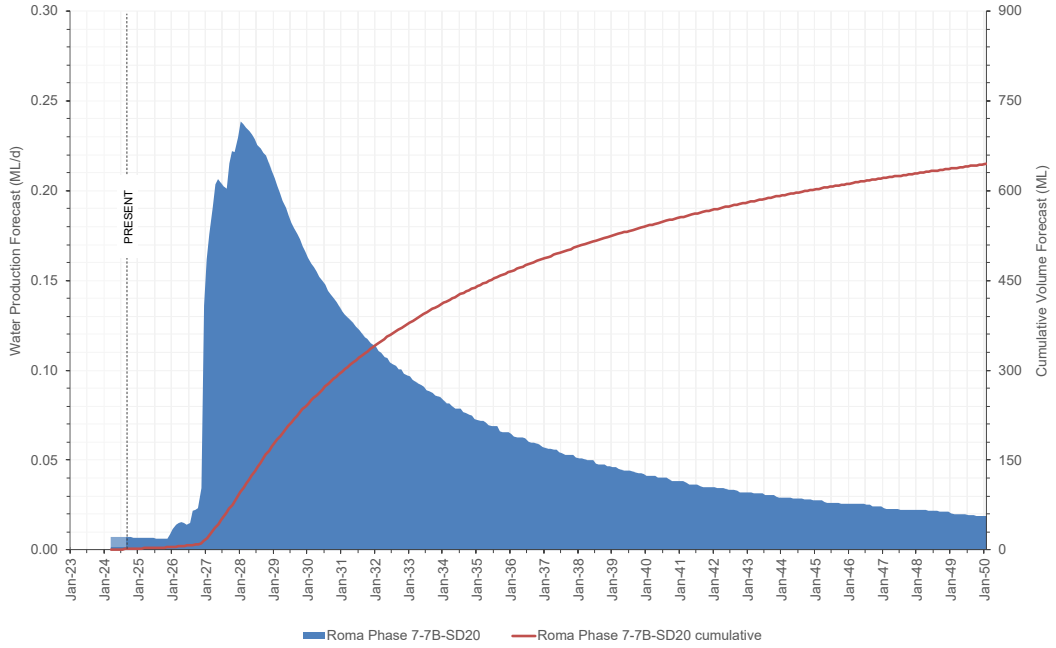

Figure 3.1 Roma Phase 7-7B-SD20 P50 water production forecast (WRM 2024)

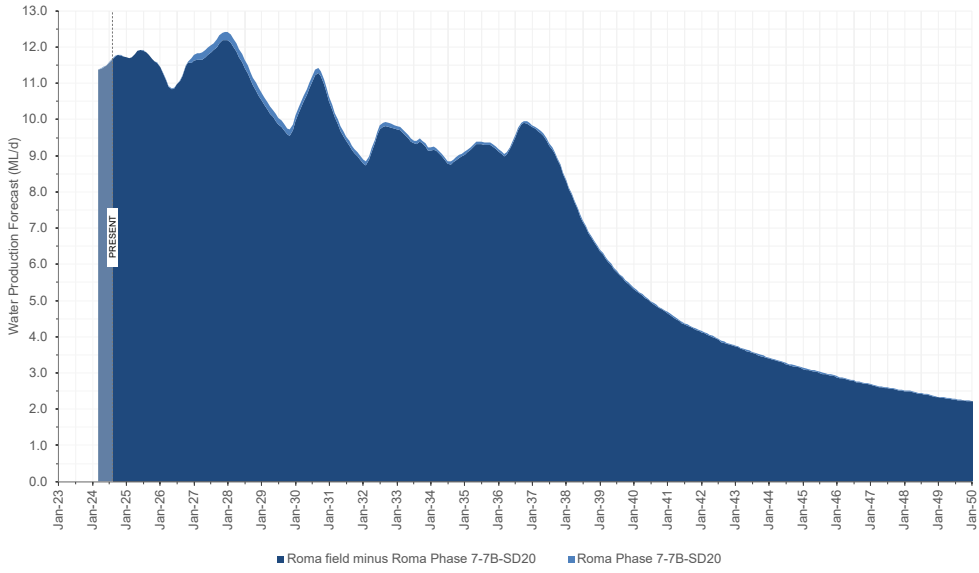

Figure 3.2 Roma Phase 7-7B-SD20 + Roma field P50 water production forecast (WRM 2024)

Produced Water Management

Produced water from the Project will be managed as follows (also refer Roma water management schematic in Figure 3.3):

- Produced water from the Project Area will be gathered to Pickanjinnie or Raslie Dam (located on adjacent PL 315).
- The bulk of produced water from Pickanjinnie / Raslie Dams will be transferred to the existing water management facilities located on PL 314.
- Produced water will also be extracted from Pickanjinnie / Raslie Dams as required to supply field water usage demands (e.g. dust suppression and construction water supply) in accordance with the conditions of EA EPPG00898213.On PL 314, produced water from Pickanjinnie / Raslie Dams will be processed through, or bypassed around, the desalination unit, Roma Reverse Osmosis Plant (ROP), which comprises of fines and sludge removal and a ROP. ROPs are used where necessary to achieve the requisite water quality for beneficial reuse of water. ROPs work by partitioning select constituents entrained within produced water into a waste stream (reverse osmosis (RO) concentrate) leaving a permeate stream of significantly better-quality water.
- The permeate stream from the ROP is blended with produced water to achieve the required water quality objectives for the intended beneficial use of the water (land amendment irrigation and operational purposes). The RO concentrate stream is stored within brine storage dams on PL 314.
- The blended permeate and produced water stream is distributed to several irrigation dams and irrigation areas on PL 314.
- The blended water is irrigated on a third-party property in accordance with the Queensland Government's *End of Waste Code Irrigation of Associated Water (including coal seam gas water)* (ENEW07546918).
- There is currently 490 hectares of Land Amendment Irrigation (LAI) area located on Santos owned as well as third-party properties in the Santos project area. This area is required to maximise the beneficial use from all water directed through the centralised facilities.
- Land amendment irrigation (LAI) describes the application of stoichiometric amounts of agricultural amendments (sulphur and gypsum) to treat the soil prior to the application of irrigation water. This is undertaken to manage risks to soil structure and crop health due to the quality of the irrigation water. Fertilised Rhodes grass is irrigated with irrigation management activities maintaining soil salinity (ECse) within the tolerances stated within the ANZECC 2000 guidelines.

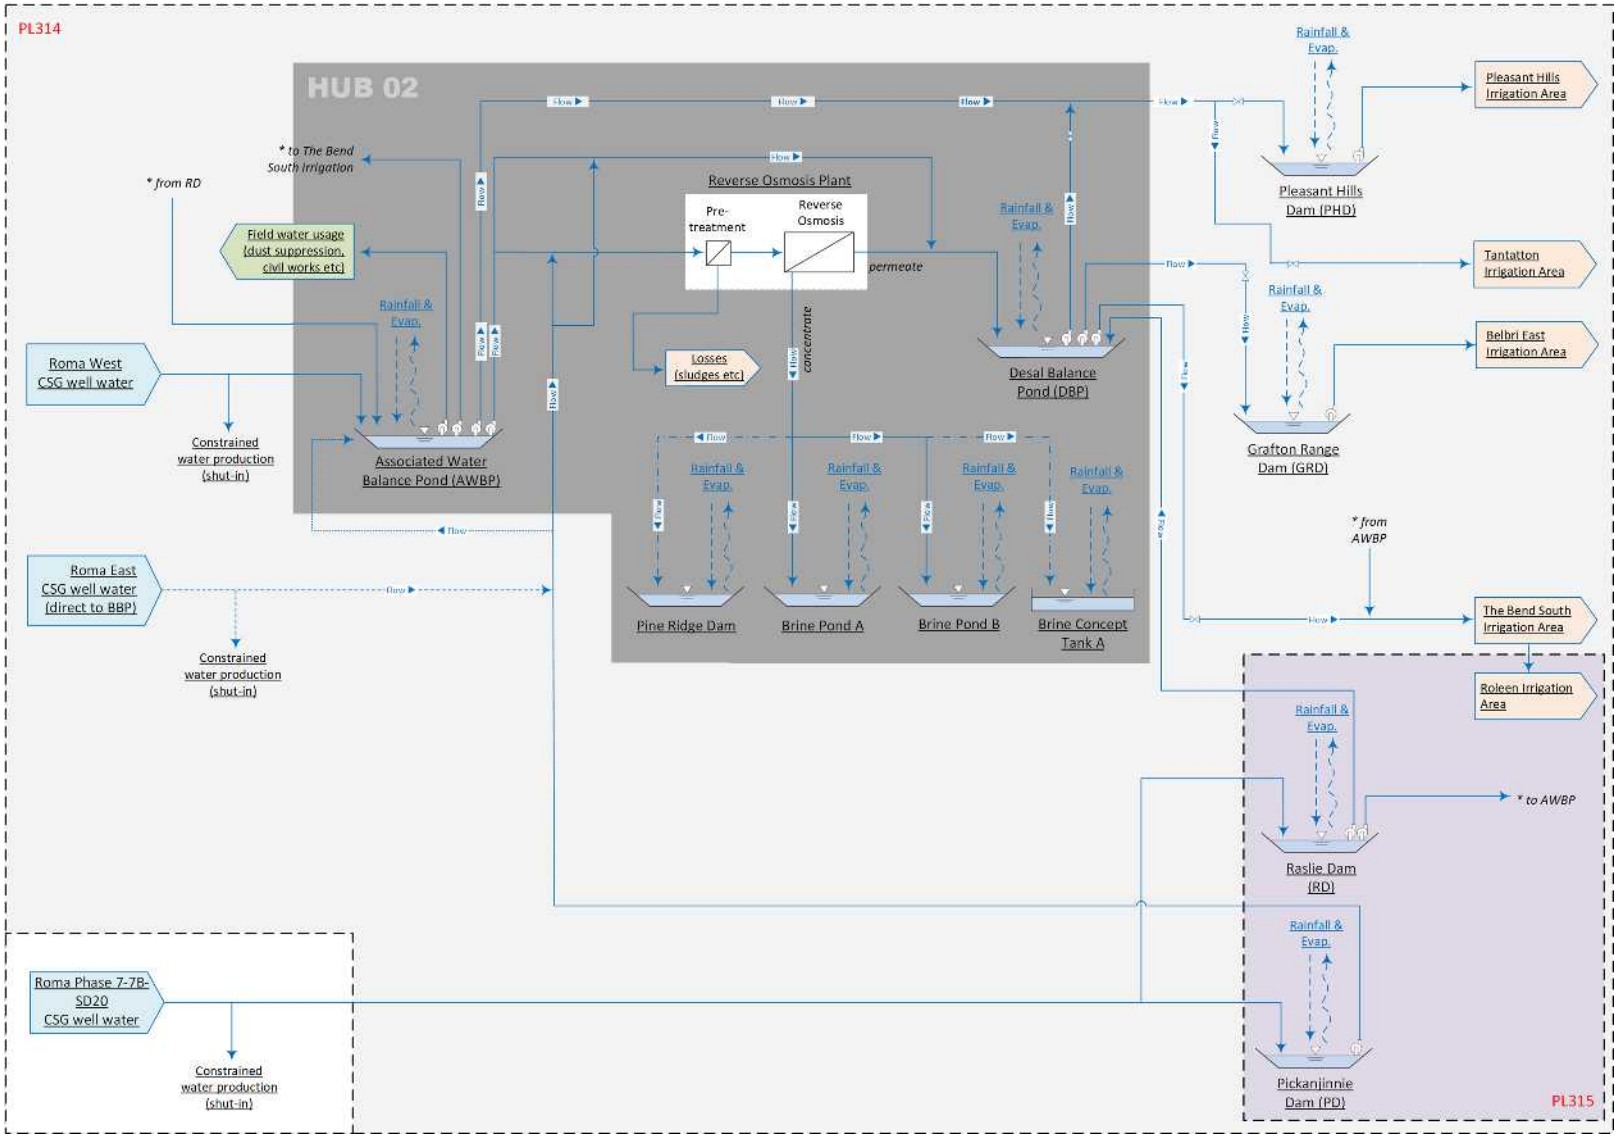

Figure 3.3 Roma Water Management Schematic (PL314) (WRM 2024)

Key attributes of the various water storage facilities are summarised in Table 3.2.

All water storage dams described in Table 3.2 are designed and operated as 'regulated structures' in accordance with the requirements of the EP Act. All storage tanks are designed and constructed to relevant Australian Standards.

Table 3.2 Santos Regulated Water Storages Affected by the Project (WRM 2024)

Asset	Purpose	Storage Construction	Linear Composition	Leak Detection Type	Maximum Operating Storage Volume (ML)
ROMA ROP CSG Water Management Pond	Produced water storage	In ground and above ground	Clay and HDPE	Leak detection layer and seepage bores	116
ROMA ROP Desalinated Water Pond	Permeate water storage	In ground and above ground	Clay and HDPE	Seepage bores	155
ROMA ROP Brine containment Pond A	Brine / concentrate storage	In ground and above ground	Clay and HDPE	Leak detection layer and seepage bores	324
Roma ROP Brine Containment Pond B	Brine / concentrate storage	In ground and above ground	Clay and HDPE	Leak detection layer and seepage bores	321
Pleasant Hills Dam	Irrigation water storage	In ground and above ground	Clay and HDPE	Seepage bores	170
Grafton Range Dam	Irrigation water storage	In ground and above ground	Clay and HDPE	ELIMS testing and seepage bores	170
Pine Ridge Dam	Brine / concentrate storage	In ground and above ground	Clay and HDPE	Leak detection layer and seepage bores	165
ROMA ROP Brine Concept Tank	Brine / concentrate storage	Above ground tank	Double walled liner	Leak detection layer	47
Raslie Dam	Produced water storage	Above ground	Clay and HDPE	Seepage bores	185
Pickanjinnie Dam	Produced water storage	In ground and above ground	Clay and HDPE	Seepage bores	177

Roma gas field water storage (produced water, permeate and brine) dams are classified as 'Regulated Structures' under EAs EPPG00898213 and EPPG00662213. Further, Roma water storage dams have been designed and constructed (and certified) in accordance with *The Manual for Assessing Consequence Categories and Hydraulic Performance of Structures* (version 5.03) (DESI 2024) hereinafter referred to as 'The Manual'.

The Roma dams have been designed as turkey nest structures for the containment of produced water / permeate / brine. A portion of the dam crest storage is below existing ground level in an excavated void. Overland flows have been diverted away from the storages by diversion bunds designed to divert peak flows up to and including 0.0005 Annual Exceedance Probability (AEP) (1 in 2,000 year). The turkey's nest design and diversion of overland flow results in only rainfall that falls within the dam crest entering the storages.

The water storages are operated such that once a Maximum Operating Volume (MOV) is reached, water flows into the storage must cease (i.e. wells turned down) until the volume returns to below the MOV. Above the MOV there is a Design Storage Allowance (DSA) volume available (designed to store a 100% runoff from a 3-month wet season, in accordance with The Manual) before the Full Supply Volume (FSV) (spillway level) is reached. This is designed to specifically minimise the likelihood of release from a regulated dam.

Above the MOV is the Mandatory Reporting Level (MRL) which is the level at which the remaining volume is equivalent to the Extreme Storm Storage (ESS) allowance (short-duration, intense rainfall event). When MRL is reached, Santos must notify the Department of Environment, Tourism, Science and Innovation (DETSI) immediately to minimise actual or potential environmental harm.

In summary, the water storages have significant 'freeboard' available to store intense rainfall events for the site-specific wet season (3-month period during summer).

3.4.2 Salt Balance

Large scale produced water treatment is not proposed to be undertaken within the Project Area. Therefore, no brine or residual salt will be generated, stored or otherwise managed in the Project Area.

Produced water from Project will be transferred to existing Roma gas field water storage and treatment facilities located on PLs 314 and 315 for treatment (as described in Section 3.4.1). The resulting treated water permeate will be stored in a dam and used for beneficial purposes. The brine will be stored in regulated brine storage which will naturally concentrate the brine over time. The final stage will be crystallisation of a solid salt for beneficial reuse or disposal to a licensed landfill. The treatment processes, and storage and management of brine and salt, are not located within the Project and are therefore not part of the proposed action. Details of these processes are included in the *Revised Coal Seam Gas Water Monitoring and Management Plan GLNG Project EPBC* (2008/4059) (Santos 2023b).

The Roma ROP has the capacity to process up to 7.5 ML/day of produced water. Figure 3.4 shows the ROP has sufficient capacity to manage the Project and Roma forecast water production for P50 climatic conditions.

Figure 3.4 Flow into ROP with and without the Project (Roma Phase 7-7B-SD20) Flows (WRM 2024)

Figure 3.5 shows forecast brine volumes to be contributed by the Project and Roma field and indicates there is sufficient brine storage capacity to manage the combination of Roma and the Project forecast brine production, for P50 climatic conditions.

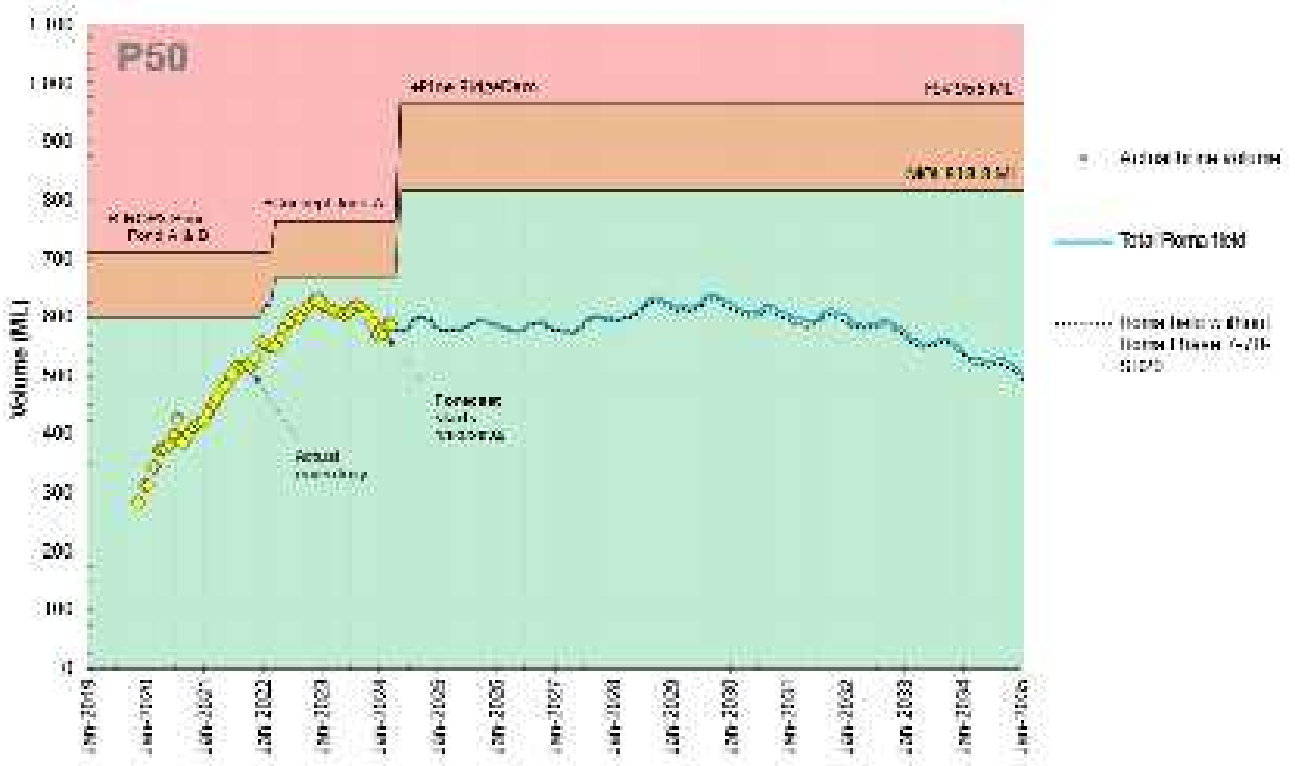

Figure 3.5 Brine Inventory (WRM 2024)

The Project is forecast to add approximately 82 tonnes of salt to the brine storages located on PL 314. This represents about 0.1% of the salt stored in Roma brine storages.

3.4.3 Waste Management and Rehabilitation

On PL 314 the Roma ROP permeate flushes are transferred to brine storages – refer to Section 3.4.2 for a description of the management of this waste.

The Roma ROP Actiflo sludge and treated oily water is transferred to the Roma ROP CSG Water Management Pond which then either gets treated through the Roma ROP or bypassed for blending with permeate and irrigation. At the end of the life of the Roma ROP CSG Water Management Pond, all liquid and solid material will be removed from the dam prior to rehabilitation. The liner will be removed and transported to a regulated waste facility for disposal. These treatment processes and resultant waste are not located within the Project and are therefore not part of the proposed action.

3.4.4 Water Use During Project Development

As discussed in Section 6.6, the Project Area occurs within the Condamine and Balonne Tributaries WMA CBT-02, which is an unsupplemented surface water trading zone.

Santos estimates it will require approximately 158 ML of water to develop the Project (24% of estimated produced water volume). Water will be utilised during construction and operation to support development, maintenance, dust suppression, drilling, hydraulic stimulation and construction activities.

Santos will preferentially utilise produced water generated from and located in the Project Area and surrounding approved Santos and JV partner-owned tenures, in accordance with EA conditions.

Santos is not expecting to require additional water allocations / licenses to develop the project, nor is Santos expecting to require notable surface water take from landholder dams to develop the project.

Further, produced water may be sourced from on-site temporary water storage tanks (concrete panel tanks for similar) (henceforth referred to as ‘tanks’) in accordance with EA conditions. The tanks will comply with relevant Australian Standards.

Santos would only extract water from farm dams for construction purposes with the permission from the landholder when water supplies are abundant of appropriate quality for the proposed use/ activities.

It is noted that some landholders may require Santos to use water sourced on-site for drilling and construction activities, particularly where a landholder holds organic certification for the property.

4 METHODOLOGY

4.1 Existing Environment and Environmental Values

The existing environment across the Project area was considered through a desktop assessment to establish the baseline groundwater conditions, EVs, and potential receptors. The assessment area, for the purposes of this report, includes the surface water features within the Project area, hydrogeological units underlying the Project within the Surat Basin and overlying Quaternary deposits. For the identification of groundwater receptors relevant to this Project, a 25 km buffer around the Project area (which also includes ATP 2053) was established to capture potential adjacent groundwater receptors that may be impacted by the proposed development.

Primary data and information utilised in this assessment are listed below.

A preliminary desktop assessment utilised data and information provided by Santos, OGIA and publicly available reports and data. Primary data and information utilised in this assessment includes:

- 1:100 000 scale geological maps for the Surat Basin, including the Detailed Surface and solid Geology – Queensland (State of Queensland 2018a).
- Registered bore data from the Queensland Groundwater Bore Database (GWDB) (State of Queensland 2024j).
- The Queensland Spring Database provides a comprehensive catalogue of springs and potential GDEs at fixed locations in Queensland. The Queensland Spring Database is updated annually (Queensland Herbarium 2021).
- Department of Science, Information Technology, and Innovation (DSITI) Queensland Groundwater Dependent Ecosystem Mapping (State of Queensland 2018c), which indicates the locations of potential GDEs at a catchment scale (both surface expression and terrestrial).
- Surface water flow and quality data sourced from the Queensland Government Water Monitoring Information Portal (State of Queensland 2024n).
- Local Climate, including temperature, precipitation and evaporation data from SILO (Department of Environment and Science 2024).
- Surat CMA aquifer attribution dataset, provided by OGIA (OGIA 2024).
- Petroleum well completion reports, sourced from Queensland QDEX database.

- Roma Phase 7-7B-SD20 Environmental Management Plan (EMP) (Santos 2024a).

4.1.1 Bore Baseline Assessment

The Water Act 2000 requires Santos to undertake baseline assessments of existing water bores located within the Project Area. Baseline assessment of the two existing water bores located within the Project Area is discussed in Section 7.11.3.

4.2 Impact Assessment

4.2.1 Groundwater

Based on information provided by Santos and as broadly described in Section 3 (e.g., number and location or wells, productions scheduling and durations), OGIA simulated the predictive model scenario for the Project using the regional groundwater flow model that underpins the Surat CMA UWIR. Outputs from the model have been used to predict drawdown impacts to groundwater as a result of the Project. OGIA have modelled a Project only scenario, which includes only CSG water production from the Project, and a Cumulative scenario, which includes the simulation of all current and proposed developments (including reasonably foreseeable Santos developments ATPs 1187 and 2052).

Outputs from the modelling have been processed by KCB for this assessment, and the results considered as part of this assessment (Section 8 and 9).

The assessment criteria used to consider the groundwater drawdown impacts associated with the Project refers to the Water Act 2000, trigger thresholds, as outlined in Section 2.2.2:

- Bore trigger thresholds, represents the maximum allowable groundwater level decline in a groundwater bore, due to petroleum tenure holders' activities, prior to triggering an investigation into the water level decline. These triggers are based on:
  - For a consolidated aquifer – 5 m
  - For an unconsolidated aquifer – 2 m
- Spring trigger threshold represents the maximum allowable decline in the water level of an aquifer in connection with a spring, at the spring location, prior to triggering an investigation into the water level decline.
  - Spring – 0.2 m

An assessment of the potential impacts also includes the development of the conceptual understanding of the system, in particular, hydraulic connection between identified receptors and the hydrostratigraphic units being drawn down/depressurised.

Other potential impacts associated with the Project in relation to groundwater are presented in Section 9, with the relevant mitigation, management and monitoring measures to address these potential impacts provided in Section 10.

4.2.2 Surface Water

Potential impacts that may result from Project activities to the hydrological system are summarised below. These potential impacts are associated with the general construction and day-to-day operations of CSG surface facilities rather than CSG production; and could comprise:

- Alteration of a watercourse character or changes to riparian buffers due to construction works and / or infrastructure; and
- Altered surface water runoff characteristics from construction / developed areas.

The proposed Project does not include planned material discharges / abstraction from natural surface water systems or interaction with surface water bodies and therefore direct impacts to surface water from Project activities are not anticipated. A review of other potential impacts to surface water as a result of the Project are discussed in Section 9. Potential impacts are managed and mitigated by adopting and implementing the appropriate monitoring, management, and mitigation strategies (Section 10).

4.2.3 Chemical Contamination

A CRAF has been developed to guide the assessment of risk associated with chemicals used during CSG operations (drilling and completions, and hydraulic fracturing) for the Project.

The CRAF incorporates best practice risk assessment methodology for the assessment of potential impacts associated with the use of chemicals to MNES and MSES. The CRAF is based on existing Santos approved chemical risk assessment frameworks and aligns with best practice methodologies. Further, a Project specific CRAR (EHS Support 2024a) has been developed in accordance with the requirements of the CRAF to identify the potential risks and effects of chemicals used during CSG operations (drilling and completions, and hydraulic fracturing) specific to the Project.

The CRAF / CRAR assessment process is designed to align with national guidance and other regulatory frameworks and assesses the full lifecycle of chemicals that are stored, transported, handled, used and / or disposed during or following drilling and completions, and hydraulic fracturing activities.

The CRAR summarised the potential risks and effects of chemicals used during the life cycle of CSG extraction to MNES / MSES as identified in the EAR (Boobook 2024b).

The life cycle of drilling, completions and hydraulic fracturing was assessed specifically for the Project and included:

- Storage, usage (e.g., blending, injection), and recovery of chemicals throughout operations;
- Beneficial reuse of recovered drilling fluids and cuttings for well lease rehabilitation; and
- Storage of produced water.

A high level overview of Project activities including the installation of gas field infrastructure, well drilling and completion, hydraulic fracture stimulation, production operations and decommissioning and rehabilitation is provided in EMP (Santos 2024a) and RMP (Santos 2024d).

In addition to the CRAF / CRAR, EMP and RMP, a Hydraulic Fracturing Risk Assessment (HFRA) has been completed for Santos's Eastern Queensland activities which includes the Project (EHS Support 2021). The HFRA describes the process by which hydraulic fracturing is conducted and monitored. It addresses the regulatory requirements of Santos' Eastern Queensland EAs and synthesizes the findings of several hydraulic fracturing risk assessments completed to date.

5 EXISTING ENVIRONMENT

The topography of the Project Area is generally gently sloping with an elevation of between 300 – 350 metres above Australian Height Datum (mAHD), as shown in Figure 5.1. The elevation of the wider Project Area increases to 450 – 600 mAHD in the north and 350 – 400 mAHD to the east and southeast. The lower lying drainage to the southwest / south ranges between 250 – 300 mAHD and is associated with the watercourses discussed later in Section 6.2.1.

5.1 Climate

The climate of the Project Area is classified as subtropical with a moderately dry winter based on the modified Köppen classification system (BOM 2005). Climate statistics sourced from SILO (Scientific Information for Land Owners) are presented in Table 5.1, for the climate station Wallumbilla Post Office (43038). SILO data is an enhanced synthetic climate database that provides a daily time series of data at a point location consisting of station records which have been supplemented by interpolated estimates when observed data are missing. Wallumbilla Post Office climate station is located 3 km west of the Project Area as shown on Figure 5.1.

Table 5.1 Climate Statistics for Wallumbilla Post Office (43038)

Statistic Element	Wallumbilla Post Office (43038)			
	Mean Daily Maximum Temperature (°C)	Mean Daily Minimum Temperature (°C)	Mean Monthly Rainfall (mm)	Mean Monthly Evaporation (mm)
Period of Record	1889-2023	1889-2023	1889-2023	1889-2023
January	34.0	20.2	77.0	261.4
February	33.0	19.7	76.9	202.5
March	31.3	17.4	63.4	200.5
April	27.9	12.9	32.1	144.9
May	23.5	8.3	34.0	100.9
June	20.0	5.2	35.2	73.4
July	19.6	3.8	34.1	81.0
August	21.8	5.1	24.1	113.9
September	25.8	9.0	29.0	165.4
October	29.4	13.5	50.4	212.0
November	32.0	16.8	62.7	234.2
December	33.7	19.0	75.3	258.4
Annual	27.6	12.6	592.7	2042.3

* Data range: 1/1/1889 – 4/2/2023

Mean maximum temperatures range between 34°C in the summer months and 20°C in the winter months. Mean minimum temperatures range between 20°C in the summer months and 4°C in the winter months. The highest average monthly rainfall occurs during October to March (50 – 77 mm), with the lowest average monthly rainfall occurring during April and August (24 – 35 mm).

The highest monthly evaporation occurs during the summer months (October to March, 200 – 259 mm), while the lowest evaporation occurs during the winter months (April to September, 73 – 165 mm).

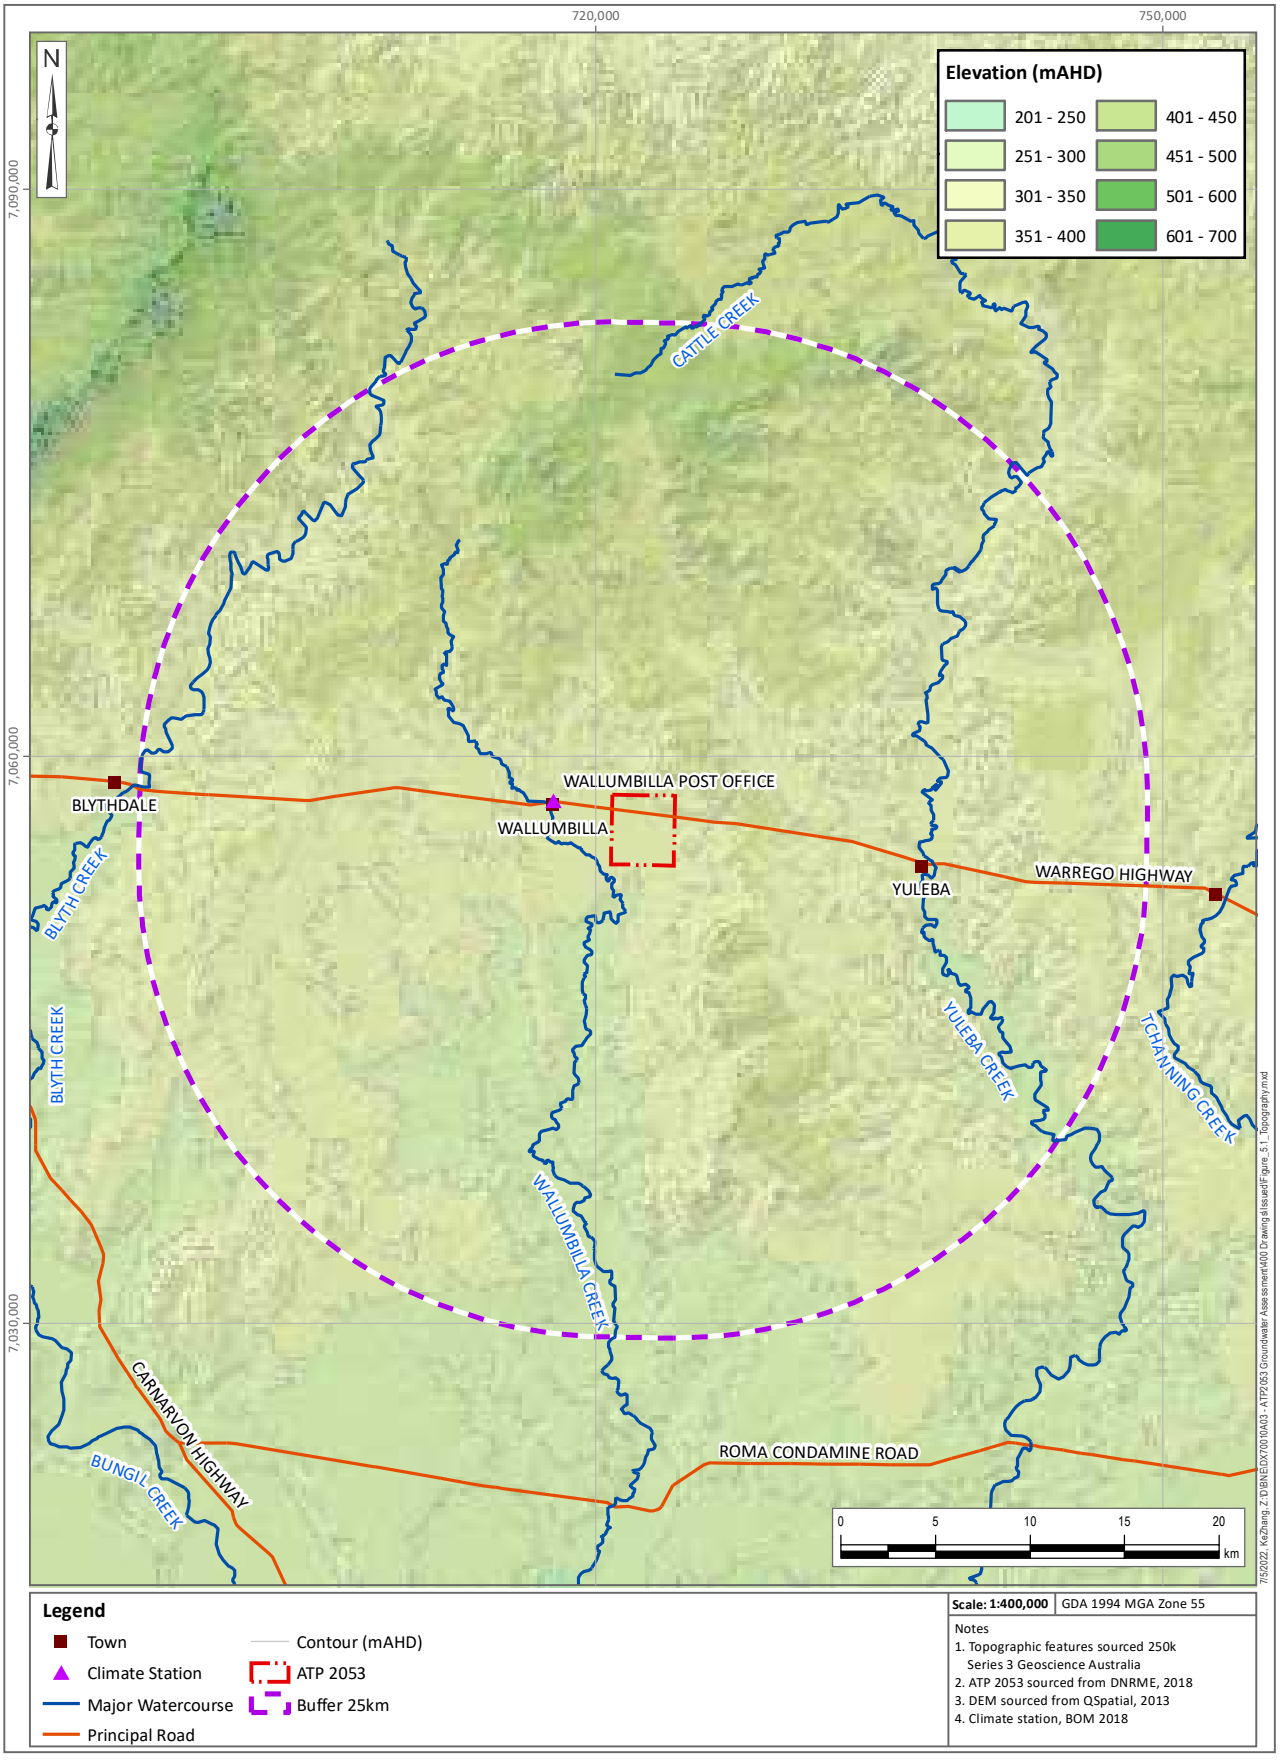

Figure 5.1 Topography within the Vicinity of the Project Area

Figure 5.2 presents daily rainfall between January 1963 and February 2023 for Wallumbilla Post Office climate station, and a rainfall excess / deficit trend for the same period. Rainfall excess / deficit trends present a running deviation of long-term actual rainfall against the average. This provides seasonal-scale identification of trends (wet / dry) and longer term (e.g. decadal) deviation from average conditions. These trends result in a natural tempering of peaks for rainfall events and therefore support the correlation of rainfall events to aquifer responses.

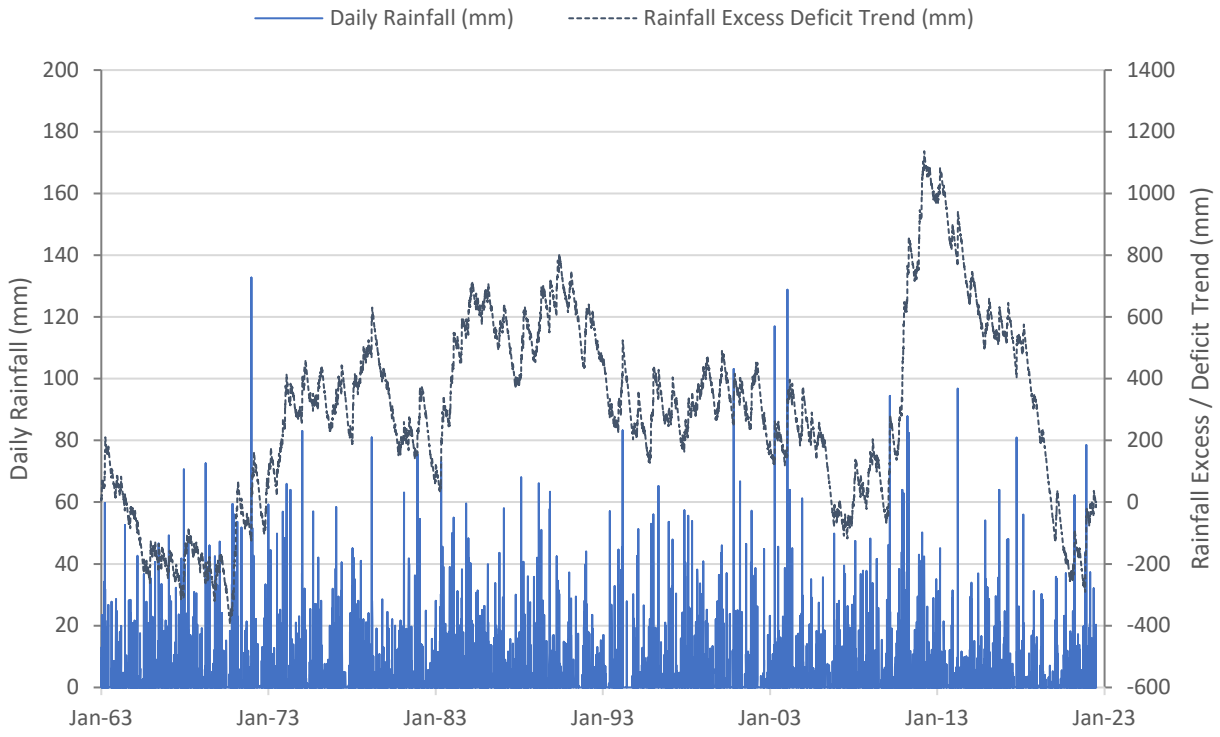

Figure 5.2 Daily Rainfall and Rainfall Excess / Deficit Trend (Wallumbilla Post Office 43038)

Observations from the rainfall excess / deficit (CRD) trend include:

- The overall rainfall trend is characterised by the cyclic nature of the wet and dry seasons, with fluctuations of 150 -200 mm evident across the record.
- The 2010 / 2011 above average rainfall resulted in 900 mm increase in the rainfall excess / deficit trend.
- The general rainfall excess / deficit trend increased gradually between 1970 and 1990, where after it decreased gradually until 2010.
- Between 2010 and 2012 the rainfall excess / deficit trend increased steeply in response to above average rainfall, followed by a steady decline and trend reversal in 2021.

5.1.1 Climate Change

The Queensland Government has developed an interactive map to help understand the impact of climate change for specific council regions (State of Queensland 2024a).

The Project Area is located in the Central Queensland region, which is potentially subject to the following predicted climatic scenario in 2050, under a modelled high emissions case:

- 1.9ºC increase in median annual temperature (1.4ºC for low emissions case);
- 8% decrease in median annual rainfall (2% for low emissions case); and
- 7% increase in median annual evaporation (5% for low emissions case).

These trends (decreased annual rainfall and increased annual evaporation) are also evident in the low and high emissions case for 2030, 2070 and 2090. The low and high emission cases forecast a reduction in rainfall and an increase in evaporation.

Individual rainfall events are naturally highly variable, and this will continue to be a factor that requires careful consideration in future, especially since the intensity of heavy rainfall events are likely to increase under climate change conditions. Furthermore, groundwater recharge may be expected to decrease under these conditions.

5.2 Land Use

Land use information specific to the Project Area has been sourced from the Queensland Government datasets (DES 2018a). The land use dataset classifies land use type using the Australian Land Use and Management (ALUM) Classification system which provides a nationally consistent method to collect and present land use information in Australia. This classification system categorises 32 land use classes and subclasses. There are six primary classes used in the ALUM classification system, and these are further divided into secondary and Tertiary classes. A description of the primary classes (ABARES 2010) is detailed below:

- Conservation and natural environments – Land is used primarily for conservation purposes, based on the maintenance of essentially natural ecosystems already present.
- Intensive uses – Land is subject to substantial modification, generally in association with closer residential settlement, commercial or industrial uses.
- Production from dryland agriculture and plantations – Land is used mainly for primary production, based on dryland farming systems.
- Production from irrigated agriculture and plantations – Land is used mainly for primary production, based on irrigated farming.
- Production from relatively natural environments – Land is used mainly for primary production based on limited change to the native vegetation.
- Water – Although primarily land cover types, water features are regarded as essential to the classification.

Figure 5.3 presents the land use in the vicinity of the Project Area, with a summary of the land use distribution (area and percentage) (DES 2018a) directly within the Project Area provided in Table 5.2. There are three types of primary land use within the Project Area. The dominant land use is production from relatively natural environments specifically grazing from native vegetation (94%). Grazing modified pastures and cropping is also undertaken in 4% of the Project Area, with intensive uses only constituting 0.8%.

Table 5.2 Summary of the Current Land Use within the Project Area

Land Use Category			Area (km^2)	Percentage of Total Area
Primary	Secondary	Tertiary		
Intensive uses	Services	Recreation and Culture	0.10	0.80%
Production from dryland agriculture and plantations	Cropping	Cropping	0.12	1.01%
	Grazing modified pastures	Woody fodder plants	0.50	4.12%
Production from relatively natural environments	Grazing native vegetation	Grazing native vegetation	11.54	94.07%
Total			12.26	100%

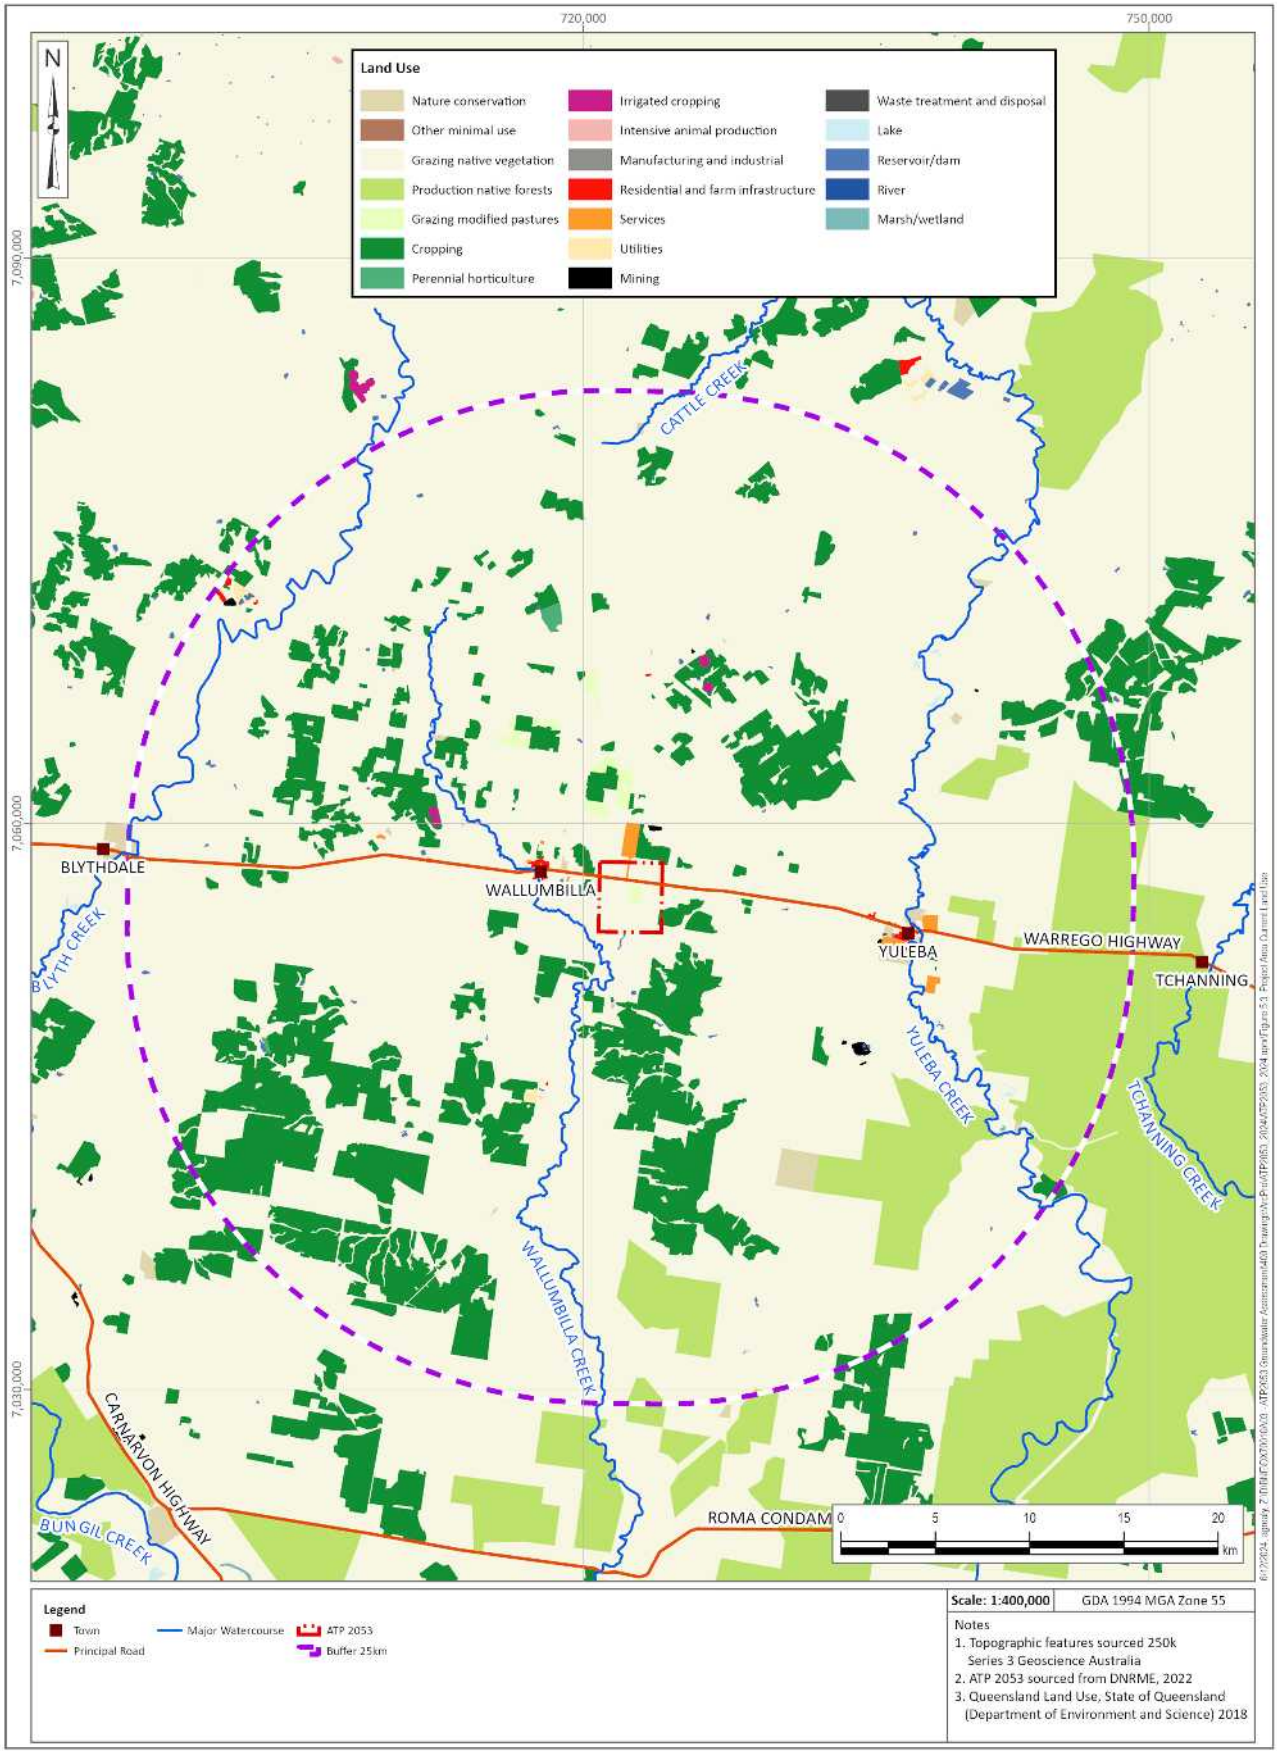

Figure 5.3 Project Area Current Land Use

6 HYDROLOGICAL SETTING

6.1 Location and Catchment Context

The Project Area is located in the Balonne River sub-basin (within the wider the Condamine-Balonne Basin). The Condamine-Balonne Basin covers an area of 136,649 km^2 (in Queensland) and represents 14 % of the larger Murray-Darling Basin. The majority of the Condamine-Balonne Basin is located in Queensland, with 16% in New South Wales (Commonwealth of Australia 2020). The Balonne River flows east to west until Surat where it flows towards the southwest. Many tributaries flow into the Balonne River. The Balonne River flows into Lake Kajarabie (Beardmore Dam) near St George (approximately 140 km to the southwest of the Project Area), before becoming a braided network of channels, waterholes and floodplains that form the Narran, Bokhara, Ballandool and Culgoa Rivers, and Briarie Creek.

Major river sub-catchments within the vicinity of the Project Area include:

- Balonne River sub-catchment which includes upper Balonne River tributaries; and
- Yuleba Creek sub-catchment.

6.2 Key Surface Water Bodies

6.2.1 Watercourses

Key watercourses within / in close proximity to the Project Area are shown in Figure 6.1, and include:

- Washpool Creek: is a minor creek, which originates 5 km north of the Project Area and flows through the Project Area before joining Wallumbilla Creek 2 km south of the Project Area.
- Wallumbilla Creek: originates 16 km northwest of the Project Area and flows south – southeast close to the township of Wallumbilla. The creek continues to flow south before reaching the Balonne River confluence downstream of Yuleba Creek, 54 km south of the Project Area.
- Middle Creek: is a tributary of Wallumbilla Creek, which originates 15 km northwest of the Project Area and flows south between the township of Wallumbilla and the Project Area before joining Wallumbilla Creek 2 km west of the Project Area.

Other watercourses in the greater area include:

- Yuleba Creek is identified by the Water Act 2000 as a major watercourse and flows for approximately 187 km from near the Great Dividing Range before joining the Balonne River 45 km south of Yuleba. Yuleba Creek originates close to the Balonne River catchment area. Yuleba Creek flows predominately south, close to the township of Yuleba, located 13 km east of the Project Area and joins the Balonne River, 46 km southeast of the Project Area.

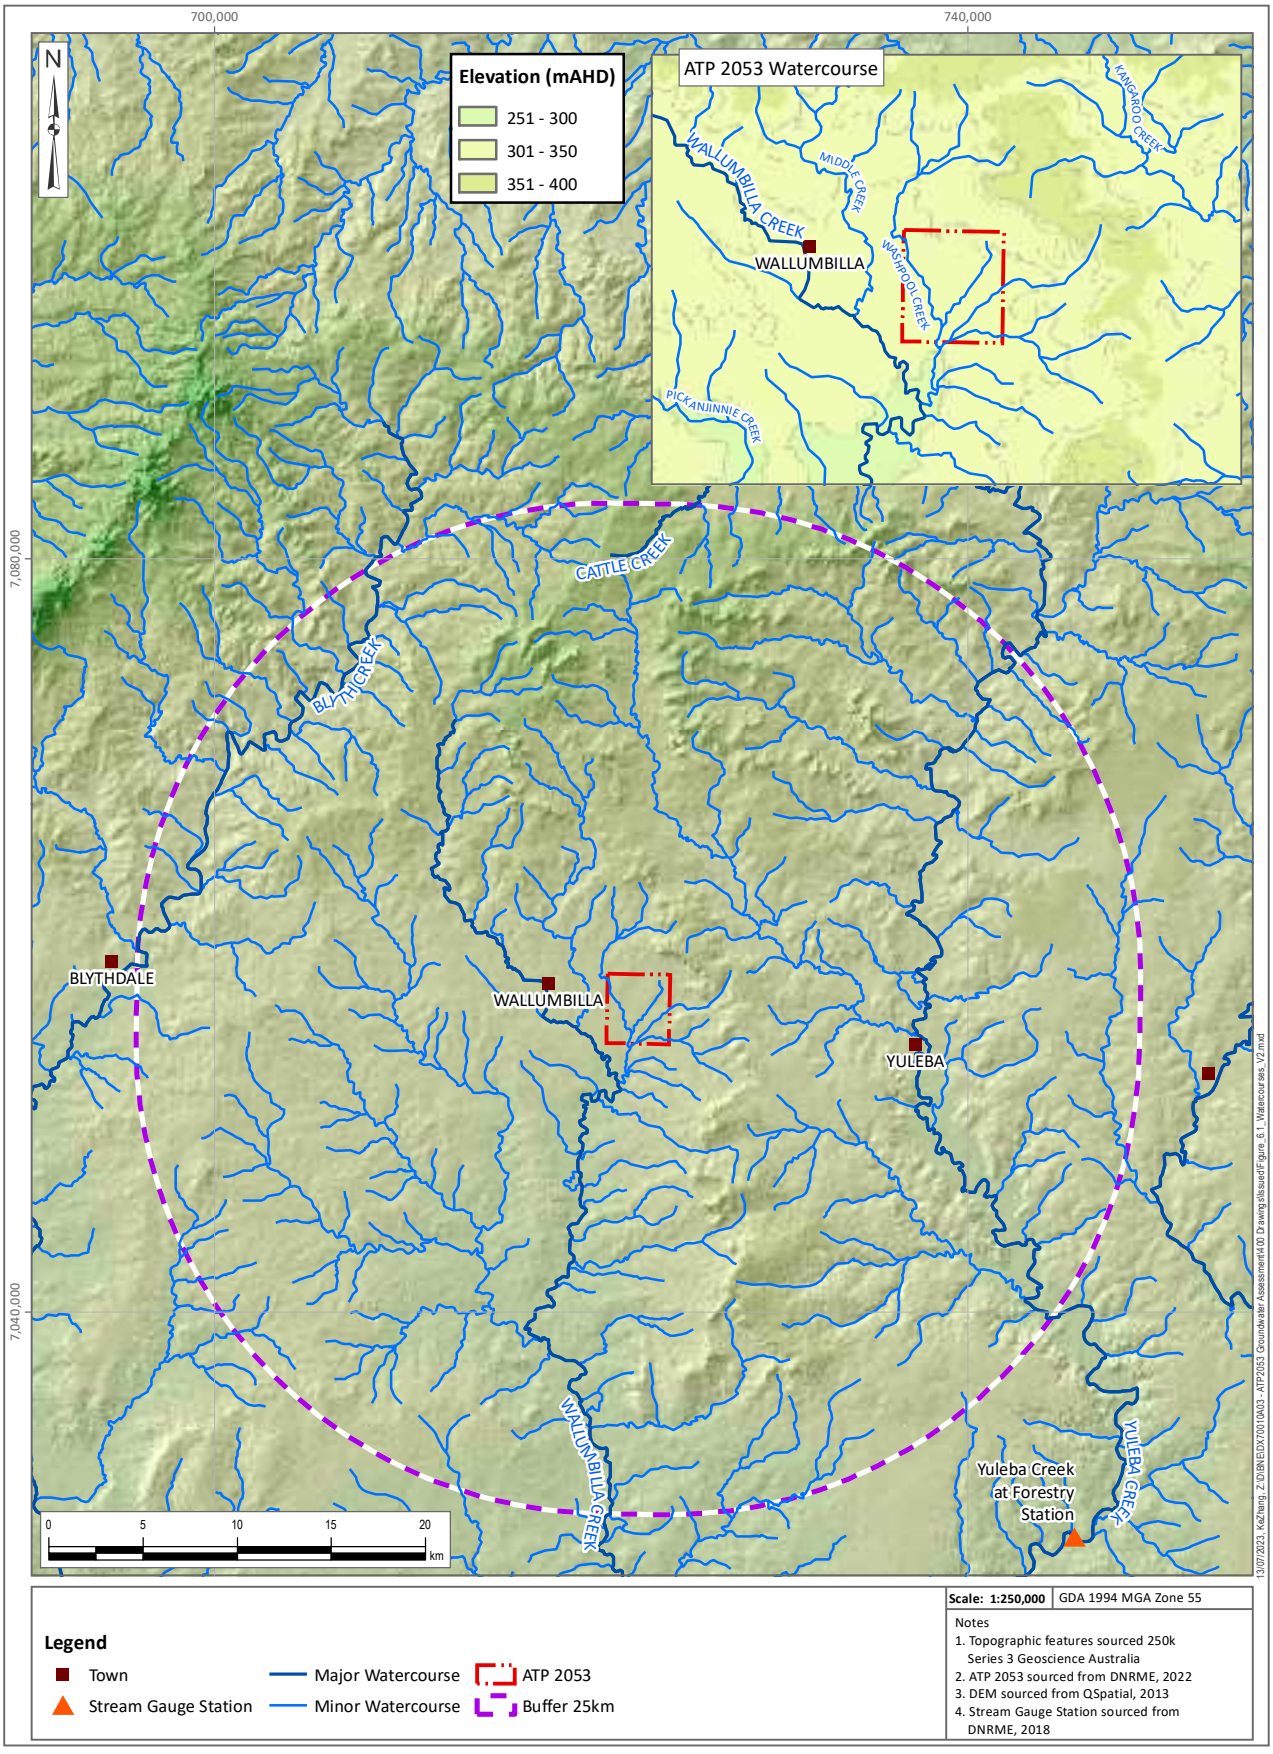

Figure 6.1 Watercourses in the Vicinity of the Project Area

The watercourses in close vicinity to the Project Area are classified as Stream Order 1 to Stream Order 5 based on the Strahler method (DNRM 2010). A list of watercourses and associated stream orders within the Project Area are presented in Table 6.1.

Table 6.1 Stream Order Classification

Sub-Catchment	Stream	Stream Order(s)
Yuleba (Balonne-Condamine Basin)	Washpool Creek	1, 2, 3
	Wallumbilla Creek	3, 4
	Middle Creek	2,3

6.2.2 Wetlands

Wetlands listed in the '*Directory of Important Wetlands in Australia*' (Environment Australia 2001) are not identified to be located in or within 25 km of the Project Area, respectively. The closest wetlands are located more than 120 km from the Project Area and are therefore not considered material to this assessment.

No wetlands of High Ecological Significance or wetlands of General Ecological Significance, as shown on a Map of Referable Wetlands (DETSI 2024a), were mapped by the EAR as present within the Site (Boobook 2024b).

A review of the Project Area on the Queensland Government's interactive wetland mapping website 'Wetland Info' (DETSI 2024b) was undertaken. Wetland Info mapping indicated the Project Area includes lacustrine, riverine and minor palustrine wetlands as shown in Figure 6.2.

Lacustrine wetlands are open water dominated systems (e.g. dams and lakes). In turn, palustrine wetlands lack open or flowing water (e.g. marsh or bogs). The Project Area is also identified to contain four areas that may include wetlands (indicated as remnant regional ecosystems (REs) containing 1-50% wetlands). Potential wetlands (1-50%) are also indicated along the banks of Middle and Wallumbilla Creeks located 1 km to the west of the Project Area.

Ground-truthed vegetation surveys undertaken by the EAR identified several wetlands of limited extent and general ecological significance within the Project Area. Ground-truthed wetlands are shown in Figure 7.28.

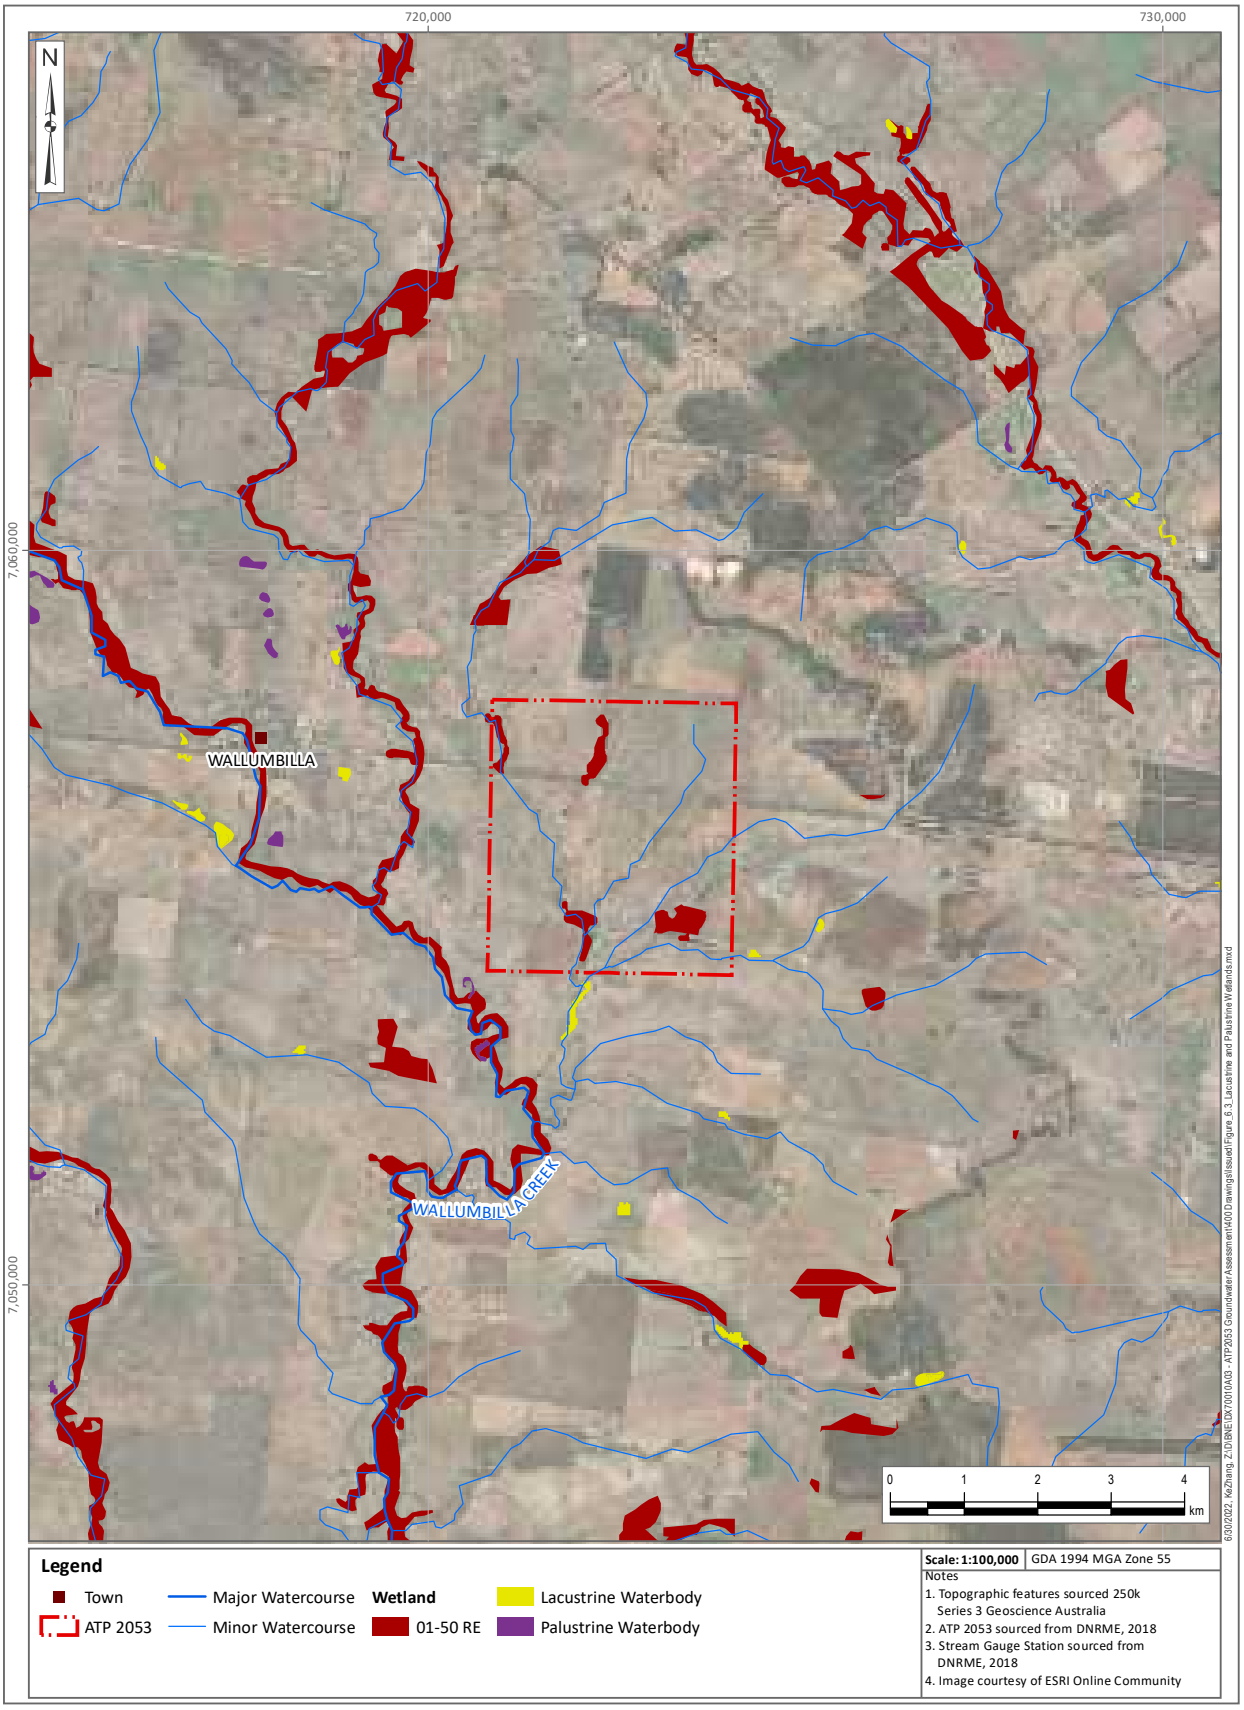

Figure 6.2 Location of Mapped Lacustrine and Palustrine Wetlands in Relation to the Project Area

6.3 Geomorphology

The Condamine-Balonne rivers catchment is one of the largest catchments in the Murray-Darling Basin. The main rivers of the catchment, the Condamine and the Maranoa Rivers, arise in elevated areas of Queensland. However, two-thirds of the catchment, is flat floodplain country, with a complex system of rivers and creeks joining and breaking away from the Balonne River.

Detailed geomorphological descriptions of the creeks within the Project Area were not available at the time of report compilation. An elevation section including Washpool Creek and its tributaries sourced from Google Earth indicate that the creeks beds are gently sloping and open.

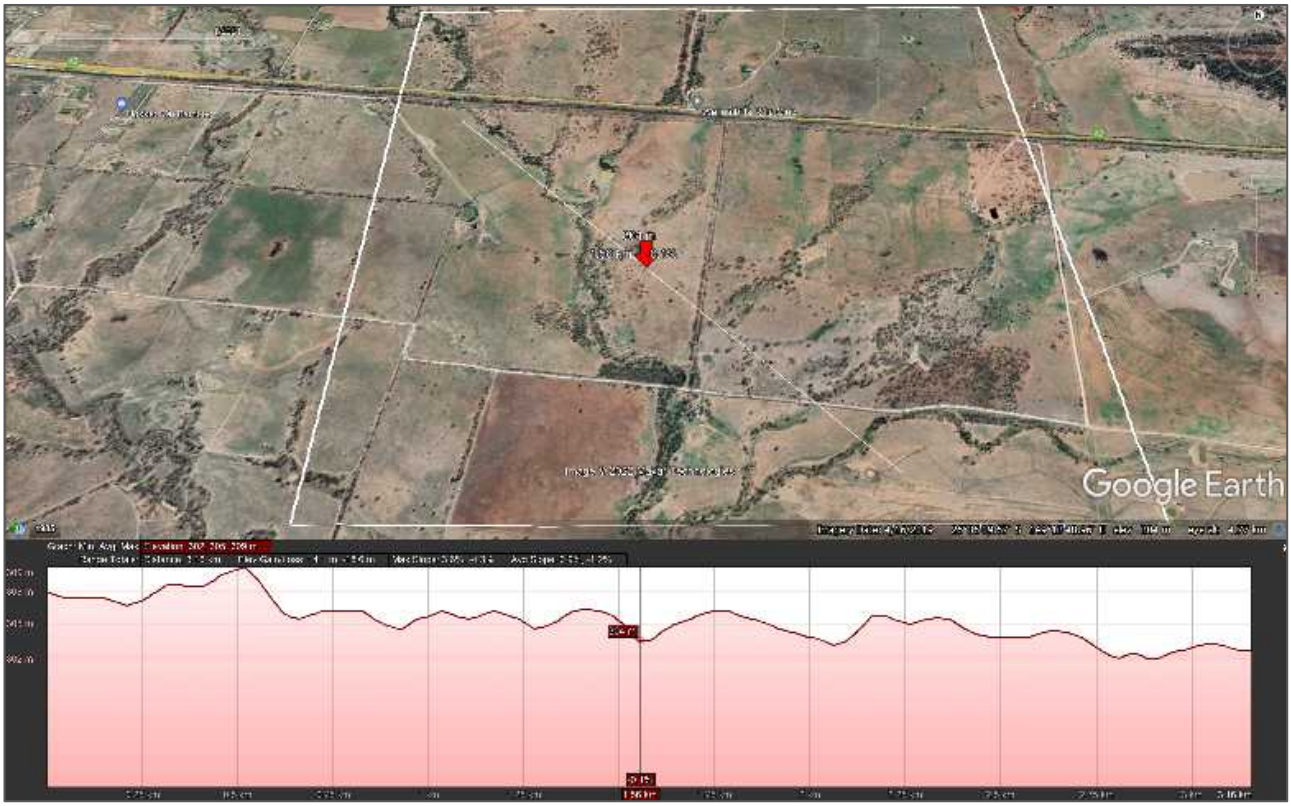

Figure 6.3 Elevation Profile (Google Earth 2022)

6.4 Flood Regime

Floodplain mapping sourced from the Queensland Government (State of Queensland 2022a) is presented in Figure 6.4. The mapped data indicates that Wallumbilla Creek and Washpool Creek floodplain areas cover a portion of the south and southwest corner of the Project Area.

Flood modelling maps are available through Queensland Globe (State of Queensland 2022c). Flood modelling mapping for a 1% AEP, or 1 in 100-year flood, are available. The mapping indicates that for a 1 in 100-year flood event, flooding may occur in Wallumbilla Creek and Yuleba Creek (5 km east of the Project Area) as well as in branching tributaries, including Washpool Creek and Middle Creek. Flooding of these tributaries during a 1 in 100-year flood event is identified in the southern extent of the Project Area. In tributaries, flood depths are generally less than 0.8 m, while in the main channels of Wallumbilla Creek and Middle Creek, flood depths are generally less than 2.0 m, but in some areas, such as at the Wallumbilla Creek and Middle Creek confluence, it can be greater than 2.0 m.

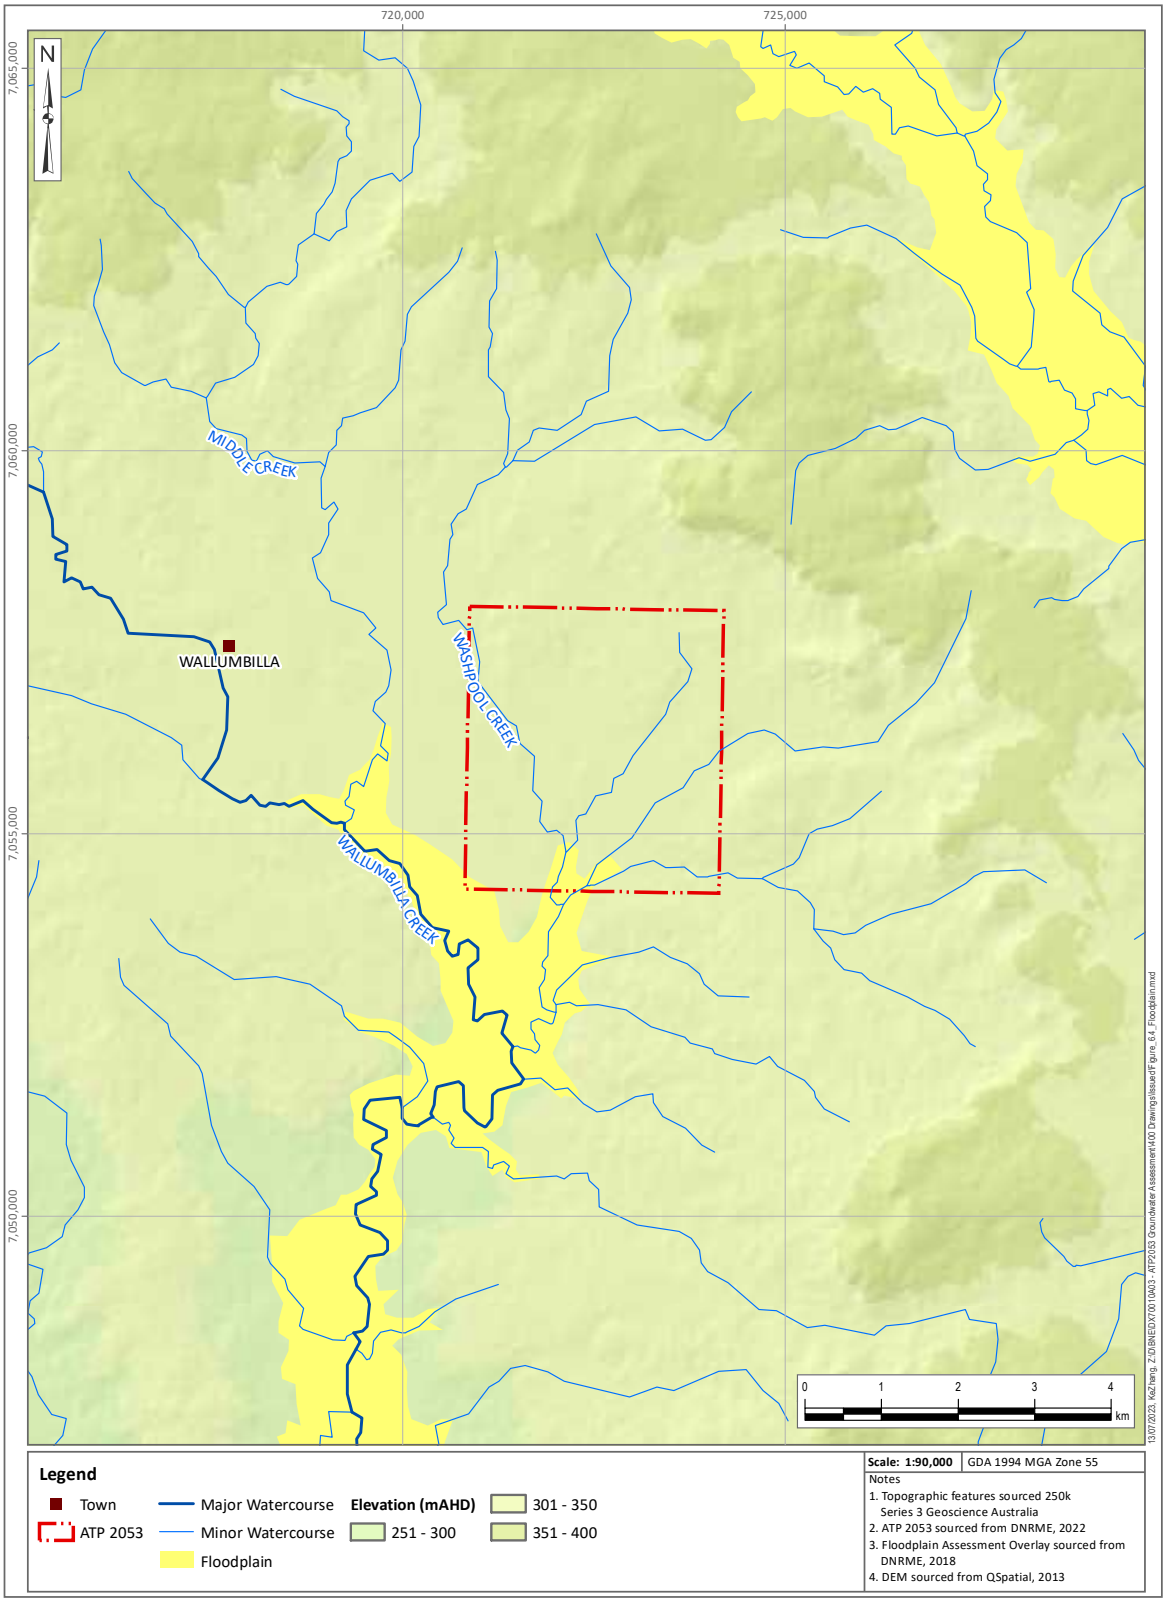

Figure 6.4 Floodplain Assessment Overlay – Flood Extent for 1% AEP

6.5 Surface Water Flow

6.5.1 Watercourse Classification

Hydrologic flow can be classified into three regimes; permanent, semi-permanent and ephemeral based on Kennard et al. (2010):

- Permanent: Stream discharge persists during both high-rainfall (typically summer wet season) and low rainfall (typically winter dry season) periods. During drought years, some 'cease to flow' periods may occur, however non-flowing, connected pools will persist throughout the waterway channel.
- Semi-Permanent: A watercourse that contains water for more than 70% of the time on average. These watercourses experience high discharges during heavy rainfall periods (i.e. summer wet season), however are typically reduced to a series of disconnected, non-flowing series of pools during the dry season.
- Ephemeral: These watercourses will typically only experience surface water flow during or immediately after heavy or sustained rainfall events (i.e. summer wet season). Following periods of flow surface water will persist in the form of non-flowing, disconnected pools separated by dry / exposed stream beds. Surface water (flowing or non-flowing) is only present for a small part of the hydrological cycle.

The watercourses within the Project Area are characteristically ephemeral and typically flow only during significant runoff events.

6.5.2 Flow and Discharge

There are no Department of Regional Development, Manufacturing and Water (DRDMW) surface water gauges located within the Project Area. The closest gauge in the relevant catchment (Balonne-Condamine) is located 32 km southeast of the Project Area. Table 6.2 provides details of this station, with its location shown on Figure 6.1 and a discussion of the data provided below.

Table 6.2 Summary of Surface Water Gauge (State of Queensland 2022c)

Basin	Sub-Basin	Gauge Number	Gauge Name	Easting[1]	Northing[1]	Status	Period of Operation	Location in Relation to Project Area
Balonne-Condamine	Upper Balonne River Tributaries	422219A	Yuleba Creek at Forestry Station	745678	7028063	Open	September 1972 to present	32 km SE, Downstream

[1]Coordinates in GDA94, Zone 55.

Yuleba Creek at Forest Station (422219A)

Surface water flow and stage height data is available for Yuleba Creek (422219A) between September 1972 and July 2022. The flow gauge is located 20 km upstream of the confluence of Yuleba Creek with the Balonne River.

The monthly median discharge for Yuleba Creek (422219A) is shown in Figure 6.5 and indicates the majority of flow occurring during December to March in response to wet season rainfall events, highlighting the highly ephemeral nature of the watercourse. Creek flow in the dry season (April to November) is generally zero or close to zero. The stage height data presented in Figure 6.6 highlights the seasonality of the flow in the creek.

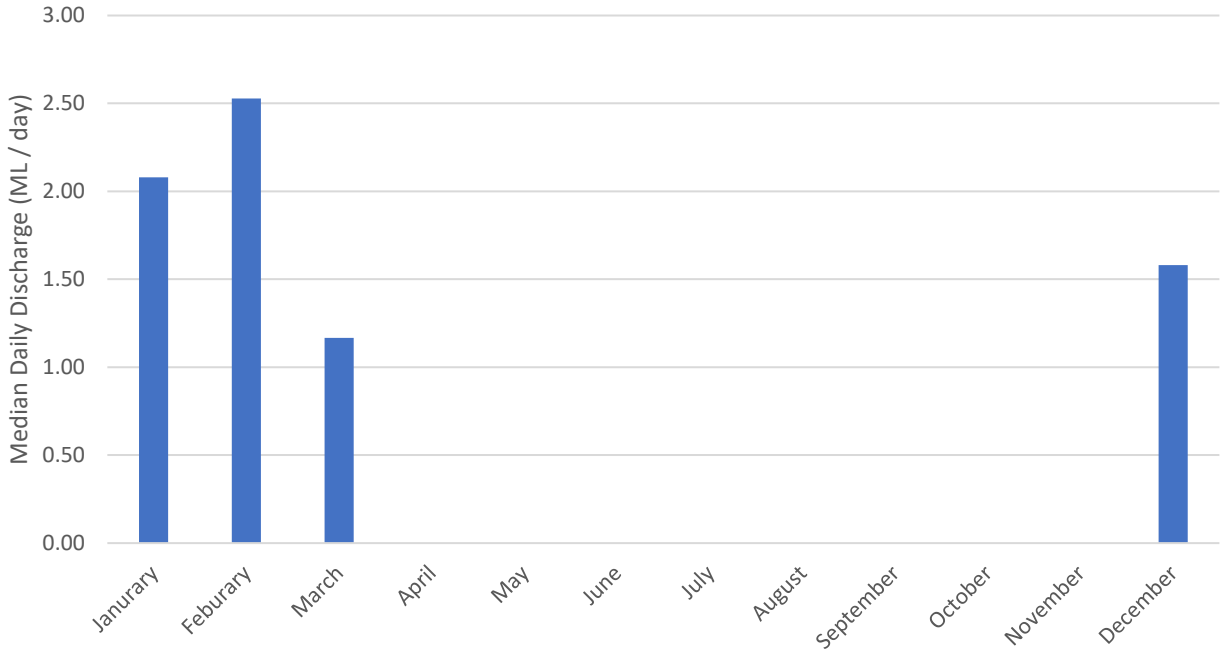

Figure 6.5 Monthly Mean Daily Discharge at Yuleba Creek at Forestry Station (422219A), 1972 to 2022

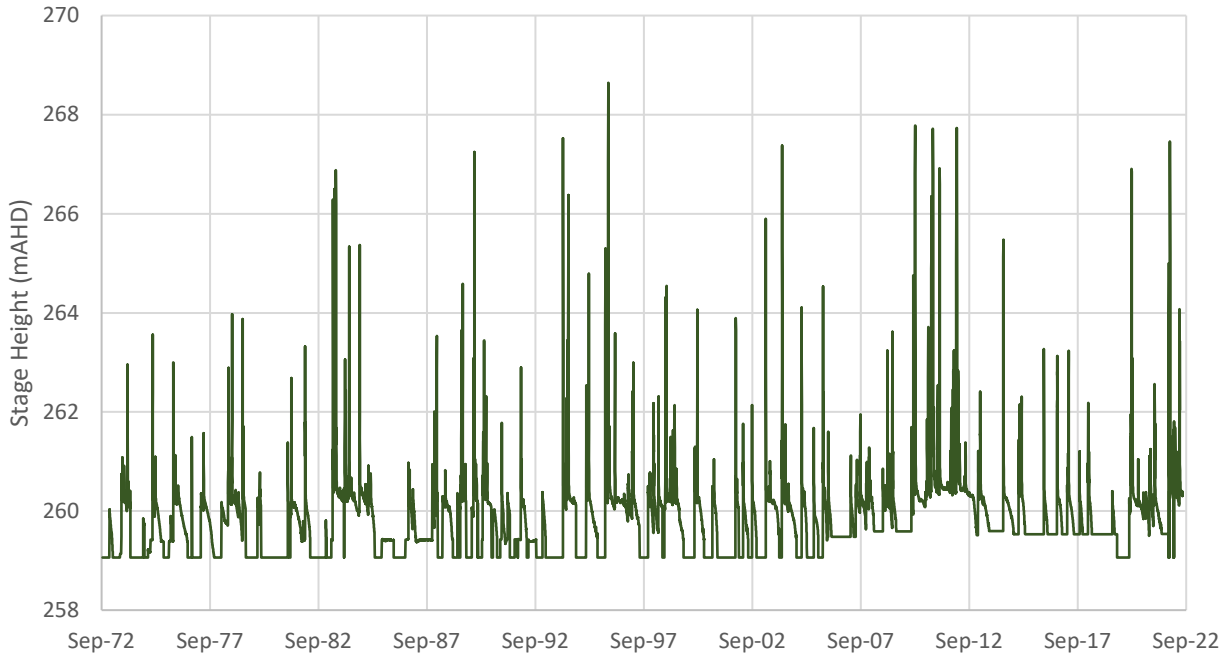

Figure 6.6 Stage Height at Yuleba Creek at Forestry Station (422219A), Downstream of the Project Area

The cumulative exceedance probability for the average daily recorded flow is shown in Figure 6.7 and indicates that flows are present in Yuleba Creek, downstream of the Project Area, for 27% of the gauged period. The flow, which is exceeded 5% of the time, is approximately 108 ML/day which is also identified as a flow equalled, or not exceeded 95% of the time, based on the available records. This highlights the ephemeral nature of the watercourse.

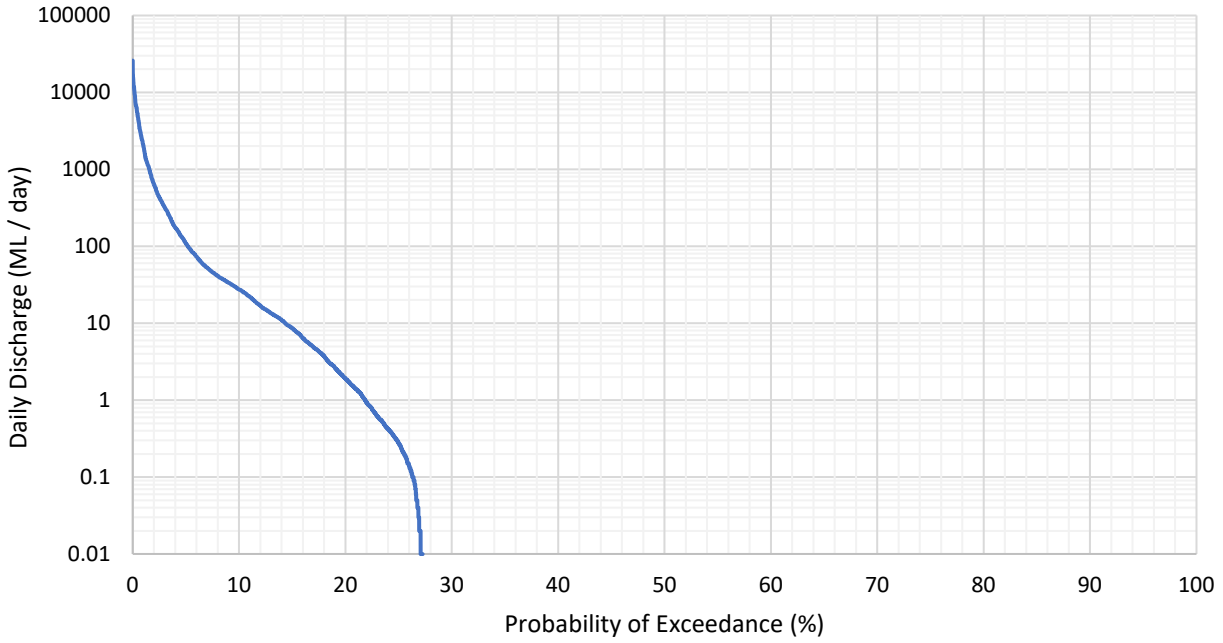

Figure 6.7 Cumulative Exceedance Probability for Recorded Daily Discharge at Yuleba Creek at Forestry Station (422219A)

6.5.2.1 Surface Water Quality

Surface water quality data was sourced from the Queensland Government for the flow gauge at Yuleba Creek at Forestry Station (422219A). Data is available between 1973 and 2010 and summarised in Table 6.3.

Table 6.3 Summary of Surface Water Quality for Yuleba Creek at Forestry Station (422219A)

Parameter	Count	5th Percentile	95th Percentile	Mean	Standard Deviation
Field EC @ 25°C	9	90.4	260.6	158.7	69.7
Turbidity (NTU)	6	55.3	100.0	87.8	21.5
Colour True (Hazen units)	4	24.7	70.0	52.8	23.6
Water Temperature (°C)	19	12.4	27.2	22.0	5.9
Field pH (pH units)	10	6.7	7.8	7.3	0.4
Total Alkalinity as $CaCO_3$ (mg/L)	10	20.5	102.4	52.2	31.2
TDS (mg/L)	10	61.2	227.5	127.9	62.1
Calcium as Ca soluble (mg/L)	10	4.7	19.6	9.9	6.1
Chloride as Cl (mg/L)	10	5.5	51.4	23.2	18.5
Magnesium as Mg soluble (mg/L)	10	2.0	8.9	4.7	2.8
Potassium as K (mg/L)	10	3.7	7.3	5.2	1.3
Sodium as Na (mg/L)	10	9.5	39.2	21.1	11.6
Sulfate as SO_4 (mg/L)	10	2.2	13.1	7.9	3.9
Fluoride as F (mg/L)	7	0.1	0.1	0.1	0.0
Iron as Fe soluble (mg/L)	7	0.4	5.5	2.7	2.1

Time series data is not available for Yuleba Creek (422219A), however intermittent electrical conductivity (EC) data is available from 1973 to June 2010 and is presented in Figure 6.8. The data shows the EC ranges between 72 and 455 µS/cm. The mean daily flows are also included in Figure 6.8 and highlights the relationship between the EC and surface water flow.

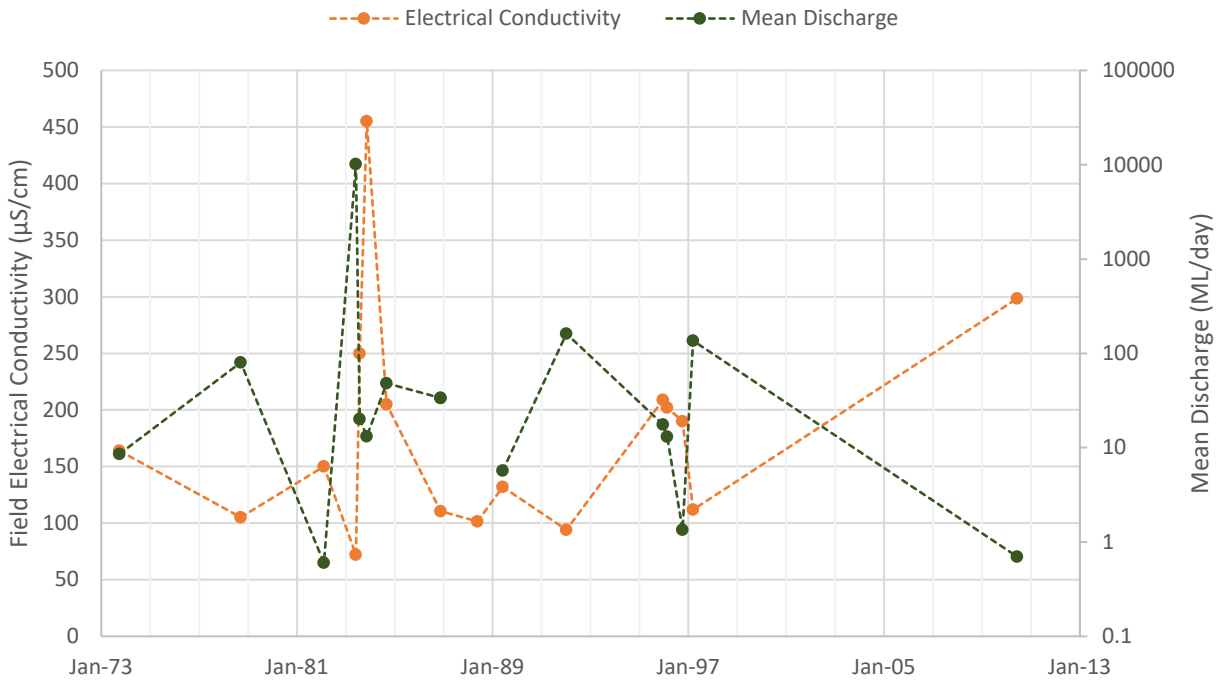

Figure 6.8 Electrical Conductivity from Yuleba Creek at Forestry Station (422219A)

Piper and Durov diagrams have been prepared for surface water quality monitored at Yuleba Creek (422219A) flow gauge Figure 6.9. The surface water is characterised as sodium-potassium - bicarbonate water type.

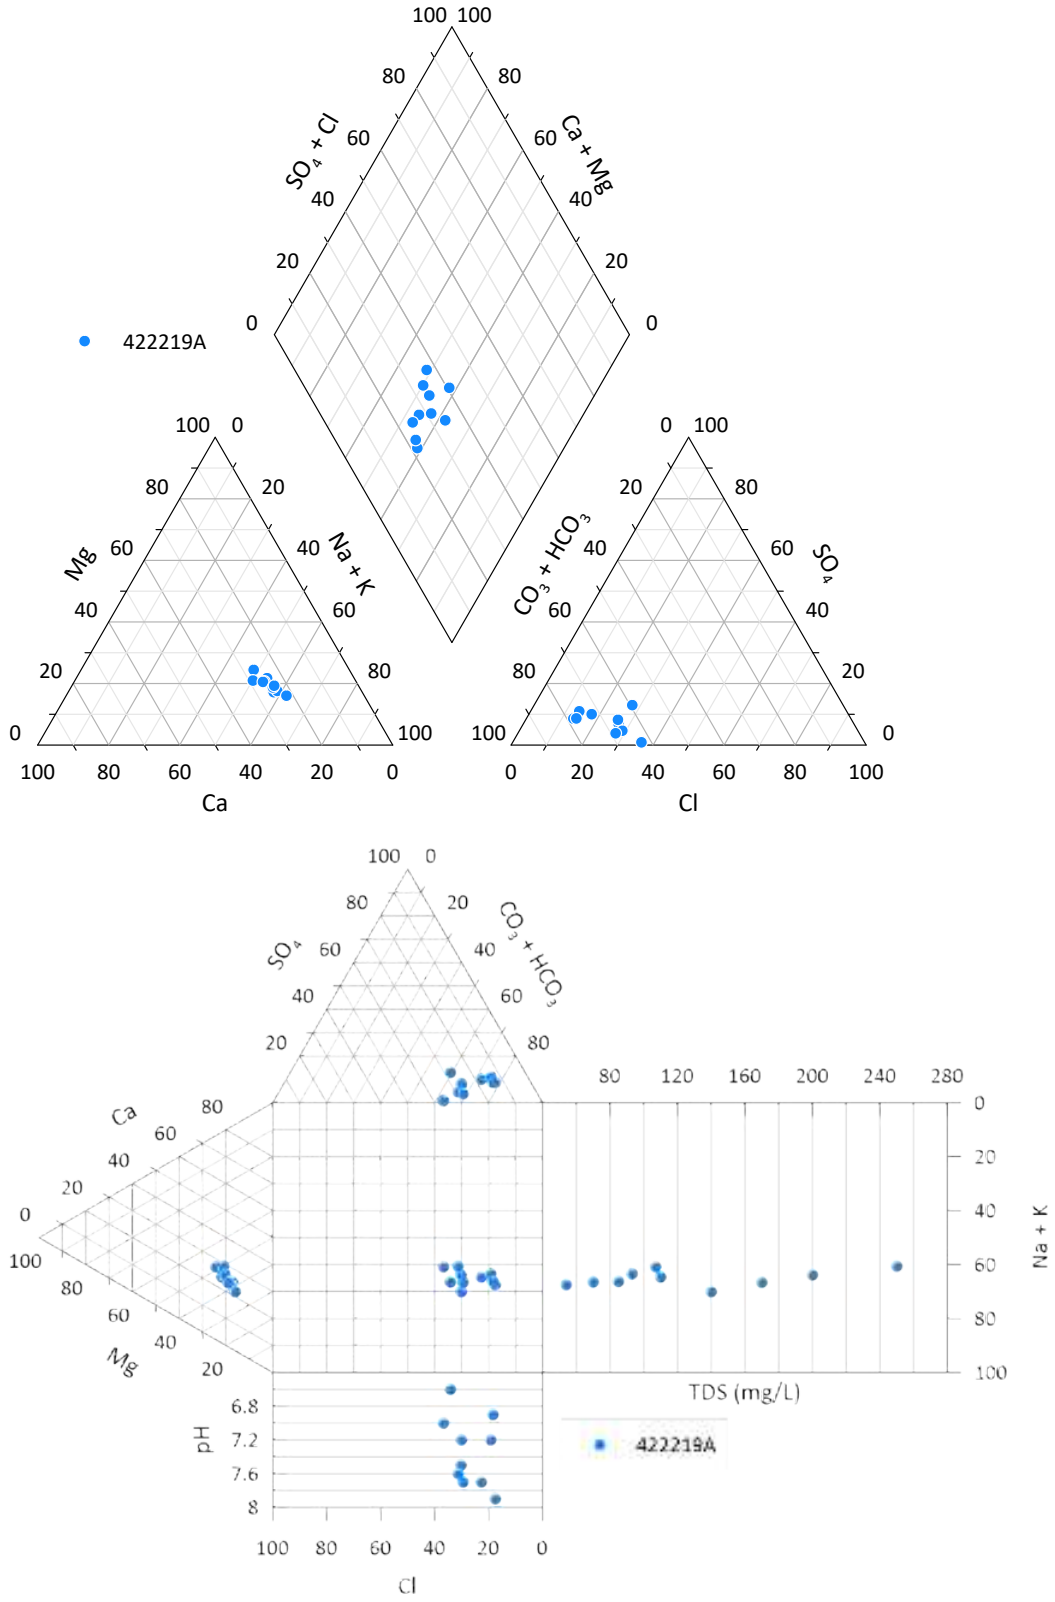

Figure 6.9 Piper and Durov Diagrams for Surface Water Samples from Yuleba Creek at Forestry Station (422219A)

6.6 Current Surface Water Stressors

Water management in the Condamine-Balonne catchment is described by the Murray-Darling Basin Authority (Commonwealth of Australia 2021). While a few main waterways of the Condamine-Balonne rivers catchment flow to the Barwon–Darling River system, most end in lakes and wetlands in southwest Queensland and northwest New South Wales.

The Condamine-Balonne catchment is home to almost 10% of the population of the Basin. Toowoomba, the largest centre, has a population of around 150,000. The region is significant for its agricultural diversity, with a wide range of winter and summer crops produced on the Darling Downs, as well as very large cotton production areas in the west.

The lands of the Condamine-Balonne catchment have been important to First Nations people for thousands of years. Many First Nations people retain a connection with the region, and their history, culture and livelihoods are closely intertwined with its river systems.

Land use in the catchment is dominated by cattle and sheep grazing on dryland pasture. Grain and cotton crops are a significant contributor to the regional economy and are grown under dryland and irrigated farming respectively.

The Commonwealth Scientific and Industrial Research Organisation (CSIRO) reports, on average 53% of available surface water from the Condamine-Balonne catchment was extracted for use annually, which is extremely high compared with other catchments in the Basin. Surface water use is on average 82% of the total water use (surface and groundwater). The high level of use in the Condamine-Balonne catchment has significantly reduced end-of-system flows, particularly into the Narran Lakes system.

6.7 Aquatic Ecology

6.7.1 AquaBAMM Desktop Assessment

The aquatic habitat of watercourses in the Condamine-Balonne catchment comprises water channels during flowing conditions, as well as isolated perennial waterholes present during dry season. The lacustrine wetlands may also provide a habitat for aquatic fauna and flora. The watercourses across the Project Area are expected to be highly ephemeral, with streamflow only expected following rainfall events. Ephemeral streams can support invertebrate communities although flow intermittence has been linked to reduced taxa richness (Stubbington et al. 2017).

AquaBAMM is the state endorsed method for identifying and assessing wetlands in Queensland. AquaBAMM is also a decision support tool that utilises existing information and expert input to assess conservation value in aquatic ecosystems. The output of the AquaBAMM method is an Aquatic Conservation Assessment (ACA) for a specified study area (State of Queensland 2019e). The ACA for the wetlands of the Queensland Murray-Darling Basin was published in July 2011 (DERM 2011). ACAs provide a source of baseline, wetland conservation / ecological information to support natural resource management and planning processes. The ACAs assess riverine and non-riverine (palustrine and lacustrine) wetlands separately. The riverine or non-riverine wetlands within the sub-catchment units are then assigned an AquaScore based on an assessment of eight criteria. The criteria are:

- Naturalness aquatic;
- Naturalness catchment;
- Diversity and richness;
- Threatened species and ecosystems;
- Priority species and ecosystems;
- Special features;
- Connectivity; and
- Representativeness.

The AquaScore represents the overall conservation value of a sub-catchment unit and varies from very low to very high.

Wallumbilla and Yuleba Creeks, and their tributaries, are identified to have a medium to high riverine AquaScore. Non-riverine wetlands of limited extent with a very low to medium AquaScore are also indicated to occur at the Project Area. The upper catchment of Wallumbilla Creek (located to the northwest of the Project Area) has been identified as an area containing riverine 'special features' by flora, fauna and ecology expert panels. Special features are areas considered to be of the highest ecological importance (State of Queensland 2019).

6.7.2 Site-Specific Assessment

Ecological assessment of the Project Area, as documented by the EAR, included a desktop assessment followed by a field survey with a focus on verification of desktop findings. Additional findings of significance were also noted. No specific stream assessments were undertaken within the scope of works(Boobook 2024b).

The EAR (Boobook 2024b) does not identify MNES or MSES threatened aquatic fauna or flora to be present within the Project Area extent.

6.8 Existing Surface Water Users

Wallumbilla Creek occurs within Zone 2 of the Condamine – Balonne Tributaries Water Management Area (WMA), as defined under the Condamine-Balonne Water Resources Plan (State of Queensland 2019b). Yuleba and Wallumbilla Creeks occur within the Condamine and Balonne Tributaries WMA CBT-02, which is an unsupplemented surface water trading zone (where water entitlements for unsupplemented surface water (natural flow) may be traded). Tradeable water allocations in the Condamine and Balonne Tributaries Zone 2 total 22,162 ML/year (Figure 6.10).

Both creeks flow south before joining the Balonne River 50 km south of the Project Area within the Condamine-Balonne WMA – Zone CBU-07 (also an unsupplemented surface water trading zone). Details of CBU-07 are listed in Table 6.4.

Table 6.4 Water Management Area for Water Allocation (State of Queensland 2019f)

WMA	AMTD[2] (km)	Flow Management Location	Location in Relation to Project Area
CBU-07	466.8 – 405.2	The Balonne River, from the confluence of Yuleba downstream to Surat Weir	46 km south southeast

There are no surface water supply schemes present within 90 km of the Project Area and no surface water users within 15 km of the Project Area.

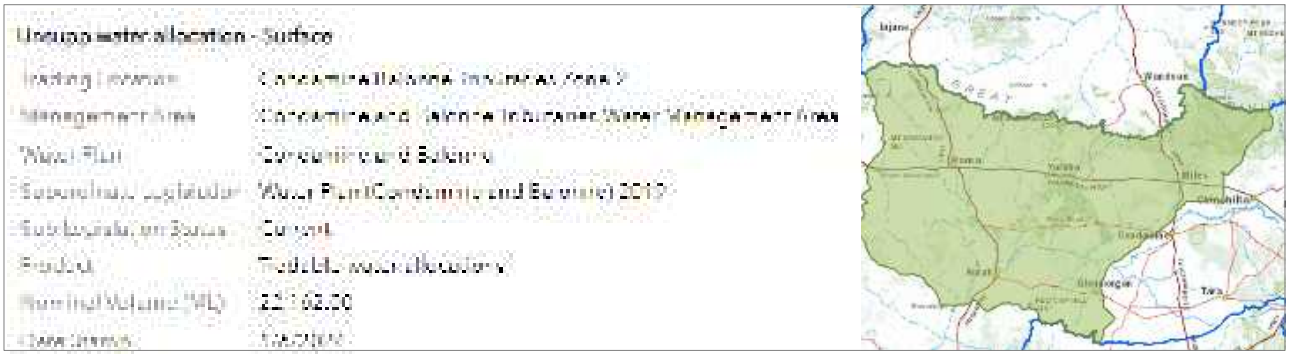

Figure 6.10 Unsupplemented Water Allocation – Condamine and Balonne Tributaries Zone 2

[2] Adopted Middle Thread Distance: the distance in kilometres, measured along the middle of the watercourse, that a specific point in the watercourse is from the water course mouth or confluence with a main water course

7 HYDROGEOLOGICAL SETTING

7.1 Geological Setting

7.1.1 Regional Geology

The Project Area is located within the geographical extent of the Surat Basin, a basin of Jurassic-Cretaceous age, which is underlain by the Permo-Triassic Bowen Basin. Cenozoic-age formations are present overlying the Surat Basin formations. The Bowen Basin, which contains up to 10 km of terrestrial and shallow marine sediments, is elongated, trending north-south, and extending over 160,000 km^2 from central Queensland, south beneath the Surat Basin, into New South Wales where it eventually connects with the Gunnedah and Sydney basins (PM Green 1997; Korsch Totterdell 2009 and OGIA 2019a). The southern Queensland and northern-most New South Wales portion of the Bowen Basin is overlaid by up to 2.5 km of Early Jurassic to Early Cretaceous Surat Basin sedimentary sequences (Fielding et al. 2000; Korsch and Totterdell 2009), followed by Cenozoic-age formations comprising unconsolidated alluvial sediments (sand, silt and clay), which have been deposited along pre-existing watercourses (OGIA 2019a).

The Surat Basin underlies approximately 180,000 km^2 of southeast Queensland and is connected to the Eromanga Basin in the west, the Clarence-Moreton Basin in the east and Mulgildie Basin to the northeast (KCB 2016). Deposition of the Surat Basin was relatively continuous and widespread. Deposition in the basin commenced with the onset of a period of passive thermal subsidence over much of eastern Australia. During the Early Jurassic, deposition was mostly fluviolacustrine, while, by the Middle Jurassic, coal swamp environments predominated over much of the basin, except in the north where fluvial sedimentation continued (Geoscience Australia 2017; OGIA 2016c).

There are currently no formally recognised sub-basins for either the Bowen or Surat Basins. However, the Bowen and Surat Basins are divided into distinct regions based on the structural features that control both the location and thickness of the sedimentary sequences. The Project Area is located in the Maranoa-Balonne-Condamine subregion, in the centre of the Surat CMA, on the far western flanks of the Taroom Trough (Exon 1976a). The surface geological map within the vicinity of the Project Area is shown in Figure 7.2.

The Taroom Trough is the major sediment depositional centre in the basin and extends throughout the Maranoa-Balonne-Condamine subregion (Draper 2013; Cadman, Pain, and Vuckovic 1998). It formed during crustal extension in the Late Carboniferous to Early Permian (McKellar 1998). The Taroom Trough is bounded to the east by a line of faults along the margins of basement blocks, created by the half-graben structure. Dips seldom exceed 15°, but fault displacements are as much as 2,000 m. The structures in the Bowen Basin are generally reflected in the overlying Surat Basin sequence.

7.1.2 Geological Structures

The Hutton-Wallumbilla Fault is a regional scale fault trending in an northwest-southeast direction; with the displacement on the fault reported as 450 m in the Bowen Basin units, but less than 100 m in the overlying Surat Basin units (Draper 2013).

Major deformation occurred in the late Triassic with reactivation after the deposition of the Surat Basin sediments. Copley et al. (2017) suggest that the fault was reactivated in the Cenozoic, but with only a small fraction of the amplitude of the Triassic deformation.

The southeasterly extent of the Hutton-Wallumbilla Fault is indicated to occur 4 km northwest of the Project Area. Structural elements directly within the Project Area are discussed in Section 7.2.

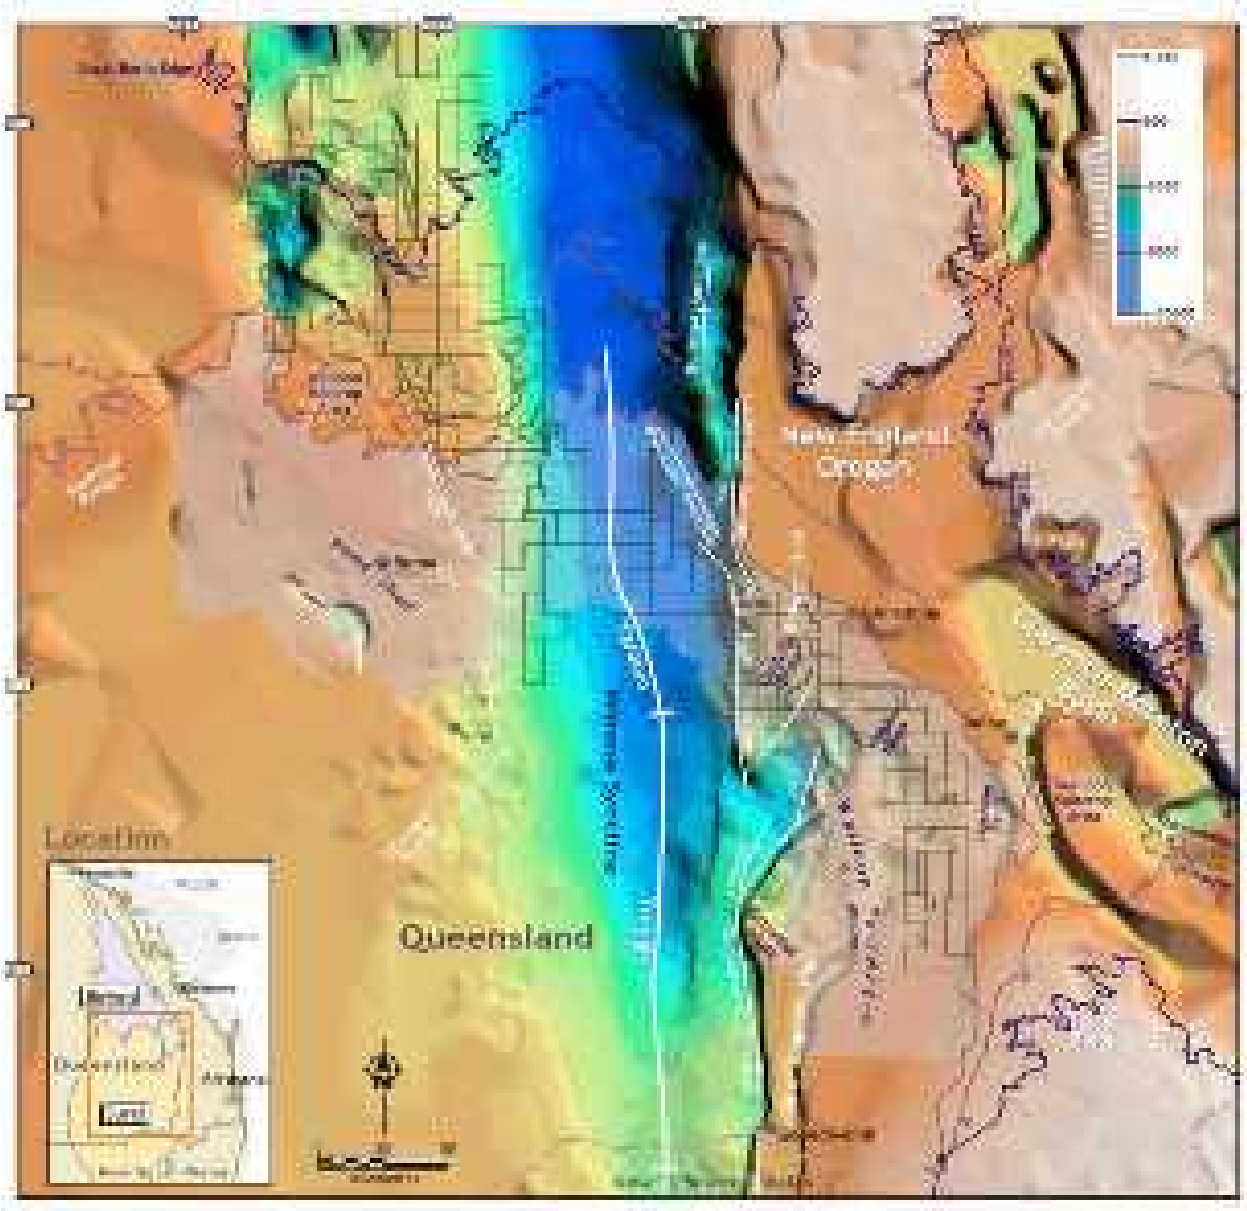

Figure 7.1 Key Structural Features of the Surat Basin (Frogtech 2012; Origin Energy 2023)

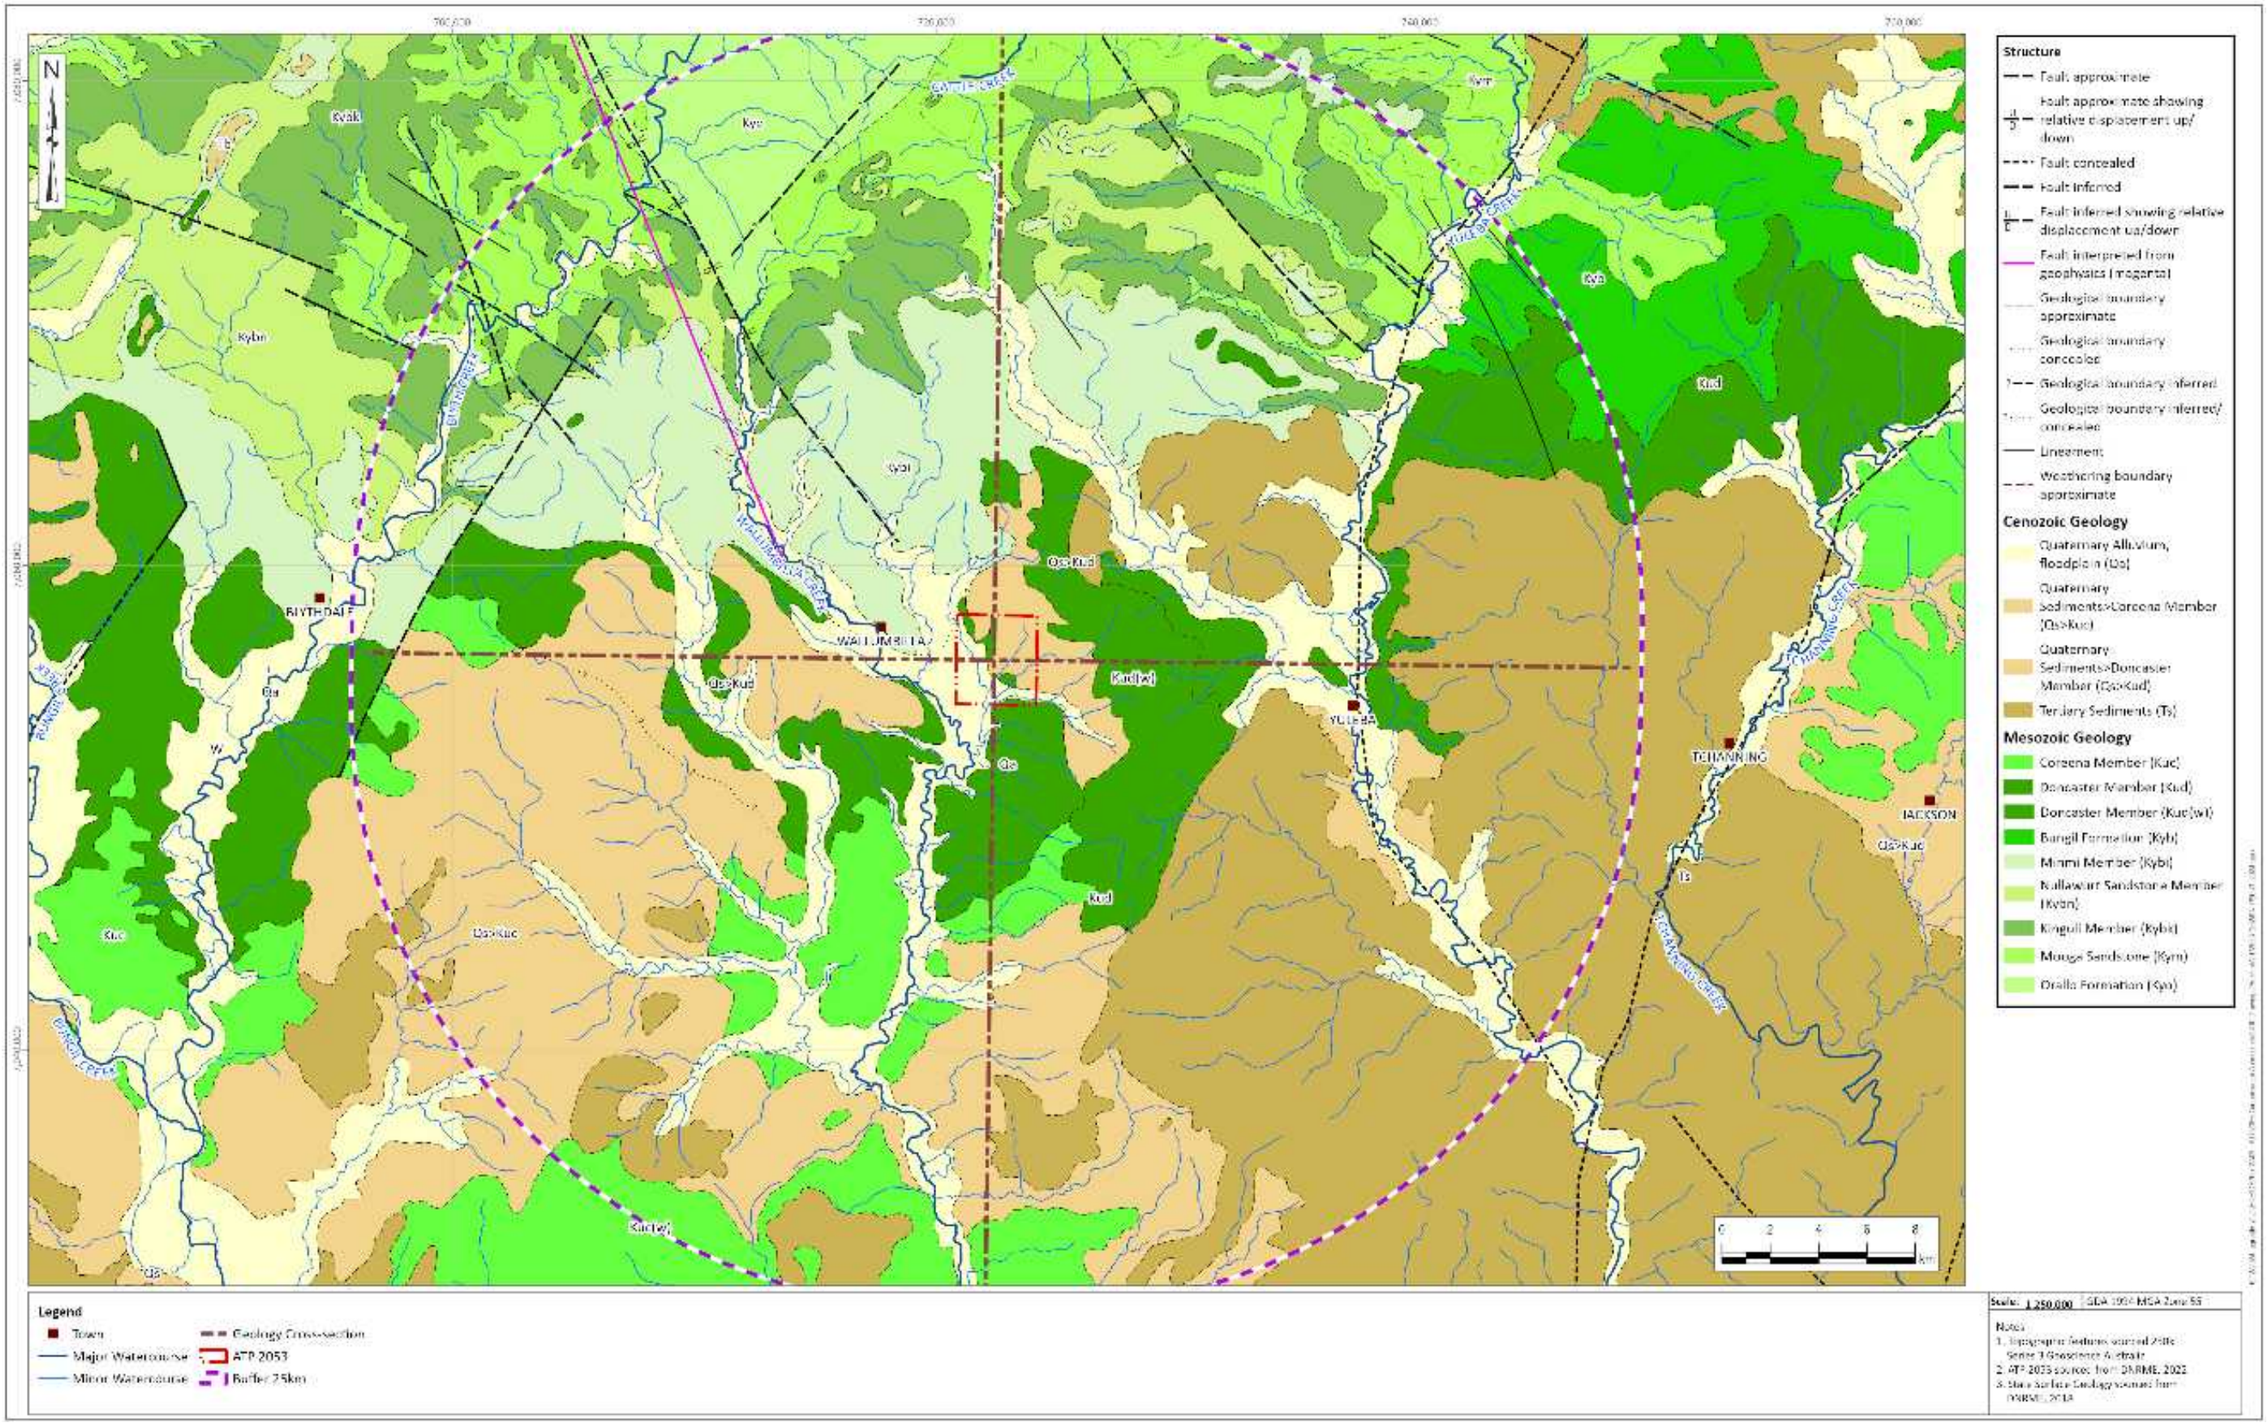

Figure 7.2 1: 100,000 Surface Geology and Cross Section Locations in Vicinity of the Project Area (State of Queensland 2018b)

7.1.3 Regional Hydrostratigraphy

The Surat Basin forms part of the Great Artesian Basin (GAB), which comprises several aquifers and confining aquitards. Aquifers of the Surat Basin are a significant source of water used for stock, public water and domestic supply.

OGIA (OGIA 2021h) presents the hydrostratigraphy of the Surat and Bowen Basin as shown in Table 7.1. Stratigraphic units of relevance to the Project Area include:

- Quaternary alluvial deposits located along Wallumbilla Creek and major tributaries;
- Cenozoic sediments;
- Cretaceous sediments of Wallumbilla Formation and Blythesdale Group; and
- Jurassic aged sediments of the Gubberamunda Sandstone, Westbourne Formation, Springbok Sandstone, the WCM, Eurombah / Durabilla Formation, Hutton Sandstone, Evergreen Formation and Precipice Sandstone.

OGIA have collected an additional 4,000 permeability measurements since 2019 and have reclassified formations to account for heterogeneity present in the hydrostratigraphic units. The definitions as proposed by OGIA (OGIA 2021h) are:

- *Regional aquifer*: high transmissivity, bore yields that are vertically and laterally consistent at a regional scale, e.g. Precipice Sandstone;
- *Partial aquifer*: medium transmissivity, bore yields that are vertically and laterally inconsistent at a regional scale and exhibiting a high degree of heterogeneity, e.g. Hutton Sandstone;
- *Tight aquifer*: medium to low transmissivity, bore yields that are regionally inconsistent and exhibiting a high degree of heterogeneity e.g. Springbok Sandstone;
- *Interbedded aquitard*: similar to a tight aquifer but with thin, spatially limited water-yielding zones are interbedded in an otherwise tight aquitard, e.g. WCM; and
- *Tight aquitard*: predominantly low permeability, regionally extensive and thick formations.

Table 7.1 Stratigraphic Column for the Project Area (OGIA 2021h)

Age		Formation			Hydrostratigraphic Description (OGIA 2021)		Relevance to Project Area	
Quaternary		Alluvium			Partial Aquifer		Mapped associated with watercourses	
		Unconsolidated sediments					Deposits across Project Area	
		Tertiary Sediments					3 km to the northeast and 8 km to east	
Cretaceous	Early	Wallumbilla Formation	Coreena Member		Tight Aquitard	Partial Aquifer	Outcrops 7 km south	
			Doncaster Member			Tight Aquitard	Outcrops within Project Area	
		Blythesdale Group	Bungil Formation	Kingull Member	Partial Aquifer		Outcrops 9 km north	Outcrops 20 km northwest
				Minmi Member			Outcrops 2 km north	
				Nullawurt Sandstone Member			Outcrops 14 km northwest	
			Mooga Sandstone		Regional Aquifer		Outcrops 16 km north	
			Orallo Formation		Tight Aquitard		Outcrops 26 km north	
Jurassic	Late		Gubberamunda Sandstone		Regional Aquifer		Outcrops 31 km north	
		Westbourne Formation			Tight Aquitard		Outcrops 33 km north	
		Springbok Sandstone			Tight Aquifer		Outcrops 38 km north	
	Middle	Walloon Subgroup	Walloon Coal Measures		Productive Coal Seam		Target CSG formation	
			Eurombah / Durabilla Formation		Tight Aquitard		Underlying aquitard of regional relevance	
		Hutton Sandstone	Upper Hutton Sandstone		Partial Aquifer		Underlying aquifer of regional relevance	
			Lower Hutton Sandstone		Tight Aquifer			
	Early	Evergreen Formation	Upper Evergreen FM		Tight Aquitard		Regional Relevance	
			Boxvale Sandstone		Partial Aquifer			
			Lower Evergreen FM		Tight Aquitard			
		Precipice Sandstone			Regional Aquifer		Regional Relevance	

A summary of each of these units is provided in the following sections (from youngest to oldest).

Alluvium *Partial / Regional Aquifer*

Quaternary-age alluvium is mapped as occurring within the Project Area (Figure 7.2). These alluvial deposits are associated with Washpool Creek, Middle Creek and Wallumbilla Creek and associated major tributaries. The alluvium consists of unconsolidated clay, silt, sand and gravel. The sediments in major river channels in the Surat CMA are typically between 14 - 26 m thick and narrow (OGIA 2019a), with the alluvium thickness decreasing in the smaller tributaries.

No bores within the Project Area are screened in the alluvium, thus the alluvial thickness is not known for Washpool Creek, Middle Creek and Wallumbilla Creek.

Cenozoic Sediments *Not Specified*

Thin accumulations of Cenozoic unconsolidated and semi-consolidated residual and colluvial sheetwash sediments occur within, and in the vicinity of the Project Area, at thicknesses of less than 50 m (OGIA 2019a).

The Wallumbilla Formation *Partial Aquifer (Coreena Member Only)*

The Wallumbilla Formation is sub-divided in two sequences, the Coreena and Doncaster Members. The upper Member (Coreena) is siltstone-dominated with minor coal seams. The lower Member (Doncaster) is mudstone dominated (OGIA 2016a).

The Coreena Member comprises interbedded siltstone, mudstone and fine to very fine-grained labile sandstone, limestone and coal deposited from shallow marine lagoons, shoreline swamps and estuaries, most likely reflecting a regional marine regression. The siltstone is in part calcareous, grading to silty limestone. The thickness of the Coreena Member averages 70 m and is conformably overlain by the Surat Siltstone (OGIA 2016a).

The Doncaster Member (which outcrops / sub-crops in the Project Area) comprises dominantly blue-grey mudstone with glauconitic siltstone and fine-grained sandstone. The Doncaster Member accumulated with a rapid marine transgression with deep water conditions in the centre of the basin, grading to shallow marine coastal environments around the margins (Exon 1976). Average thickness of the member is between 100 m and 150 m(OGIA 2016a).

The Doncaster Member of the Wallumbilla Formation is a tight aquitard. The Coreena Member is a partial aquifer.

The Bungil Formation *Partial Aquifer*

The Bungil Formation conformably overlies the Mooga Sandstone and outcrops 20 km northwest of the Project Area. This unit comprises interbedded fine-grained lithic sandstones, siltstones and mudstones with minor quartzose sandstone present. Day (1964b) identified three members: the Minmi, Nullawurt Sandstone and Kingull members, however, these are not easily recognised in the subsurface (Green et al. 1997, Exon 1976). Deposition of the Bungil Formation represents the initial marine transgression into the Surat Basin (OGIA 2016a). The Bungil Formation is considered as an aquifer.

The Mooga Sandstone *Regional Aquifer*

The Mooga Sandstone generally conformably overlies the Orallo Formation, with local disconformities (Exon 1976b). Deposits tend toward fine to medium grain size sand, although siltstones, mudstones, and shale are present (Exon 1976b). The Mooga Sandstone is at the base of the fifth major sedimentary cycle in the Surat Basin and was deposited in southwesterly flowing braided to meandering stream environments. (Exon 1976) recognised three major sub-units in outcrop. The upper Mooga Sandstone and lower Mooga Sandstone are considered aquifers. The middle Mooga Sandstone consists of siltstones, mudstones, and shale and is considered an aquitard. The Mooga Sandstone is considered a regional aquifer.

The Orallo Formation *Tight Aquitard*

The Orallo Formation conformably overlies the Gubberamunda Sandstone. It was deposited in a relatively low energy fluvial environment with local ponding (Green 1997). The Orallo Formation consists of fine to coarse-grained sandstone interbedded with clay, siltstone, silty mudstone, bentonite clay, and coal (OGIA 2016a). The Orallo Formation is considered a tight aquitard.

Gubberamunda Sandstone *Regional Aquifer*

Regionally, the Gubberamunda Sandstone conformably overlies the Westbourne Formation, but locally, is disconformable, particularly around the margins of the basin (Green 1997). It was deposited by braided and meandering stream systems draining surrounding highlands (Exon 1976). Consistent with a fluvial depositional environment, repeated packages of siltstone and fine to coarse sandstone were deposited. Deposits of carbonaceous shale along with minor coal fragments are typically present. The Gubberamunda Sandstone is considered a usable aquifer.

Westbourne Formation *Tight Aquitard*

The Westbourne Formation conformably overlies the Springbok Sandstone. It was deposited in an environment with characteristics consistent with a low energy, lacustrine deltaic plain (Green 1997). The Westbourne Formation comprises predominately siltstone layers with thick interbeds of fine to medium-grained sandstone and minor mudstone. Small coal fragments, lenses and lamina are common throughout the formation. Within the GAB sequence, the Westbourne Formation is considered an aquitard.

Springbok Sandstone *Tight Aquifer*

The Springbok Sandstone overlies the WCM and was deposited by streams and includes overbank and swamp deposits in the upper part of the unit which indicates streams becoming less energetic with time (Exon 1976). The Springbok Sandstone consists mostly of feldspathic sandstones, commonly with calcareous cement (Green 1997). At the basin scale, the sandstones range from very fine to coarse-grained, although some very coarse-grained, poorly sorted pebbly beds also occur. Minor interbedded siltstones, mudstones, and thin coal seams are also present, primarily in the upper part of the unit. Within the GAB, the Springbok Sandstone is considered a usable water source, however it is highly variable in hydraulic properties and yield across the basin. The Springbok Sandstone also has a very high content of mudstone and siltstone at many locations with very low permeability (OGIA 2016a).

The Walloon Coal Measures *Productive Coal Seam; Interbedded and Leaky Aquitard*

The WCM of the Surat Basin are the target gas production formation for the Project. Within the WCM, the two coal-dominated formations are the Juandah Coal Measures and the Taroom Coal Measures, as presented in Figure 7.3. A low permeability sandstone, siltstone and mudstone typically forms the base and is known as the Durabilla / Eurombah Formation. The WCM were deposited in a low energy meander-belt river system, with the coal layers deposited mainly in an overbank environment (Exon 1976). Comprising of very fine to medium-grained argillaceous, siltstone, mudstone, and coal with minor calcareous sandstone, impure limestone, and ironstone (Swarbrick 1973). Typically, the coal layers are positioned in the upper half to three-quarters of the coal measures, with mudstones, siltstones and lithic sandstones dominant in the lower part. At a regional scale the WCM are considered an interbedded aquitard (OGIA 2021h).

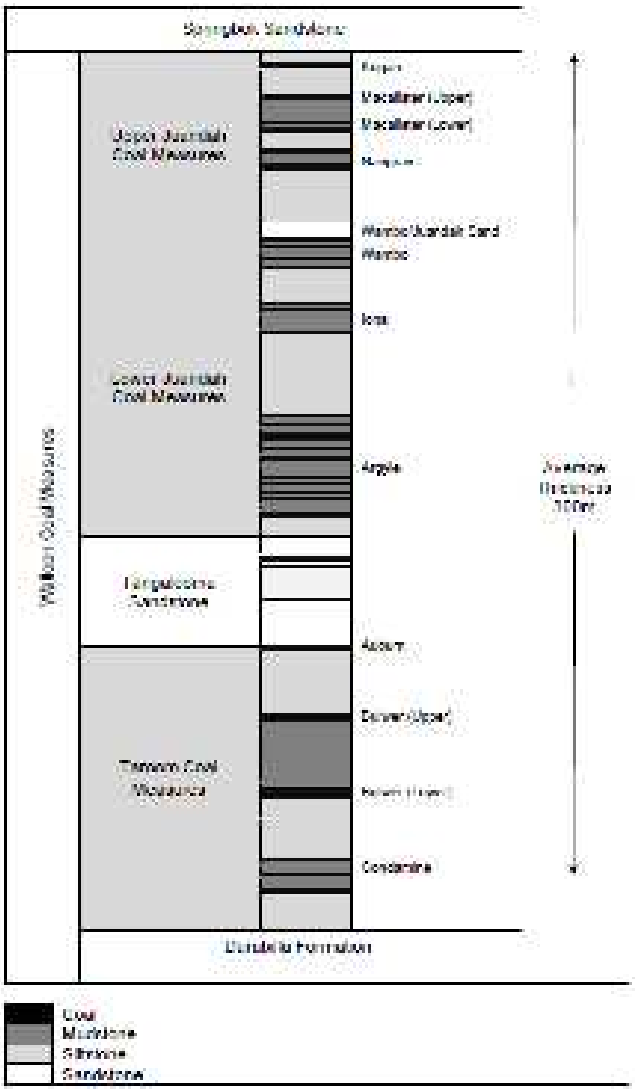

Figure 7.3 Stratigraphy of the WCM (OGIA 2021g) after (Hamilton, Esterle, and Sliwa 2014)

The Surat Basin is underlain by sediments of the Bowen Basin at depth. The Bowen Basin contains the Late Permian aged Bandanna Formation which is another coal-bearing horizon. The Bandanna Formation is not targeted for gas production by the Project.

Eurombah / Durabilla Formation *Tight Aquitard*

The Eurombah Formation, often referred to as the Durabilla Formation, conformably overlies the Hutton Sandstone. The depositional environment for this unit was fluvial with periods of rapid sedimentation. It is often difficult to differentiate the Eurombah Formation from the WCM. It is more restricted in extent than either the Hutton Sandstone or the WCM (Green 1997). The Eurombah Formation is considered an aquitard, consisting of siltstone, mudstone and fine to medium-grained poorly sorted sandstone, with almost no coal and consequently, little permeability (OGIA 2016a).

The Hutton Sandstone *Partial / Tight Aquifer*

The Hutton Sandstone was deposited in a non-marine environment by meandering streams on a broad floodplain (Exon 1976b) and consists mainly of sandstone with interbedded siltstone, shale, minor mudstone, and coal. The sandstone is white to light grey, fine to medium-grained, well sorted, generally quartz rich, partly porous with some pebble bands, shale, and siltstone clasts in the lower part. Siltstones and shales are light to dark grey, micaceous, carbonaceous and commonly interlaminated with very fine-grained sandstone (Green 1997). It is highly heterogeneous, with sand bodies limited in vertical and lateral extent.

The Evergreen Formation *Tight Aquitard*

The Evergreen Formation conformably overlies the Precipice Sandstone and separates the Precipice Sandstone from the Hutton Sandstone. The upper and lower Evergreen Formations are considered aquitards and generally consists of mudstones laminated with fine-grained sandstone, siltstone and shale (Green 1997).

The Precipice Sandstone *Regional Aquifer*

The Precipice Sandstone is the basal unit of the Surat Basin, which overlies the Moolayember Formation and sedimentary sequences of the Bowen Basin. Lower and upper sub-units are recognised, often separated by a siltstone or shale unit. The layers with the coarsest grain sizes were deposited by transverse bars in a braided stream system and the sediment layers with finer grain sizes were deposited in a lower energy fluviatile meandering system (Martin 1981). The lower subunit, also known as the Precipice Braided Stream Facies (or Precipice BSF), consists of white, fine to very coarse-grained, in part pebbly, thin to very thickly bedded, porous, quartz rich sandstone with a white clay matrix (Exon 1976b).

7.2 Local Hydrogeology

Quaternary-age alluvium (Qa) is mapped to the west and within the Project Area. Cenozoic sediments comprising Quaternary-Tertiary aged residual / colluvium is present in the east of the Project Area while the underlying Doncaster Member of the Wallumbilla Formation outcrops in the centre and to the northwest of the Project Area.

Alluvium and Tertiary Deposits

Alluvium in the vicinity of the Project Area is associated with Wallumbilla Creek, Washpool Creek and Middle Creek and associated tributaries. As discussed in Section7.1.3, no bores within the Project Area are screened within the alluvium or Tertiary age deposits, thus a thickness for these units cannot be verified.

Surat Basin Units

The Doncaster Member of the Wallumbilla Formation outcrops within the Project Area and underlies the Quaternary-Tertiary aged sediments, while the Coreena Member, also of the Wallumbilla Formation, is mapped as outcropping southwest and south of the Project Area. The Bungil Formation underlies the upper Cretaceous units and outcrops to the north of the Project Area. Successively older geological units outcrop in a northerly direction, with distance from the Project Area.

Two cross-sections, orientated north-south and west-east through the Project Area are presented in Figure 7.4. The location of the cross-sections is shown on Figure 7.2. These sections have been prepared using the OGIA groundwater model geometry (OGIA 2021b).

The north-south section indicates that the WCM dips in a southerly direction and occurs between 350 m and 650 m beneath the surface; and, has a mean thickness of 243 m.

Table 7.2 presents the mean thickness for each of the underlying hydrostratigraphic units within the Project Area. Isopachs for the key hydrostratigraphic units are presented in Figure 7.5, with the top of the unit elevation presented in Figure 7.6.

Both cross-sections indicate the thickness of the Quaternary / Tertiary aged sediments and underlying Wallumbilla Formation to be limited across the Project Area; with the Wallumbilla Formation shown in Table 7.2 to have a mean thickness of 2.8 m in the Project Area. These surficial units are separated from the WCM by the tight aquitards of the Orallo and Westbourne Formations, while the Durabilla and Evergreen Formations underlie the WCM. The abovementioned aquitards are observed to be laterally and vertically extensive within and beyond the Project Area, with mean thicknesses of 51 m and 198 m, respectively.

There are no major geological structures (e.g., faults) identified within the Project Area. Five 2D seismic lines are available across the Project Area, with a selection of representative seismic survey results presented in Figure 7.7. Seismic sections extend to include the WCM and the deeper-seated Bandanna Formation.

Table 7.2 Aquifer / Aquitard Thicknesses within the Project Area (OGIA 2021g)

Hydrostratigraphic Unit	Aquifer / Aquitard	Mean Thickness (m)
Wallumbilla Formation (Doncaster Member)	Tight Aquitard	2.8
Bungil Formation	Partial Aquifer	120.3
Mooga Sandstone	Regional Aquifer	90.2
Orallo Formation	Tight Aquitard	198.3
Gubberamunda Sandstone	Regional Aquifer	61.9
Westbourne Formation	Tight Aquitard	63.0
Springbok Sandstone	Tight Aquifer	112.9
Walloon Coal Measures	Productive Coal Seams	243.6
Eurombah / Durabilla Formation	Tight Aquitard	51.6
Hutton Sandstone	Partial / Tight Aquifer	243.6
Evergreen Formation	Tight Aquitard	161.2

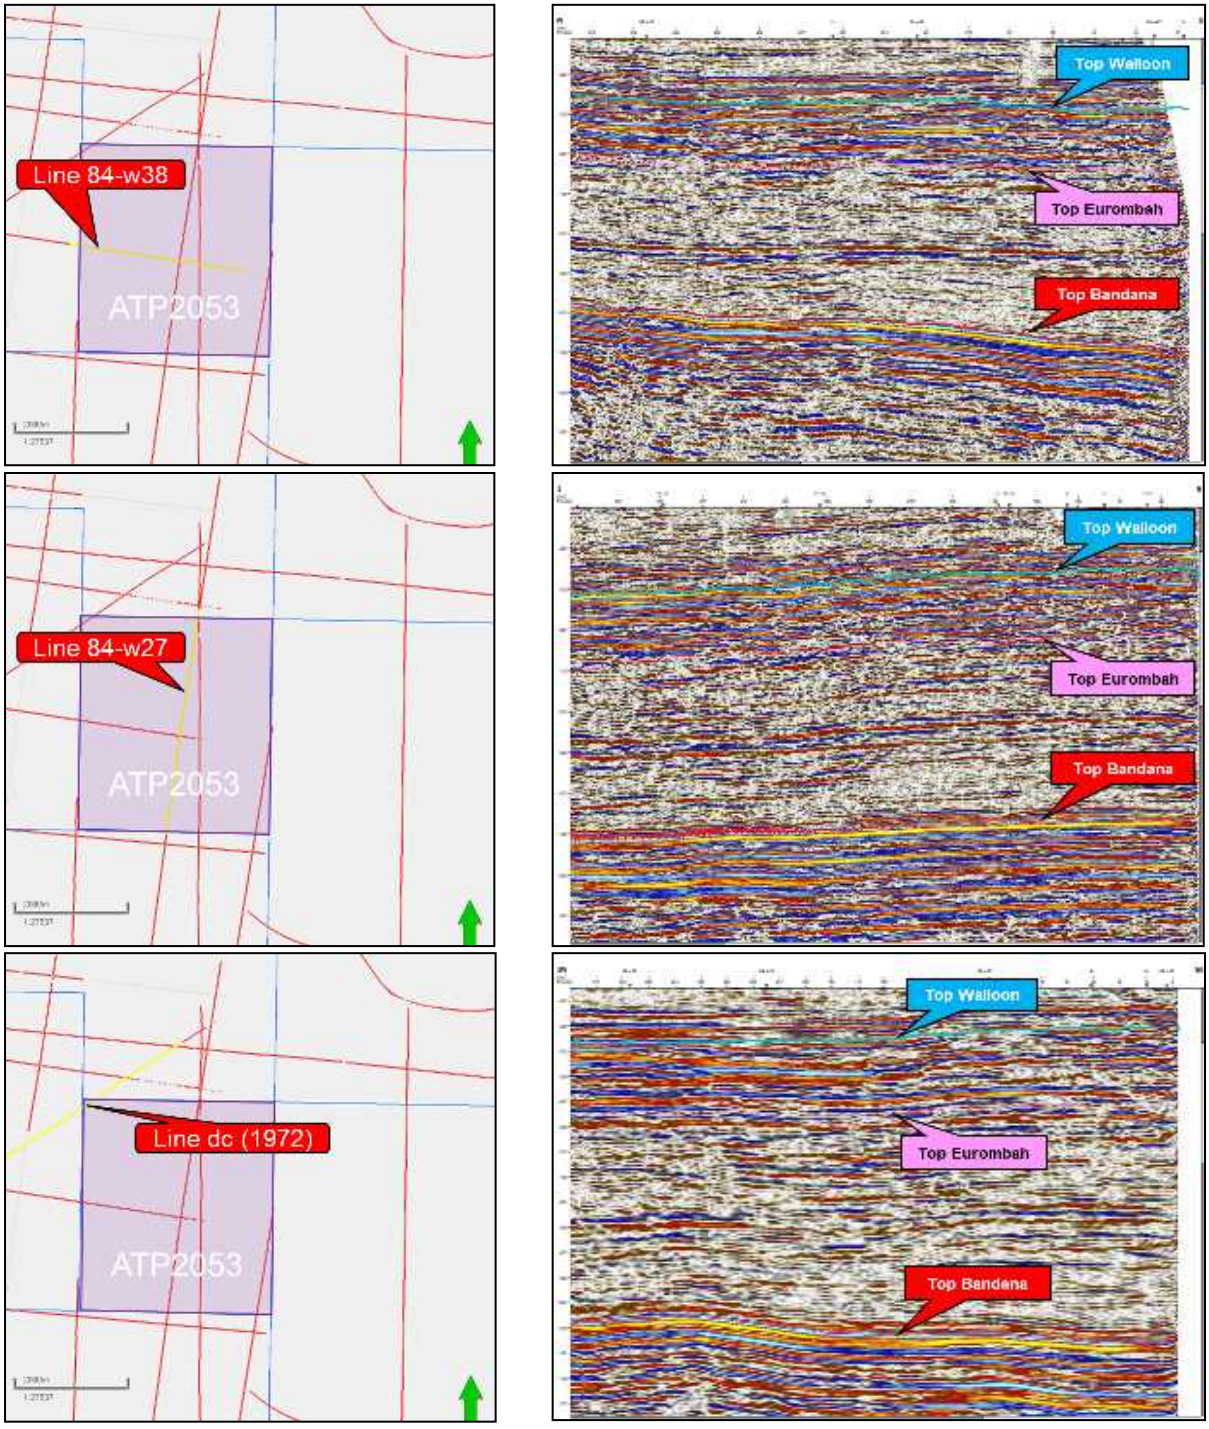

Figure 7.7 Selected Seismic Surveys and Interpretations Across the Project Area

7.3 Aquifer / Aquitard Hydraulic Properties

A number of hydraulic tests, to determine hydraulic properties of the hydrosratigraphic units, have been conducted across the Surat Basin on formations overlying and underlying the WCM. Site-specific data was not available at the time of reporting.

OGIA (OGIA 2019a) present a range of hydraulic conductivities, which have been estimated from core, drill stem tests (DSTs) and pumping tests within the Surat CMA.

The data was compiled as part of the 2016 UWIR (OGIA 2016b) from a range of sources including the GWDB, Queensland Petroleum Exploration Database (QPED), GAB Water Resource Assessment (Smerdon et al. 2012) and public domain sourced investigations undertaken by other CSG proponents.

Figure 7.8 presents the measured hydraulic conductivities presented in the 2019 OGIA UWIR(OGIA 2019d). The figure also presents the pre- and post-calibrated groundwater model ranges for each formation.

The hydraulic properties presented in the 2019 UWIR, are discussed further in the Hydrogeological Conceptualisation Report for the Surat CMA (OGIA 2016b); which includes the location and value of the hydraulic property data points for each of the hydrostratigraphic units of the Surat CMA. Ranges of horizontal hydraulic conductivities from these tests, together with model calibrated values indicate that the Gubberamunda and Precipice Sandstones are the most permeable consolidated formations in the Surat CMA Figure 7.8.

A summary of the information collated and presented in (OGIA 2019d)(OGIA 2019a) is provided in Table 7.3.

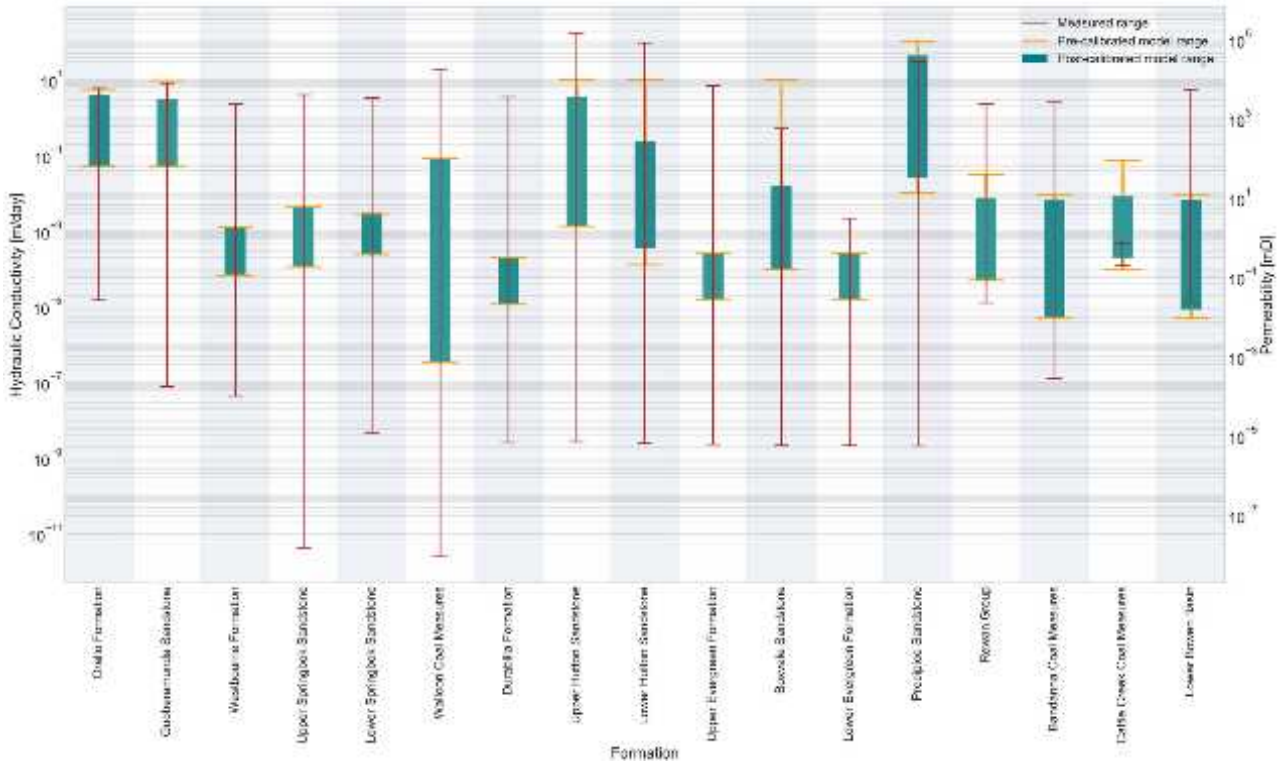

Figure 7.8 UWIR Hydraulic Conductivity Estimations (OGIA 2019a)

Table 7.3 Summary of Hydraulic Properties for Hydrostratigraphic Units in the Surat CMA (OGIA 2016b; 2019a)

Unit	Summary
Alluvium	Hydraulic conductivity of alluvial aquifers ranges between 2 and 116 m/day (10^{th} and 90^{th} percentiles), with a median value of 16 m/day.
Wallumbilla Formation	Horizontal hydraulic conductivity is reported between 8.00 x 10^{-5} and 1.25 m/day (core, DST and pumping test data), with median values reported between 3.31 x 10^{-4} and 4.72 x 10^{-2} m/day.
Bungil Formation	Hydraulic conductivity values are reported between 6.18 x10^{-5} and 1.52 m/day (core, DST and pumping tests). Median values range between 5.80 x 10^{-3} and 6.37 x 10^{-2} m/day.
Mooga Sandstone	Hydraulic conductivity values are reported between 3.59 x 10^{-3} and 2.86 m/day (core, DST and pumping test data). Median values range between 7.37 x 10^{-2} and 1.20 x10^{-1} m/day.
Orallo Formation	Hydraulic conductivity values are reported between 3.34 x 10^{-4} and 1.85 m/day (core and pumping test data). Median values appear high for the unit and may be due to miss-attribution of the formation.
Gubbermunda Sandstone	Median horizontal hydraulic conductivity values are reported between 1.28 x 10^{-1} and 7.76 x 10^{-1} m/day (core and pumping test data). Median vertical hydraulic conductivity is reported between 5.13 x 10^{-2} to 3.30 x 10^{-1} m/day (core and pumping test data).
Westbourne Formation	Median horizontal hydraulic conductivity values are reported between 8.0 x 10^{-4} and 1.37 x 10^{-1} m/day (core, DST and pumping test data). Median vertical hydraulic conductivity is reported between 1.83 x 10^{-4} to 2.41 x 10^{-2} m/day.
Springbok Sandstone	Separated into the Upper and Lower Springbok Sandstone permeability varies between the lower and upper units. The upper Springbok Sandstone hydraulic conductivity values are reported between 6.35 x 10^{-6} to 2.17 m/day, with a median of 1.02 x10^{-3} to 8.89 x10^{-3} m/day (core, DST, petrophysical and pumping test data). The Lower Springbok Sandstone hydraulic conductivity values are reported between 2.49 x 10^{-5} and 4.01 x 10^{-1} m/day (core, DST, petrophysical and pumping test data).
Walloon Coal Measures	Two distinct permeability groups: the low permeability interburden and the more variable coal. The interburden permeability is reported to be between 1x10^{-7} to 1x10^{-3} m/day (core tests). The coal ranges between 1x10^{-3} and 1.0 m/day (DST and core tests). A permeability-depth relationship also exists within the WCM with lower permeability associated with greater depth. Spatial variability associated with high fracture density shows a strong correlation to higher permeability zones.

7.4 Aquifer Inter-Connectivity

The Surat Basin comprises layers of aquifers and aquitards of varying hydraulic properties. The formations predominantly comprise fluvial sedimentary deposits that have formed stratifications of sand, silt and clay within and across hydrostratigraphic formations (OGIA 2016b). Groundwater flow within the Surat Basin hydrostratigraphic units is predominantly horizontal, as vertical flow is restricted by the spatial extent and continuity of aquitards, and by lower permeability horizons within the aquifers (OGIA 2016b).

Across the Project Area, there is potential for interaction between the WCM, and the aquifers present at depth, and specifically those immediately above and below the WCM, such as the overlying Springbok Sandstone and underlying Hutton Sandstone (separated from the WCM by the Durabilla Formation). The Durabilla / Eurombah Formation is classed as a tight aquitard and is laterally extensive across the Project Area, with a mean thickness of 51 m (Table 7.2). This provides a significant vertical barrier between the WCM and underlying Hutton Sandstone.

An upper WCM aquitard has been mapped by OGIA (the WCM non-productive zone, OGIA 2021f) as being up to 25 m thick across the Project Area, separating the WCM coal seams from the overlying Springbok Sandstone (which is also classed as a tight aquifer due to its low horizontal permeability and significant proportions of siltstone and mudstone).

As mentioned in Section 7.2, surficial Quaternary and Tertiary units mapped across the extent of the Project Area, are separated from the WCM by the outcropping / sub-cropping Doncaster Member (a tight aquitard part of the Wallumbilla Formation), and deeper tight aquitard units such as the Orallo Formation and Westbourne Formation. The thickness of these aquitards is presented in Table 7.2 and visually represented in Figure 7.4. The deeper-seated aquitards are observed to be laterally and vertically extensive within and beyond the Project Area, with mean thicknesses of 63 m and 198 m, respectively.

Aquitards present above and below the WCM in the vicinity of the Project Area provide a significant vertical barrier between the WCM and overlying / underlying partial and regional aquifers, as well as the surficial Quaternary and Tertiary mapped units. Isopachs for Westbourne and Durabilla / Eurombah Formation aquitards as well as the Springbok Formation and WCM are presented in Figure 7.5, with the top of the unit elevation presented in Figure 7.6.

7.5 Groundwater Recharge

Recharge processes within the Surat CMA are summarised in the 2021 UWIR (OGIA 2021g). Dominant recharge occurs along the zones of increased permeability in outcrop areas through fractures and permeable beds. Key processes of recharge include localised recharge, preferential pathway flow and diffuse recharge:

- Localised recharge occurs beneath drainage features including rivers, and free-draining unconsolidated sedimentary cover, such as alluvium.
- Preferential pathway flow arises from changes in permeability within aquifers and in overlying regolith, providing conduits for water to infiltrate. Zones of higher permeability may include fissures, faults, joints, tree roots and high-permeability beds within individual formations and along bedding planes (Kellett et al. 2003; Sucklow et al. 2016). This mechanism is considered the dominant recharge process in the GAB (Kellett et al. 2003).
- Diffuse recharge is the process by which high-intensity rainfall events and high-volume infiltrate and sufficiently saturate surficial sediments.

Recharge in the vicinity of the Project Area is expected to occur mainly as diffuse recharge with rainfall infiltration occurring at outcropping hydrostratigraphic units within, and surrounding, the Project Area. Quaternary and Tertiary aged systems are also likely to be replenished during prolonged wet periods when the ephemeral creek system is flowing (where sufficient saturation and hydraulic head allows water to infiltrate into surficial aquifers).

Estimates of long-term mean recharge rates for the Surat CMA have been made by OGIA as part of the 2016 UWIR (OGIA 2016b) using the chloride mass balance recharge estimation method. From this work, OGIA estimates the majority of surficial recharge to flow towards watercourses and discharge locally to streams and rivers such that only 10% of their recharge reaches the deeper confined aquifer.

For the units outcropping within the vicinity of the Project Area, the following regional recharge rates were estimated by OGIA (2019):

- Wallumbilla Formation[3] – 2.4 mm/yr.
- Bungil Formation (outcrops to northwest) – 1.3 mm/yr.
- Mooga Sandstone (outcrops to the north) – 2.7 mm/yr.
- Orallo Formation (outcrops to the north) – 4.3 mm/yr.
- Gubberamunda Sandstone (outcrops to the north) – 4.6 mm/yr.
- Westbourne Formation (outcrops to the north) – 2.1 mm/yr.
- Springbok Sandstone (outcrops to the north) – 1.3 mm/yr.

7.6 Groundwater Levels and Flow

7.6.1 Regional Groundwater Flow

At a regional scale, groundwater flow within the Surat Basin is typically north to south, from the outcrop areas located to the north (OGIA 2021c).

Groundwater movement is slow in the GAB with flow velocities estimated to be 1 to 5 m/year (Habermehl 1980). Generally, groundwater flow and movement occurs as sub-horizontal flow, with limited vertical leakage across formations, where pressure differences may exist (OGIA 2016c). Vertical flow generally only occurs downward in outcropping areas where recharge occurs. Local groundwater flow conditions may be different from regional flow conditions with potential steeper gradients and increased velocities in response to hydraulic stresses such as groundwater abstraction.

7.6.2 Groundwater Elevation and Monitoring Bores

Groundwater levels in the vicinity of the Project Area have been considered using available records from the GWDB (State of Queensland 2022b). A number of groundwater monitoring bores exist within the proximity of the Project Area as displayed in Figure 7.9, however transient groundwater level records are limited. Figure 7.10 displays the location of bores in the vicinity of the Project Area for which temporal groundwater elevation data is available (as presented in this section). The majority of these bores are installed as part of the UWIR and other programs such as CSG monitoring program or CSG Net Program which are coordinated by the Queensland Government.

The following section provides a summary of the available groundwater monitoring data from the GWDB, for all monitoring bores (existing, abandoned and usable, and abandoned and destroyed) as shown in Figure 7.9. Individual maps for each formation are also provided in the following sections.

[3] The Coreena Member of the Wallumbilla Formation is classed as a 'partial aquifer' while the Doncaster Member is classed as a 'tight aquitard'. The closest outcrop of the Coreena Member is 7 km to the south of the Project. Recharge associated with the Doncaster Member of the Wallumbilla Formation in the vicinity of the Project may therefore be expected to be less than the number presented; limited diffuse recharge is expected in outcropping areas.

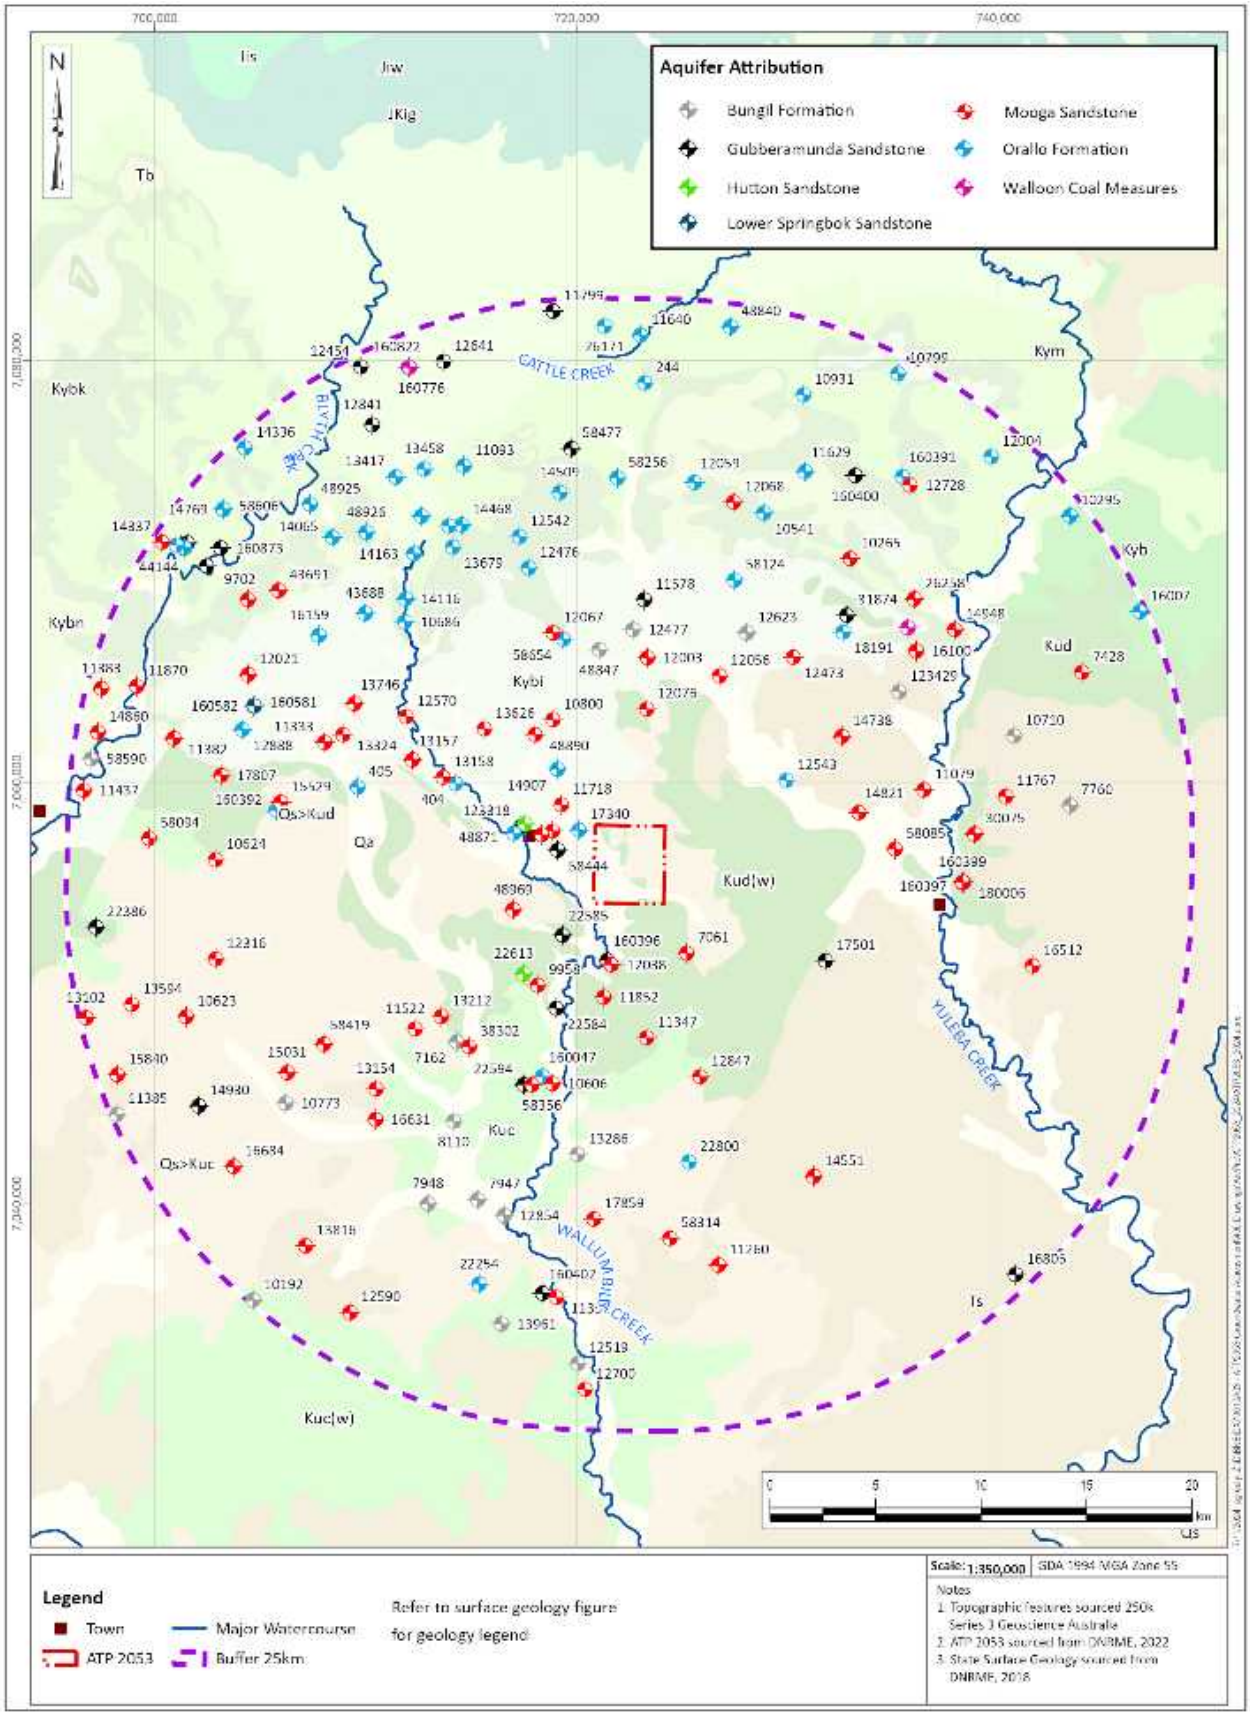

Figure 7.9 Location of Registered Water Level Monitoring Bores in the Vicinity of the Project Area (State of Queensland 2022b)

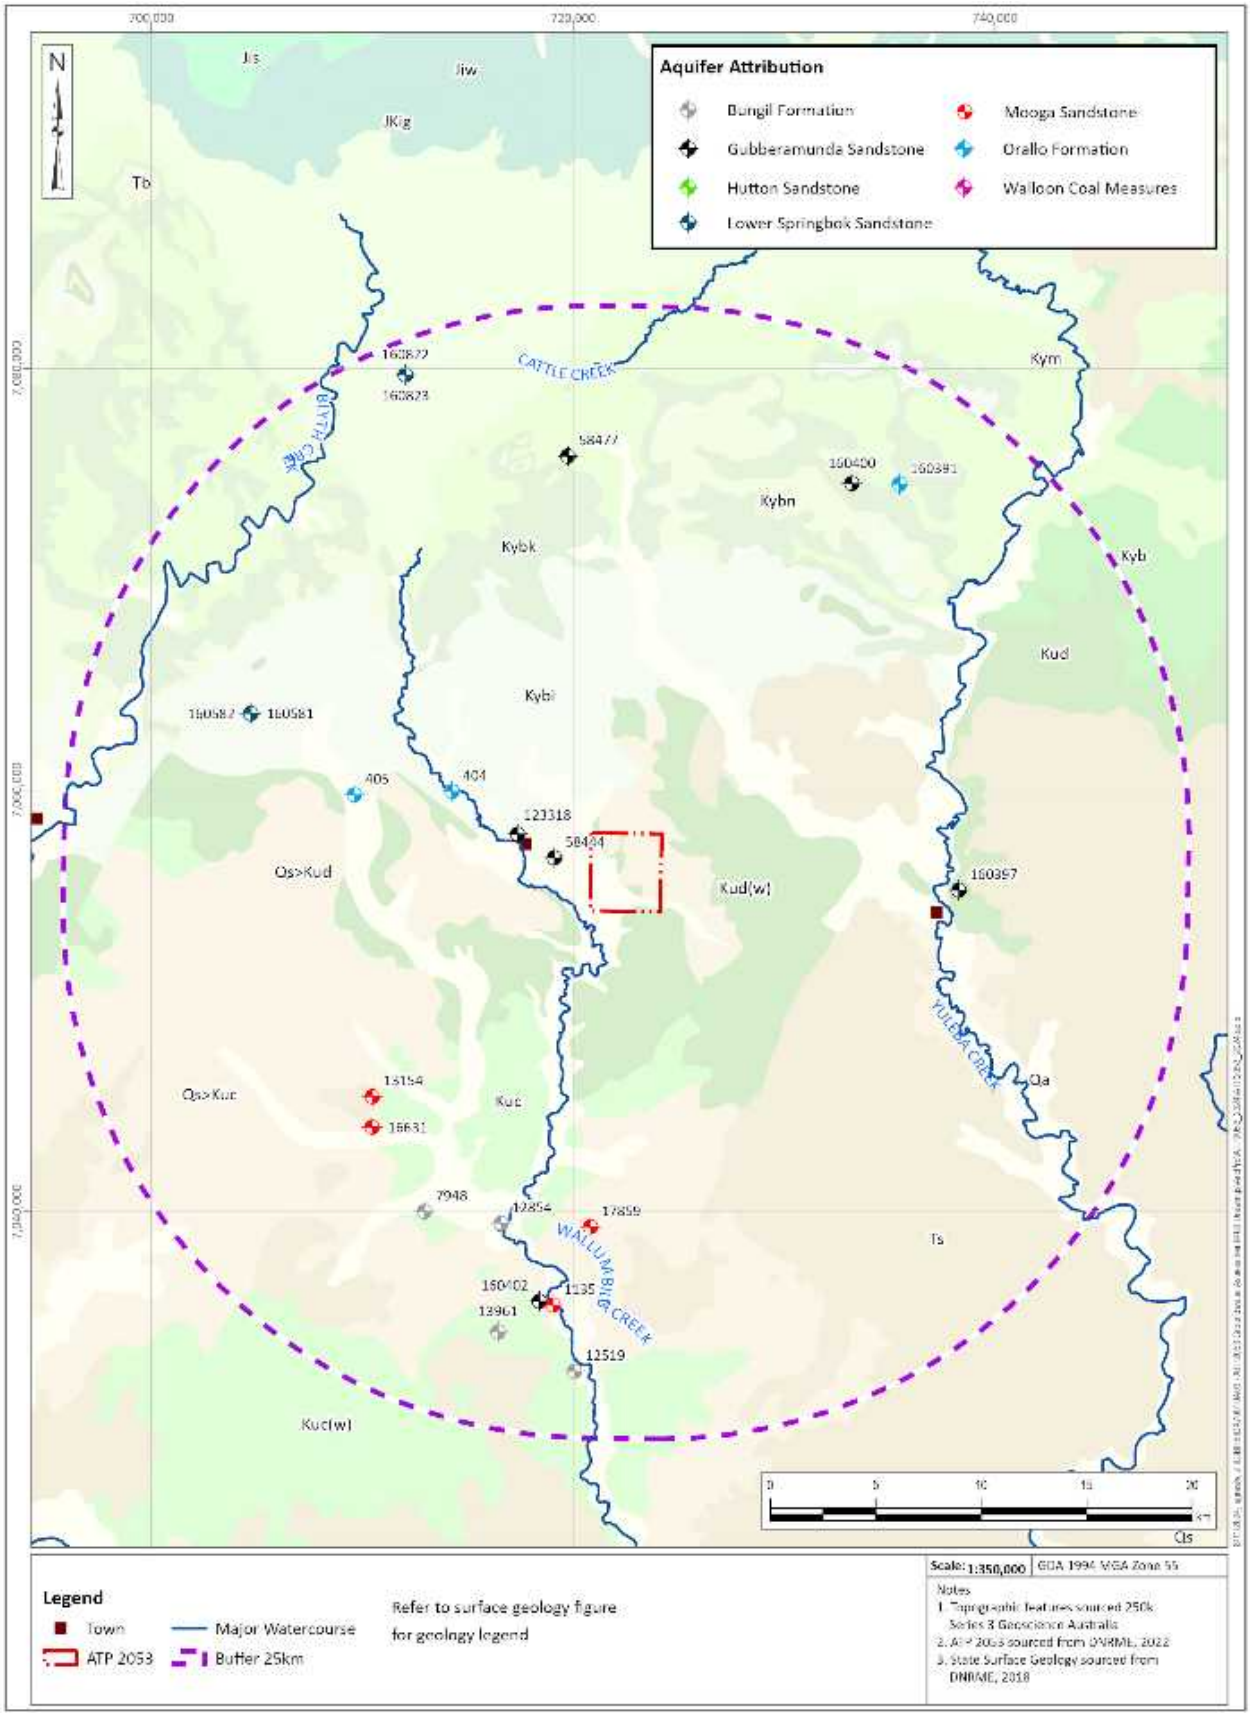

Figure 7.10 Bores with Temporal Water Level Monitoring Data in the Vicinity of the Project Area

Alluvium Monitoring Bores

There are no monitoring bores located in the alluvium. The lack of groundwater level monitoring records from alluvium associated with Wallumbilla Creek (and its tributaries including Washpool Creek and Middle Creek) in and around the Project Area, as well as the lack of third-party groundwater users sourcing groundwater from these alluvial deposits (refer to Section 7.11) highlights the limited water resource the alluvium represents in this region.

Wallumbilla Formation Monitoring Bores

Limited monitoring data is available for bores located in the Wallumbilla Formation with only six measurements recorded between 1937 and 1962. Water levels at five of the six bores were only recorded once. These historical measurements indicate water levels within the Wallumbilla Formation to range between 0 metres below ground level (mbGL) and 22 mbGL. One of the bores that recorded water at 0 mbGL is situated immediately adjacent to a farm water dam while the other bore is attributed to more than one aquifer and extends to the Mooga Sandstone, which is under artesian conditions.

Bungil Formation Monitoring Bores

The groundwater levels for bores monitoring the Bungil Formation are available within the vicinity of the Project Area, with the temporal trends of five bores with recent data presented in Figure 7.11. The location of these bores is shown in Figure 7.12 with the most recent recorded groundwater elevations also presented.

Observations from the available data include:

- Groundwater elevations from the available data (February 2012 to November 2019) range between 333.5 mAHD and 283.4 mAHD. Most of the bores presented are controlled flow artesian water supply bores.
- Earlier water level data is available for RN12519, RN12854, RN7948 and RN13961, (December 1969 to July 1988) however no data was collected between 1988 and 2012. The early data shows a decline between the 1970s and 2012 / 2013, which correlates to the rainfall excess / deficit trend (CRD).
- A slight correlation between groundwater elevation and CRD trend may be interpreted at RN12519 and RN123429.
- A review of the available groundwater levels at individual monitoring locations for the Bungil Formation was undertaken for bores within the vicinity of the Project Area. Several historical records were available (the most recent water level measurement was used) located to the northeast and southwest of the Project Area, as shown in Figure 7.9. These results indicate that the groundwater level elevations have ranged from 263 mAHD to 342 mAHD, with lower groundwater level elevations occurring at lower surface elevations.
- Monitoring data infers groundwater flow within the Bungil Formation in this area to be in a southwesterly direction, with the highest groundwater elevations located towards the northeast of the Project Area.

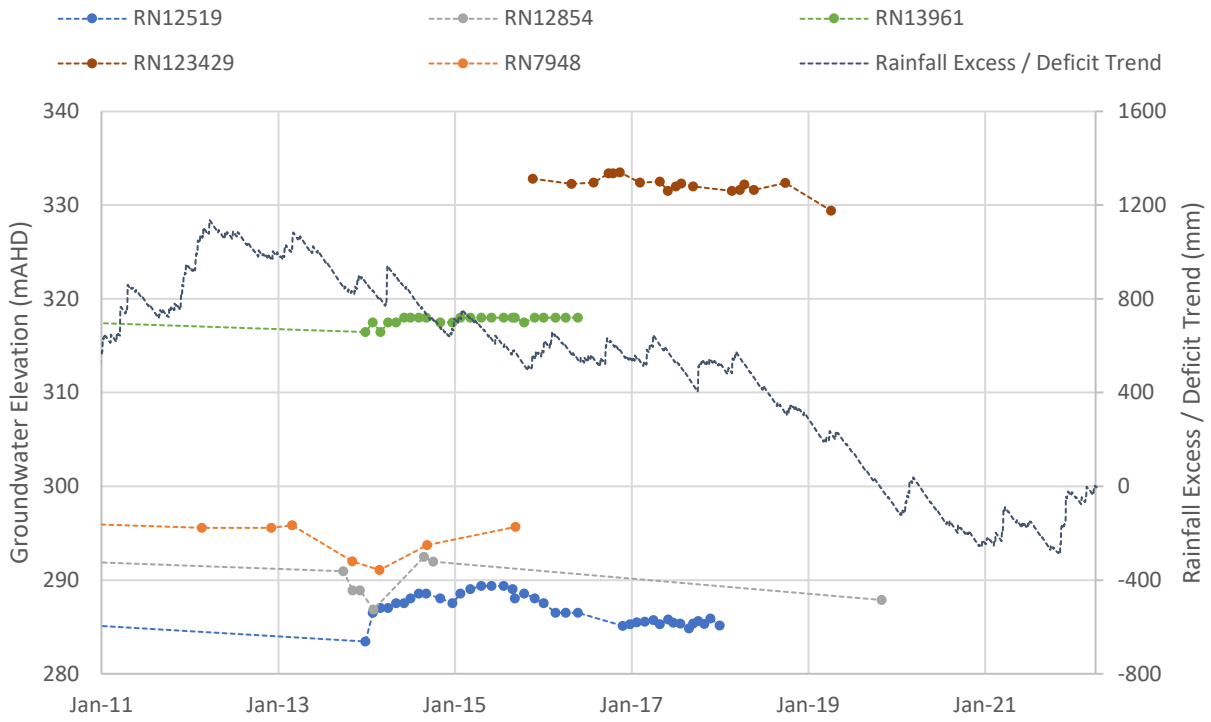

Figure 7.11 Bungil Formation Groundwater Elevation Hydrographs

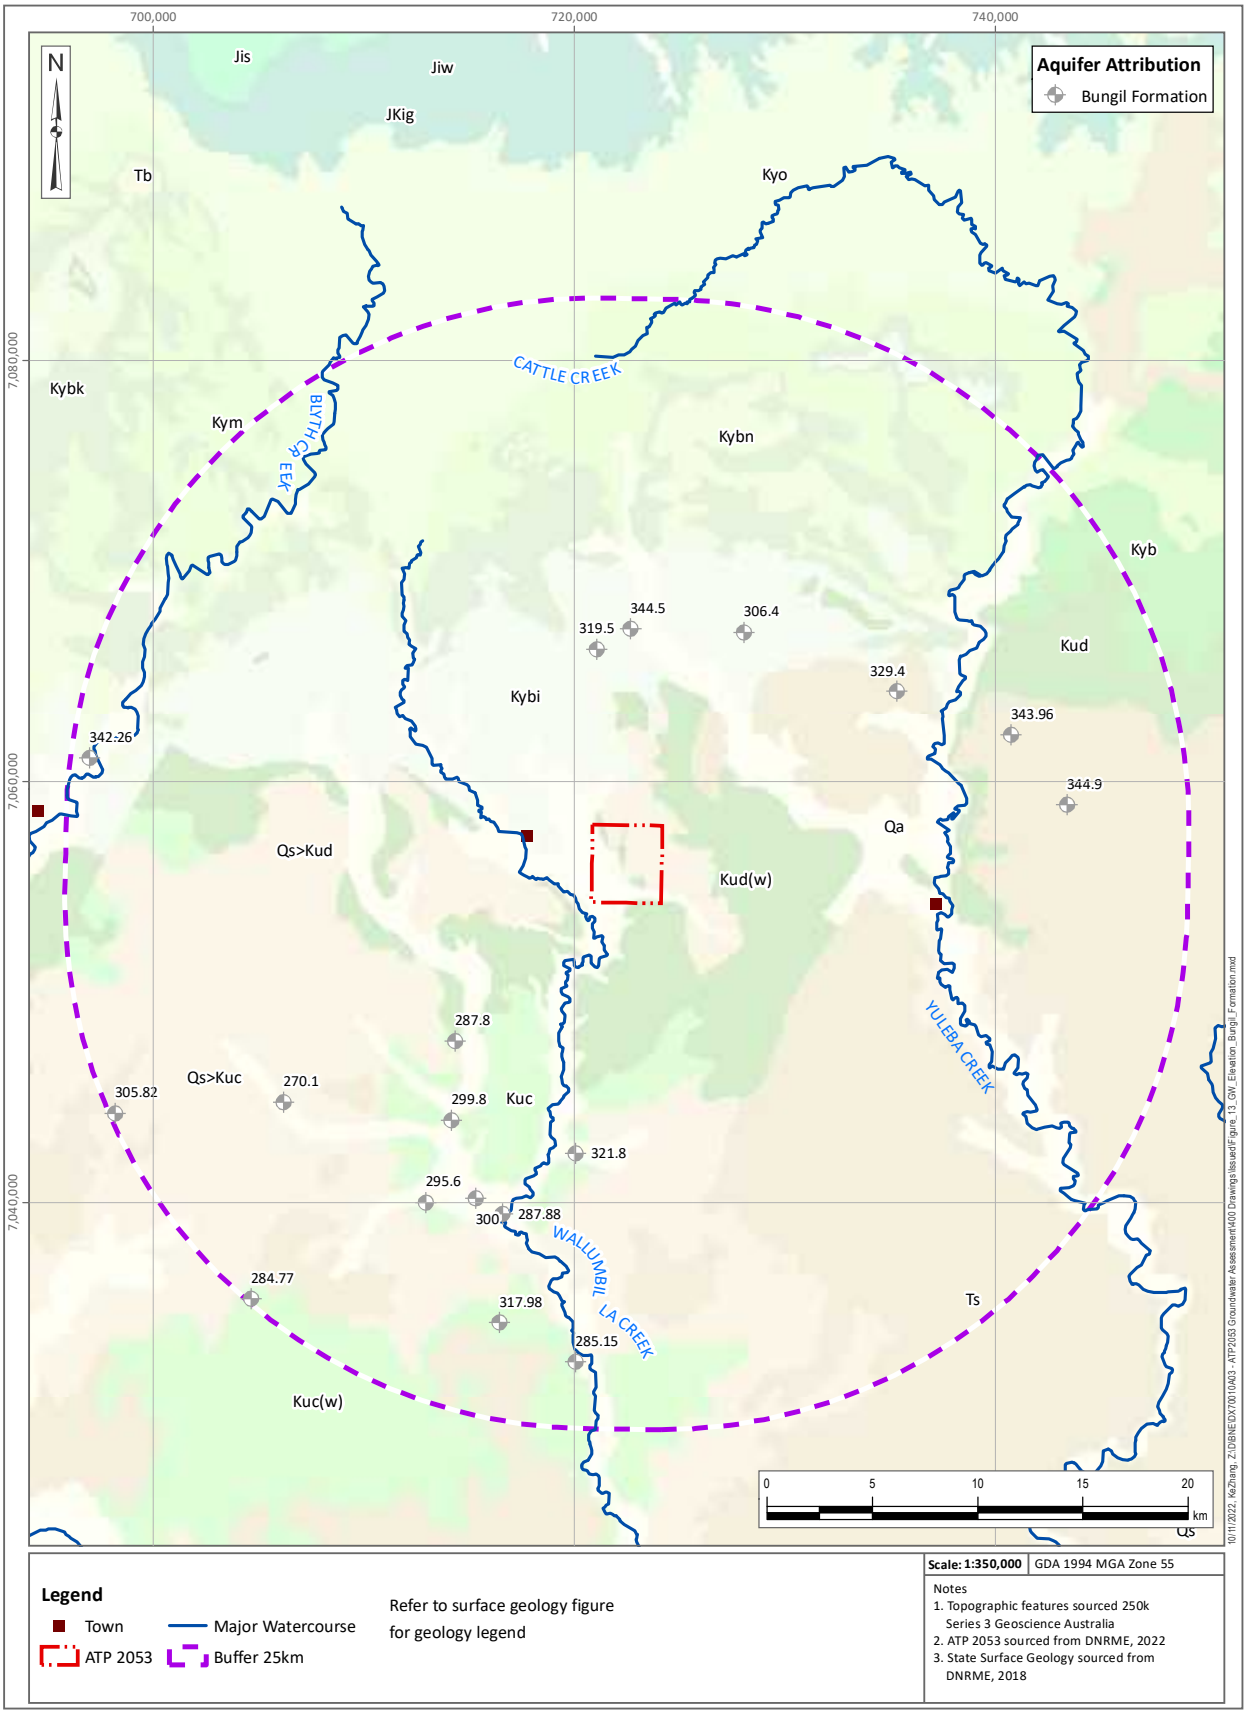

Figure 7.12 Location of Bungil Formation Monitoring Bores and Most Recent Groundwater Elevation in the Vicinity of the Project Area (State of Queensland 2022b)

Mooga Sandstone Monitoring Bores

The groundwater levels for five monitoring bores with recent temporal records in the Mooga Sandstone within the vicinity of the Project Area, is presented in Figure 7.13. The location of these bores and groundwater elevations are shown in Figure 7.14.

Observations from the available data include:

- Groundwater elevations from the available data (August 2012 to April 2022) range between 306.4 and 284.2 mAHD. Most of the bores for which data is available are controlled flow artesian water supply bores. A few artesian bores that have ceased to flow are also present. The exception is RN160399, which displays sub-artesian characteristics, was installed to facilitate monitoring as part of the Surat CMA UWIR.
- Limited data is available for RN17859, RN11351, RN13154 and RN16631 (between July 1957 and March 1987). Available data indicates that groundwater levels at these locations declined over time by around 15 – 20 m before consistent monitoring was resumed in 2012-2014, presumably due to pumping / dewatering.
- A declining trend in groundwater elevation in line with the CRD is observed in available data since 2012-2014.
- RN160399 displays multiple sudden decreases in groundwater elevation in July 2014, July 2017 and June / June 2019. These can likely be attributed to biannual groundwater sampling events.
- A review of the available groundwater levels at individual monitoring locations for the Mooga Sandstone was undertaken for bores within the vicinity of the Project Area. Several historical records were available (the most recent water level measurement was used) located evenly around the Project Area, as shown in Figure 7.12. These results indicate that the groundwater level elevations have ranged from 268 mAHD to 342 mAHD.

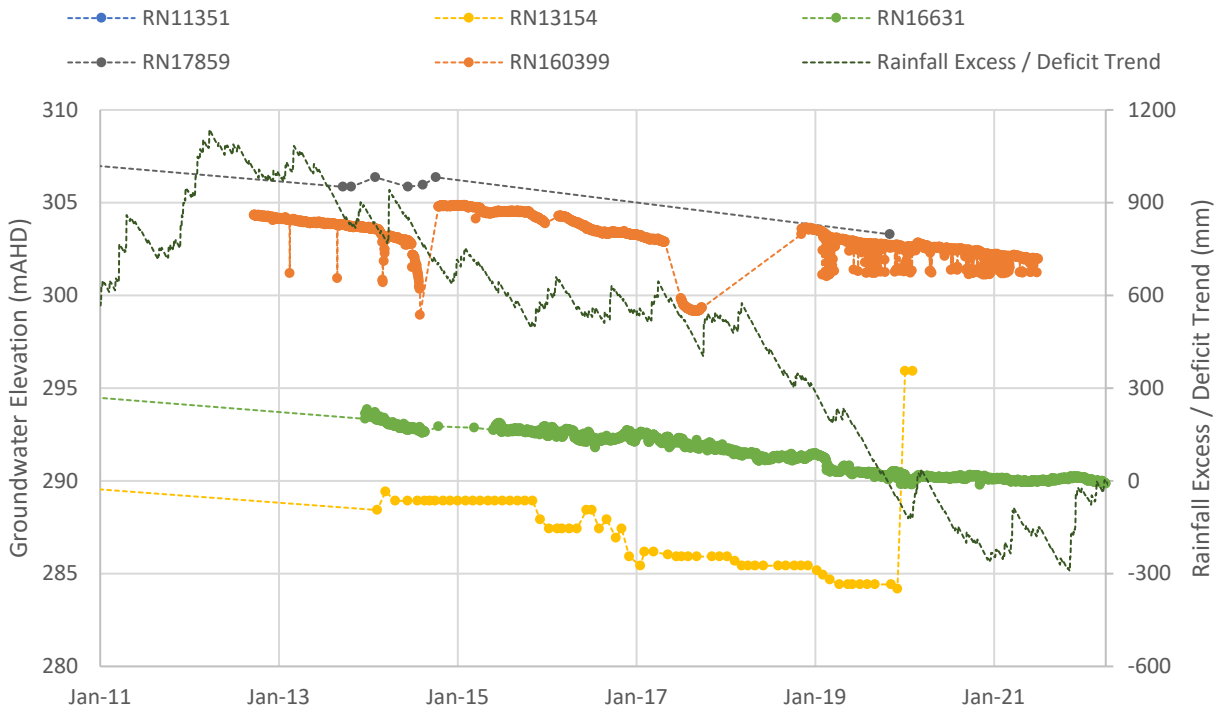

Figure 7.13 Mooga Sandstone Groundwater Elevation Hydrographs in the Vicinity of the Project Area

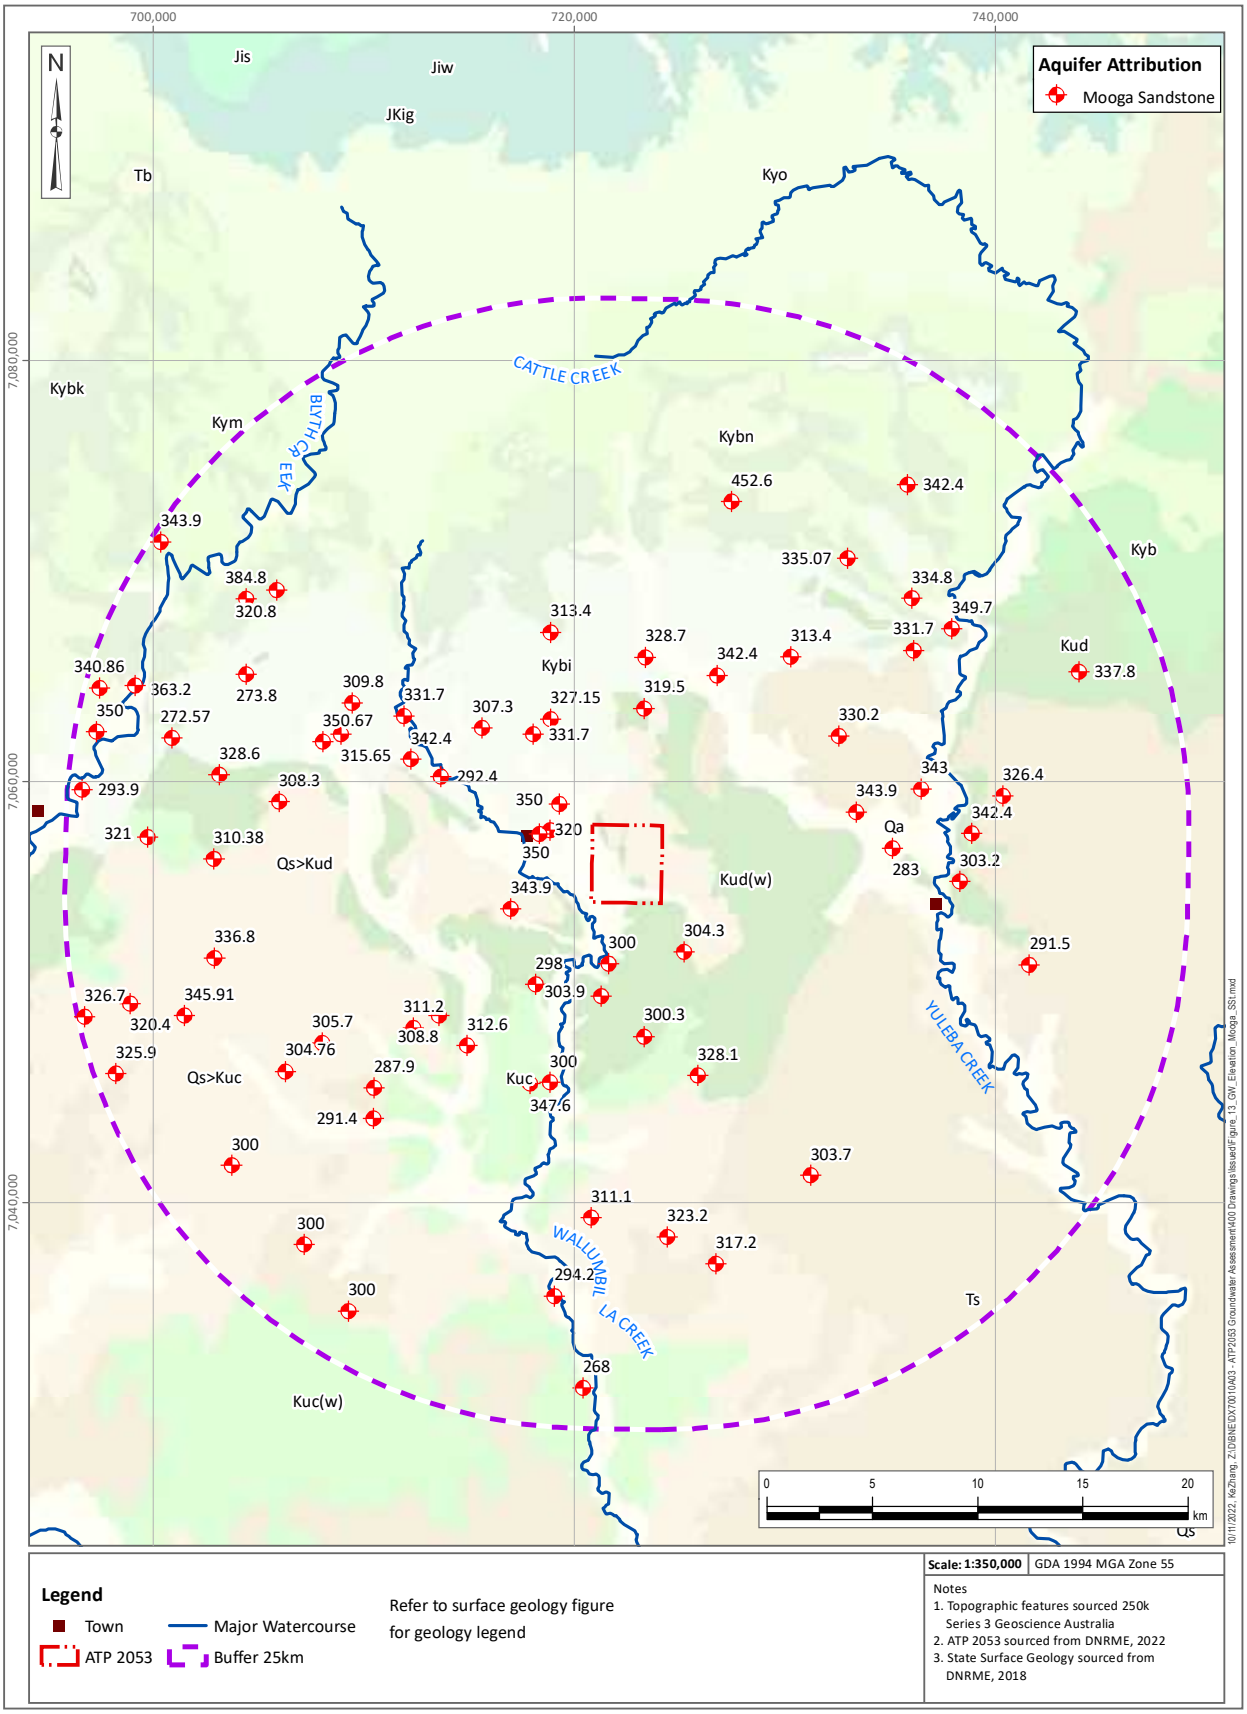

Figure 7.14 Location of Mooga Sandstone Monitoring Bores and Most Recent Groundwater Elevation in the Vicinity of the Project Area (State of Queensland 2022b)

Orallo Formation Monitoring Bores

The groundwater levels of three bores (RN404, RN405 and RN160391) with recent temporal records monitoring the Orallo Formation, within the vicinity of the Project Area are presented in Figure 7.15. The location of these bores and groundwater elevations are shown in Figure 7.16.

Observations from the available data include:

- Groundwater elevations from the available data (February 1964 to July 2021) range between 316.6 and 290.2 mAHD. Most of the bores for which data is available are sub-artesian bores and not used for water supply.
- Earlier data is available for RN404 and RN405, from May 1949 and February 1959, respectively; however, there is a 15-year gap between these and the following monitoring records.
- RN404 and RN405 show a declining trend between 1963 and 1997, however the data points are too far apart to show a correlation with the CRD. The reason for the declining trends is not well understood, it is however unlikely to be attributed to CSG activities.
- RN1600391, installed as part of the Surat CMA UWIR, displayed multiple sharp decreases in groundwater elevations (July 2014, July 2017, June / June 2019). These may be attributed to biannual groundwater sampling events.
- RN160391 shows a decline from 2012 to 2019, with small increases correlating to the CRD trend. Between August 2019 and November 2019, the groundwater elevation increases by 0.4 m, when the trend is still declining. This may be related to leakage from the Gubbermunda Sandstone (underlying lithology), which is the target formation for Santos' reinjection scheme at the Roma gas field (OGIA 2021g).
- A review of the available groundwater levels at individual monitoring locations for the Orallo Formation was undertaken for bores within the vicinity of the Project Area. The majority of historical records available (the most recent water level measurement was used) for the Orallo Formation are located to the north of the Project Area, as shown in Figure 7.16.
- These results indicate that the groundwater level elevations have ranged from 228 mAHD to 385 mAHD.

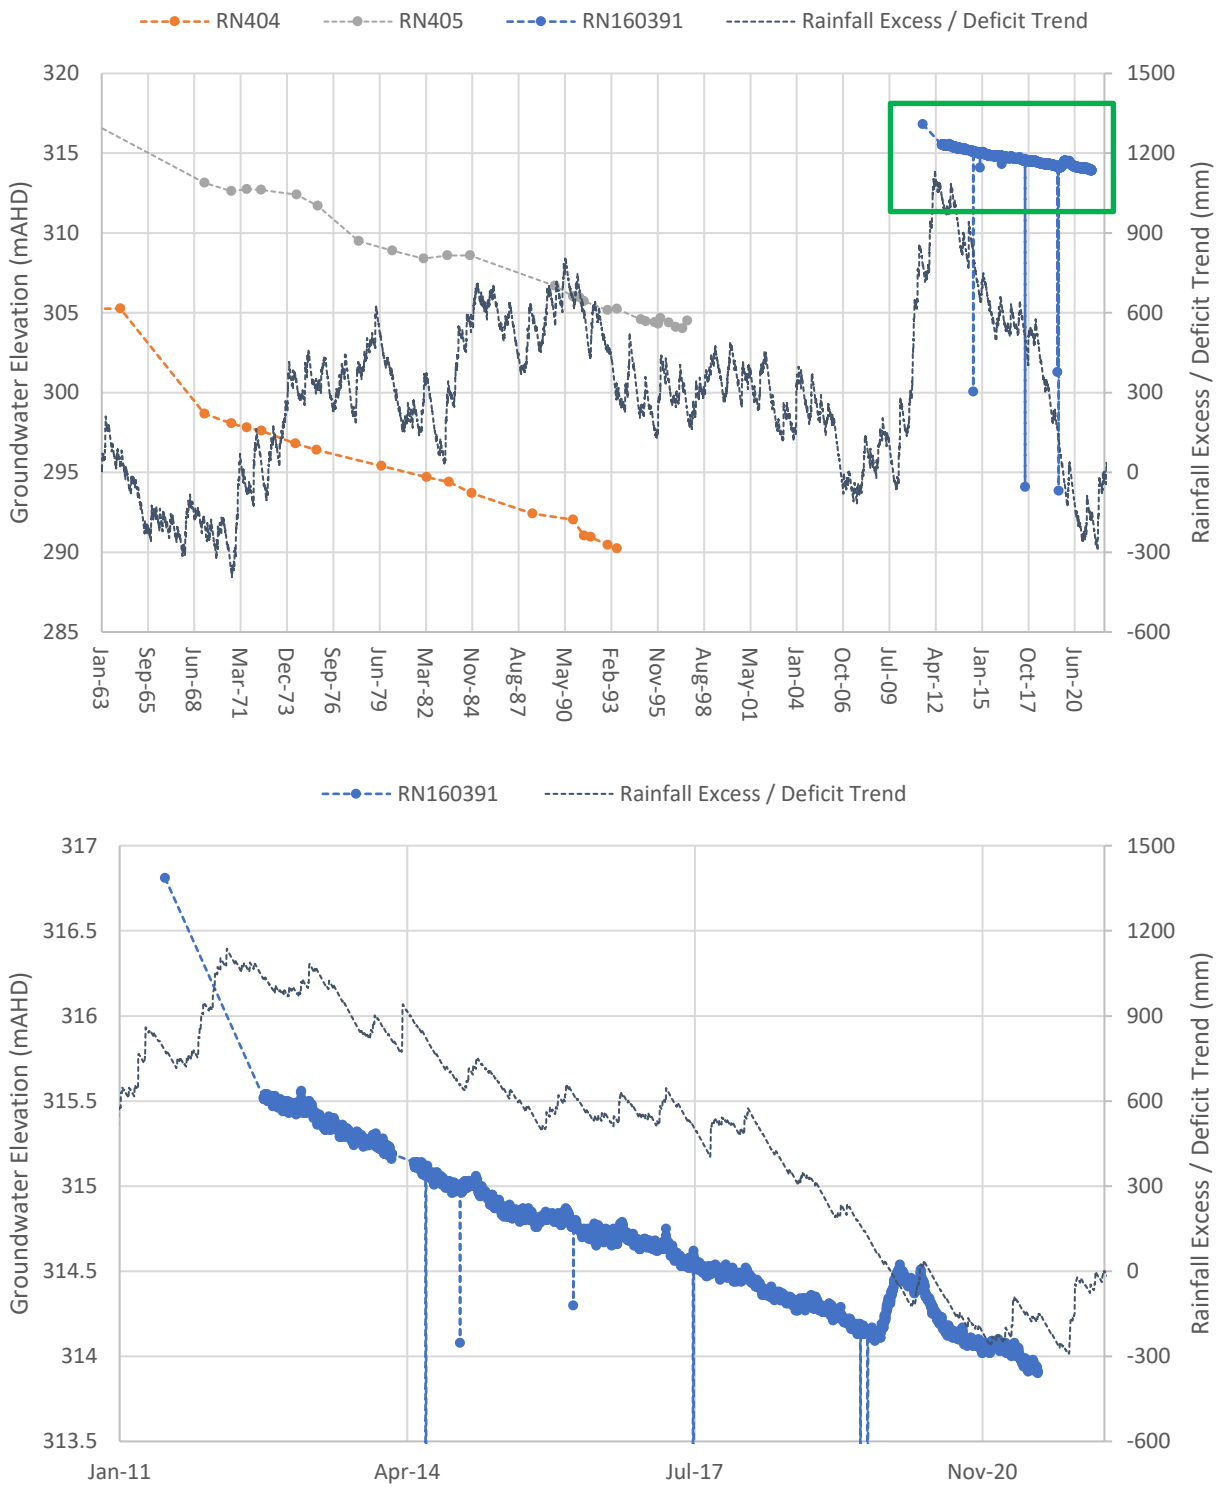

Figure 7.15 Orallo Formation Groundwater Elevation Hydrographs

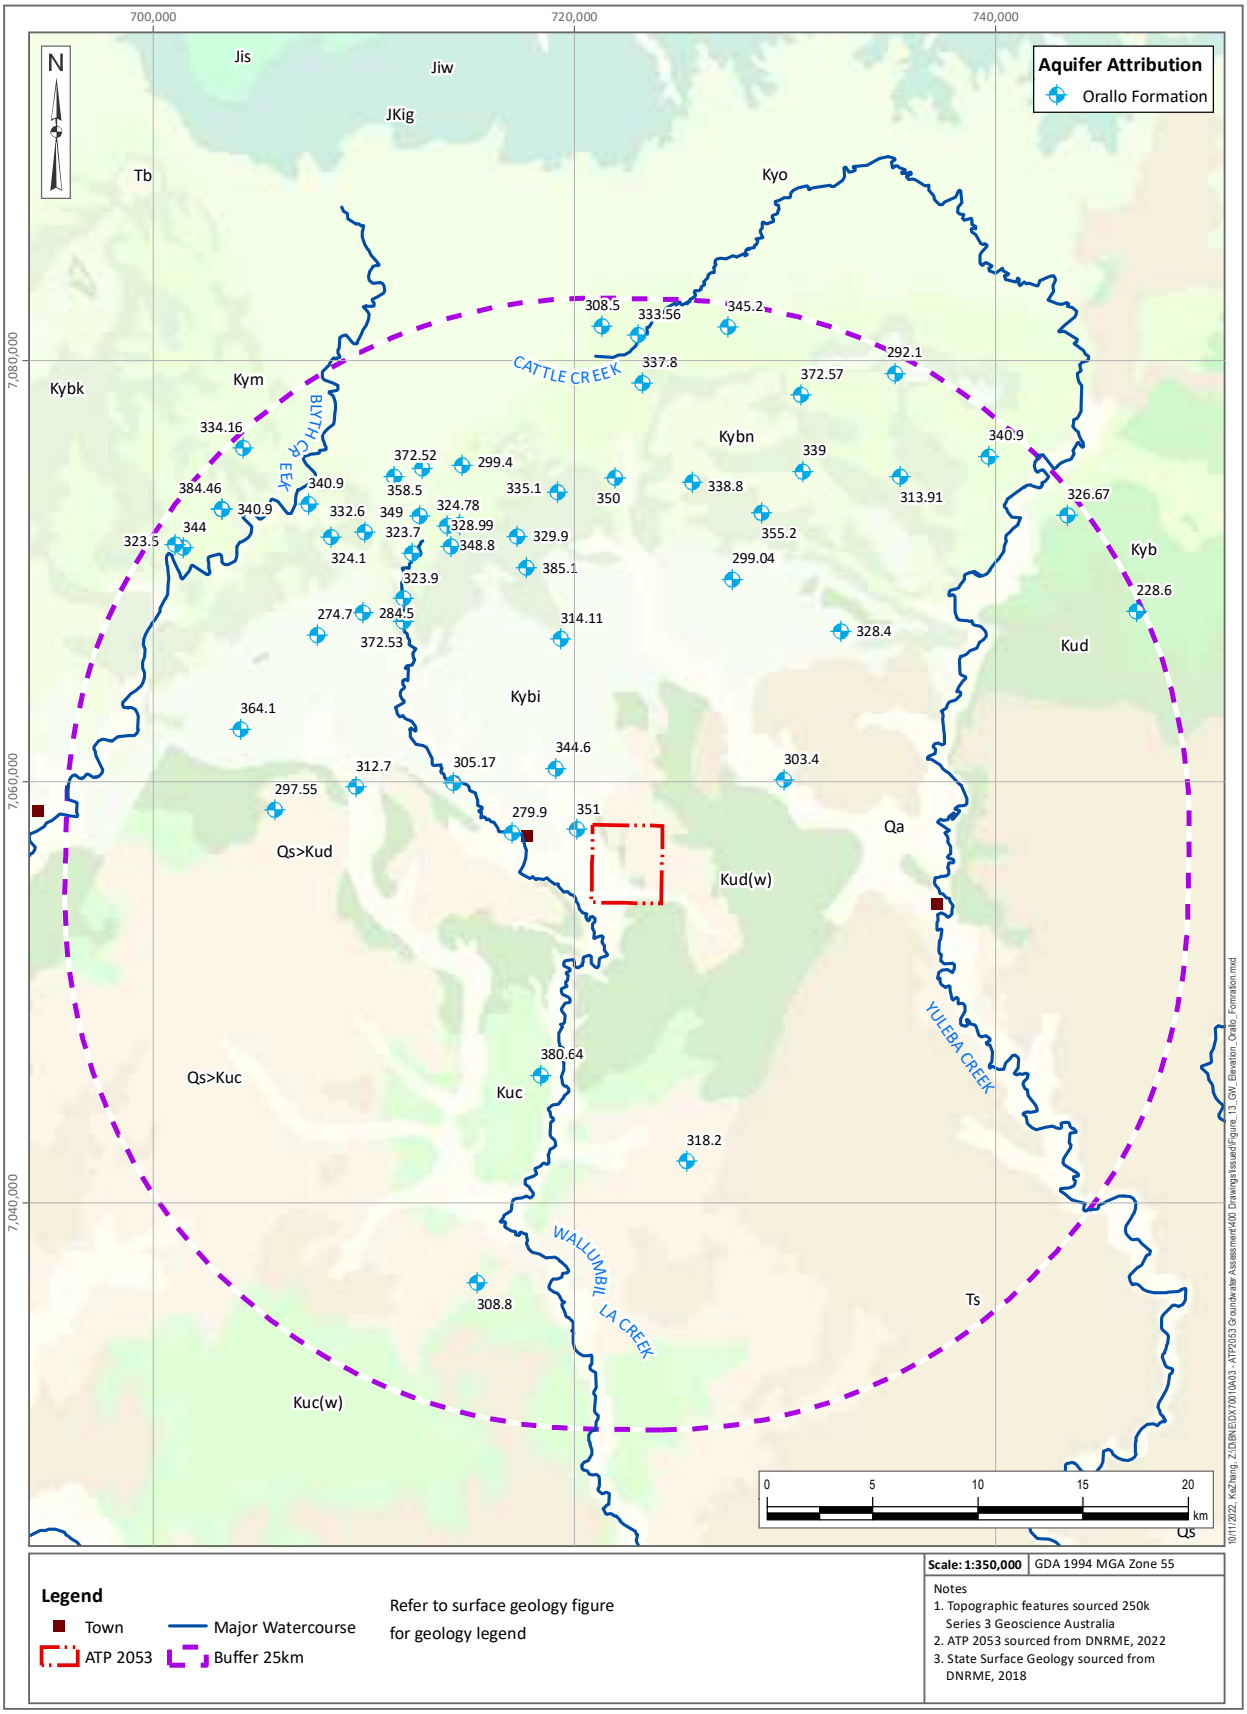

Figure 7.16 Location of Orallo Formation Monitoring Bores and Recent Groundwater Elevation in the Vicinity of the Project Area (State of Queensland 2022b)

Gubberamunda Sandstone Monitoring Bores

The groundwater levels of nine bores with recent temporal records monitoring the Gubberamunda Sandstone within the vicinity of the Project Area are presented in Figure 7.17. The location of these bores is shown in Figure 7.18, with most recent recorded groundwater elevations also presented.

Observations from the available data include:

- Groundwater elevations from the available data (January 2011 to April 2022) range between 330 mAHD and 260 mAHD. These bores are all sub-artesian bores. Bores RN17501, RN58444, RN58477, RN123318 and RN160394 are water supply bores.
- Single data points are available for RN17501, RN58477 and RN58447 between 1967 and 1991, however transient data was not collected again until 2011 or later, thus historical data is not shown on Figure 7.17.
- Groundwater elevations at most bores show no correlation to the CRD and remain relatively static.
- A review of the GWDB for additional groundwater levels was undertaken for bores within the vicinity of the Project Area.
- A review of historically available groundwater levels at individual monitoring locations for the Gubberamunda Sandstone was undertaken for bores within the vicinity of the Project Area. Several historical records were available (the most recent water level measurement was used) for the Gubberamunda Sandstone, located to the north and south of the Project Area, as shown in Figure 7.18. These results indicate that the groundwater level elevations have ranged from 259 mAHD to 378 mAHD.
- Monitoring data infers groundwater flow within the Gubberamunda Sandstone in this area to be generally southward, with the highest groundwater elevations located towards the north.

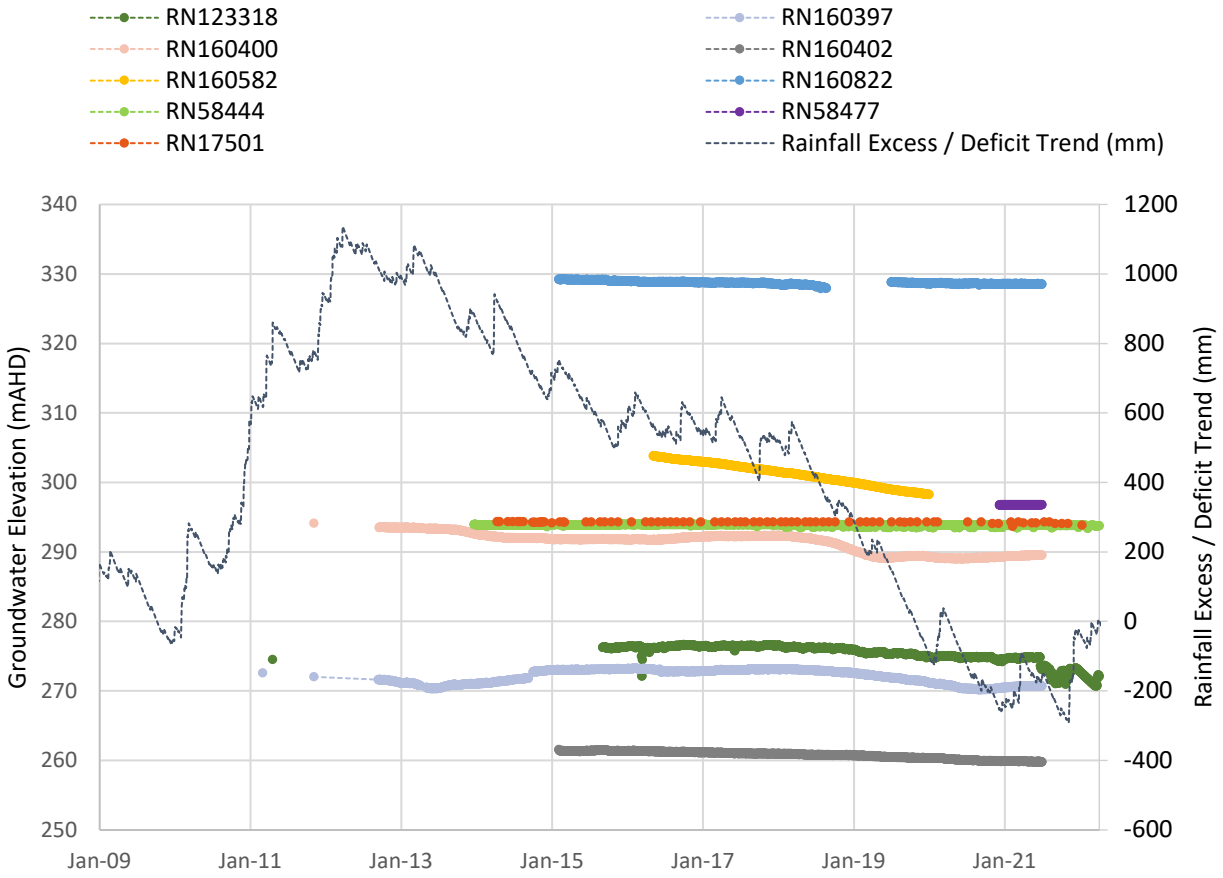

Figure 7.17 Gubberamunda Sandstone Groundwater Elevation Hydrographs

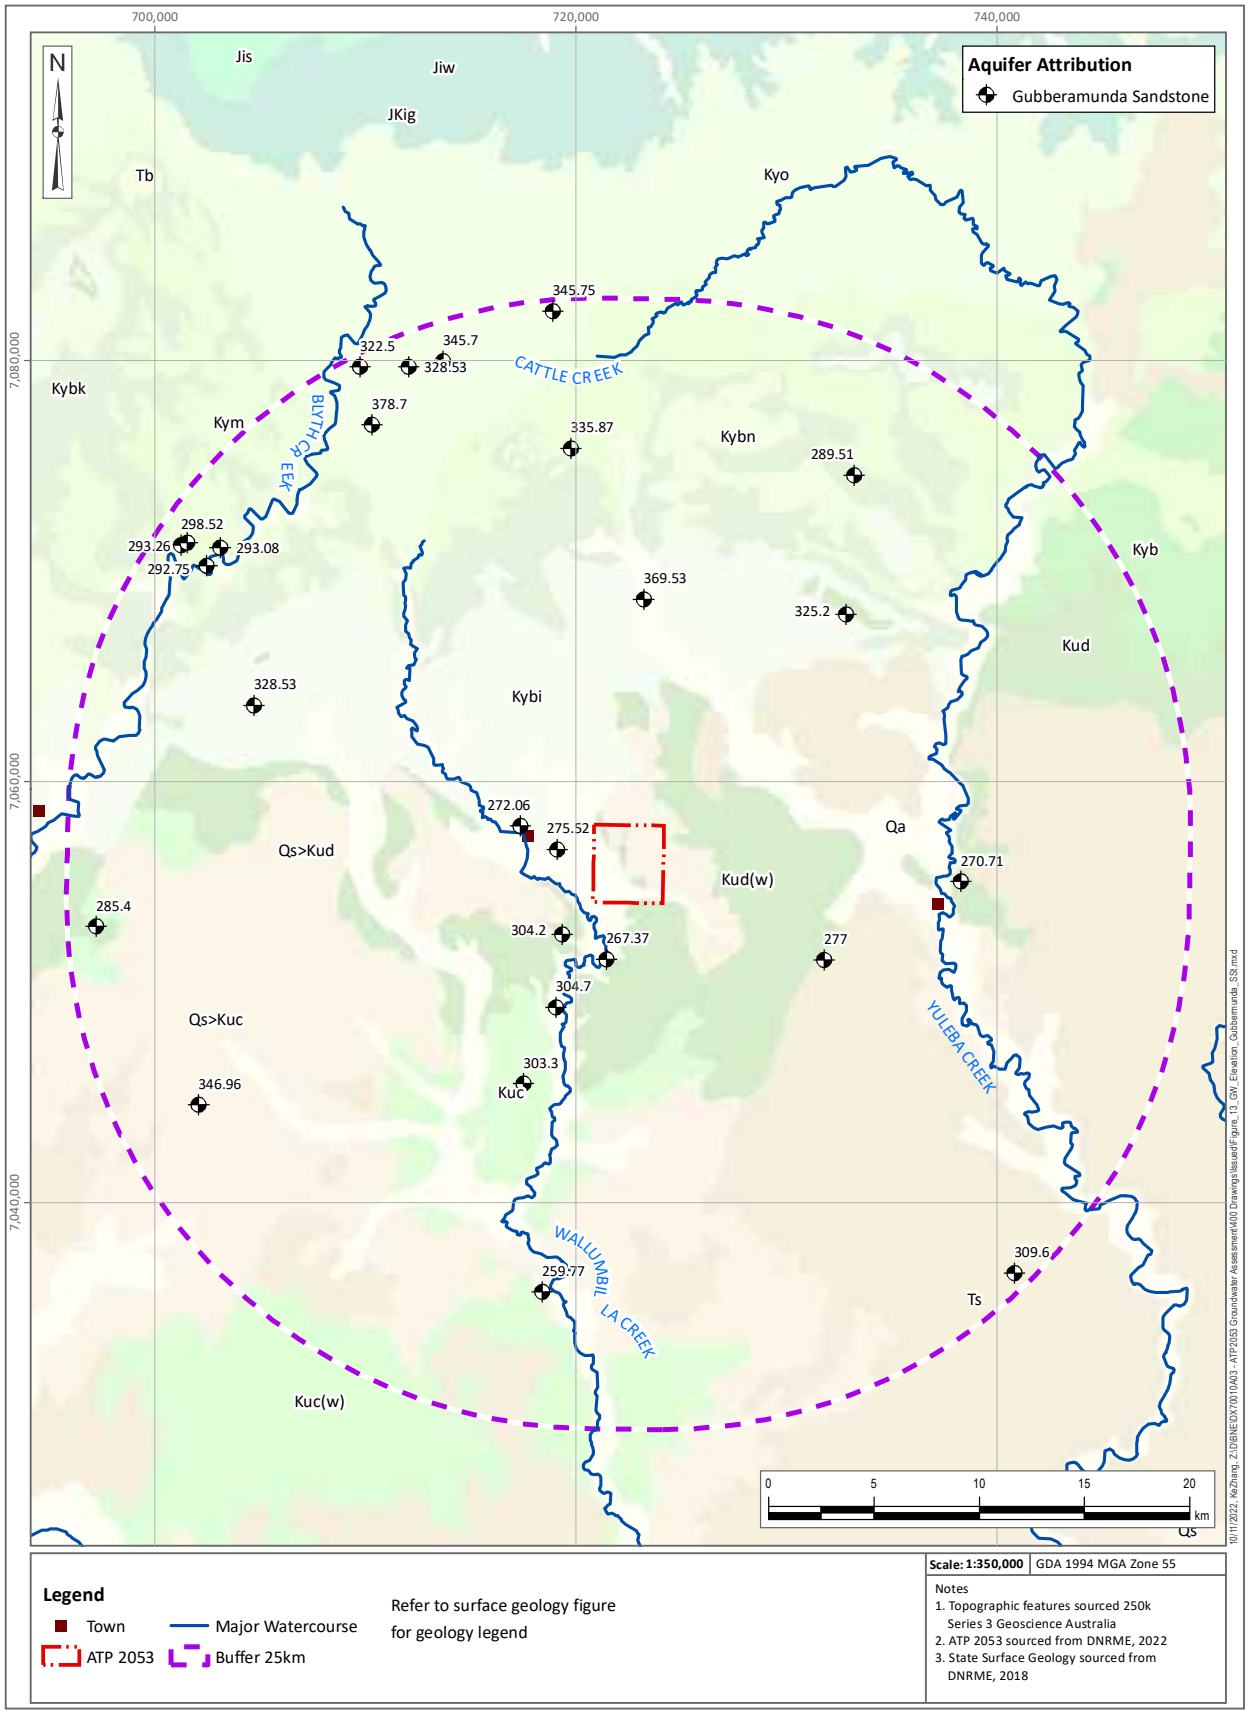

Figure 7.18 Location of Gubberamunda Sandstone Monitoring Bores and Groundwater Elevations in the Vicinity of the Project Area (State of Queensland 2022b)

Springbok Sandstone Monitoring Bores

Groundwater levels for the only two bores monitoring the Lower Springbok Sandstone within the vicinity of the Project Area are presented in Figure 7.19. The location of these bores is shown in Figure 7.20, with most recent groundwater elevations also presented.

Observations from the available data include:

- Groundwater elevations data presented between November 2011 to June 2021 for the Lower Springbok Sandstone range between 290 mAHD and 325 mAHD. The bores for which data is available are sub-artesian bores and are not used for water supply.
- Recorded groundwater levels remain relatively static and do not correlate with the CRD.
- RN160581E show a decline of 20 m, between 2016 and 2018, which may be associated with CSG production.
- RN160823A shows responses to pumping events and associated recovery. This response is common within the Springbok Sandstone. The slow and frequently incomplete recovery provides indication of the highly variable nature of the Springbok Sandstone and the very low permeability observed at many locations (OGIA 2016c).
- Based on the available data for the Springbok Sandstone, it is difficult to distinguish the groundwater flow directions within the vicinity of the Project Area, due to the lack of data points. Regionally, the groundwater system is multi-directional, and a groundwater divide occurs to the north of Roma and Miles, therefore it is likely that groundwater flow occurs northwest to southwest (OGIA 2021g).

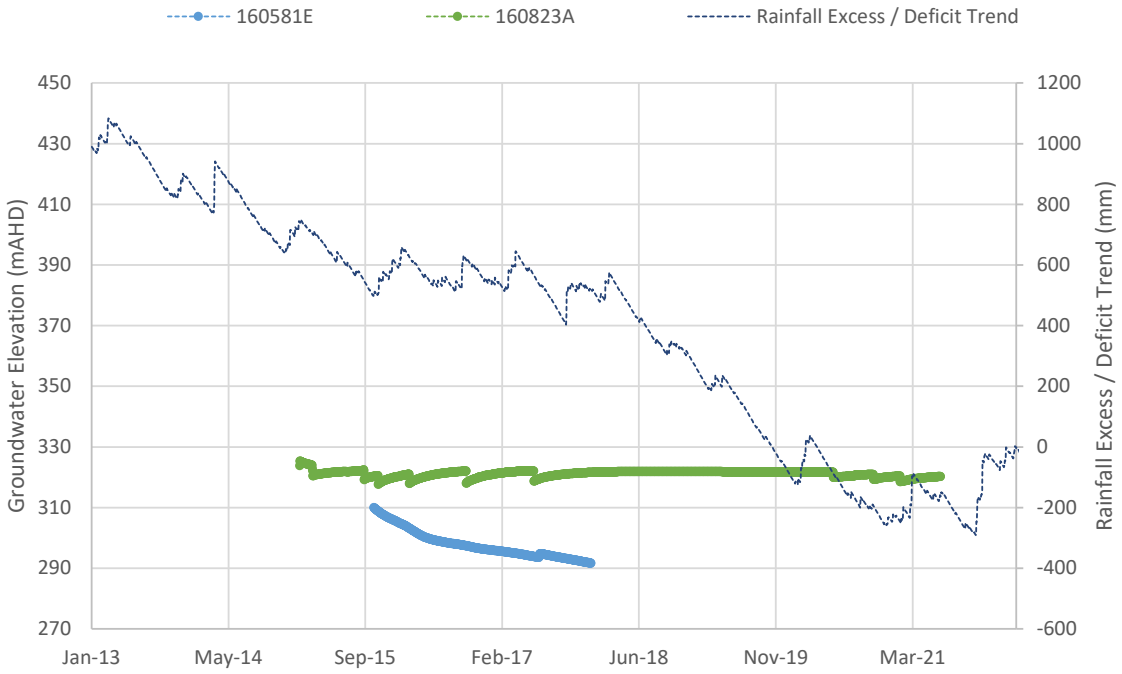

Figure 7.19 Lower Springbok Sandstone Groundwater Elevation Hydrograph

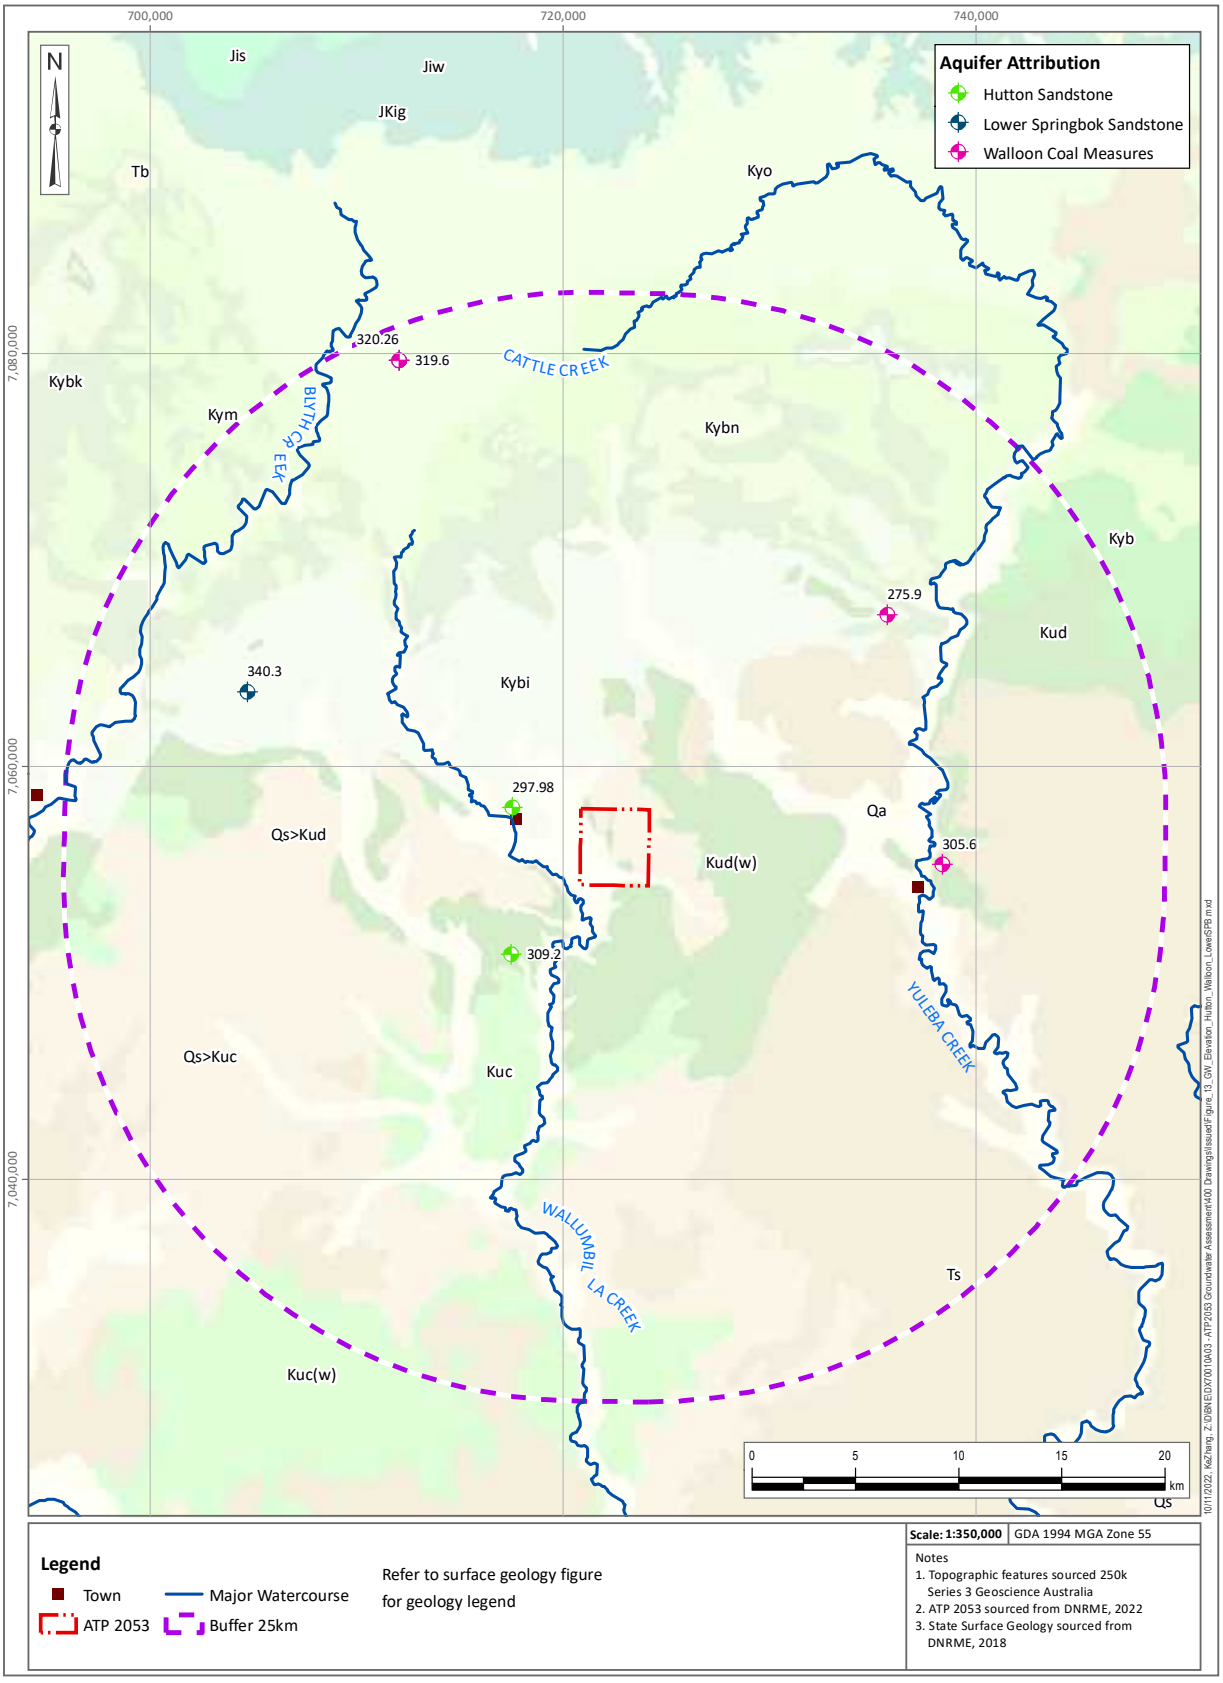

Figure 7.20 Location of Springbok Sandstone, Hutton Sandstone and Walloon Coal Measures Monitoring Bores and Recent Groundwater Elevation in the Vicinity of the Project Area

Walloon and Taroom Coal Measures Monitoring Bores

The groundwater levels for the three GWDB bores monitoring the WCM within the vicinity of the Project Area are presented in Figure 7.20 and Figure 7.21. The bores are screened within the following units:

- RN180006 – Upper Juandah.
- RN160776 – Lower Juandah.
- RN160646 – Taroom Coal Measures.

The location of these bores is shown in Figure 7.20, with groundwater elevations also presented.

Observations from the available data include:

- Groundwater elevations recorded between August 2010 to June 2021 range between approximately 340 and 260 mAHD. Available monitoring data are sourced from bores which are sub-artesian and are not used for water supply, with the exception of RN180006 which is identified as a potential water supply well.
- Groundwater levels remain relatively static in RN180006A, with a decline observed since January 2021 which may be attributed to groundwater abstraction.
- Groundwater elevation changes observed in other bores attributed to the WCM and Taroom Coal Measures are likely caused by CSG production activities.

Based on the available data for the WCM, the groundwater flow directions within the vicinity of the Project Area, is inferred to be towards the south, which aligns with the regional groundwater flow direction towards the southeast caused by radially convergent drawdown patterns observed due to CSG development (OGIA 2021c).

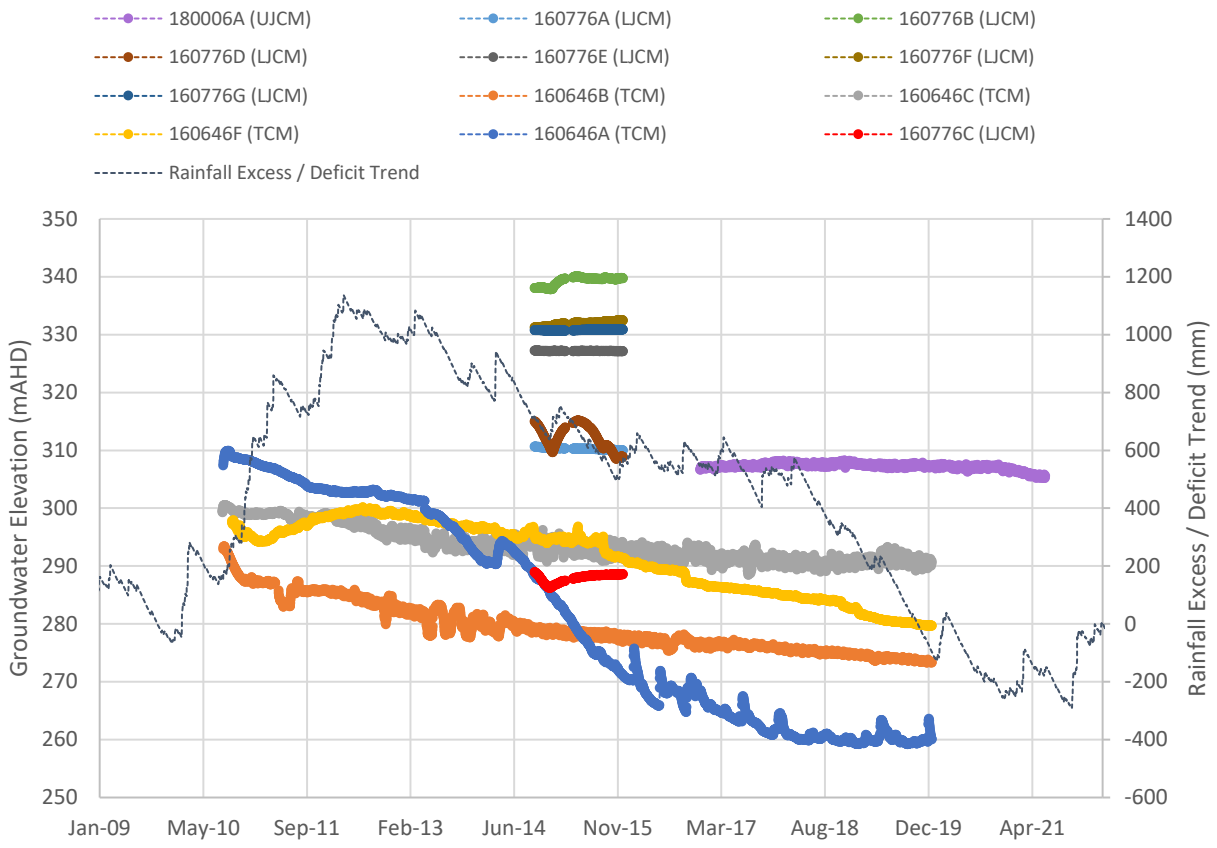

Figure 7.21 Walloon Subgroup Groundwater Elevation Hydrograph (RN180006, RN160776 and RN160646)

Upper Hutton Sandstone Monitoring Bores

The groundwater levels for the Upper Hutton Sandstone are available for three bores within the vicinity of the Project Area. The location of these bores is presented in Figure 7.20 and Figure 7.9. The groundwater elevations from the available data (June 1934 to November 1990) range between 315.3 mAHD and 297.0 mAHD.

Bore RN406 is identified as 'abandoned and destroyed' in the GWDB. Only four historical records were collected from this bore between 1934 and 1990. RN22613 has one data point (November 1975) and is identified as existing, however no recent data has been collected. Bore RN160581A is attributed to the Upper Hutton and a hydrograph indicating a stable trend is presented in Figure 7.22.

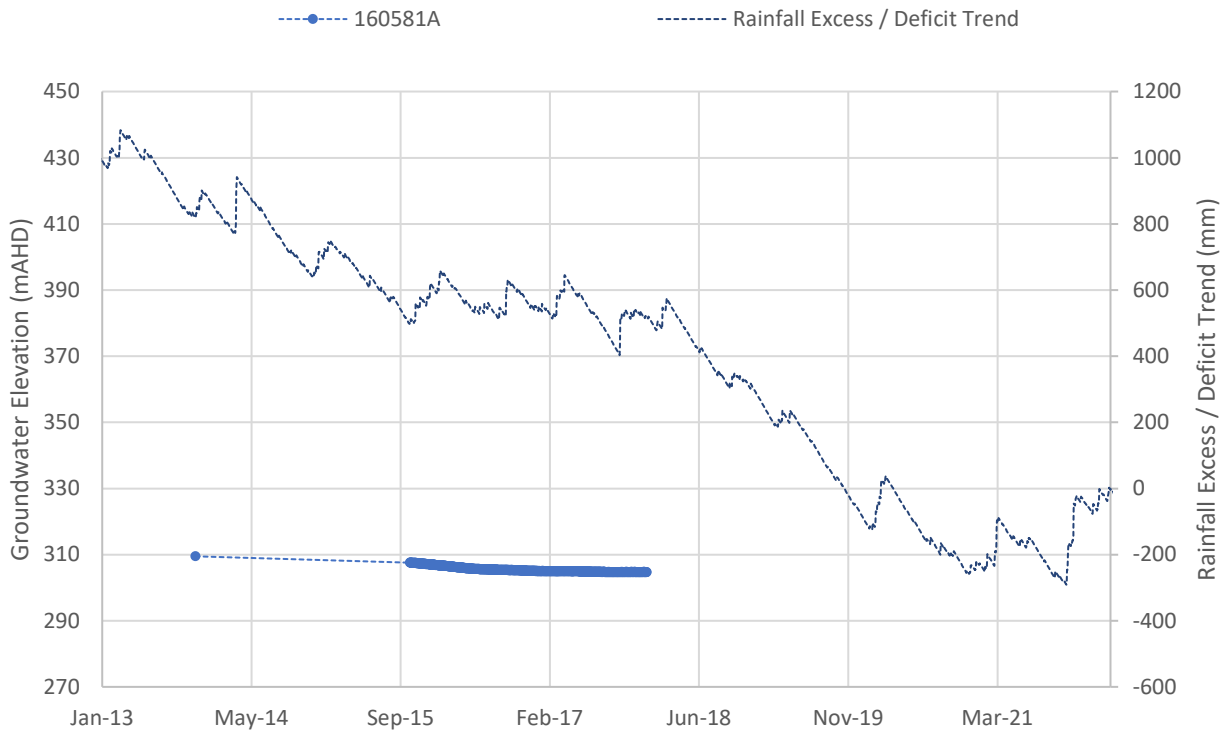

Figure 7.22 Upper Hutton Groundwater Elevation Hydrograph (RN160581A)

7.7 Groundwater Chemistry

Groundwater chemistry of the hydrostratigraphic units present at the Project Area has been considered using information reported in the UWIR 2021(OGIA 2021f), UWIR 2019 (OGIA 2019a) and data sourced from the GWDB. The primary factors influencing groundwater quality are formation mineralogy, proximity to areas where the formation is recharged, and groundwater flow dynamics within the formation. Table 7.4 presents water chemistry results for formations present within the Project Area as sourced from UWIR 2021 and UWIR 2019.

Table 7.4 Surat CMA Groundwater Chemistry (formations present within the Project Area) (sourced from OGIA 2019a Table D-2 and OGIA 2021f)

- UJCM = Upper Juandah Coal Measures, LJCM = Lower Juandah Coal Measures, TCM = Taroom Coal Measures; TDS: Total Dissolved Solids

Further groundwater chemistry data has been sourced from the GWDB for bores within a 25 km radius of the Project Area. The location of the bores with groundwater chemistry and OGIA aquifer attribution (OGIA 2022a) is shown in Figure 7.23.

The GWDB chemistry records are generally limited to analysis of the major cations and anions, with few samples analysed for metals.

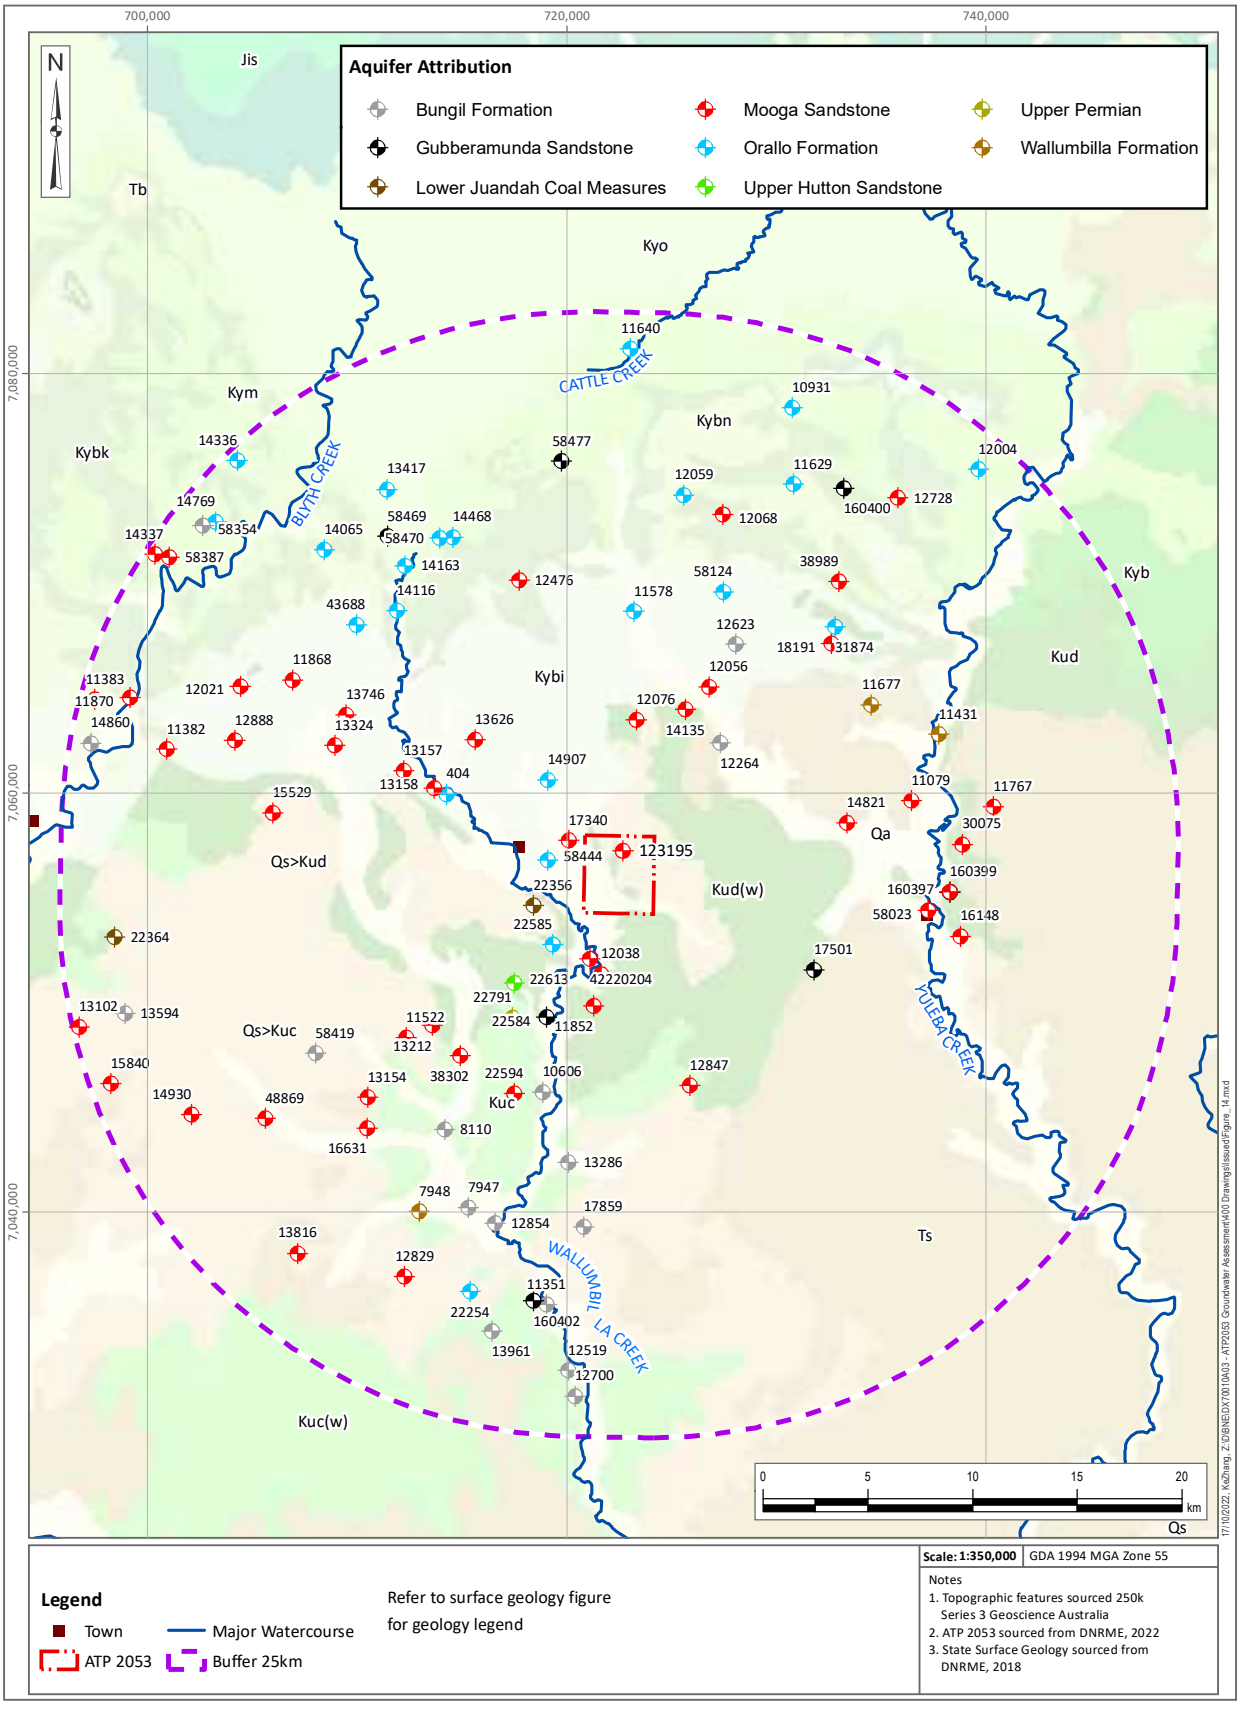

Figure 7.23 GWDB Bores with Chemistry Data in the Vicinity of the Project Area (State of Queensland 2022b)

Figure 7.24 presents a Piper diagram for each relevant hydrostratigraphic unit from the GWDB records, with a Durov diagram shown in Figure 7.25. The following observations can be made for the local hydrochemistry:

- The majority of the samples (regardless of formation) display a sodium bicarbonate to sodium-chloride water type.
- The majority of formations have TDS concentrations <2000 mg/L.

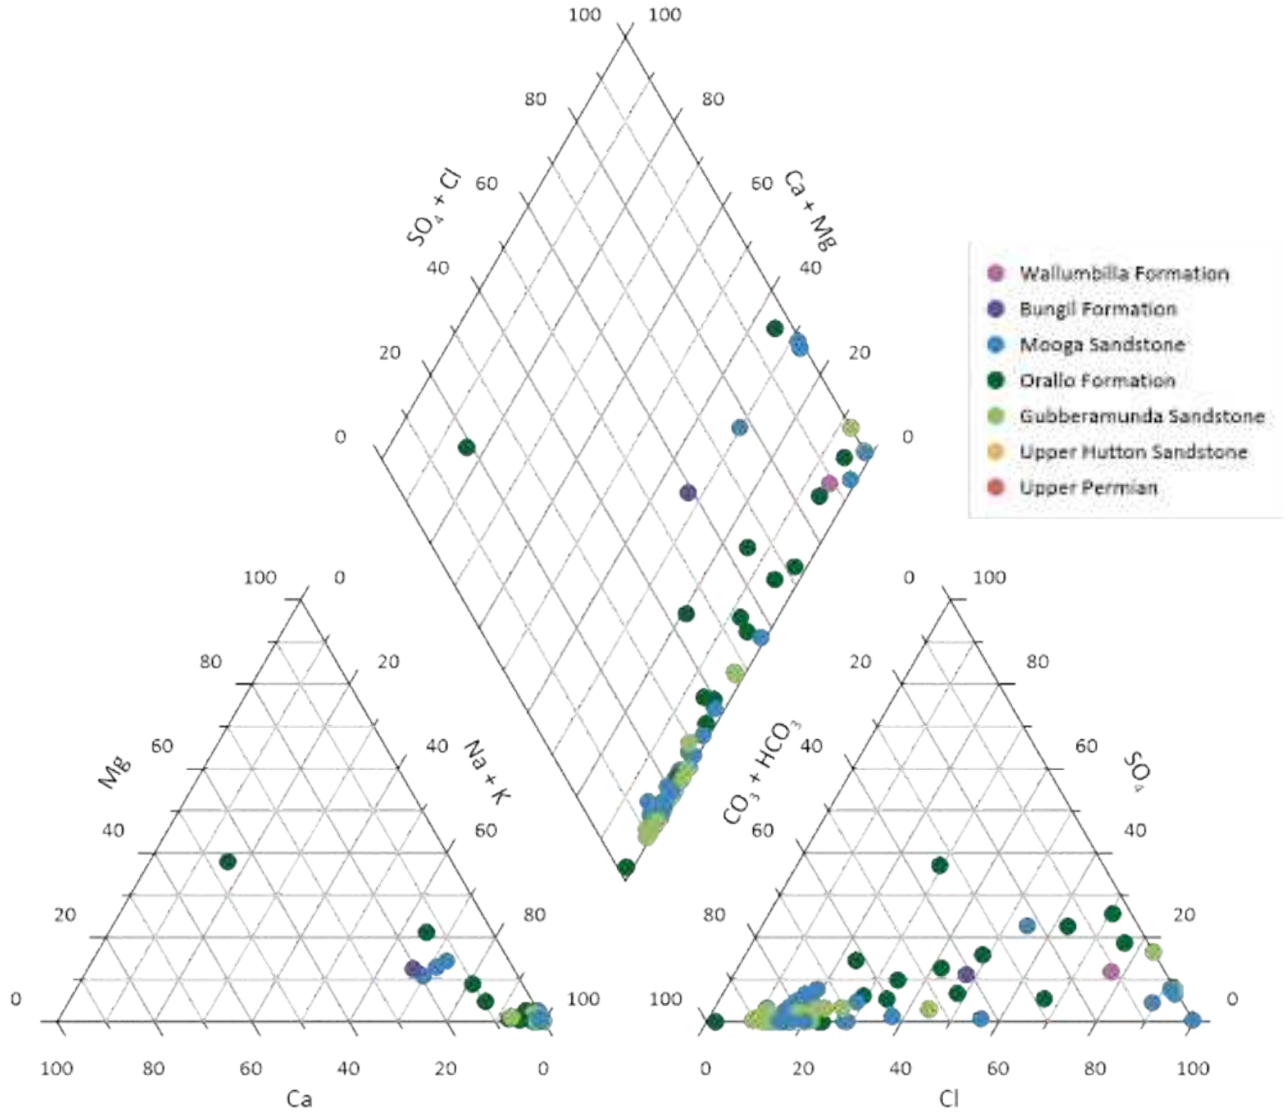

Figure 7.24 Piper Diagram from GWDB Chemistry Records from Bores within a 25 km Radius of the Project Area (State of Queensland 2022b)

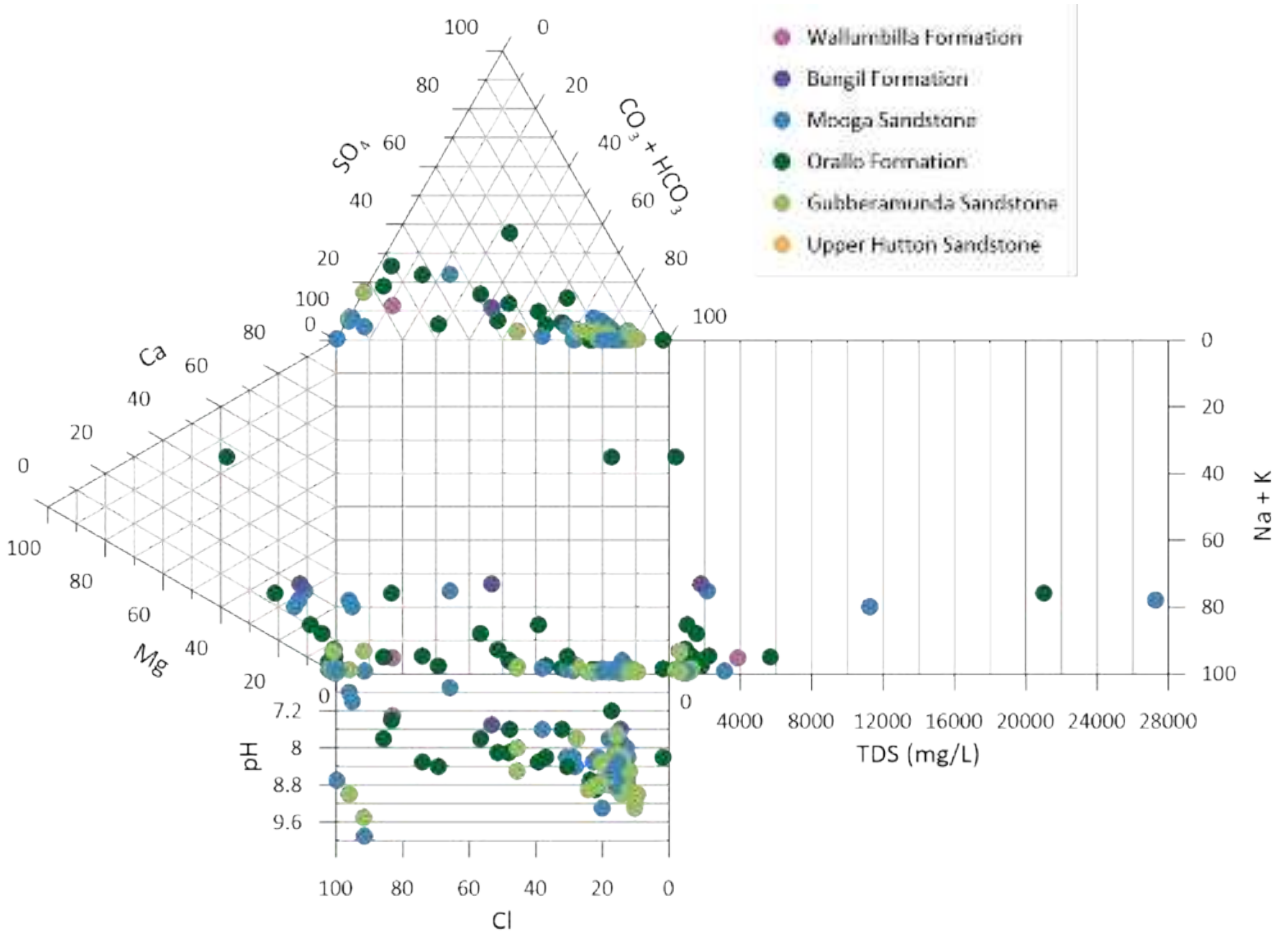

Figure 7.25 Durov Diagram from GWDB Chemistry Records from Bores within a 25 km Radius of the Project Area (State of Queensland 2022b)

7.8 Groundwater-Surface Water Interactions

Groundwater-surface water interaction in the vicinity of the Project Area may occur as a result of two key processes:

- Discharge of groundwater to watercourses as baseflow; and
- Recharge of aquifers from leakage from watercourses.

Quaternary-age alluvium (Qa) is mapped in the west within, and to the west of the Project Area along larger creeks. Cenozoic sediments comprising Quaternary-Tertiary aged residual / colluvium are present in the east of the Project Area while the underlying Doncaster Member of the Wallumbilla Formation outcrops in the centre and to the northwest of the Project Area.

There are no monitoring or groundwater supply bores located in the Quaternary or Tertiary aged deposits within 25 km of the Project Area indicating the limited potential of these units as a water resource. The Doncaster Member of the Wallumbilla Formation is a mudstone dominated unit. Very little monitoring data is available for this unit, no monitoring records more recent than 1962. The Doncaster Member of the Wallumbilla Formation is conceptualised as a tight aquitard by OGIA (OGIA 2019e).

The watercourses in the vicinity of the Project Area are highly ephemeral, and streamflow only occurs following material rainfall events (refer to Section 6.4). Recharge to groundwater systems from watercourses may occur at the Project Area, however this only occurs when there are conditions of sufficient saturation and hydraulic head to allow water to infiltrate into surrounding aquifers (e.g. alluvium). Temporary perched groundwater conditions may result due to percolation of infiltrated rainwater along streamlines and collection of rainwater in low lying areas underlain by material with low permeability.

In summary, available information infers that limited to no groundwater contribution from the regional system to watercourses as baseflow is likely at the Project Area.

7.9 Current Groundwater Stressors

The Surat CMA UWIR provides for the assessment and management of cumulative groundwater impacts resulting from the incidental extraction of groundwater by resource development activities – i.e. CSG, conventional oil and gas, and coal mining (OGIA 2021e).

The UWIR reports CSG to be the dominant, and expanding, resource development activity in the Surat Basin with five major operators – QGC, Santos, Origin Energy, Arrow Energy and Senex Energy. The existing and planned CSG production area has increased by 8% since 2019, with current projection of about 22,000 CSG wells – of which about 8,600 are already in place. Current associated water extraction by the CSG operators is around 54,000 ML per year and is likely to average around the same over the life of the industry. There are approximately 8,000 water supply bores, half of which are in the GAB, within and in the immediate proximity of the CSG production areas, extracting 59,000 ML of groundwater per year for consumptive use.

Groundwater modelling predicts 450 m of drawdown or less in the CSG and coal target formations in the Surat, and 80 m in the Springbok Sandstone. Minor impacts of less than 12 m are predicted in the Hutton Sandstone and Precipice Sandstone.

Predicted drawdown in aquifers of interest in the vicinity of the Project Area are shown in Figure 7.26. The Project Area is located in an existing CSG area, with notable additional CSG operations planned. Drawdown due to approved projects at the time of UWIR compilation (2021) in excess of 200 m was predicted in the WCM to the north of the Project Area. Notable drawdown in the Springbok Sandstone (> 100 m) was also predicted, while the drawdown in the Hutton and Precipice Sandstones is generally less than 1 m. These impacts exclude the current Project.

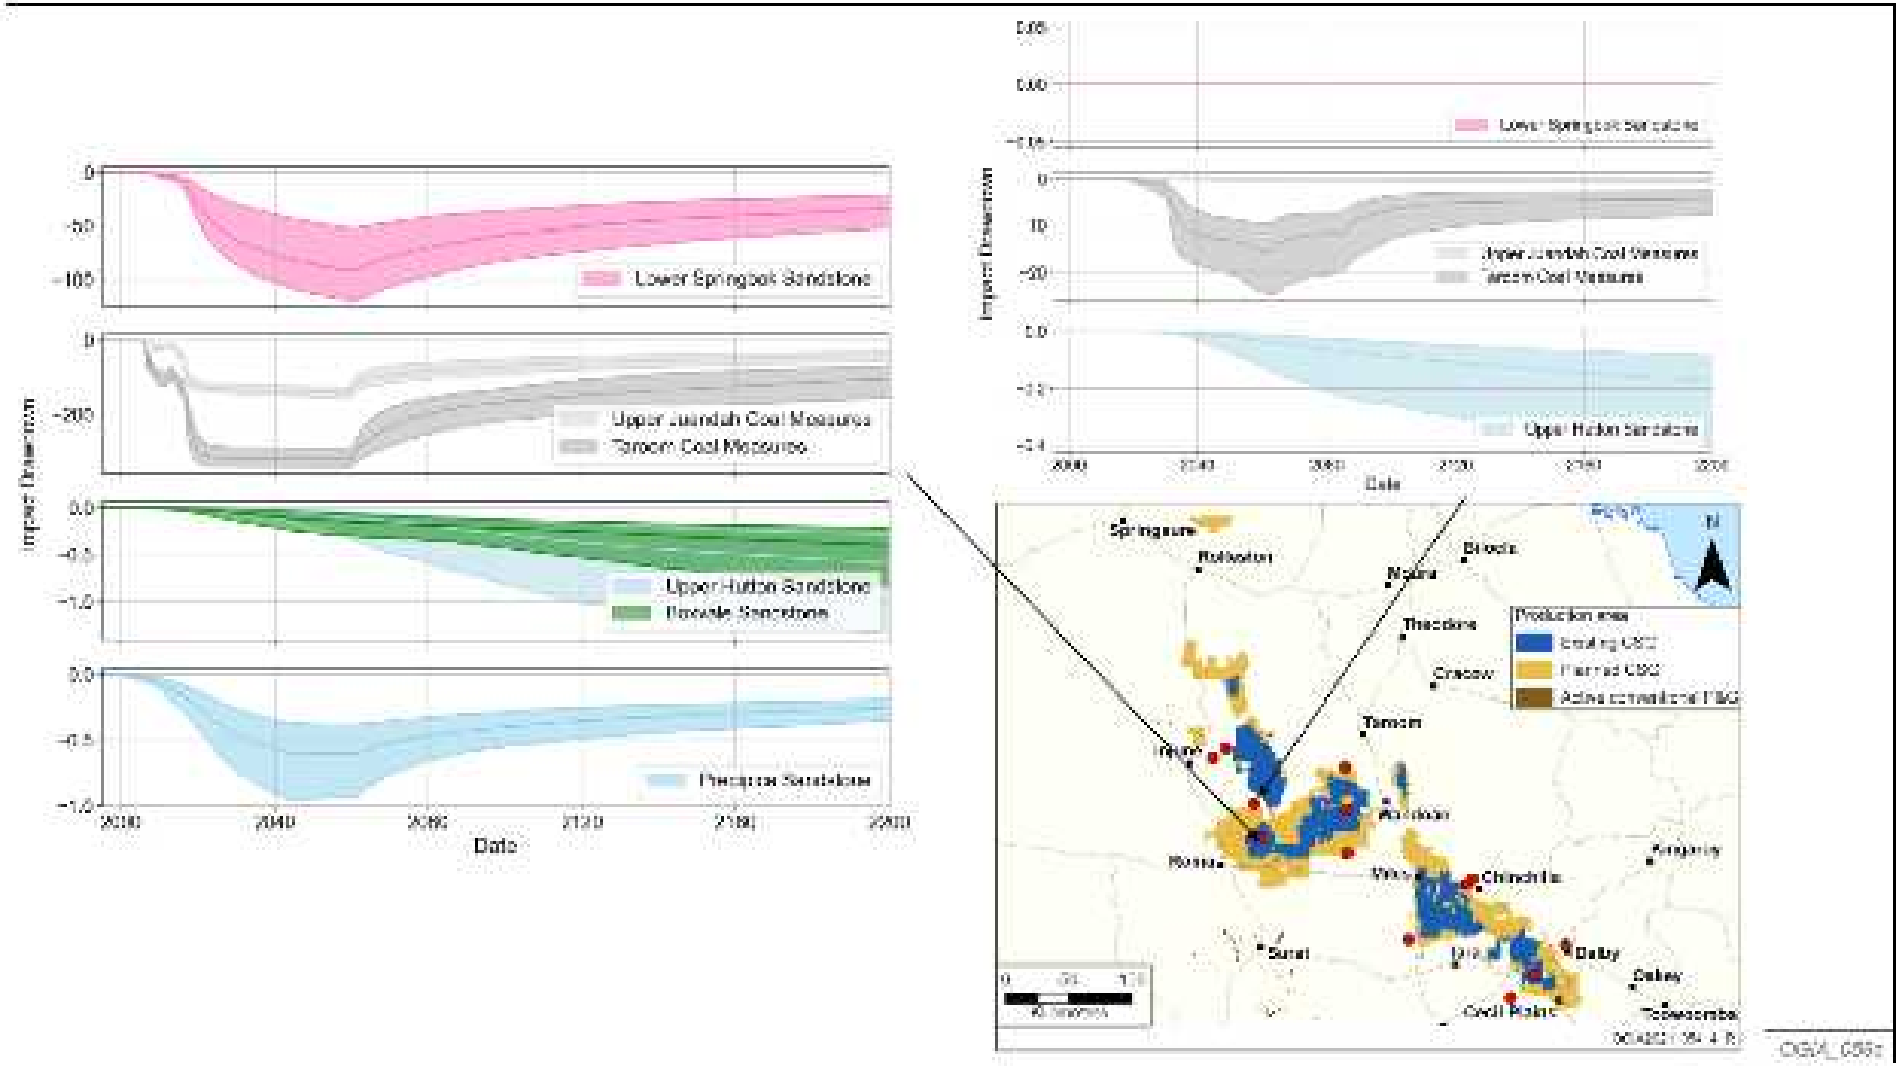

Figure 7.26 Predicted Drawdown Time Series, CSG Development Area North-East of Roma (OGIA 2021e)

7.10 Groundwater Dependent Ecosystems

Potential GDEs have been mapped within the vicinity of the Project Area (State of Queensland 2018d). GDEs are defined in water-related responses to CSG extraction and coal mining (DoEE 2015) as:

> *"Natural ecosystems which require access to groundwater on a permanent or intermittent basis to meet all or some of their water requirements so as to maintain their communities of plants and animals, ecological processes and ecosystem services (Richardson et al. 2011). The broad types of GDE are (Eamus et al. 2006):*
>
> - *Ecosystems dependent on surface expression of groundwater;*
> - *Ecosystems dependent on subsurface presence of groundwater; and*
> - *Subterranean ecosystems."*

OGIA (2019a) provides further terminology relating to surface expression GDE's, which include spring vents / complexes:

- Spring vents are described as a single location in the landscape where groundwater discharges at the surface. A spring vent can be mounded or flat and can also present as wetland vegetation, with no visible water at the location of the spring.
- A spring complex is a group of spring vents located close to each other. The spring vents are located in the same surface geology and share the same source aquifer and landscape position. No adjacent pair of spring vents in the complex is more than 10 km apart.
- A watercourse spring is a section of a watercourse where groundwater from an aquifer enters the stream through the streambed. This includes waterholes and flowing sections of streams dependent on groundwater. This type of spring is also referred to as a baseflow-fed section of a watercourse.
- Spring group, a collection of complexes and / or watercourse springs, which share the same source aquifer and are in the same geographic area.

Potential Terrestrial GDEs (TGDEs) are mapped as present in the vicinity of the Project Area and are discussed in the following sections.

7.10.1 Potential TGDEs

The Project Area is located in the Brigalow Belt bioregion. The distribution of potential mapped TGDEs (State of Queensland 2018d), in the vicinity of the Project Area is presented in Figure 7.27. Potential TGDEs in this area are indicated to intermittently connect to aquifers with brackish salinity and alkaline pH in unconsolidated Quaternary alluvial.

Small patches of low confidence 01 – 80% derived TGDEs are mapped within the Project Area, south, southeast north and northwest of the Project Area. Limited potential TGDEs are indicated surrounding the Project Area. Low to moderate confidence potential TGDEs (81 – 100%) are mapped to the east of the Project Area. Potential high confidence TGDEs mapped to the west of the Project Area correspond with riverine areas such as the Wallumbilla and Middle Creeks (1 – 80% derived TGDEs).

Queensland Government mapped potential TGDEs agree with potential TGDEs mapped using the GDE mapping rule sets as defined by the Queensland Government (2017) in Groundwater dependent ecosystem mapping rule sets for the Eastern Murray-Darling Basin. The rule sets occurring in the vicinity of the Project Area include:

- *eMDB RS 01D* – Ecosystems intermittently connected to aquifers with brackish salinity and alkaline pH in unconsolidated Quaternary alluvium. Potential surface GDEs dependent on these alluvial aquifers include lacustrine and palustrine wetlands, riverine water bodies and channels identified through prior research and deep-rooted REs including ecosystems dominated by Eucalyptus camaldulensis, Eucalyptus intertexta, Corymbia tessellaris, and / or Eucalyptus coolabah.
- *eMDB RS 04D* (located to the east of the Project Area) – Ecosystems intermittently connected to aquifers with brackish salinity and alkaline pH in unconsolidated inland sand ridges. Potential TGDEs dependent on these inland sand ridge aquifers include regional ecosystem 11.3.19 and 6.3.17.

No remnant vegetation is mapped within the Project Area.

7.10.2 Springs and Potential Surface Expression GDEs

There are no spring vents or complexes within the 25 km buffer of the Project Area. The closest watercourse springs are located along the Blyth and Yuleba Creeks (associated with the Mooga Sandstone) more than 20 km to the northeast and northwest of the Project Area, respectively.

The watercourses in the vicinity of the Project Area are expected to be highly ephemeral, with streamflow only occurring following rainfall events. This is likely a consequence of the catchments being in the uppermost reaches with limited runoff area. Limited to no groundwater contribution from the regional groundwater system to watercourses as baseflow is anticipated in the vicinity of the Project Area.

Surface expression GDEs are not indicated to be present in the Project Area. Small patches of low confidence surface expression GDEs associated with the Wallumbilla Creek are mapped to the west of the Project Area.

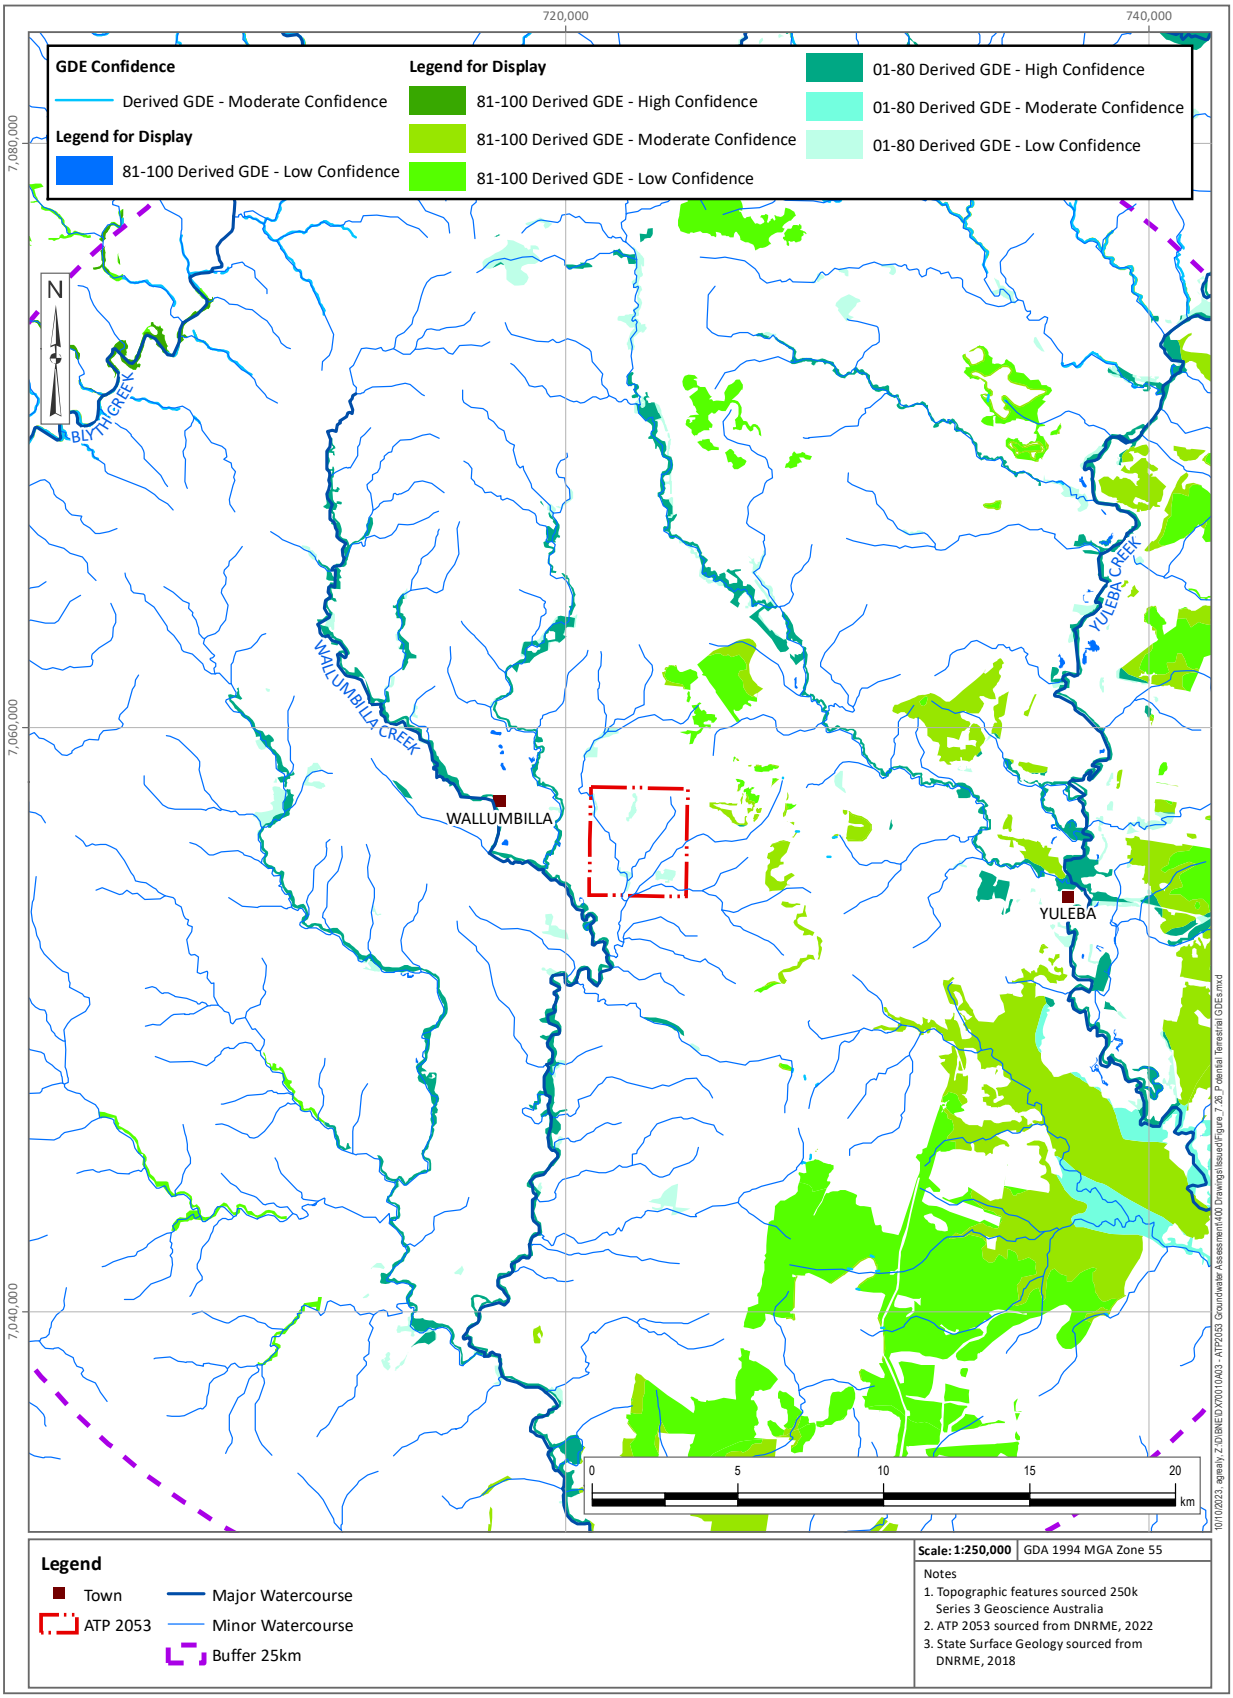

Figure 7.27 Location of Mapped Potential TGDEs in the Vicinity of the Project Area (State of Queensland 2018d)

7.10.3 RE Verification

Much of the Project Area has been largely cleared of native vegetation to form a non-remnant derived grassland dominated by introduced pastoral grasses, with occasional native trees and shrubs (Boobook 2024b).

Ground-truthed vegetation surveys undertaken by Boobook (2024) identified five RE types within the Project Area. Vegetation in the southern part of the Project Area is on land zone 3 (Quaternary alluvium) associated with streamlines and alluvial plains. Vegetation in the northern part of the Project Area includes areas on land zone 9 (fine-grained sediments). Ground-truthed areas of regrowth native vegetation is identified to occur as irregular, discontinuous corridors along streamlines, road easements and fence line corridors or as small, isolated fragments. Regrowth vegetation comprises Poplar Box (*Eucalyptus populnea*) woodland in riparian corridors, on narrow floodplains and on gently undulating terrain.

River Red Gum (*Eucalyptus camaldulensis*) dominates riparian woodland along the banks of larger streams, while Poplar Box (*E. populnea*) dominates floodplain woodlands. Brigalow (*Acacia harpophylla*) and / or Belah (*Casuarina cristata*) are prominent in areas of heavy soil and patches of Weeping Myall (*A. pendula)* occur on floodplains. Some low-lying areas have groundcover dominated by characteristic wetland fringe plants including sedges, Nardoo (*Marsilea spp.),* forbs and grasses. These floodplain wetlands include areas of non-remnant vegetation and modified drainage structures such as channels and overflow areas around dams (Boobook 2024b).

Boobook assessed vegetation conditions using the BioCondition methodology which indicates significant disturbance and consequent loss of ecosystem integrity relative to intact areas of each RE. The scores also reflect landscape level fragmentation of native vegetation, which is in small patch size, low connectivity and a low proportion of remnant and regrowth vegetation in the surrounding landscape.

The location and extent of ground-truthed REs from field surveys is displayed in Figure 7.28 and summarised in Table 7.5.

7.10.4 Site-Specific Ecological Assessment

Ecological assessment for the Project as detailed in the ERA identifies that no Significant Impact to MNES or MSES is expected as a result of the proposed development (Boobook 2024b). This is due to the existing severe fragmentation, generally poor habitat quality and the very small and localised disturbance area relative to surrounding habitat patches as well as citing of infrastructure to largely avoid disturbance to vegetation. Cumulative impacts resulting from the Project are assessed to be negligible. The conclusions included in the ERA are summarized in this section. Conservation status of REs are indicated in Figure 7.28 and MNES and MSES species potentially present in the Project area are listed per RE in Table 7.5.

Matters of National Environmental Significance

- **Threatened Ecological Communities (TEC):** Two TEC were identified to be present within the Project Area; Poplar Box grassy woodland on alluvial plains, and Weeping Myall woodlands.

- **MNES Flora:** No EPBC Act-listed threatened flora species were detected within the Project Area and no suitable habitat is present for species identified within desktop searches.
- **MNES Fauna:** No EPBC Act-listed threatened fauna species were detected within the Project Area. Potential habitat for eight EPBC Act-listed threatened fauna species is present within the Project Area. Potential habitat for multiple species of EPBC Act-listed migratory fauna species is present within the Project Area. These are all widespread and mobile species occurring in habitats that are common in the landscape surrounding the Project Area. These species do not depend on specific resources within the Project Area.
- **Weeds of National Significance:** Four species of WoNS were detected within the Project Area.

Matters of State Environmental Significance

- **Regional Ecosystems:** Two endangered REs are present within the Project Area and three Of Concern REs. BioCondition scores for regrowth and remnant vegetation within the Project Area varied from 0.47 to 0.60 indicating significant disturbance and loss of ecological integrity relative to benchmark sites.
- **MSES Flora:** No Queensland *Nature Conservation Act 1992* (State of Queensland 2024i)(NC Act) - listed threatened flora species were detected within the Project Area and no suitable habitat is present for these species.
- **MSES Fauna:** No NC Act-listed threatened fauna species were detected within the Project Area. Potentially suitable habitat is present for multiple NC Act-listed threatened fauna species. The Project Area includes scarce potential fauna breeding and/ or shelter places.
- **Biosecurity:** Four *Biosecurity Act 2014* (State of Queensland 2024a) Category 3 Restricted Matter invasive plants were present within the Project Area.

7.10.5 Groundwater Dependence

A summary of the characteristics of ground-truthed REs identified within the Project Area is presented in Table 7.5. REs 11.3.25 and 11.3.2 have the potential to include both ephemeral and permanent wetlands.

As discussed, limited to no groundwater contribution from the regional groundwater system to watercourses as baseflow is anticipated within the Project Area. No groundwater level information is available for the Quaternary or Tertiary aged deposits, and only very limited data for the Wallumbilla Formation. No water level information is available for the Bungil Formation in the vicinity of the Project Area.

A review of available literature on tree rooting depth for the dominant species (based on available desktop information) in each of the ground-truthed REs has been completed to understand how dependent these species may be on groundwater.

The average rooting depth for species of Eucalyptus present in the dominant remnant / mature regrowth REs in the Project Area is known, based on literature reviews, to range from 9 m to 22.6 m, depending on the species and the interactions between geomorphology and plant physiological traits.

Eucalypts (including Forest Red Gums, *E. tereticornis*) have two rooting systems (known as a dimorphic rooting system), with the ability to access deep groundwater during periods of time where shallower soil moisture is limited, they have shown physiological responses allowing them to adapt to water stress (CDM Smith 2021).

Groundwater dependence of ground-truthed vegetation was inferred using GDE assessment guidelines (Serov, Kuginis, and Williams 2012). Partial reliance on groundwater is considered possible along creek lines where Tertiary sediment and alluvial systems are replenished during prolonged wet periods (when ephemeral creek systems are flowing).

Potential TGDEs may also be associated with percolation of infiltrated rainwater along streamlines and collection of rainwater in low lying areas underlain by material with low permeability which may result in temporary / seasonally perched groundwater conditions. If GDEs are present, a high resilience in the vegetation and aquatic communities may be expected due to the ephemeral nature of the creek systems.

OGIA completed a regional scale desktop risk assessment of TGDEs that may potentially be impacted by CSG and coal mining activities as part of the Surat CMA UWIR (OGIA 2021g). The assessment was conservative because it was applied to vegetation that has been classified, mostly through desktop studies, by the Queensland Herbarium as a potential TGDE (therefore, it included vegetation that may not be dependent on groundwater). No potential TGDE areas in the vicinity of the Project Area were identified as being at risk.

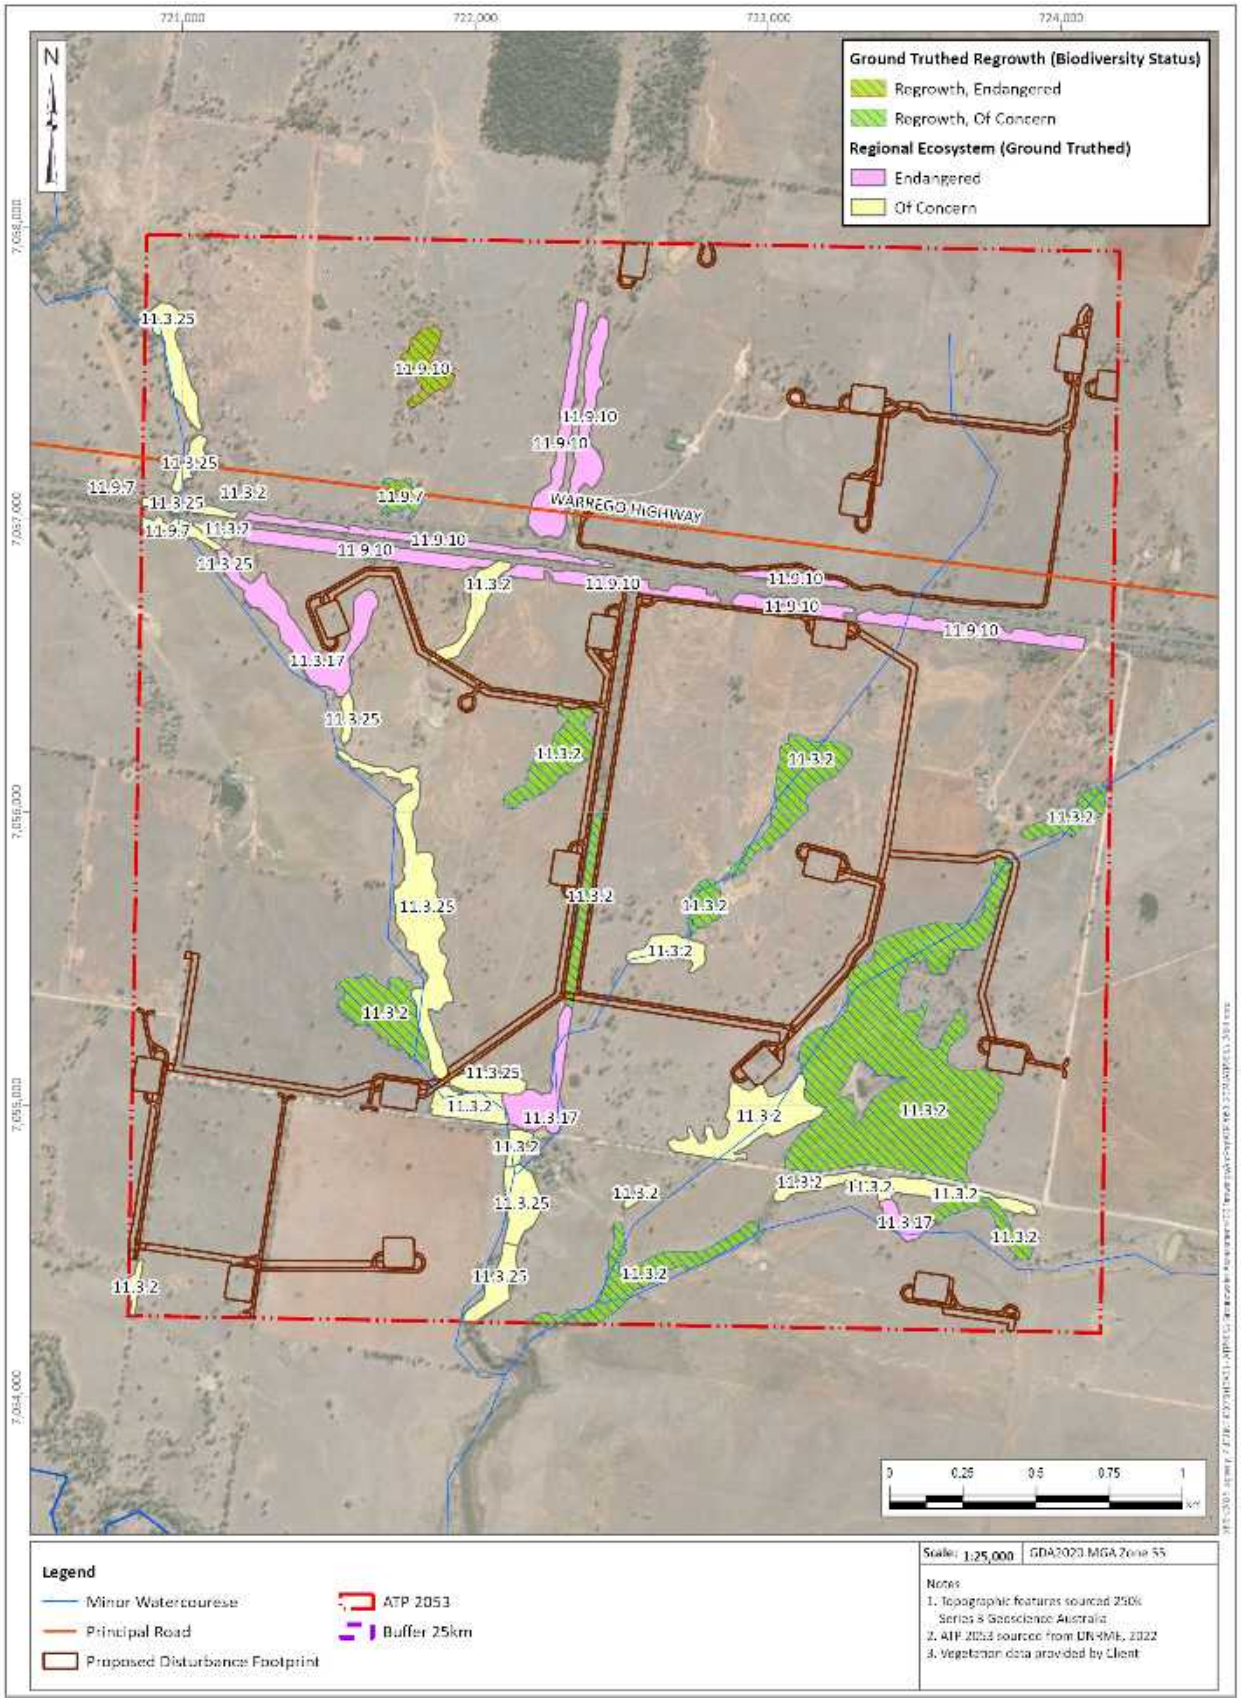

Figure 7.28 Ground-Truthed Regional Ecosystems and Wetlands in the Project Area (Boobook 2024b)

Table 7.5 Ground-Truthed Regional Ecosystems in the Project Area

Regional Ecosystem	Land Zone	Biodiversity Status	VM Act Class	Short Description	Available Rooting Depths	Potential for Groundwater Dependance	Extent in the Project Area (ha)	EPBC Act-Listed Threatened Species Potentially Present	NC Act-listed Endangered and Vulnerable Species Potentially Present
11.3.2	Alluvium (river and creek flats)	Of concern - dominant	Of concern	*Eucalyptus populnea* woodland on alluvial plains; may contain Palustrine wetlands	12.6 - 22.6 m *for E. populnea* / Poplar Box	Potential for groundwater / partial dependence	19.41	Glossy Black-Cockatoo, White-throated Needletail, Koala, Yakka Skink, Grey Snake, Sharp-tailed Sandpiper, Latham's Snipe, Australian Painted Snipe	Glossy Black-Cockatoo, White-throated Needletail, Australian Painted Snipe, Koala, Yakka Skink, Grey Snake
11.3.17	Alluvium (river and creek flats)	Endangered - dominant	Of concern	*Eucalyptus populnea* woodland with *Acacia harpophylla* and/or *Casuarina cristata* on alluvial plains; not a wetland	*E. populnea* / - 12.6 - 22.6m (Kath, et al., 2014)	Potential for groundwater / partial dependence	10.81	Glossy Black-Cockatoo, White-throated Needletail, Koala Yakka Skink, Grey Snake, Sharp-tailed Sandpiper Latham's Snipe, Australian Painted Snipe	Glossy Black-Cockatoo, White-throated Needletail, Australian Painted Snipe, Koala, Yakka Skink, Grey Snake
11.3.25	Alluvium (river and creek flats)	Of concern - dominant	Least concern	*Eucalyptus tereticornis* or *E. camaldulensis* woodland fringing drainage	At least 9m and assumed to reach groundwater reservoirs (*E. tereticornis* / Forest Red	Potential for groundwater / partial dependence	20.94	White-throated Needletail, Koala Grey Snake, Sharp-tailed Sandpiper Latham's Snipe,	White-throated Needletail, Australian Painted Snipe, Koala, Grey Snake

7.10.6 Subterranean Fauna

Stygofauna are predominantly crustaceans that are between 0.3 mm and 15 mm in length (Humphreys 2006). They are predominantly found in aquifers with large (mm or greater) pore spaces, especially alluvial, karstic and some fractured rock aquifers (Hose et al. 2015). The size of the pore spaces is a key determinant of the suitability of an aquifer as *stygofauna* habitat.

Stygofauna have been recorded occasionally in coal seam aquifers, particularly where those aquifers are hydrologically connected to a shallow alluvial aquifer (Hose et al. 2015). Hose et al. (2015) indicates the following related to the presence of *stygofauna*:

- The abundance and diversity of *stygofauna* typically decreases with depth below ground. Fauna are rarely found more than 100 mbGL.
- *Stygofauna* are found across a range of water quality conditions (from fresh to saline), but most common in fresh and brackish water (EC less than 5,000 µS/cm).
- *Stygofauna* are rarely found in hypoxic groundwater (< 0.3 mg O_2/L); and
- *Stygofauna* are more abundant in areas of surface water-groundwater exchange, compared to deeper areas or those further along the groundwater flow path remote from areas of exchange or recharge.

In the context of the Project Area, it is unlikely that *stygofauna* will be present within the target coal seams, or in the formations surrounding the coal seams due to the depth below ground level.

Saturated conditions (and therefore suitable habitat for *stygofauna*) within the surficial Tertiary and Quaternary sediments are expected to be variable and dependant on rainfall and ephemeral creek flow.

7.11 Existing Groundwater Users

7.11.1 Registered Groundwater Bores

There are 427 registered groundwater bores located within a 25 km buffer of the Project Area. Of these bores, 376 are existing bores (which include water supply and monitoring bores), with the remainder either abandoned and destroyed, abandoned but usable or proposed. A summary of registered bores is presented in Table 7.6 and displayed in Figure 7.29. (OGIA 2022b; State of Queensland 2024j).

Table 7.6 GWDB Registered Bore Statistics for the Project Area and a 25 km Buffer

Type		Abandoned and Destroyed (AD)	Abandoned but Usable (AU)	Proposed (PR)	Existing (EX)	Total
Artesian	Condition Unknown (AB)	1	1	0	16	18
	Ceased to flow (AC)	5	0	0	25	30
	Controlled Flow (AF)	17	1	0	71	89
	Uncontrolled Flow (AU)	0	0	0	1	1
Sub-Artesian (SF)		23	1	2	263	289
Total		46	3	2	376	427

AB: artesian condition unknown; AC: artesian bores, which have ceased to flow; AF: bores that are under artesian pressure and capped to control free flow; AU: artesian bores, which are uncontrolled; SF: bores which do not flow under any condition and where active pumping is required to abstract water.

Groundwater bores not registered in the GWDB may be present in the vicinity of the Project Area (e.g. this may include bores installed prior to the requirement to register water bores with the State of Queensland). It is not known how many unregistered bores may exist; however, these bores may be identified during future baseline assessments. The data from baseline assessments is provided to OGIA and the State of Queensland for incorporation into future updates to the GWDB.

7.11.2 Groundwater Use and Purpose

Groundwater is used for a number of purposes in the Surat CMA, including stock and domestic; agriculture, including general agriculture, irrigation and stock intensive; town water supplies; and industrial / mining purposes. Groundwater abstraction for stock and domestic purposes is likely to be the dominant water use within the vicinity of the Project Area, with 368 existing, abandoned but usable and potential water supply bores identified within 25 km of the Project Area (Table 7.7).

OGIA completed an assessment to estimate groundwater use within the Surat CMA as part of the UWIR (OGIA 2021f). This estimate forms part of the non-CSG water component within the regional groundwater flow model which predicts impacts associated with CSG (Section 8.2).

As part of the UWIR, OGIA also completed an assessment to assign an aquifer to each bore within the Surat CMA. Their approach sourced data from the GWDB, tenure holder bore assessments, research projects, State of Queensland datasets, previous aquifer attribution for the 2012 and 2016 UWIR (QWC 2012; OGIA 2016b) and the 2018 Surat CMA geological model (OGIA 2019a). The approach used a hierarchical approach to estimate the source aquifer, with the hierarchy taking into account the confidence level of the data source. OGIA have provided this dataset to Santos to use as part of this assessment of existing groundwater users within the vicinity of the Project Area (OGIA 2022b). Updated registered bore data were also sourced from the GWDB (State of Queensland 2024j). Bore logs were assessed and attribution assigned for bores where OGIA attribution was not available.

A summary of aquifer attribution for water supply bores (potential, existing and abandoned but usable) within a 25 km buffer of the Project Area is provided in Table 7.7, with the bore purpose presented in Figure 7.30. The majority of water use is attributed to the Mooga Sandstone and Orallo Formation, followed by the Gubberamunda Sandstone and Bungil Formation.

There are six bores located within 25 km of the Project Area that do not have an aquifer attribution assigned to them. Three (RN168013, RN168178 and RN208460) of the six are water supply bores. For the purposes of this report and for conservatism, these two have been assigned to the Gubberamunda Sandstone as this is the closest aquifer above the WCM.

Table 7.7 Aquifer Attribution and Number of Water Supply Bores within a 25 km buffer of the Project Area

Aquifer Attribution	Number of Bores	% of total bore count
Wallumbilla Formation	8	2%
Bungil Formation	22	6%
Mooga Sandstone	118	32%
Orallo Formation	102	28%
Gubberamunda Sandstone	59	16%
Westbourne Formation	3	1%
Lower Springbok Sandstone	2	1%
Upper Juandah Coal Measures	1	1%
Lower Juandah Coal Measures	2	1%
Taroom Coal Measures	5	1%
Upper Hutton Sandstone	29	8%
Lower Hutton Sandstone	1	0%
Precipice Sandstone	6	2%
Moolayember Formation	2	1%
Upper Bandanna Formation	1	0%
Lower Bandanna Formation	1	0%
Upper Permian	1	0%
#N/A	5	1%
Total	**368**	

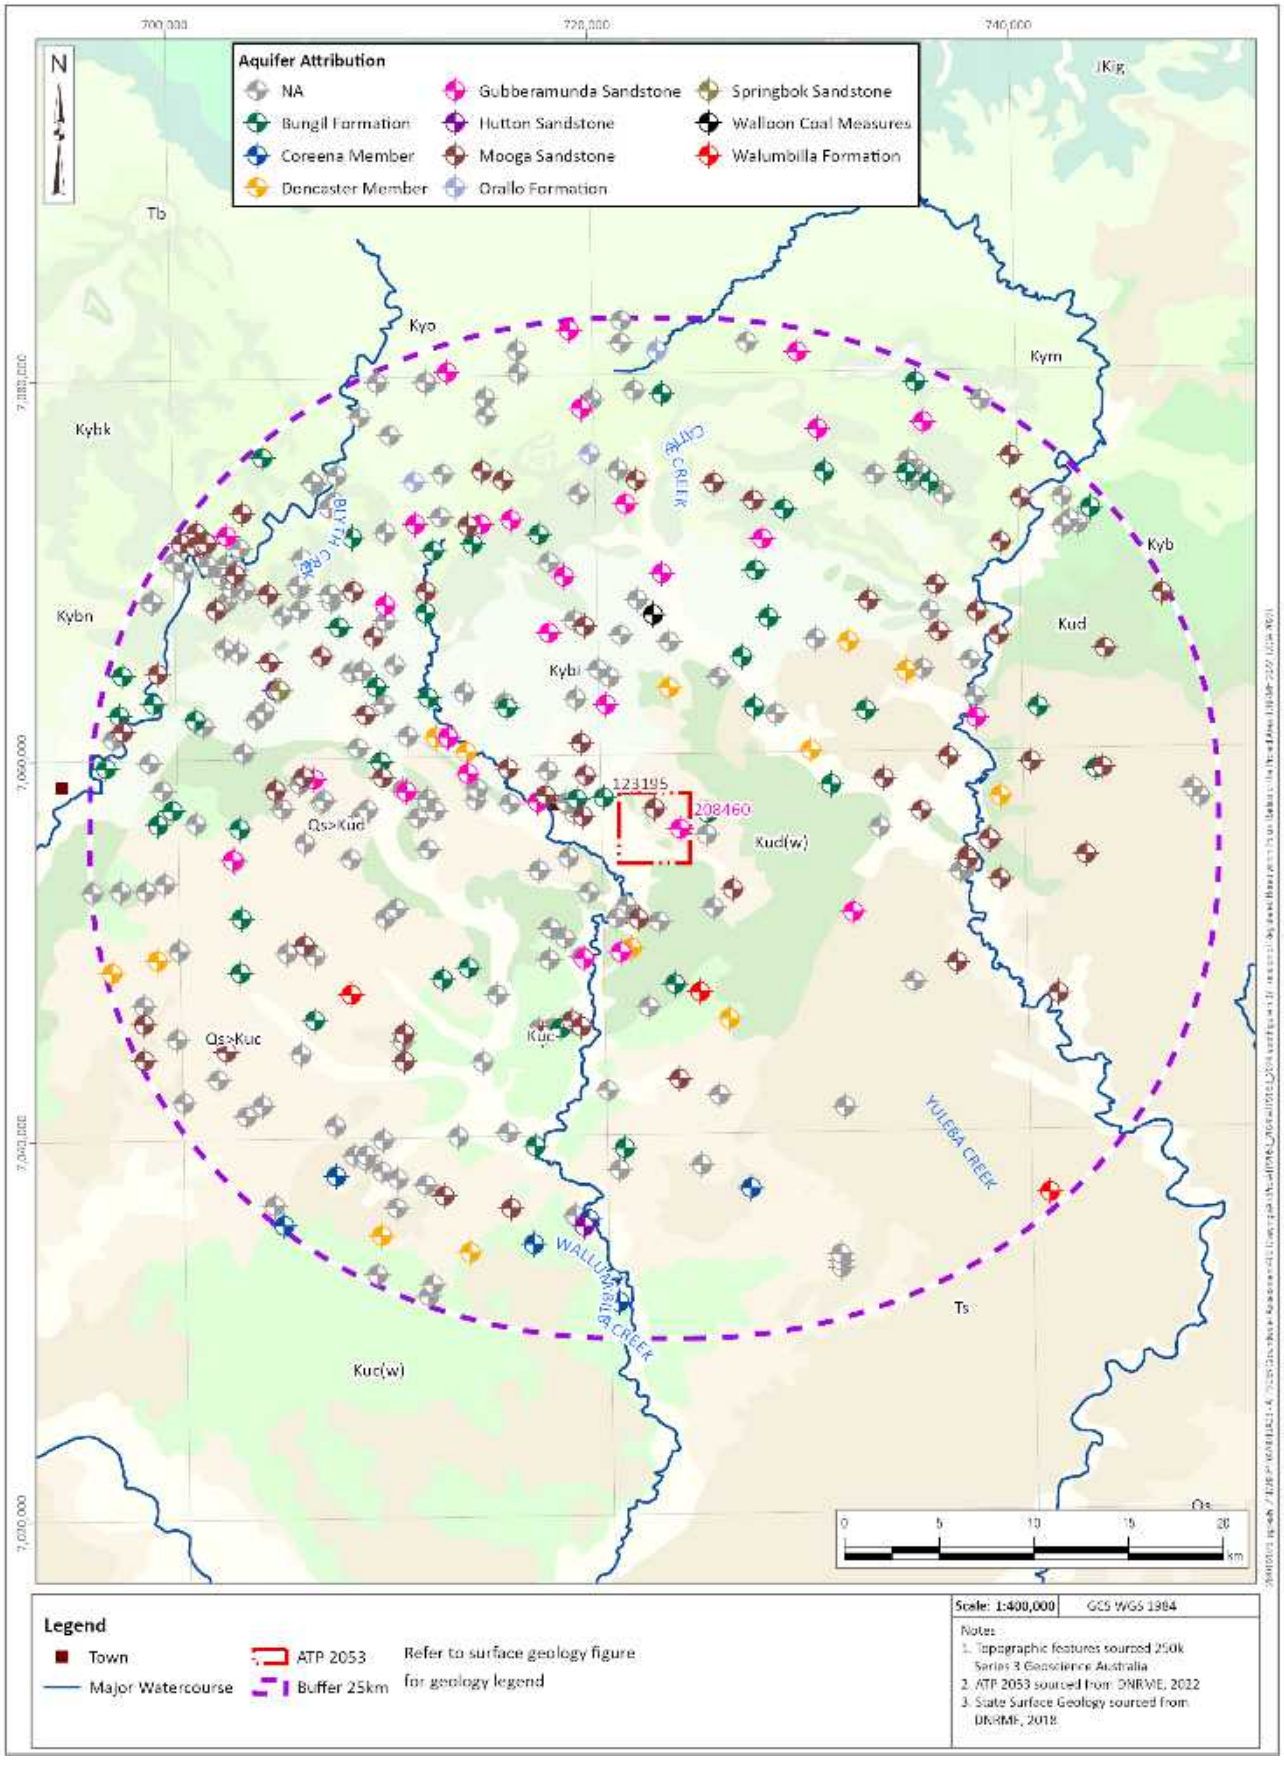

Figure 7.29 Location of Registered Bores within 25 km Radius of the Project Area

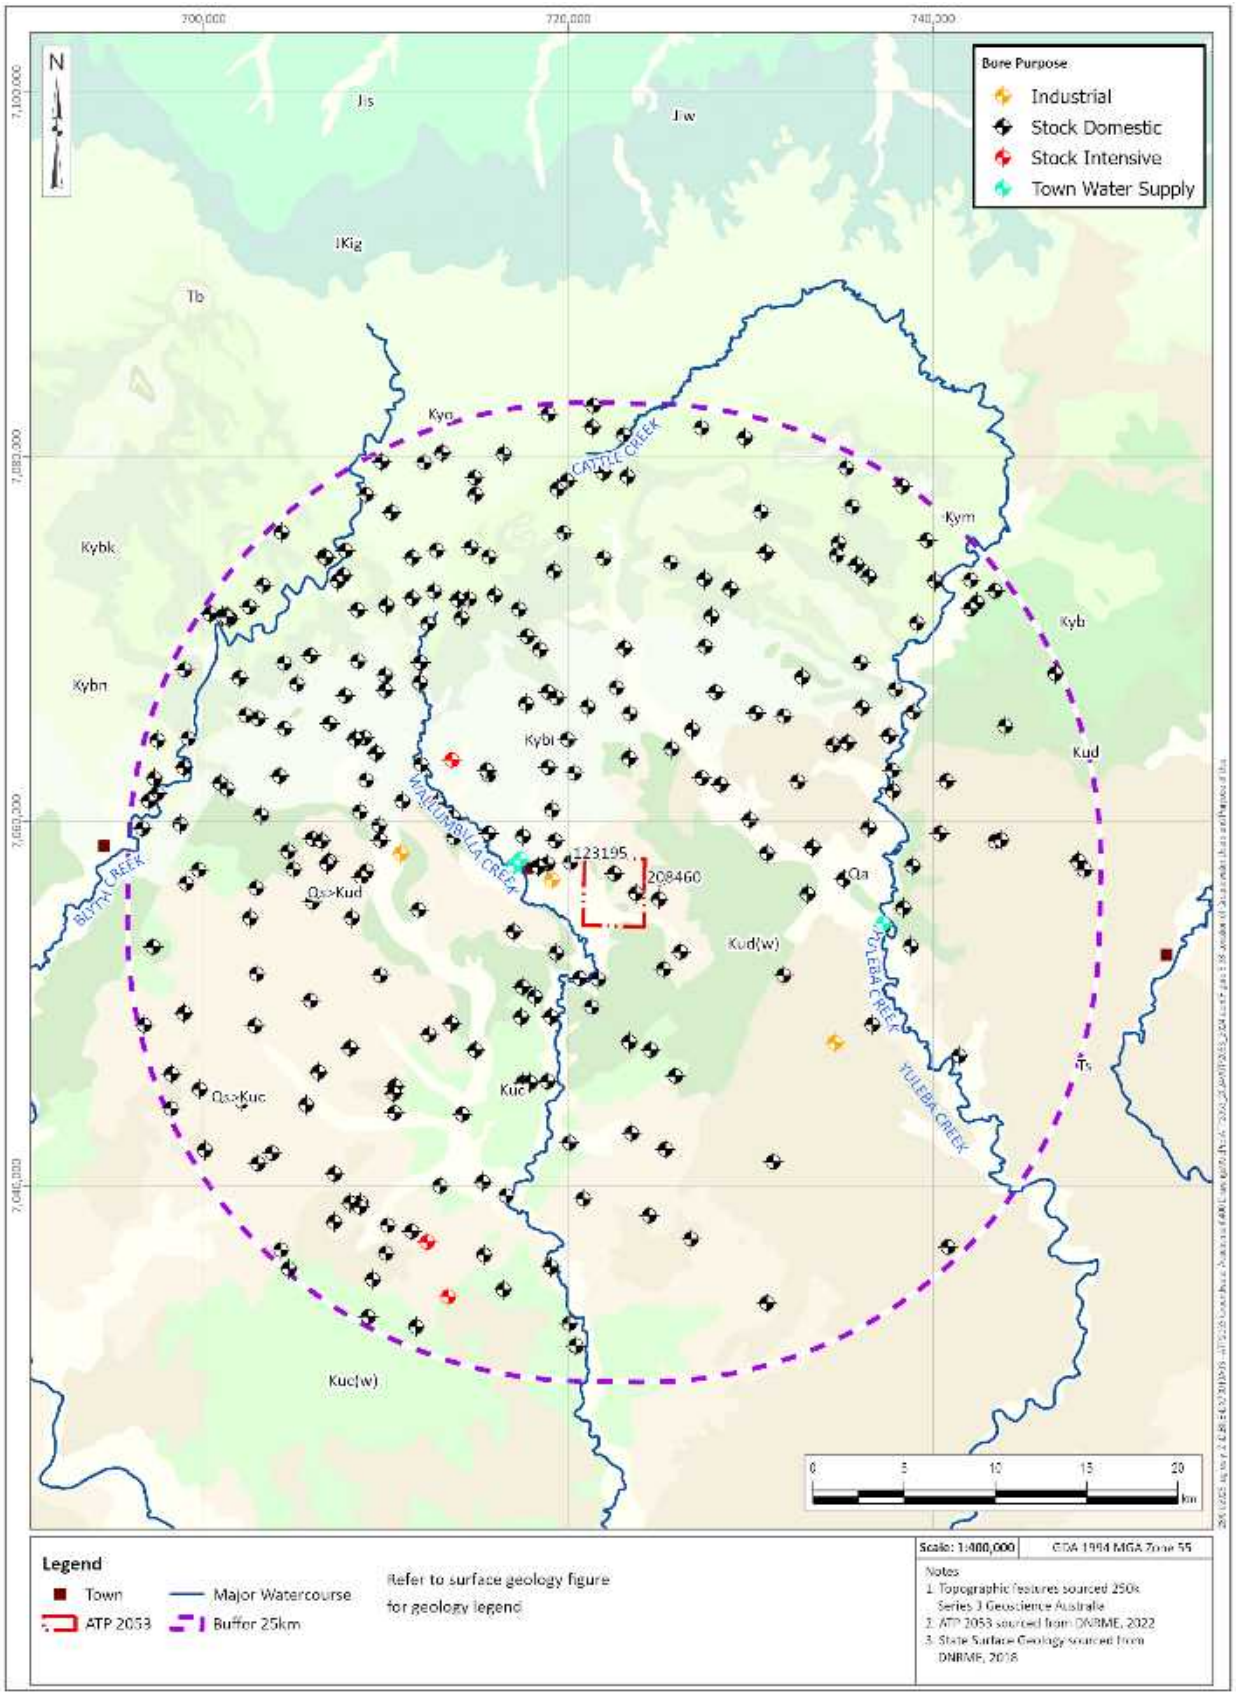

Figure 7.30 Location of Groundwater Users and Purpose within 25 km Radius of the Project Area

7.11.3 Bore Baseline Assessment

Under the Water Act 2000, CSG proponents are required to undertake baseline assessments of water bores located within their petroleum tenures prior to commencement of production. Baseline assessments are undertaken in accordance with the *Baseline Assessment Guideline* (DES 2017), to obtain information such as: bore status, type and purpose; information related to the construction of the bore, including depth installed, screen interval and source aquifer; groundwater level and quality and field gas measurement; and bore equipment including pump depth, pumping frequency and flow rate.

There is one operational water bore located within the Project Area attributed to the Mooga Sandstone, as shown in Figure 7.29. Baseline assessment was undertaken in 2009 for RN 123195. Another groundwater bore (RN208460) was drilled on the tenement in June 2024. This new bore is indicated as “no longer used”. Bore locations are shown in Figure 7.29. Santos are in the process of revising their Baseline Assessment Plan to consider the new bore, with baseline assessment planned to occur in 2025 (prior to commencement of the Project).

Table 7.8 Baseline Assessment Bore Details

Bore Registration Number (RN)	Bore Name	Property	Easting (GDA94)	Northing (GDA94)	Purpose	Date of Existing Baseline Assessment	Aquifer Attribution	Baseline Assessment Date
123195	House Bore	123WV468	722513	7057126	Domestic	4/11/2009	Mooga Sandstone	04/11/2009
208460	-	-	723709	7056052	Domestic / Stock	-	-	2025; prior to project commence-ment

7.11.4 Town Water Supply

Maranoa Regional Council operates reticulated water networks in several towns including Roma and Yuleba. The Surat's municipal water allocation is 350 ML per annum. This water allocation has been exceeded by more than 5% in 5 of the last 10 years (Maranoa Regional Council 2024).

Town water supply in the vicinity of the Project Area is sourced from the Gubberamunda Sandstone (township of Wallumbilla) and Orallo Formation (Yuleba), located >3 km and > 12 km from the Project Area boundary, respectively (refer to Table 7.9). In future, water may also be sourced from the Mooga Sandstone.

Table 7.9 Current / Historical Town Water Supply Bores

RN	Easting (GDA94)	Northing (GDA94)	Status	Aquifer Attribution	Location
58023	737254	7054389	Existing	Orallo Formation	Yuleba
48871	717033	7057579	Abandoned but usable	Orallo Formation	Wallumbilla
123318	717375	7057909	Existing	Gubberamunda Sandstone	Wallumbilla

7.12 Hydrogeological Conceptual Model Summary

This section summarises the information of the previous sections in terms of the conceptual models for the hydrological and hydrogeological systems and identifies the water-dependent assets for consideration in the impact assessment. A summary of the conceptual model is as follows:

- The surface geology within the vicinity of the Project Area comprises Quaternary-age alluvium associated with the watercourses (Wallumbilla Creek, Washpool Creek and Middle Creek), with Cenozoic aged residual / colluvium in the east of the Project Area. The Doncaster Member, a tight aquitard of the Wallumbilla Formation, outcrops with limited extent in the centre of the Project Area and underlies the Quaternary and Tertiary aged alluvium and residual / colluvium across the Project Area (larger outcropping areas are present to the east and south of the Project Area). The Wallumbilla Formation has a limited vertical extent in the Project Area with a mean thickness of 2.8 m. The Wallumbilla Formation appears to confine the underlying Bungil and Orallo Formation in some areas; the majority of bores in these formations are artesian.
- The Coreena Member, also of the Wallumbilla Formation, is a partial aquifer and outcrops to the south of the Project Area while other Cretaceous units outcrop to the north of the Project Area. The Wallumbilla Formation is underlain by the Bungil Formation, a partial aquifer of the Blythesdale Group.
- The southeasterly extent of the Hutton-Wallumbilla Fault is indicated to occur 4 km northwest of the Project Area. There are no major or observable local geological structures (e.g. faults) intersecting the Project Area.
- The watercourses within the Project Area are characteristically ephemeral and typically only flow during and immediately following significant rainfall events.
- Potential TGDEs associated with the watercourses, if partially groundwater, would likely be sourcing groundwater from the shallow unconsolidated sediments within and adjacent to watercourses within the Project Area (Washpool Creek). Quaternary and Tertiary deposits present across the Project Area are expected to be primarily recharged during prolonged wet periods due to rainfall infiltration and when the ephemeral creek systems are flowing. Limited water level monitoring data is available for the Quaternary and Tertiary aged units as well as the Doncaster Member and Bungil Formation, which highlights each of these units as having a limited potential to be a water resource. This does not facilitate robust conclusions regarding groundwater level depth and the potential for interaction with surface water systems; however, available information indicate that limited to no groundwater contribution from the regional system to watercourses as baseflow is likely at the Project Area, particularly considering the watercourses are ephemeral.
- There are no spring vents or complexes within the 25 km buffer of the Project Area. The closest watercourse springs are located along the Blyth and Yuleba Creeks (associated with the Mooga Sandstone) more than 20 km to the northeast and northwest of the Project Area, respectively.

- Groundwater use is predominately associated with the Mooga Sandstone (32% of the total groundwater use) and the Orallo Formation (28% of the total groundwater use), followed by the Gubberamunda Sandstone (16%). Most are used for stock and domestic purposes, with 368 water supply bores (existing, abandoned but usable and potential) identified within 25 km of the Project Area.
- The target for gas production is the WCM which occurs at 650 mbGL (vertical depth) at the Project Area.
- The WCM and Springbok Sandstone (a tight aquifer that directly overlies the coal measures) are over- and underlain by thick sequences of several tight aquitards (which limit propagation of drawdown into the overlying and underlying aquifers), including most notably the overlying Westbourne Formation (which has a mean thickness in the Project Area of 63 m) and the Orallo Formation (with a mean thickness of 198 m), as well as the underlying Eurombah / Durabilla Formation (which has a mean thickness of 52 m) and the Upper Evergreen Formation (with a mean thickness of 161 m).
- The WCM is also separated from the overlying Springbok Sandstone by the Upper WCM Non-Productive Layer; also, identified as an aquitard.

The conceptual model is summarised in Figure 7.31.

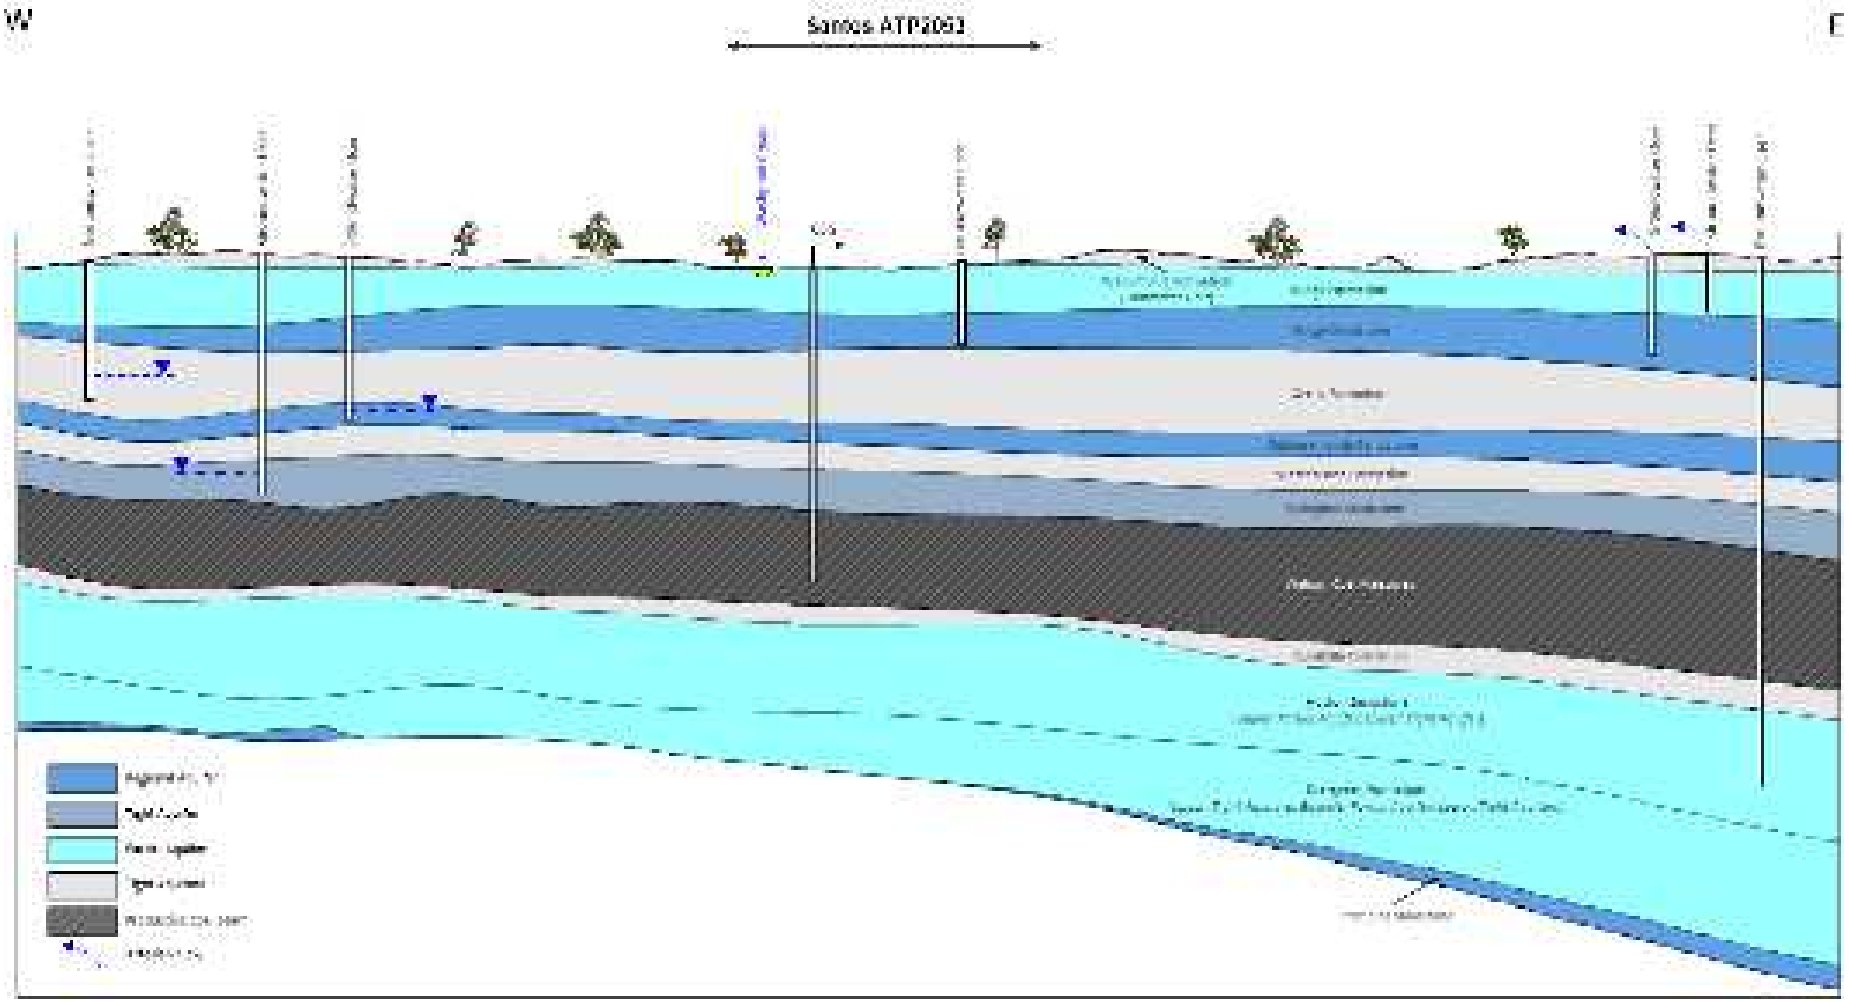

Figure 7.31 Conceptual Model of the Project Area

8 NUMERICAL GROUNDWATER MODELLING

8.1 Overview

As detailed in Section 3.1, the Project Area is located within the Surat CMA, which was declared under the Water Act 2000, as a result of concentrated development by multiple tenure holders.

The Project Area is located adjacent to other active and proposed CSG developments. As groundwater is removed via CSG production wells to depressurise the coal seams, there will be a degree of interaction between the individual tenure holders.

OGIA, established under the Water Act 2000, is responsible for predicting regional impacts on water pressures in the hydrostratigraphic units of the Surat CMA and identifying potentially impacted groundwater bores and springs as presented in the UWIR, which is updated and published every three years.

As part of the Surat CMA UWIR, OGIA developed a regional numerical groundwater flow model to predict cumulative groundwater pressure impacts due to activities from multiple P&G tenure holders. The model was first developed and utilised as part of the 2012 UWIR (QWC 2012b). An updated UWIR and updated numerical groundwater model was published by OGIA in September, 2016 (OGIA 2016c), July, 2019 (OGIA 2019a) and most recently May 2022 (OGIA 2021g). Since the previous UWIR in 2019, the most recent UWIR addresses a new legislative requirement to include coal impact in the assessment and to assimilate contemporary data and conceptualisation work.

The primary purpose of the model is to predict regional water pressure or water level changes in aquifers within the Surat CMA footprint in response to extraction of groundwater associated with CSG, coal mining and conventional oil and gas. In particular, the OGIA numerical groundwater model is used to assess potential impacts to landholder groundwater bores and springs relative to the Water Act 2000 trigger thresholds (State of Queensland 2024m).

The current OGIA groundwater model is the agreed basis for assessment for all Surat CMA CSG impacts, even at the scale of individual bores for make good investigation purposes, therefore, also appropriate to use at the GDE scale for this assessment where it applies to non-alluvial units.

The Surat CMA UWIR is updated periodically (every three years), therefore, the OGIA numerical groundwater model for the Surat CMA is also updated periodically to support the UWIR. Key updates to the model include recalibration of the model based on monitoring data provided by proponents operating within the CMA, extraction records, and the incorporation of newly approved CSG developments within the CMA. Therefore, each update to the OGIA model results in the additional incorporation of site data and an update of the predicted cumulative drawdown impacts across the CMA.

The model domain includes the extent of the Surat CMA, with hydrostratigraphic units from the Surat Basin as well as interconnected basins (Bowen Basin and Clarence-Moreton Basin). The model domain is shown in Figure 8.1. The model consists of 35 layers, with the additional layer in the WCM (Taroom Coal measures) as shown in Figure 8.2.

This additional layer, added since the UWIR 2019, improves representation of flow between units within the WCM and will assist in predicting drawdown impacts within this formation.

A summary of key aspects of the model is presented in Table 8.1.

Table 8.1 Summary of the OGIA Regional Groundwater Flow Model (after OGIA 2019a) and (OGIA 2021a)

Model Component	Description
Modelling Platform	MODFLOW-USG
Model Domain	Model covers the entire Surat CMA (Figure 8.1), including all coal seam formations and potentially connected aquifers in the Surat, southern Bowen and Clarence-Moreton Basins. The model domain is 460 x 650 km.
Model Layers	Model consists of 35 layers (Figure 8.2). Addition of Taroom Coal Measures (2021 UWIR)
Grid Spacing	Model grid spacing is 1.5 km x 1.5 km
Parameterisation	Initial parameters for use in the Surat CMA model were developed using an innovative workflow, developed by OGIA, centred around a suite of detailed numerical permeameters. This workflow was initially developed for use in the 2016 regional groundwater flow model and has been further enhanced for the current model. This approach extracts full value from the large geological and hydraulic parameter dataset available for the CMA. Outputs from this process include formation scale horizontal and vertical permeabilities that are then used as inputs to the regional groundwater flow model for further calibration against water level and other observed data.
Water Production Simulation	Simulated using the MODFLOW-USG 'drain' boundary condition. Multiple MODFLOW-USG drains are assigned to each well; these descend over time as pressures in the CSG well are reduced.
Calibration	Calibration was undertaken using the automated calibration software PEST_HP and PESTPP_IES. Calibration of the model was achieved using a three-stage simulation: 1. The first simulation was to replicate conditions that existed prior to the commencement (1947) of any groundwater extraction, for petroleum, gas or other purposes. 2. The second simulation was to replicate pre- P&G extraction conditions in 1995 to provide starting or initial conditions for the third and final stage. 3. The third stage was a transient simulation to replicate the period from January 1995 to December 2020, during which P&G production commenced initially from the Bandanna Formation and then from the WCM.

PROJECT CSG TARGET

Figure 8.2 Model Layers and Corresponding Units Represented in the OGIA Regional Groundwater Flow Model (OGIA 2021b)

8.2 Model Parameters, Boundary Conditions and Calibration

The information provided in the following sections has been summarised from the *Groundwater Modelling Report for the Surat Cumulative Management Area* (OGIA 2016c), *Underground Water Impact Report for the Surat CMA* (OGIA 2021i), and *modelling of cumulative groundwater impacts in the Surat CMA: approach and methods* (OGIA 2021b).

8.2.1 Model Parameters

OGIA improved their approach to assigning initial numerical groundwater model parameters as part of the update to the regional model for the 2016 UWIR and have continued to further refine the model for the 2021 UWIR.

The approach included three steps, as described in OGIA (OGIA 2019a):

- Initial values of hydraulic conductivity for each of six lithology types (clean sand, dirty sand, siltstone, mudstone, carbonaceous shale, and coal) from geophysical logs are derived from expert knowledge, literature, and analysis of geophysical logs.
- These initial values are then input to a stochastic permeability model and calibrated (or 'conditioned') through comparison with around 13,000 hydraulic test results at three different scales (i.e. pump tests, core test and geophysical measurement).
- Once calibrated, these values are then used to populate numerical permeameters – detailed 21 x 21 km numerical models of each stratigraphic unit, generated using lithological data for about 6,000 CSG wells and covering the full extent of the 12 stratigraphic units modelled. In total, more than 138,000 model runs were carried out during this part of the process.

OGIA model parameters (horizontal and vertical hydraulic conductivity) for the Project Area are displayed in Appendix I.

8.2.2 Groundwater Abstraction – Boundary Conditions

Optimal flow conditions for gas production are typically achieved when water pressures within the production well are equivalent to 25 to 80 m of water head (OGIA 2019a). To simulate water production, OGIA have used the MODFLOW-USG 'drain' boundary condition, with multiple drains assigned to each production well descending over time as pressures in the CSG production well reduce.

The simulation using the drain boundary condition, is based on the sequencing of development and production well spacing provided by tenure holders across the model domain. Water is removed from the model to achieve the optimal head conditions (25 to 80 m), rather than removing a volume predicted using a modelling tool (e.g. estimated abstraction volume in Section 3.4.1).

Groundwater abstraction for non-P&G purposes, such as stock and domestic, are simulated using the MODFLOW-USG 'well' boundary condition.

8.2.3 Model Calibration

Calibration of the 2021 model was achieved using a three-stage simulation (OGIA 2021b). The first was a pre-development (1947) simulation was to replicate conditions that existed prior to the commencement of any groundwater extraction, for petroleum, gas, or other purposes.

The second simulation was to replicate pre- P&G extraction conditions in 1995 to provide starting or initial conditions for the third and final stage.

The third stage was a transient simulation to replicate the period from January 1995 to December 2020, during which P&G production commenced initially from the Bandanna Formation and then from the WCM.

The calibration was undertaken using the automated calibration software PEST, with a range of qualitative and quantitative measures used to assess each calibration iteration, consistent with the *Australian Groundwater Modelling Guidelines* (Barnett et al. 2012).

8.3 Project Model Scenarios

Santos has recently planned to advance development of the Project, and as such the tenure has not been included in previous versions of the UWIR (including the recently published 2021 UWIR).

To assist Santos with approval applications, and to maintain consistency with the 2019 UWIR predictions, OGIA agreed to simulate the proposed CSG production for the Project within the UWIR model based on information provided by Santos. These outputs have been provided for use and processed as part of this assessment. All processing and analysis of model outputs were undertaken by KCB based on raw model outputs provided by OGIA.

Scenarios simulated by OGIA include:

- **Project only scenario** - includes future development at the Project only (24 wells, including two multi-wells comprising two wells each).
- **A cumulative CSG production model scenario** - includes all current and proposed non-P&G and P&G groundwater abstraction (original UWIR 2021 model) *plus* the Project *plus* reasonably foreseeable production at Santos ATP 1187 and ATP 2052.

Predicted drawdown of the Project only scenario and Cumulative scenarios are presented in Section 8.5.1 and Section 8.5.2, respectively.

8.4 Assumptions and Limitations

Assumptions and limitations of the regional groundwater model are provided in OGIA (2016a). Key assumptions and limitations of the model associated with its use for this assessment are provided as follows:

- Since the model is required to cover the full extent of the Surat CMA and all aquifers potentially impacted by P&G water extraction within the Surat CMA, groundwater numerical model cell sizes are relatively large in lateral extent (1.5 km × 1.5 km). One outcome of the large cell size is that shallow, unconfined groundwater systems, and the interaction of these systems with deeper systems, can be simulated only approximately.

- Model cell sizes are large in vertical extent. Other than the WCM, most stratigraphic layers in the Surat and Bowen Basins are represented by only one or two model layers. Vertical head gradients within these layers, and geological details which lead to variations of these gradients, are only an approximation for the entire stratigraphic thickness.

  (i.e. heterogeneity of the stratigraphic unit is not fully captured in the numerical model although considerable efforts were made to generate upscaled parameters and test that the model could replicate impact predictions made using highly detailed models with minimal upscaling).

- Depressurisation of coal measures leading to desorption of gas, and hence the resulting dual phase flow (gas and water), is simulated using a van Genuchten function in which water saturation is a function of pressure alone. This is a simplification of more complex processes that include desorption of gas and then flow of gas together with water towards extraction centres. Buoyant potential up-dip movement of gas, not captured in CSG production wells, is also not represented.
- The effect of local faulting, and abandoned and poorly constructed wells, on vertical propagation of drawdown to stratigraphic units adjacent to the WCM units is not considered. However, major regional fault systems are represented in both the model structure and parameterisation, and hence their effects on impact propagation are considered.
- Limited site-specific hydraulic parameter data is available for the Project Area. Therefore, the values utilised in the model in the vicinity of the Project Area have been inferred and calibrated through reference to data outside of the Project Area. This may increase / decrease the effects of CSG production, and associated groundwater abstraction, in the vicinity of the Project Area.
- CSG production is represented by drain boundary conditions with elevations set for optimal gas production. As a result, the produced volume of water from the drain cells may not necessarily represent actual CSG water production due to localised variability in aquifer hydraulic parameters. The model, however, has been calibrated to historic actual production data and is able to replicate production in most current fields to a high degree of accuracy.

8.5 Scenario Results

8.5.1 Project Only Scenario Results

Numerical model outputs provided by OGIA, for the scenarios detailed in the previous section, have been used by KCB to assess the extent and magnitude of drawdown related to CSG production from the Project.

Appendix II includes the predicted drawdown for the individually modelled hydrostratigraphic units where drawdown of more than 0.2 m is observed (as detailed in Figure 8.2). The figures in Appendix II presents the Project only scenario drawdown and recovery post-development.

Summary figures are presented in Figure 8.3 to Figure 8.5, which show the maximum predicted Project only scenario drawdown for the relevant hydrostratigraphic unit, irrespective of date. Figures were not generated for formations where predicted drawdown is less than 0.2 m.

Observations include:

- Drawdown exceeding the trigger levels are not predicted in the surficial unconsolidated Quaternary and Quaternary-Tertiary units (layer 1), or in Cretaceous-aged formations (layers 2 to 6), the Gubbermunda Sandstone (layer 7) and the Westbourne Formation (layer 8).
- There is no notable drawdown predicted in the Hutton Sandstone (layer 19) and in formations beneath the Hutton Sandstone.
- Drawdown greater than 0.2 m (spring trigger threshold) is predicted in model layer 9 (Lower Springbok Sandstone) to model layer 18 (Durabilla Formation).
- Drawdown greater than 5 m (consolidated bore trigger threshold) is only predicted in model layers 12 to 18 (WCM and the underlying Durabilla Formation); and
- The highest drawdown is predicted in model layers 13 to 17, which represent the WCM (target for CSG production).

Appendix II presents the predicted Project only scenario drawdown and recovery post-development where notable drawdown is observed. The post-development timesteps presented are for Project recovery year 0 (end of Project), 56, 176, 326, 526 and 726. These figures show rapid groundwater level drawdown within the WCM during Project implementation and slow recovery following Project completion. Drawdown impact is still evident in the WCM 700 years after Project completion.

Limited drawdown is predicted to propagate into the overlying / underlying layers (as described above) during Project development, and recovery is pronounced following Project cessation.

Drawdown within the Durabilla Formation is shown to decrease to below 5 m between 200 – 500 years following Project completion. The Upper and Lower Springbok Sandstone reflects complete recovery between 180 - 320 years following Project completion.

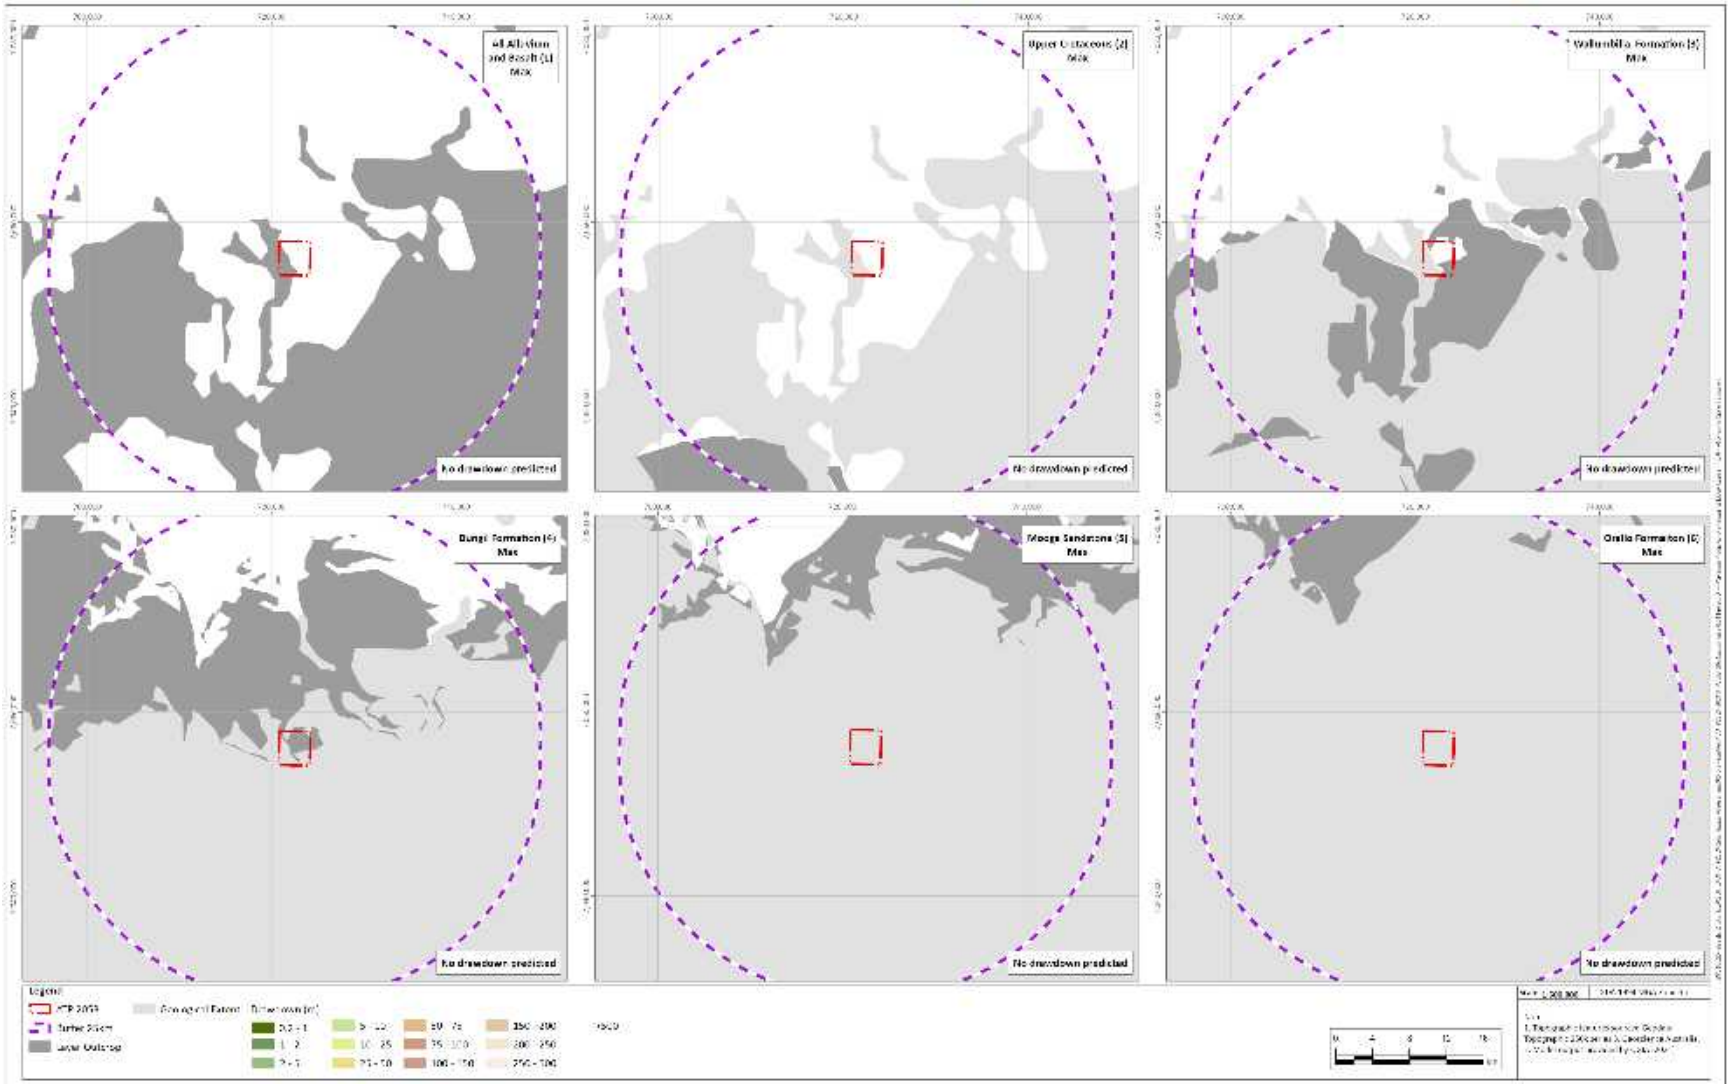

Figure 8.3 Project Only Scenario Maximum Drawdown Pattern for Model Layers, 1 to 6 – Upper Springbok to Upper Juandah Coal Measures

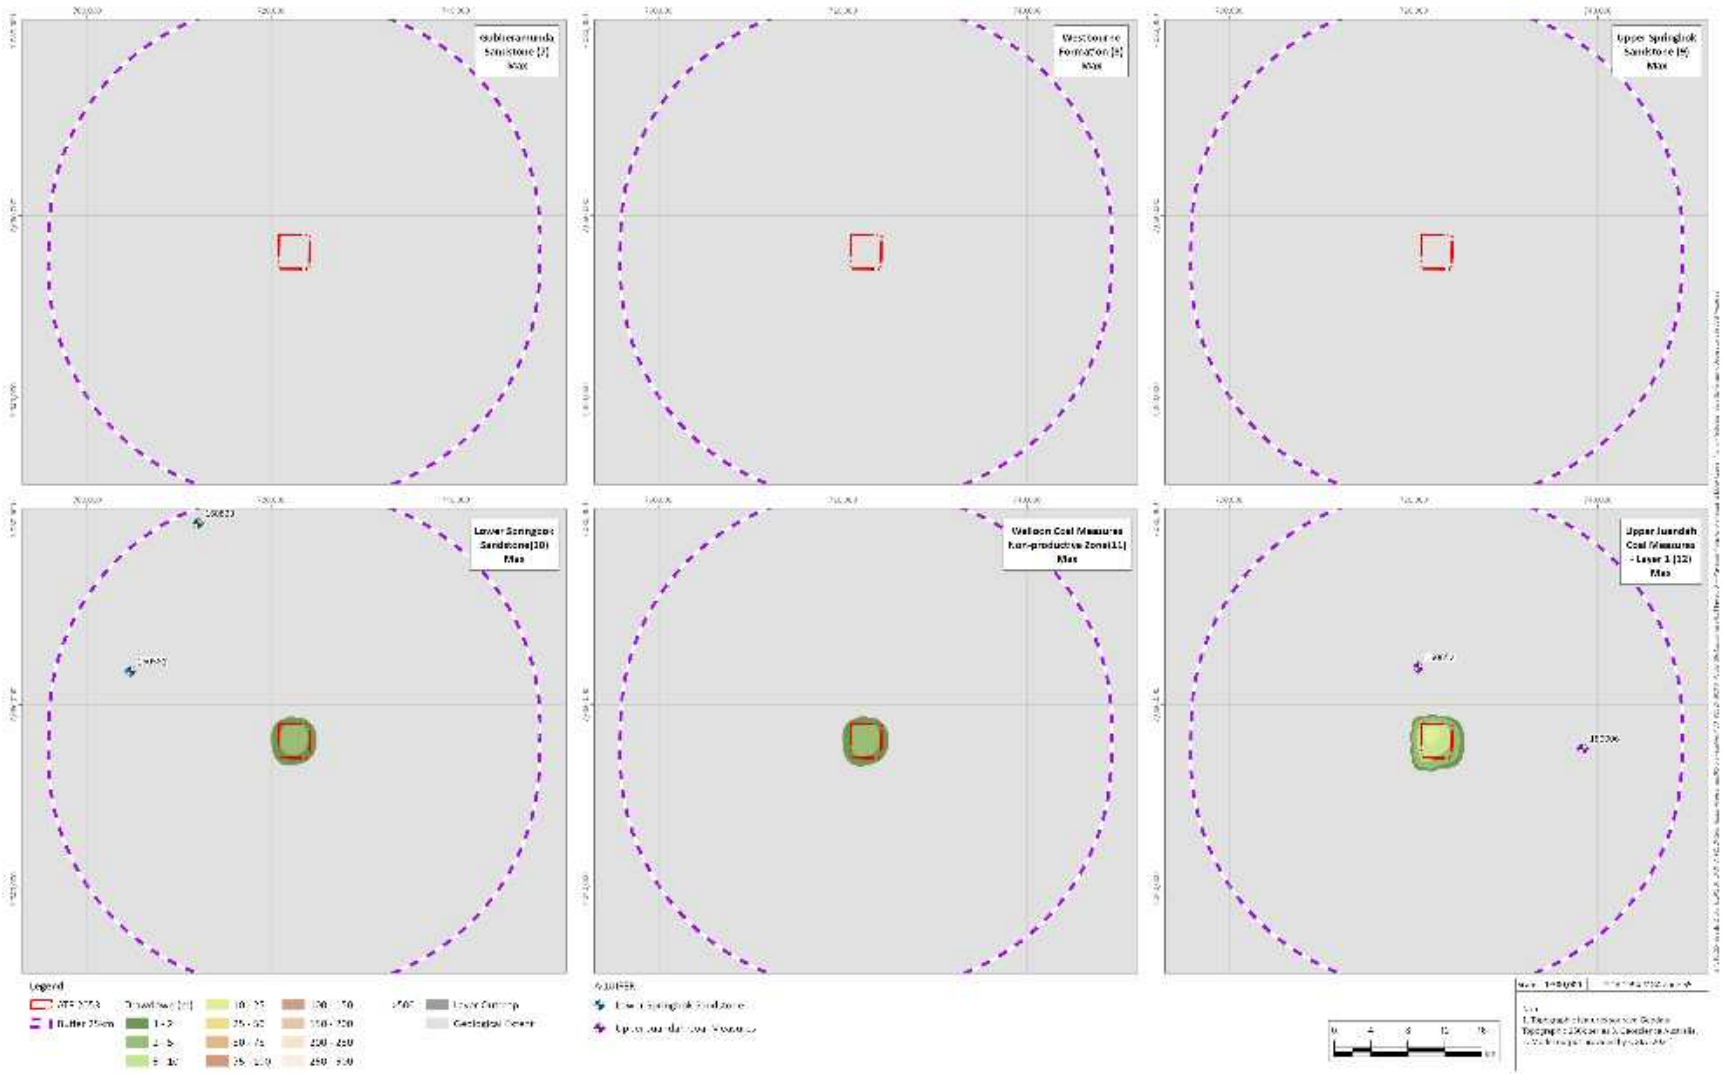

Figure 8.4 Project Only Scenario Maximum Drawdown Pattern for Model Layers, 7 to 12 – Upper Springbok to Upper Juandah Coal Measures

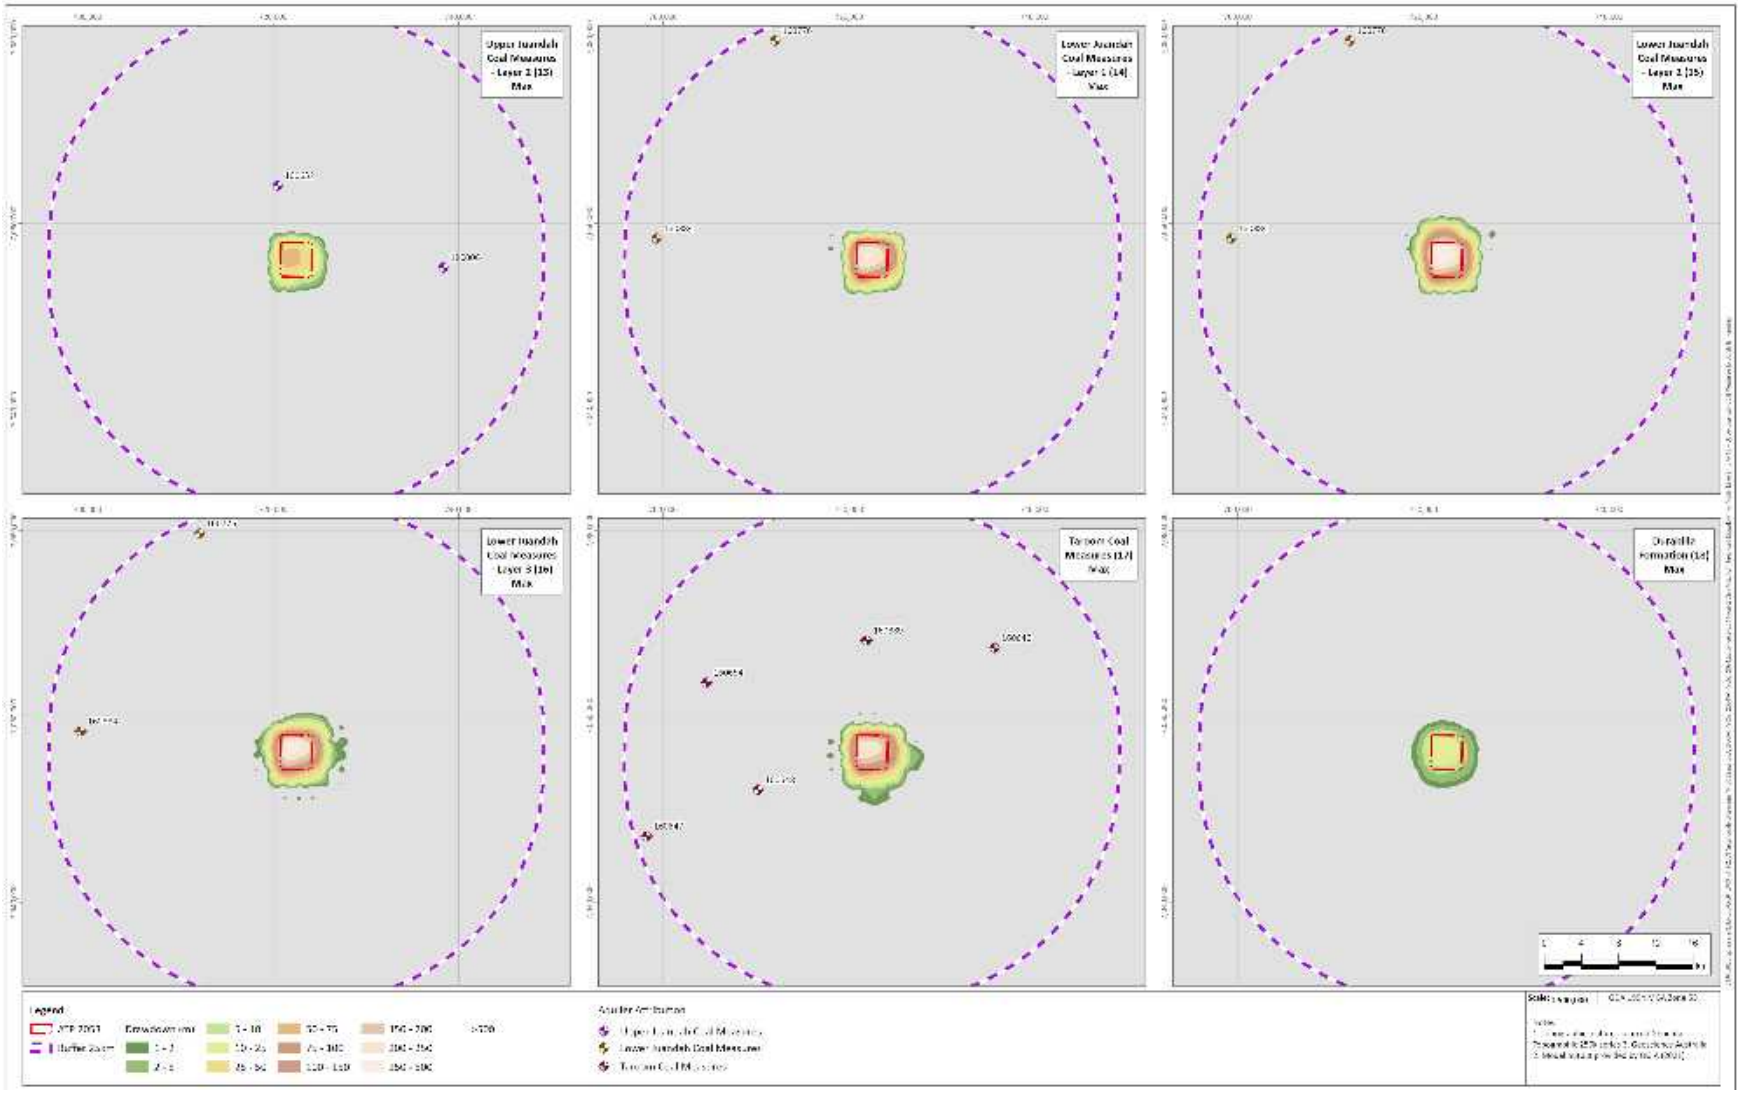

Figure 8.5 Project Only Scenario Maximum Drawdown Pattern for Model Layers, 13 to 18 – Lower Juandah Coal Measures to Durabilla Formation

8.5.2 Cumulative Scenario Results

The cumulative drawdown scenario includes includes all current and proposed non- P&G and P&G groundwater abstraction (as reported in the original UWIR 2021 model) *plus* the Project *plus* reasonably foreseeable production at Santos's neighbouring future development tenures - including ATPs 1187 and 2052.

Summary figures for the Cumulative scenario are presented in Figure 8.6 to Figure 8.8. These figures show the maximum predicted cumulative drawdown for the relevant hydrostratigraphic unit, irrespective of date.

Observations include:

- The cumulative drawdown results indicate that drawdown greater than 0.2 m is not predicted within the vicinity of the Project Area in surficial unconsolidated Quaternary and Quaternary-Tertiary units (layer 1), and in the upper Cretaceous and Wallumbilla formations (layers 1 to 3).
- Drawdown of between 0.2 – 1 m is predicted in the Bungil Formation, the Mooga Sandstone, the Orallo Formation and the Gubberamunda Sandstone (layers 4 – 7) >12 km to the north of the Project Area (in the vicinity of existing CSG operations), where drawdown greater than 5 m is predicted to extend from the Westbourne Formation to the Durabilla formation (layers 8 – 18). This drawdown is not associated with the proposed Project but is rather associated with the water production from neighbouring CSG developments operating on tenures located closer to these outcropping units.
- The largest drawdown in the Upper Juandah Coal Measures and Springbok Sandstone is also predicted to occur to the north of the Project Area, corresponding with neighbouring CSG developments. Drawdown also occurs to the south, where other CSG proponents are operating.
- Drawdown in the Lower Juandah Coal Measures and Taroom Coal Measures, as well as the Durabilla Formation is anticipated to be widespread.

Project Contribution to Cumulative Scenario in Outcropping Areas

The proportion of cumulative drawdown (in excess of 0.2 m) in outcropping formations within 25 km of the Project Area, and which can be attributed to the Project, has been quantified as follows:

- Bungil Formation: Project contribution to the predicted cumulative drawdown is 0 – 4%.
- Mooga Sandstone: Project contribution to the predicted cumulative drawdown is 0 - 2 %; and
- Orallo Formation: Project contribution to the predicted cumulative drawdown is 0 - 1 %.

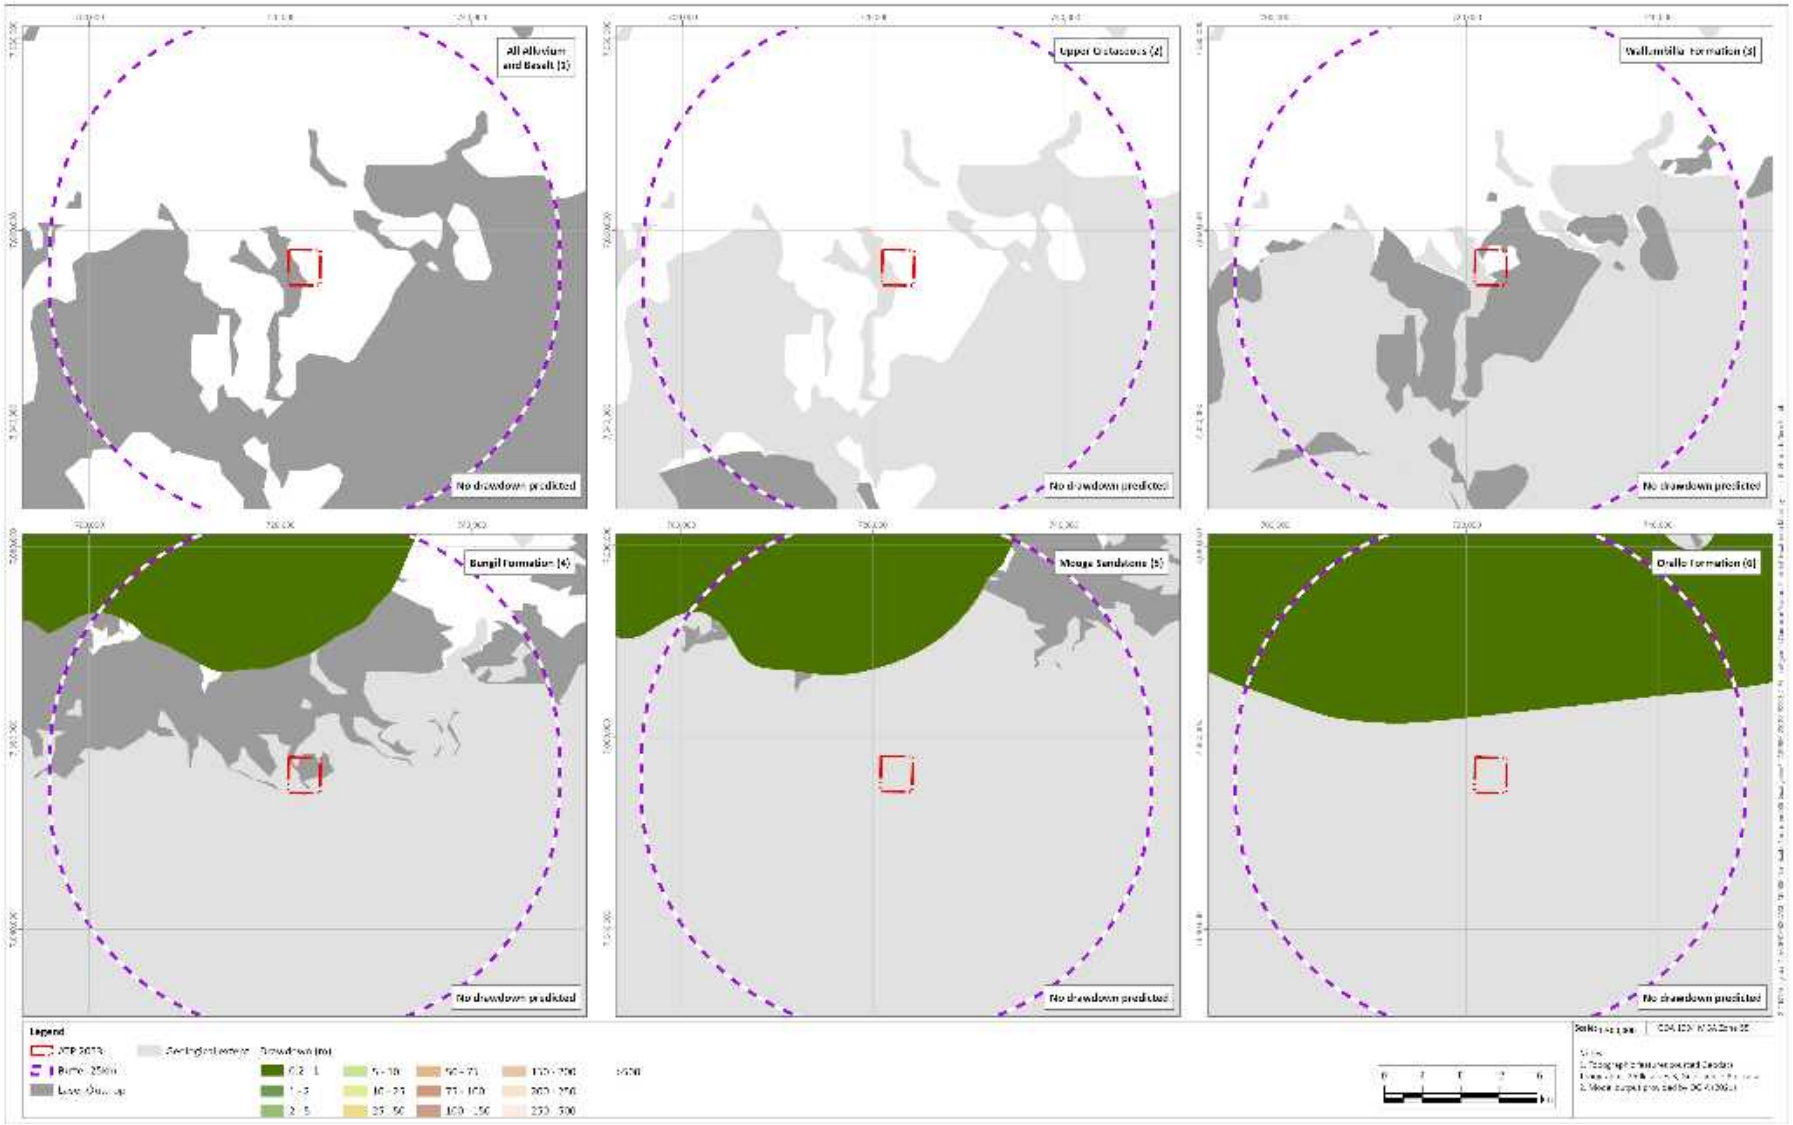

Figure 8.6 Cumulative Maximum Predicted Drawdown for Model Layers, 1 to 6 – Alluvium to Orallo Formation

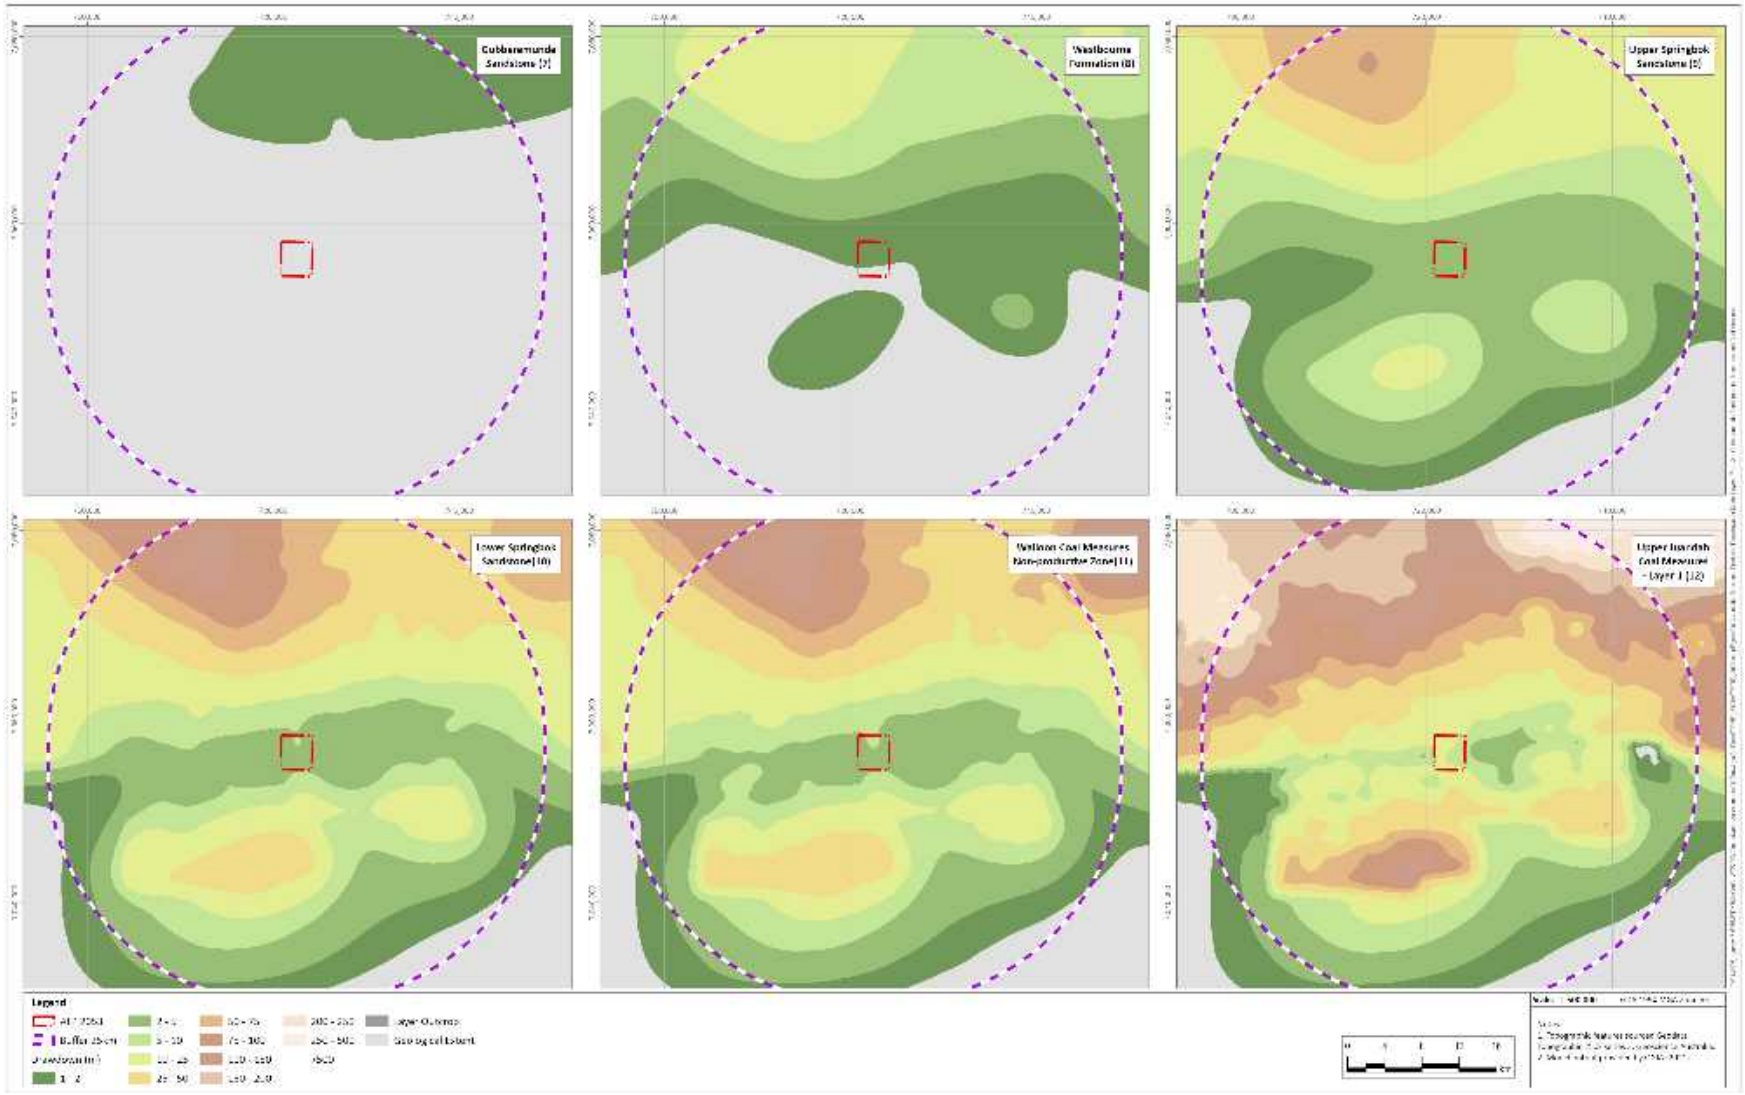

Figure 8.7 Cumulative Maximum Predicted Drawdown for Model Layers, 7 to 12 – Gubberamunda Sandstone to Upper Juandah Coal Measures

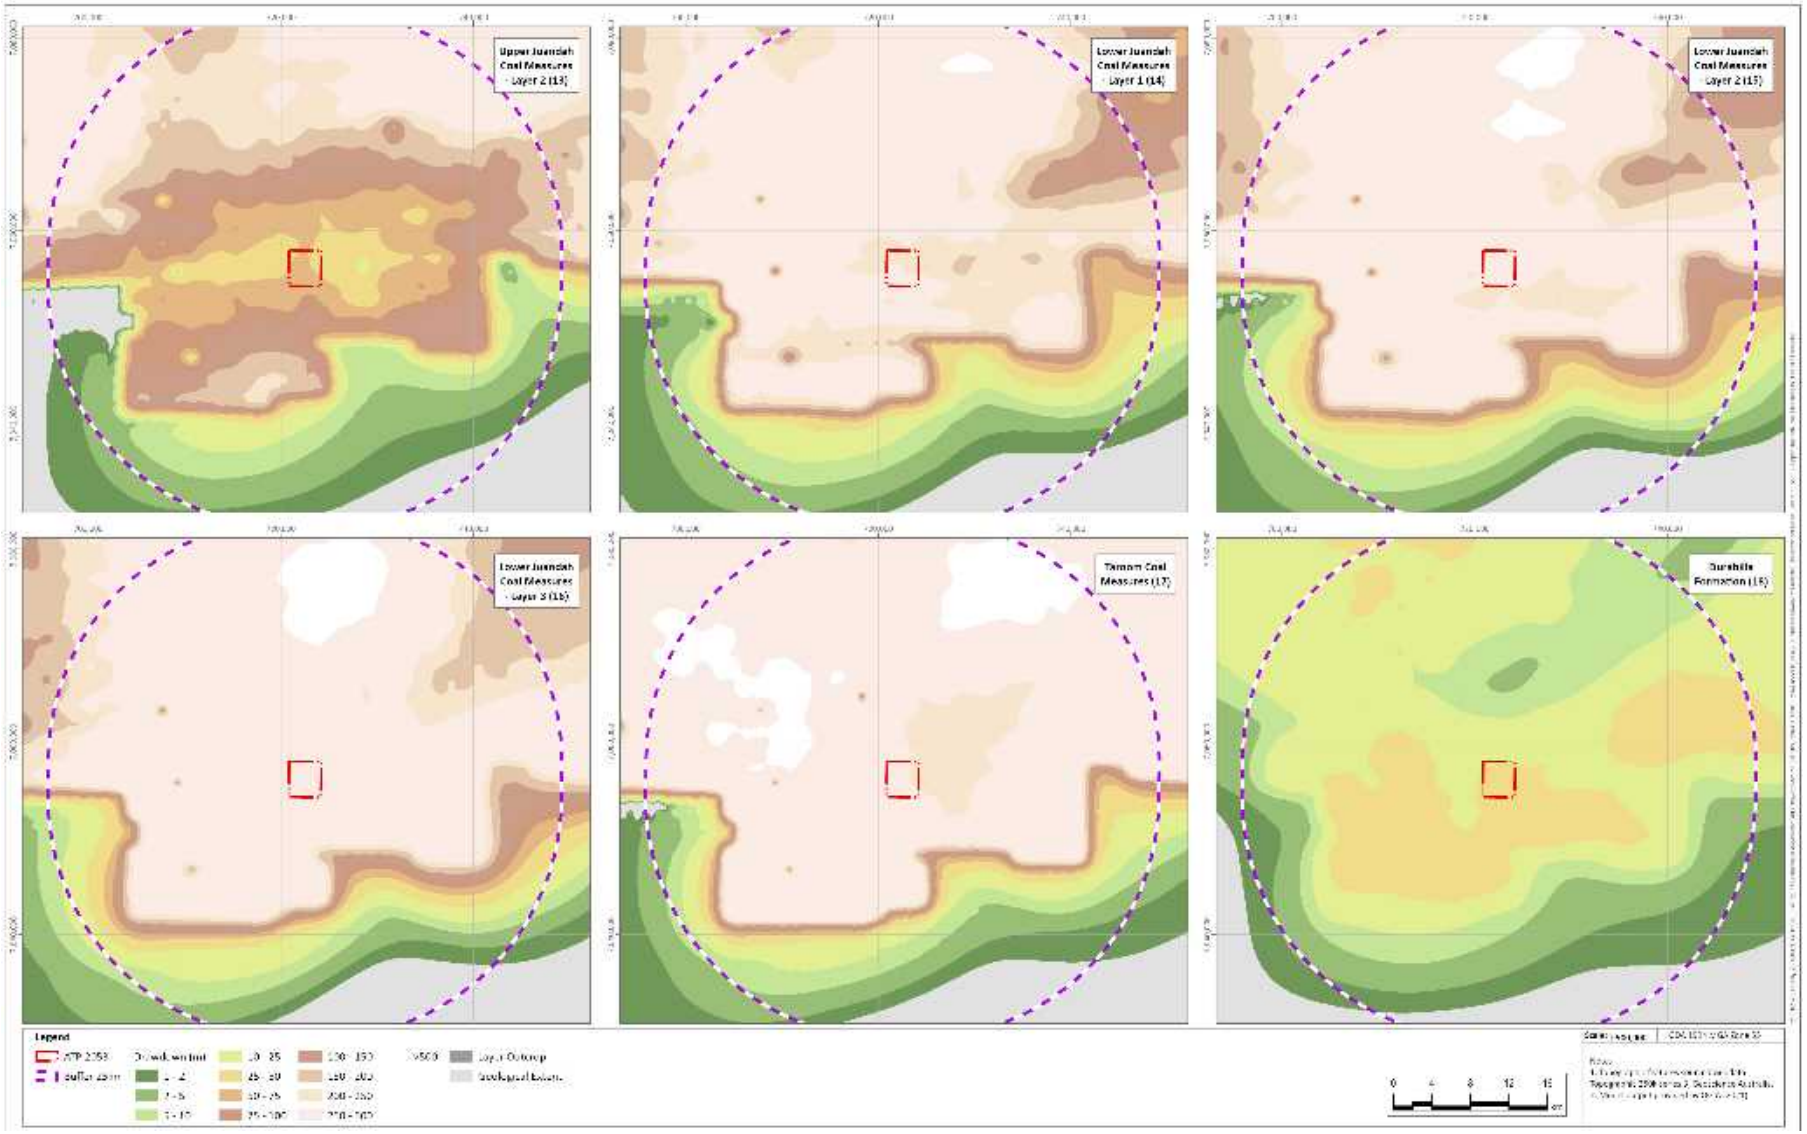

Figure 8.8 Cumulative Maximum Predicted Drawdown for Model Layers, 13 to 18 – Upper Juandah Coal Measures to Durabilla Formation

9 IMPACT ASSESSMENT

9.1 Potential Project Impacts

9.1.1 Groundwater

Water production occurs as part of the CSG production process. Groundwater is removed via CSG wells during the coal seam depressurisation process, which then liberates gas flow. This depressurisation and gas flow sustains groundwater flow from each CSG well to maintain the target gas producing operational pressure.

Santos intend to exercise their underground water rights under the P&G Act (Section 2.2.1) to produce CSG. Several other authorised petroleum lease holders are also exercising their underground water rights in the vicinity of the Project Area.

Potential impacts resulting from CSG related water production include:

- Decline in groundwater level / pressure at water bores, reducing water availability and potentially impacting groundwater EVs.
- Reduction in groundwater head resulting in a reduction of groundwater discharge at spring complexes, potentially causing degradation of GDEs; and
- Reduction of baseflow to watercourses, potentially resulting in degradation of GDEs and reduced water availability to potential users downstream.

These impacts have been quantitatively assessed in the following sections using modelling outputs from the UWIR 2021 numerical groundwater model. Potential impacts to water-dependent assets have been assessed based on the Water Act 2000 trigger threshold for springs (0.2 m drawdown) and bores (5 m drawdown in consolidated aquifer; 2 m drawdown in unconsolidated aquifer) using the predicted drawdown for both the Project only scenario and Cumulative scenarios.

Other potential impacts associated with groundwater are mitigated and managed by adopting the appropriate monitoring, management, and mitigation strategies. These impacts may include:

- Potential to introduce a connection between hydrostratigraphic units (which were previously isolated units) though drilling and construction of CSG production wells, resulting in the potential for alteration of flow regimes and quality; and
- Potential impacts such as an increased demand in groundwater use as a result of the Project (e.g. from the establishment of site camps) are not anticipated. Temporary camp facilities may be located within the Project Area, however the majority of the personnel for the operations will utilise existing accommodation at nearby Santos camp facilities.

Avoidance, mitigation, management and monitoring practices associated with the above activities are discussed further in Section 10.

Impacts relating to climate change (increase in median annual temperature, decrease in median annual rainfall and increase in median annual evaporation) will likely result in a reduction of groundwater recharge and slightly depressed groundwater levels over time, specifically in near-surface aquifers. It is not anticipated that climate change effects will result in exacerbation of

Project related impacts, since notable Project related drawdown does not extend to near-surface aquifers.

9.1.2 Surface Water

Impacts to surface water from the Project are anticipated to be minimal. The Project does not include any:

- Planned material discharge to / abstraction from natural surface water systems; or
- Watercourse diversions.

Potential impacts that may result from Project activities to surface water are summarised below. These potential impacts are associated with the general construction and day-to-day operations of CSG surface facilities rather than CSG production, and could comprise:

- Alteration of a watercourse character or changes to riparian buffers due to construction works and / or infrastructure; and
- Altered surface water runoff characteristics from construction / developed areas;

No material impacts to surface water environmental values are anticipated, including to aquatic ecosystems and cultural and spiritual values, due to development of the Project.

Regardless of the low potential for impact, avoidance, mitigation, management and monitoring plans will be implemented to address any risks that my develop during operations. Further discussion of these management plans is included in Section 10.

As discussed in Section 3.1, the Project Area is surrounded by other resource tenements, including PLs 315, 318, 1020, 281 and 282. Further, reasonably foreseeable nearby tenures for CSG development include ATPs 1187, 2052 and 2054. Due to the local and limited nature of potential surface water impacts associated with the Project, **the Project contribution to potential cumulative impacts (if present) is anticipated to be low.**

9.1.3 Chemical Contamination

As discussed in Section 4.2.3, Santos has developed the CRAF and CRAR for the Project to assess the full lifecycle of chemicals that are stored, transported, handled, used and / or disposed during or following drilling and completions, and hydraulic fracturing activities.

The CRAF / CRAR assessment process is designed to align with national guidance and other regulatory frameworks and assesses the full lifecycle of chemicals that are stored, transported, handled, used and / or disposed during or following drilling and hydraulic fracturing activities.

The CRAF includes the following:

- Consideration of potential risks and effects of chemicals used during CSG operations (defined as drilling and completions and hydraulic fracturing) and the potential risks and effects of geogenic (naturally occurring) constituents that may be present in recovered drilling fluids and produced waters during coal seam gas operations.

- It details the conceptual exposure model (CEM) that describes the chemical source(s), pathways of chemical migration through environmental media and the potential susceptible populations (both human and ecological) that may be exposed.

  In the development of the exposure pathways current environmental setting and land uses, environmental fate and transport mechanisms, and life cycle stages of usage of chemicals and relevant receptors were evaluated to determine which pathways are potentially complete and identify potential receptors for those pathways. A complete exposure pathway exists when a source, a migration pathway, a mechanism for exposure and a potential receptor are all present.
- Assessment of fate and transport of constituents in the subsurface, which indicates that conservative constituents (soluble and mobile) will sufficiently attenuate in the subsurface such that beyond 90 m there are no potential unacceptable risks associated with potential releases during drilling.

A summary of the CRAR is provided below:

- The aim of the chemical risk assessment was to evaluate the potential risks and effects of chemicals used during CSG extraction (drilling, completions and hydraulic fracturing).
- The goal of the chemical risk assessment was to demonstrate that potential risks to water resources and receptors associated with the chemicals used in CSG extraction have been eliminated or reduced as much as is reasonably practicable.
- The life cycle of the drilling, stimulation and completion was assessed specifically for the proposed operations and included:
  - Storage, usage (e.g., blending, injection), and recovery of chemicals throughout operations;
  - Beneficial reuse of recovered drilling fluids and cuttings for well lease rehabilitation; and
  - Storage of produced water.
- In accordance with the CRAF an evaluation of all chemicals proposed for use was conducted, with the majority of chemicals classified as Tier 1 chemicals.
- One hundred and sixty-nine (169) chemicals were assessed as part of this initial Chemical Risk Assessment:
  - 140 chemicals were assessed as Tier 1 chemicals.
  - 19 chemicals were assessed as Tier 2 chemicals.
  - Seven (7) chemicals were assessed as Tier 3 chemicals.
  - Three (3) chemicals were deemed to be impurities at de minimus levels within a proposed product (CAS No 4080-31-3); and
  - No chemicals were assessed as Tier 4 or 5 chemicals.
- Screening / Hazard (Tier 1), Qualitative (Tier 2) and Quantitative (Tier 3) Risk Assessments are provided for each chemical as relevant according to the identified risk category.

Qualitative and quantitative assessments considered potentially complete exposure scenarios as identified by the CRAF CEM.

- The potential for cumulative impacts associated with chemicals proposed for this Project are considered negligible following implementation of management and monitoring controls.
- The CRAR includes a summary of / references existing management controls and include additional recommendations for risk management, based on the findings of the risk assessment. Should assessments of additional chemicals indicate additional management control, the CRAR requires that associated management plans be updated accordingly.
- The chemical risk assessments completed for each chemical indicated the effects of chemicals used during CSG operations poses a low to negligible risk (drilling and completions and hydraulic fracturing) to receptors when appropriate management and mitigation controls were in place.
- Based on the screening assessment against maximum concentrations, the geogenic chemical concentrations (and in some cases added to by drilling chemicals) of residual drilling materials exceed risk-based screening levels (RBSLs) and could pose a risk to environmental receptors if not adequately managed. Identified risk will be managed through a combination of land application methodologies, management controls and the occupational health and safety plan to prevent post-beneficial use soil conditions from exceeding RBSLs.

Santos proposes to apply a number of management and mitigation measures to reduce the risk to water resources. Implementation of existing and additional recommended management practices is expected to eliminate or reduce as much as is reasonably practicable the potential risks to water resources and receptors associated with the use of chemicals in CSG extraction.

A summary of key avoidance, mitigation, management and monitoring plans to reduce and verify the risk associated with the use of chemicals is provided in Section 10.

The overall risk to water resources and EVs associated with the use of chemicals has been assessed as being low to insignificant for the Project only and Cumulative scenarios following implementation of avoidance, mitigation, management and monitoring measures as provided in Section 10.

9.1.4 Changes to Water Quality

As discussed in Section 3.4, the majority of produced water generated from the Project will be transferred to existing approved water storage (Pickanjinnie and / or Raslie Dams) and treatment facilities located adjacent to the Project Area on PLs 314 and 315 via new and existing water gathering infrastructure. These petroleum tenures and facilities are owned and operated by Santos and are subject to independent assessment and approvals.

Small volume tanks will be utilised in the Project Area from time to time to store produced water until permanent water gathering infrastructure is installed e.g. for well production testing purposes. No large water storage or treatment facilities are proposed to be constructed or operated in the Project Area.

Potential changes to groundwater quality as a result of Project development activities may occur due to:

- The use of drilling fluids in the CSG drilling process.
- Seepage from unplanned / accidental produced water leaks; and
- Infiltration in areas potentially affected by chemical spillage, beneficial reuse activities and areas affected by accidental produced water leaks.

Potential changes to surface water quality from Project activities may occur due to:

- Localised transport of suspended sediment to waters during construction or site works.
- Accidental leaks and releases of produced water.
- Accidental release of fuel and chemicals; and
- Rainfall runoff over areas potentially affected by accidental chemical spillage, beneficial use activities and areas affected by accidental produced water leaks have the potential to impact surface water and associated ecosystems.

Impacts to water quality, related to the use of chemicals, geogenic chemicals within produced water and residual drilling material associated with the Project are discussed in the CRAF / CRAR and summarised in Section 9.1.3.

Cumulative impacts are not anticipated due to the localised nature of potential impacts. Management and mitigation controls will be implemented to ensure the potential risks to water quality have been eliminated or reduced to as low as reasonably practicable. Avoidance, mitigation and management controls are summarised discussed in further detail in Section 10.

Based on the assessment results, changes to groundwater or surface water quality are unlikely and not predicted as a result of the Project, following implementation of management and mitigation controls.

9.2 Potential Impacts to Third-Party Groundwater Users

Potential long-term impacts to groundwater bores have been assessed against the Water Act 2000 bore trigger threshold of 2 m for an unconsolidated aquifer (e.g. alluvium) and 5 m for a consolidated aquifer (e.g. Cretaceous and Jurassic aged formations), using the outputs and drawdown predictions from the UWIR numerical model.

The maximum predicted drawdown was used for this assessment, irrespective of the timing of predicted drawdown. No existing bores are screened within unconsolidated aquifers (e.g. alluvium and Tertiary sediments) within 25 km of the Project Area.

Results of the predicted drawdown for the Project only scenario and Cumulative scenarios, assessed against trigger limits at individual water bores present within 25 km of the Project Area, are presented in Appendix III.

Several groundwater bores within the vicinity of the Project Area were constructed to intersect multiple formations. OGIA have assigned each bore a dominant source aquifer, with this dominant aquifer used to assess potential drawdown at each bore.

Two (RN168013 and RN168178) water supply bores do not have an aquifer attribution assigned to them. For the purposes of the report and for conservatism, these two bores have been assigned to the Gubberamunda Sandstone as this is the closest aquifer above the WCM.

Appendix III provides the attributed formation used as part of the impact assessment.

For the Project only scenario, the maximum predicted drawdown in the target formations at the locations of the 368 (existing, abandoned but usable, proposed and potential) water supply bores, is 0.03 m.

The Cumulative scenario assessment was undertaken using the same approach adopted for the Project only scenario (e.g. Water Act 2000 trigger thresholds). No bores are indicated to exceed the trigger threshold within a 25 km buffer of the Project Area.

The bore triggers are therefore not predicted to be exceeded as a result of Project only or Cumulative scenario activities and predicted impact on groundwater supply bores is assessed as negligible. The contribution of the Project does not result in any additional bores being triggered in the Cumulative scenario.

Town water supply schemes that source water from the Gubberamunda Sandstone and the Orallo Formation in the vicinity of the Project Area will not be affected by drawdown as a result of the Project only scenario or Cumulative scenarios.

9.3 Potential Impacts to Third-Party Surface Water Users

There are no surface water users identified within the vicinity or immediately downstream of the Project Area, therefore, no impacts to third-party surface water users are predicted as a result of Project development.

9.4 Potential Impacts to Groundwater Dependent Ecosystems

Impacts to potential GDEs can occur if the following conditions are met:

- Potential GDEs have been identified in the area;
- The potential GDEs are located on a GAB aquifer outcrop / sub-crop;
- It is confirmed that the potential GDEs are sourcing water from the GAB aquifer, or the GDEs are sourcing water from an alluvial system connected to a GAB aquifer. Evidence to suggest a connection include:
  - Hydraulic evidence including groundwater levels in the underlying GAB aquifer are in connection with the alluvium or there is sufficient water in the alluvium to support the potential GDE.
  - Water quality in the GAB aquifer is suitable for GDEs to survive.
- Drawdown of >0.2 m is predicted in the GAB aquifer due to the presence of the Project.

The WCM occurs at 650 mBGL within the Project Area. The WCM is over- and underlain by thick sequences of several tight aquitards which limit propagation of drawdown into the overlying and underlying aquifers.

Project only scenario drawdown greater than 0.2 m (Water Act 2000 spring and JIF GDE threshold) is not predicted in outcropping / sub-cropping geological units (Section 8.5.1).

Predicted Cumulative drawdown of more than the spring and JIF thresholds (0.2 m) is indicated for the Bungil Formation, Mooga Sandstone and Orallo Formation at distances > 12 km to the north of the Project Area. The Project contribution to the predicted cumulative drawdown for these formations are assessed to be minor to negligible (0 – 4%). This drawdown is therefore not associated with the proposed Project but is rather associated with the water production from neighbouring CSG developments operating on tenures located closer to these outcropping units.

No new springs and GDE areas are triggered due to drawdown contribution from the Project.

9.4.1 Potential Impacts to Wetlands

The Project Area and the surrounding 25 km buffer area does not include any wetlands listed in the *Directory of Important Wetlands in Australia* (Environment Australia 2001). No wetlands of High Ecological Significance or wetlands of General Ecological Significance were mapped by the EAR as present within the Project Area.

The closest notable wetlands are situated more than 120 km from the Project Area and are therefore not considered material to the current assessment. **The Project will therefore not impact upon any internationally or nationally important wetlands, nor wetlands of High or General Ecological Significance.**

9.4.2 Potential Impacts to Springs

There are no spring vents or complexes recorded within the 25 km buffer of the Project Area. The closest watercourse springs are located along the Blyth and Yuleba Creeks (associated with the Mooga Sandstone) more than 20 km to the northeast and northwest of the Project Area respectively. Drawdown exceeding 0.2 m is not predicted in any of the outcropping formations (including the Mooga Sandstone) due to drawdown associated with the development of the Project only.

The Project only contribution to cumulative drawdown in outcropping formations is anticipated to be negligible.

No material impacts on spring vents, complexes or watercourse springs as a result of Project development are identified.

9.4.3 Potential Impact to Aquatic GDEs

Surface expression GDEs are not indicated to be present in the Project Area. Small patches of low confidence surface expression GDEs associated with the Wallumbilla Creek are mapped to the west of the Project Area.

As discussed in Section 6.5 and 7.8 the watercourses in the vicinity of the Project Area are characteristically ephemeral. Limited to no groundwater contribution from the regional

groundwater system to watercourses as baseflow is anticipated within the Project Area. Quaternary and Tertiary aged systems are likely to be replenished during prolonged wet periods when the ephemeral creek system is flowing. Temporary perched groundwater conditions may result due to percolation of infiltrated rainwater along streamlines and the collection of rainwater in low lying areas underlain by material with low permeability. The EAR for the Project Area (Boobook 2024b) does not identify threatened aquatic fauna or flora to be present.

Drawdown that exceeds the JIF threshold is not predicted for the Project only scenario in outcropping or sub-outcropping formations.

Potential exceedance of the JIF threshold (greater than the 0.2 m) is indicated in outcropping units for the Cumulative scenario > 12 km to the north of the Project Area. The Project only scenario contribution to this drawdown is anticipated to be minor to negligible.

Impacts to aquatic GDEs due to the Project are not expected. No new GDE areas are triggered due to drawdown contribution from the Project.

9.4.4 Potential Impacts to TGDEs

Potential TGDEs of limited extent, associated with unconsolidated Quaternary alluvium and unconsolidated sands which may be intermittently connected to aquifers with brackish salinity, are mapped by DES (DES 2018b) at desktop level within the vicinity of the Project Area.

The WCM is over- and underlain by thick sequences of several tight aquitards which limit propagation of drawdown into the overlying and underlying aquifers. The WCM occurs at 650 mbgL (vertical depth) at the Project Area.

As discussed in Section 7.10.3, the rooting depths identified for species present in identified RE's based on available literature reviews, range to 22.6 m. Quaternary and Tertiary aged systems are likely to be replenished during prolonged wet periods when the ephemeral creek system is flowing. Temporary perched groundwater conditions may result due to percolation of infiltrated rainwater along streamlines and the collection of rainwater in low lying areas underlain by material with low permeability. Partial reliance on groundwater in these systems is possible.

OGIA completed a regional scale desktop risk assessment which did not identify any TGDE areas in the vicinity of the Project Area as being at risk due to CSG development.

If GDEs are present, a high resilience in the vegetation and aquatic communities may be expected due to the seasonality of rainfall, ephemeral nature of the creek systems and low hydraulic conductivity of outcropping / sub-cropping formations.

Drawdown that exceeds the JIF threshold (greater than the 0.2 m) is not predicted for the Project only scenario in outcropping or sub-outcropping formations.

Potential exceedance of the JIF threshold (greater than the 0.2 m) is indicated in outcropping units for the Cumulative scenario > 12 km to the north of the Project Area. The Project only scenario contribution to this drawdown is anticipated to be minor to negligible.

It is considered unlikely that groundwater present in surficial units, that potentially support TGDEs, will be impacted by CSG related drawdown due to the Project.

9.4.5 Potential Impacts to Subterranean Fauna

As discussed in Section 7.10.6, it is unlikely that *stygofauna* will be present within the target coal seams in the vicinity of the Project Area, or in the formations surrounding the coal seams due to the depth below ground level. Saturated conditions (and therefore suitable habitat for *stygofauna*) within the surficial Tertiary and Quaternary sediments are expected to be variable and dependant on rainfall and ephemeral creek flow.

The risk threshold for subterranean GDEs identified by the JIF includes:

- A long-term predicted drawdown of more than 2 m for unconfined hydrogeological units caused by CSG development; or
- A long-term predicted drawdown that dewaters the aquifer habitat for confined hydrogeological units.

Drawdown that exceeds the JIF threshold (greater than the 0.2 m) is not predicted for the Project only scenario in outcropping or sub-outcropping formations. The Project only contribution to cumulative drawdown in outcropping formations is anticipated to be minor to negligible.

Therefore, no discernible impacts to subterranean fauna as a result of the Project only and Cumulative scenarios are predicted.

10 AVOIDANCE, MITIGATION, MANAGEMENT AND MONITORING

10.1 Key Management Documents

This section provides details on Santos' proposed mitigation, management and monitoring practices for the Project that will be adopted to manage the risk of impact to water resources.

Key Santos management plans and reports related to the monitoring and management of water include:

- Hydraulic Fracturing Risk Assessment – Santos Eastern Queensland Rev 1 (HFRA) (EHS Support 2021).
- Eastern Queensland Stimulation Impact Monitoring Program (SIMP) (Santos 2021).
- Baseline Assessment Plan (BAP) for ATP 2052 and ATP 2053 (Santos 2022).
- Roma Phase 7-7B-SD20 Chemical Risk Assessment Framework (CRAF) (Santos 2024f).
- Roma Phase 7-7B-SD20 Chemical Risk Assessment Report (CRAR) (EHS Support 2024a).
- Roma Phase 7-7B-SD20 Proposed Produced Water Management Plan (WMP) (WRM 2024).
- Roma Phase 7-7B-SD20 Ecological Assessment Report – MNES / MSES (EAR) (Boobook 2024b).
- Roma Phase 7-7B-SD20 Rehabilitation Monitoring Plan (RMP) (Santos 2024d).
- Roma Phase 7-7B-SD20 Environmental Protocol for Constraints Planning and Field Development (Constraints Protocol) (Santos 2024b).
- Roma Phase 7-7B-SD20 Significant Species Management Plan (SSMP) (Santos 2024e).
- Roma Phase 7-7B-SD20 Environmental Management Plan (EMP) (Santos 2024a).

Other documents of importance:

- Surat CMA UWIR Water Monitoring Strategy (WMS) (OGIA 2021a).
- Water Act 2000 (State of Queensland 2024m) Guidelines: baseline and bore assessments and make good requirements (State of Queensland 2024f; 2024e; 2024h).
- The Joint Industry Framework (JIF) (Australian Government 2021).
- Code of Practice for the construction and abandonment of coal seam gas and petroleum wells, and associated bores in Queensland Version 2 (State of Queensland 2019a).
- Queensland CSG Water Management Policy (DEHP 2012).
- Queensland Streamlined Model Conditions for Petroleum Activities (State of Queensland 2024k).
- Queensland CSG Water Management: Measurable criteria (DES 2013).
- Queensland Environmental Protection (Water and Wetland Biodiversity) Policy 2019 (State of Queensland 2019d).

10.2 Monitoring

10.2.1 CSG Water Monitoring

CSG Produced Water Monitoring

As per the requirements outlined in the P&G Act 2004, the volume of produced water will be monitored and recorded and provided to the DNRME in accordance with statutory obligations.

Produced water quality will be monitored in accordance with the EMP (Appendix V), the SIMP (Appendix IV) and as required by relevant EA conditions. To minimise impacts to shallow groundwater quality, as a result of beneficial use activities such as dust suppression and off-tenement irrigation, water quality will be monitored to confirm compliance with water quality objectives in the *End of Waste Code Associated Water (including coal seam gas water)* (State of Queensland 2024b), and the *End of Waste Code Irrigation of Associated Water (including coal seam gas water)* (State of Queensland 2024c), and relevant EA conditions.

The SIMP provides procedures for baseline groundwater bore assessment, stimulation fluid and flowback monitoring, and post-stimulation groundwater bore monitoring as summarised in the following sections.

Groundwater Bore Baseline Assessments

Under the Water Act 2000, Santos are required to undertake baseline assessments of water bores prior to commencement of stimulation and production activities. There is one operational water bore located within the Project Area. A baseline assessment of this water bore has been completed as documented in the ATP 2053 BAP (Santos 2022). Another groundwater bore (RN208460) was drilled on the tenement in June 2024. This new bore is indicated as “no longer used”. Santos are in the process of updating their Baseline Assessment Plan to detail baseline assessment of this bore prior to commencement of the Project.

Stimulation Fluid and Flowback Monitoring

Monitoring of stimulation fluids during the stimulation activity is to be conducted in order to characterise the quality and quantity of source water, stimulation fluid and flowback. The SIMP requires monitoring of source water, stimulation fluids and representative flowback as recovered at surface. Flowback volume(s) will be recorded to ensure 150 percent of the volume of stimulation fluids used in the stimulation event have been extracted from the stimulated well, to the extent practicable. A flowback or produced water sample will also be collected post-stimulation. In the event that an active landholder bore is pumping from an aquifer within 200 m above or below the target formation and is spatially within 2 km from the location of stimulation, Santos requires that the need for additional flowback, be assessed.

Flowback may be treated and stored for reuse in the next hydraulic fracturing event. Flowback fluid unable to be reused would be disposed of at a licensed facility or transferred to one of Santos’ engineered wastewater treatment facilities for treatment and management under existing approvals for those facilities.

Post-Stimulation Groundwater Bore Monitoring

Post-stimulation groundwater monitoring of relevant baseline bores will be undertaken at the following frequencies:

- Monthly for the first six (6) months subsequent to the stimulation activities being undertaken; then
- Annually for the first five (5) years subsequent to the stimulation activities being undertaken or until analytes and physico-chemical parameters are not detected in concentrations above baseline bore monitoring data on two (2) consecutive occasions.

Groundwater from relevant bores is to be analysed for the analytical suite detailed in Table 2, Section 5 of the (Santos 2021) (Appendix IV).

Joint Industry Framework

CSG development on tenures surrounding the Project comprises up to 4,401 CSG wells, which are authorised under existing EPBC Act approvals. These Projects are conditional to the JIF framework. The application of the JIF framework to surrounding development provides comfort that defined environmental outcomes for groundwater (as defined in the JIF) will be achieved.

10.2.2 Groundwater Monitoring

The water monitoring requirements for petroleum tenure holders within the Surat CMA are provided as part of the UWIR Water Monitoring Strategy (WMS) (OGIA 2021a), which establishes baseline trends, identifies any changes within or near petroleum development areas or locations of interest and informs future improvement of groundwater modelling. Individual tenure holders are responsible for specific monitoring obligations in accordance with the rules as outlined by the UWIR.

Under the WMS, Santos undertakes groundwater monitoring at over 150 monitoring locations throughout the Surat CMA. Revisions of the UWIR may amend the WMS according to improved understanding of groundwater risks. Santos are presently monitoring 16 nested bores in the vicinity of the site, as depicted in Figure 10.1 and listed in Table 10.1.

Two landholder bores were identified during the baseline assessment for which ongoing monitoring is required. Pre-and post-stimulation monitoring of these bores may be performed in accordance with the SIMP and applicable EA requirements.

10.2.3 Surface Water Monitoring

The Project does not involve discharges to, or abstractions from, surface water. Groundwater contribution from the regional system to watercourses as baseflow is not interpreted at the Project Area. Surface water monitoring associated with the Project is therefore not proposed.

As per the EMP, turbidity monitoring will be carried out during the construction and maintenance of linear infrastructure crossings of watercourses to ensure water release limits specified in relevant EA conditions are complied with. However, in accordance with EA conditions,

Santos preferentially undertakes construction and maintenance of linear infrastructure crossings of watercourses during periods of no or very low flows (Santos 2024a). Further discussion of mitigation and management associated with surface water systems is provided in Section 10.3.

10.3 Avoidance, Mitigation and Management

Santos have developed a comprehensive set of management documents as listed in Section 10.1, including an EMP with the objective to achieve ongoing environmental compliance with regulatory requirements and to facilitate implementation of best practice environmental management strategies. The EMP includes a set of supporting Environmental Control Plans (ECPs) that detail management actions, responsibility and timing relating to potential impacts. Reference to relevant management documents, including the EMP and ECPs will be made throughout this section. The EMP is included in Appendix V of this report.

10.3.1 CSG Production Wells Drilling and Construction

Measures to avoid and manage the risk of impacts to groundwater quality and avoid introducing connectivity between formations during the construction of production wells, include the following:

- Production wells will be designed, constructed and decommissioned in accordance with the Code of Practice (State of Queensland 2019a). This code outlines mandatory requirements and good practice to reduce the risk of environmental harm. Production wells will be designed to:
  - Prevent any interconnection between target hydrocarbon bearing formations and aquifers;
  - Ensure that gas is contained within the well and associated pipework and equipment without leakage;
  - Ensure zonal isolation between different aquifers is achieved;
  - Not introduce substances that may cause environmental harm; and
  - Operate within the maximum expected pressures and load conditions until final abandonment.

Santos will monitor and control operating wells remotely; each well has an automated shutdown system in the event of non-routine operating conditions (Santos 2024c).

Drilling fluids and additives used during drilling activities will be used in accordance with the mandatory requirements and good practice guidelines outlined in the Code of Practice as well as the Safety Data Sheets (SDS) and toxicological profiles provided for each fluid / additive (EHS Support 2024a). In relation to drilling fluids, the mandatory requirements include:

- Drilling fluids must be selected and managed to ensure all manufactured products used during well procedures are in accordance with the manufacturer's recommendations and relevant SDS.
- The name, type and quantity of each chemical used on each well throughout the life of the well must be recorded.

Good industry practice for drilling includes:

- Drilling fluid should be a carefully monitored and controlled mixture designed to:
  - Achieve best drilling results and ensure efficient removal of formation cuttings;
  - Control formation pressures; and
  - Minimise damage to formations.
- Petroleum tenure holders should ensure that the drilling fluid selected is appropriate for the well design to manage any locally experienced drilling problems and the geological conditions likely to be encountered.
- The use of biodegradable substances in the drilling fluid is preferred.
- The source of water for all well procedures (drilling, completion, workover and abandonment) should be recorded for future well monitoring purposes.
- Products should be chosen, stored, and used at concentrations that minimise the risk of causing environmental harm.
- Personnel, including contractors, should be aware of the environmental impact and emergency spill procedures for the products and substances in use on-site.
- Petroleum tenure holders should use established, effective drilling practices to achieve a stable, uniform and as far as possible, in-gauge hole.

The Hydraulic Fracturing Risk Assessment emphasises that where stimulation activities are designed and undertaken in accordance with the hydraulic stimulation procedures, the zone of hydraulic stimulation is contained entirely with the coal layer or target seam (EHS Support 2021). An overview of the stimulation process, fluid and flowback monitoring and post -stimulation groundwater bore monitoring, is provided in the SIMP and the EMP.

In summary, the hydraulic stimulation procedures and processes include:

- Casing and cementing are installed as barriers during well construction;
- A formal design and plan process where fracture geometry is modelled;
- Assess for indications of casing integrity loss into overlying formations:
  - Monitoring casing and wellhead pressures during stimulation activity; and
  - Monitor injection flow rates and total volumes of hydraulic fracturing fluids and comparing to predicted performance.
- Monitoring of stimulation fluids during the stimulation activity is to be performed at sufficient frequency and which represents the quality and quantity of source water;
- Source water to be used for stimulation activities is to be sampled prior to the commencement of the stimulation operations;

- One stimulation fluid sample per stimulation activity on each well is to be taken from the pad volume prior to the addition of the slurry volume; and
- A flowback or produced water sample is be collected post-stimulation and to be analysed.

Existing operational control of activities employed by Santos are in place in the form of the HFRA, CRAF, CRAR, EMP and RMP as listed in Section 10.1, that will limit the potential risks to human health and the environment.

Further details on the management practices associated with chemical and fuel storage are provided in Section 10.3.5.

10.3.2 CSG Water and Waste Management

CSG produced water and waste management will be undertaken in accordance with the WMP which has been developed to meet the requirements of the CSG Water Management Policy (DEHP 2012), as outlined in Section 3.4. Water management infrastructure will be based on the Australian Standards for tanks, to be used as water storages across the Project Area.

Treatment processes, and storage and management of brine and salt, are not located within the Project Area and are therefore not part of the proposed action. Details of these processes are included in the *Revised Coal Seam Gas Water Monitoring and Management Plan GLNG Project EPBC* (2008/4059) (Santos 2023b). Adequate water storage and treatment capacity is available on adjacent tenures to manage peak water and brine production from the Project. Santos have established procedures to prevent uncontrolled discharge of produced water (i.e. restriction of production by 'turning down' or 'shutting-in' wells). In future, produced water from the Project may potentially be processed elsewhere, subject to environmental approvals.

The EMP states that drilling fluids would be contained on the well lease in tanks during drilling and then either reused (or recycled and reused) at another well site or disposed of offsite at a licensed waste management facility. Residual drilling material (RDM) would be stored in tanks during drilling and then may be disposed of on-site in accordance with relevant EA conditions, where:

- RDM meets approved quality criteria, and the mix-bury-cover method is used; or
- RDM is certified by a suitably qualified third-party as being of acceptable quality for disposal to land by a proposed method, and that environmental harm will not result from the proposed disposal.

Assessments and monitoring will include:

- Sampling and characterisation of the RDM; and
- Baseline soil assessment of each representative soil type within the Project Area for which land application of RDM is proposed.

Alternatively, RDM may be transferred by road to existing approved waste management facilities on adjoining tenures, or to another licensed waste facility for management.

EPC 7 of the EMP details management actions, responsibility and timing relating to potential impacts associated with liquid and solid waste management (Appendix V).

10.3.3 Bore and Water Resource Impact Management Measures

The Water Act 2000 outlines requirements for make good obligations of a resource tenure holder for a bore located in immediately affected areas. Tenure holders must carry out a bore assessment and enter into a make good agreement with the bore owner if the bores are located within an immediately affected area. The UWIR assigns bores to tenure holders located within immediately affected areas.

Santos undertakes to engage with relevant stakeholders, comply with make good agreements required in future updates of the UWIR and undertake bore assessments as required as a result of make good obligations. Any future baseline assessments will be conducted in accordance with the *Baseline Assessment Guideline* (DES 2017). However, since no bores have been assessed to be impacted by the proposed Project development, make good agreements for this Project are not anticipated at present.

10.3.4 Infrastructure Location and Planning

The planning of development activities and associated infrastructure locations are detailed by the EMP and informed by the SSMP and Constraints Protocol.

Constraints planning provides a mechanism for avoidance and then minimisation of potential risks to environmental values through environmental value identification and location selection, without the need for further mitigation or management. The Constraints Protocol requires Santos to implement an internal assessment and approval process to ensure that the planning, design and decision-making processes for all new field development and land disturbance activities identify the required constraints prior to commencement of development activities.

Santos has therefore planned infrastructure locations within the Project Area to avoid impacts to environmental values. The proposed infrastructure has largely been located in cleared agricultural land. Disturbance to vegetation has been reduced to 0.31 ha. No disturbance to Threatened Ecological Communities (TEC) is proposed. Any minor changes to the disturbance footprint or infrastructure locations would be subject to the requirements of the Constraints Protocol.

Furthermore, in relation to the proposed Project infrastructure within the vicinity of water courses, no camps, laydowns or water storages will be located within the 1% AEP flood extent and all water course crossings (tracks and pipelines) will be constructed in accordance with relevant EA conditions, EMP requirements, design standards and the *Accepted development requirements for operational work that is constructing or raising waterway barrier works* (DAF 2018) under the Fisheries Act 1994 and Planning Act 2016. All well pads across the Project Area, within and outside of the 1% AEP flood extent, will be established at the topographic grade of the well location and all associated pipelines will be buried.

ECP 3 (Water resource management) of the EMP details applicable standard buffer distances for infrastructure from watercourses and wetlands (Appendix V).

10.3.5 Chemical Use and Storage

Key plans integral to the management of the risk of impacts to environmental values associated with chemical transportation, storage, use and management / monitoring of potential impacts are provided in the CRAF/CRAR and the EMP. ECP 9 of the EMP details general management

requirements and actions, monitoring, reporting and corrective action requirements pertaining to hazardous substances use and management.

The outcomes of the CRAR, in conjunction with the EMP and relevant EA conditions, will inform site selection for well lease placement and appropriate management of RDM. Additional recommendations for risk management provided on the basis of the risk assessment include:

- Production wells will be installed in accordance with the requirements of the Constraints Protocol and not within 90 m of a landholder bore.
- The theoretical concentrations of chemicals used in drilling muds poses a potential risk to ecological receptors. The estimated concentrations in untreated and treated drilling muds exceeded the generic chemical specific ecological criteria for soil. Management controls and monitoring are detailed in the EMP to ensure materials are managed to prevent unacceptable risks (as discussed in Section 10.3.2).
- Refer to Section 10.3.2 for information pertaining to early warning indicators, threshold triggers and management response related to application of residual drilling material to land.

10.3.6 Beneficial Use Activities

Beneficial use on-site is limited to activities such as water supply for drilling and hydraulic fracturing purposes and / or to provide a water source for dust suppression / construction (where the water meets relevant water quality objectives – refer to Section 10.2.1 for further detail).

Where produced water is to be beneficially reused on-site, it will be stored in portable tanks as described in Section 3.4.4. Produced water from the Project is planned to be transferred to existing water management facilities located on neighbouring tenures owned and operated by Santos (refer to Section 3.4.1 for further detail on produced water management).

The *Revised Coal Seam Gas Water Monitoring and Management Plan GLNG Project EPBC* (2008/4059) (Santos 2023b) outlines the proposed management, monitoring, beneficial use and disposal of CSG produced water (produced water) to avoid, mitigate and manage impacts to environmental values for the life of Santos GNLG Projects. It provides a risk assessment relating to beneficial use activities including dust suppression activities and details appropriate risk-based responses to avoid, mitigate and manage impacts to environmental values relevant to GNLG Projects.

Dust suppression aims to minimise dust generation during construction activities at a given location and / or during vehicle movements between locations. Water is applied to the surface using spray equipment. Beneficial use activities such as dust suppression, will be undertaken so that the WQOs and conditions in the *End of Waste Code Associated Water* (including CSG water) (State of Queensland 2024b) are met. In accordance with relevant EA conditions, no pooling or runoff is permitted during dust suppression activities, limiting the applicable pathway and exposure mechanism. Dust suppression within or adjacent to watercourses is prohibited.

ECP 3 of the EMP details management actions, responsibility and timing relating to activities (including beneficial use activities) that have the potential to impact on water resources (Appendix V).

10.3.7 Emergency and Incident Response: Spills

Santos has developed operating standards and procedures relating to incident and crisis management as per ECP 11 in the EMP. ECP 11 details triggers of a spill emergency and subsequent required management actions, responsibility and timing / frequency pertaining to spills, flooding, monitoring, reporting and corrective actions (Appendix V).

In accordance with the EMP, all incidents including environmental incidents, non-conformance events and complaints are recorded electronically and managed through the Santos Incident Management System (IMS). Environmental incidents and near misses are investigated in order to identify the causal factors and associated underlying systemic weaknesses (root causes). The process to determine the correct level of incident investigation is outlined in the relevant SMS Operating Standard. Upon completion of the investigation, the findings and recommendations will be distributed to relevant personnel force via daily prestart meetings. Where lessons are learnt from the investigation or current procedures are identified as being ineffective or inadequate, the EMP or other pertinent documentation will be revised to include the improved procedures or requirements.

The DETSI Pollution Hotline will be notified by the relevant environmental advisor within 48 hours of becoming aware of prescribed incidents.

10.3.8 Soil and Erosion Management

Procedures and protocols to prevent erosion and effectively manage soil are included in the EMP and RMP.

The risk of erosion will be managed through well-pad design (i.e. surface water run-on and run-off) and engineered management controls. Impacts on water quality are to be minimised by undertaking the works to the standard set out in the current version of the Best Practice Erosion and Sediment Control, published by the International Erosion Control Association Australasia (IECA 2008) (and in accordance with relevant EA conditions).

In accordance with the EMP, considerations for siting and constructing well leases and associated infrastructure will include:

- Environmental awareness training of employees and subcontractors;
- Preferential selection of non-sloping well leases;
- Avoidance of environmentally sensitive and restricted areas;
- Employment of additional management controls in sensitive area (as may be required);
- Construction of erosion control measures where appropriate (i.e. diversion banks or berms);
- Erosion and sediment control will be managed so as to:
  - Erosion: minimise the area and duration of soil exposure.
  - Sediment: sediment controls to be suited to soils, climate and catchment size.
  - Drainage: divert clean runoff around disturbed areas and convey drainage in a non-erosion manner.

- Good shaping and drainage of infrastructure to minimise erosion (according to standardised construction designs);
- Routine monitoring and maintenance; and
- Progressive rehabilitation / reinstatement of significant disturbances in accordance with relevant EA conditions to safe and stable landforms.

ECP 1 (Construction Site Management) and ECP 2 (Soil Resource Management) in the EMP detail management actions (including monitoring and reporting requirements), responsibility and frequency associated with potential impacts related to soil and erosion management.

10.3.9 General Environmental Management Practices

As discussed earlier in this section, the EMP provides a comprehensive framework to enable targeted management of environmental issues over the life of the Project. In addition to the ECPs already referred to in other parts of this section, the EMP also includes ECPs relating to construction site management, flora and fauna management, weed and pest management, air, vibration, light and noise management, cultural heritage management and plant and equipment management (Appendix V).

Further, the Santos Management System (SMS) and associated operating standards provide a risk management, assurance and investigation framework following ISO31000:2018 to ensure that risks are effectively identified, monitored, and managed.

Infrastructure will be monitored, inspected, and maintained during operation. The EMP and supporting ECPs detail inspection, reporting and record keeping requirements as well as the corrective action process.

10.3.10 Decommissioning and Rehabilitation

Santos will undertake rehabilitation in accordance with the EMP and RMP. Santos aims to progressively rehabilitate significant disturbances where possible, with the overarching objective of rehabilitating all significantly disturbed areas caused by petroleum activities to be non-polluting, stable, re-profiled to have contours consistent with surrounding land, surface drainage lines re-established, topsoil reinstated, and groundcover and vegetation is to be consistent with surrounding vegetation cover and species richness.

All wells are monitored throughout operations using a risk-based inspection and maintenance program. When a well comes to the end of its productive life (or if the well is deemed uneconomic), the well will be decommissioned. The primary objective of well decommissioning is to isolate hydrocarbon and water bearing formations and eliminate migration pathways (between the reservoir, other formation / aquifers and surface). During decommissioning, perforated hydrocarbon zones are isolated with cement plugs and / or bridge plugs and cement bond logs (CBL) used and assessed to ensure that the cement behind the production casing is adequate to avoid migration pathways. An additional cement plug is placed in the surface casing prior to cutting off the well head below ground level. Final rehabilitation of the well and lease area would include removing the well head, surface infrastructure and fencing; capping the well; filling in pits; respreading topsoil (after preparation) and revegetating the site to match its pre-disturbance vegetation type.

Disturbed areas no longer needed for operational purposes will be rehabilitated in accordance with relevant EA conditions and the EMP/RMP. Rehabilitation techniques are detailed in the RMP, together with final rehabilitation monitoring requirements and rehabilitation acceptance criteria.

10.4 Reporting

Santos will undertake all reporting in accordance with any relevant State and Commonwealth legislation and approval conditions, including OGIA as part of the UWIR requirements.

11 CLOSING

We would like to thank you for the opportunity to work on this assignment. Should you have any questions, please do not hesitate to contact the undersigned.

1.0 Introduction

This Stimulation Impact Monitoring Program (SIMP) has been prepared to meet relevant requirements of the Well Construction, Maintenance and Stimulation Activities Schedule of Santos' Eastern Queensland (EQ) Environmental Authorities (EAs). A list of the applicable EQ Project Area EAs is provided in Attachment A. Table 1 details these EA requirements with reference to the relevant section of this SIMP.

Table 1 – Stimulation Impact Monitoring Program Requirements

Number*	Condition	Section
I10 (j)	An assessment of the appropriate limits of reporting for all water quality indicators relevant to stimulation monitoring in order to accurately assess the risks to environmental values of groundwater.	Section 5
J4	Polycyclic aromatic hydrocarbons or products that contain polycyclic aromatic hydrocarbons must not be used in stimulation fluids in concentrations above the reporting limit.	Section 3.2
J5	Stimulation activities must not negatively affect water quality, other than that within the stimulation impact zone of the target gas producing formation.	Sections 2, 3, and 4
J11	***Water Quality Baseline Monitoring*** Prior to undertaking any stimulation activity(ies), a baseline bore assessment must be undertaken of the water quality of: (a) all landholders' active groundwater bores (subject to access being permitted by the landholder) that are spatially within a two (2) kilometre horizontal radius from the location of the stimulation initiation point within the target gas producing formation; (b) all landholders' active groundwater bores (subject to access being permitted by the landholder) in any aquifer that is within 200 metres above or below the target gas producing formation and is spatially located within a two (2) kilometre radius from the location of the stimulation initiation point; and (c) any other bore that could potentially be adversely impacted by the stimulation activity(ies) in accordance with the findings of the risk assessment required by conditions (J9) and (J10).	Section 2 Section 2 Section 2 Section 2
J12	Prior to undertaking stimulation activities at a well, the holder of this environmental authority must have sufficient water quality data to accurately represent the water quality in the well to be stimulated. The data must include, as a minimum, the results of analysis for the parameters in condition (J13).	Section 3.0
J13	Stimulation baseline bore assessments required in condition (J11) must include the minimum water quality analytes and physico-chemical parameters identified in the Baseline Assessment Guideline and any restricted stimulation fluids as defined in the *Environmental Protection Act 1994*, as amended from time to time, in order to establish baseline water quality.	Section 5
J14	***Stimulation Impact Monitoring Program***	This document

UNCONTROLLED IF PRINTED

Number*	Condition	Section
	A Stimulation Impact Monitoring Program must be developed prior to the carrying out of stimulation activities which must be able to detect adverse impacts to water quality from stimulation activities and must consider the	
	findings of the risk assessment required by conditions (J9) and (J10) that relate to stimulation activities and must include, as a minimum, monitoring of:	Section 5
	(a) the stimulation fluids to be used in stimulation activities at sufficient frequency and which sufficiently represents the quantity and quality of the fluids used;	Section 3.2
	(b) flowback waters from stimulation activities at sufficient frequency and which sufficiently represents the quality of that flow back water;	Section 3.3
	(c) flowback waters from stimulation activities at sufficient frequency and accuracy to demonstrate that 150 per cent of the volume used in stimulation activities has been extracted from the stimulated well; and	Section 3.3
	(d) all bores in accordance with condition (J11) at the following minimum frequency: i. monthly for the first six (6) months subsequent to the stimulation activities being undertaken; then ii. annually for the first five (5) years subsequent to the stimulation activities being undertaken or until analytes and physico-chemical parameters listed in condition (J13) are not detected in concentrations above baseline bore monitoring data on two (2) consecutive monitoring occasions.	Section 4
J15	The Stimulation Impact Monitoring Program must provide for monitoring of:	
	(a) analytes and physico-chemical parameters relevant to baseline bore and well assessments to enable data referencing and comparison including, but not necessarily being limited to the analytes and physico-chemical parameters in condition (J13); and	Section 5
	(b) any other analyte or physico-chemical parameters that will enable detection of adverse water quality impacts and the inter-connection with a non-target aquifer as a result of stimulation activities including chemical compounds that are actually or potentially formed by chemical reactions with each other or coal seam materials during stimulation activities.	Section 3.3

** Condition numbering may vary between EAs.*

Stimulation is defined in Santos EQ EAs and means a technique used to increase the permeability of natural underground reservoir that is undertaken above the formation pressure and involves the addition of chemicals. Stimulation includes hydraulic fracturing / hydrofraccing, fracture acidizing and the use of proppant treatments.

Restricted stimulation fluids means fluids used for the purpose of stimulation, including fracturing, that contain the following chemicals in more than the maximum amounts prescribed under section 81B of the *Environmental Protection Regulation 2008*:

- petroleum hydrocarbons containing benzene, ethylbenzene, toluene or xylene; or
- chemicals that produce, or are likely to produce benzene, ethylbenzene, toluene, or xylene as the chemical breaks down in the environment.

UNCONTROLLED IF PRINTED

The restrictions on PAHs and/or restricted stimulation fluids apply to stimulation fluid (concentrate) prior to being mixed with water (source water).

An overview of the monitoring described in this Stimulation Impact Monitoring Program, including groundwater bore baseline monitoring (pre-stimulation monitoring), stimulation source water, stimulation fluid and flowback monitoring, and post-stimulation monitoring is provided in Figure 1.

The certification of this SIMP by a suitably qualified person is provided in Attachment B.

UNCONTROLLED IF PRINTED

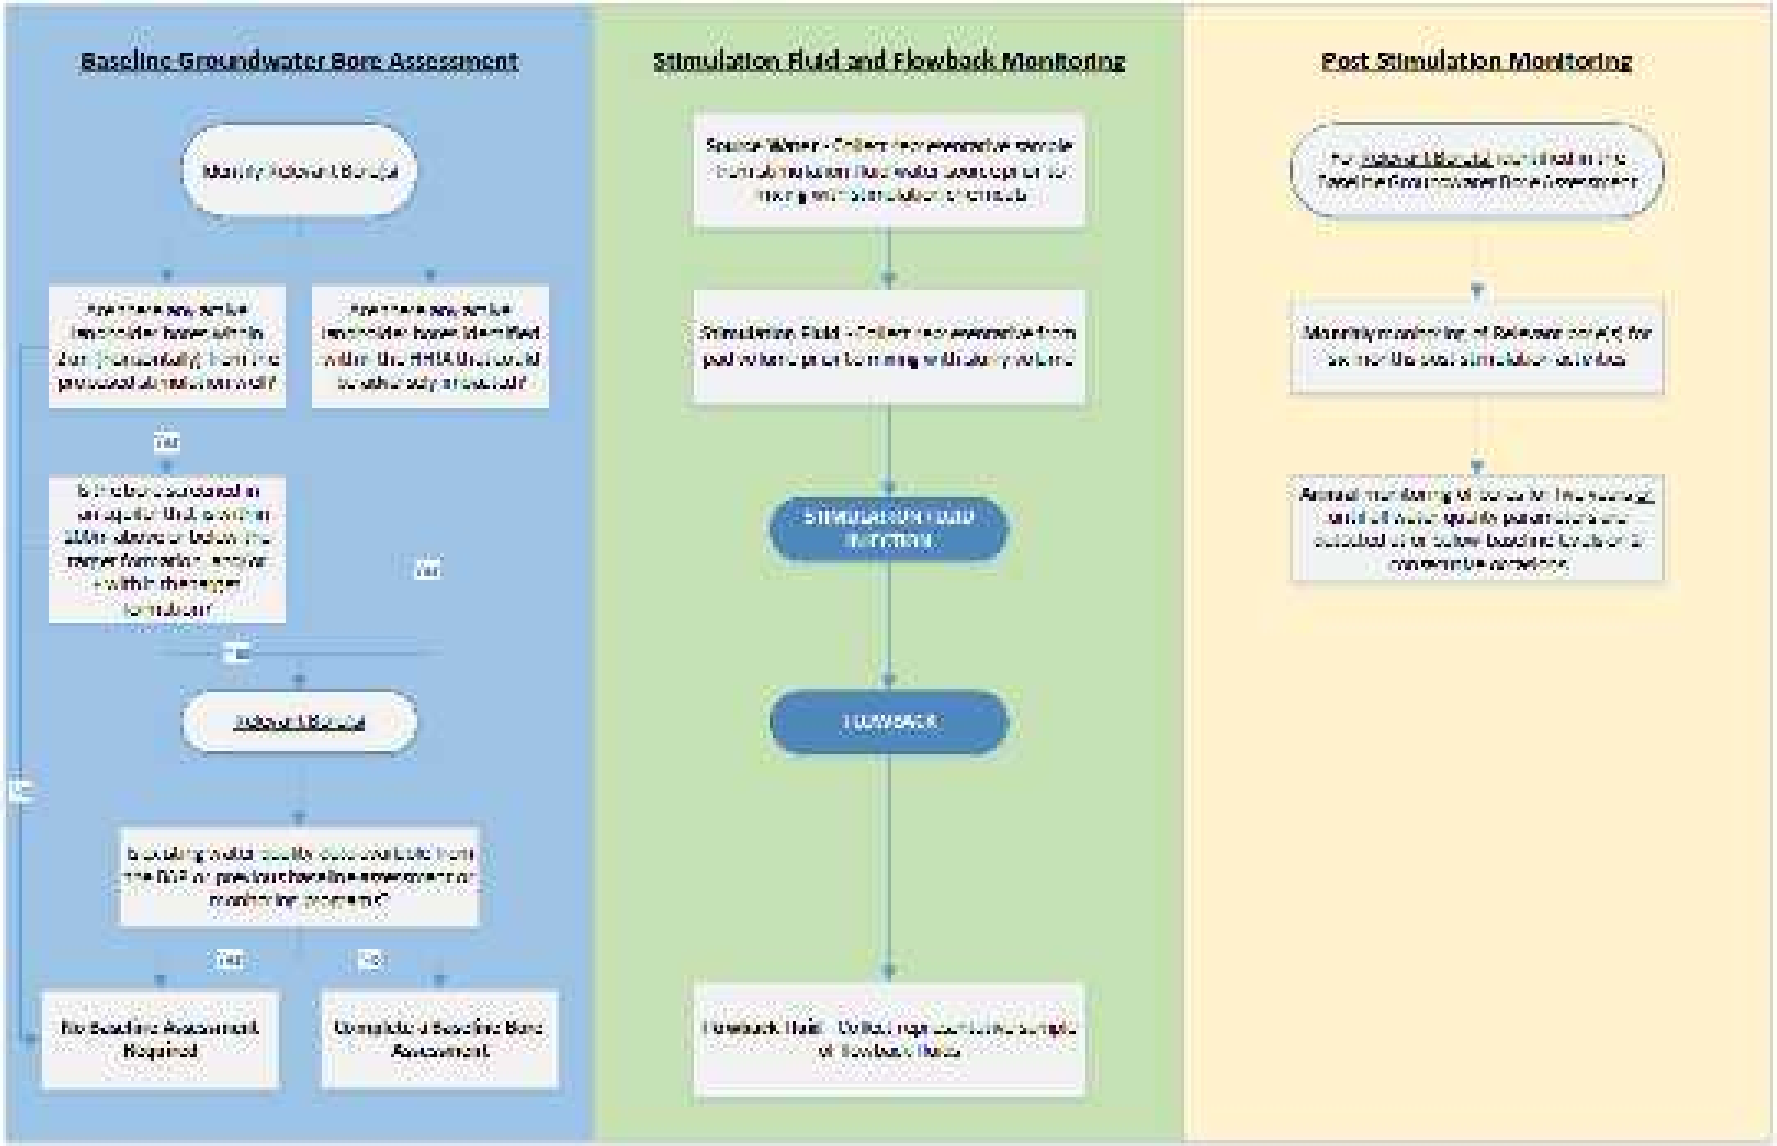

Figure 1 – Stimulation Monitoring Overview

Santos

2.0 Baseline Groundwater Bore Assessment

Prior to undertaking stimulation activities a baseline groundwater bore assessment is be undertaken as follows:

1. Determine the target depth and formation of proposed stimulation activity.
2. Complete a search of Santos WebGIS and Queensland Government Groundwater Database (e.g. QLD Globe) to determine the potential presence of active landholder groundwater bores screened within 200 metres from the target formation and spatially located within two (2) kilometres of the well to be fractured.
3. Identify other bores from the Hydraulic Fracturing Risk Assessment (HFRA) that could potentially be adversely impacted by the proposed stimulation activity.
4. For groundwater bores identified in Steps 2 and 3 (relevant bore(s)), review existing bore information (boring logs and completion details) and water quality data obtained from studies such as:
    a) baseline assessment plan (BAP);
    b) regional monitoring assessments; and
    c) previous baseline monitoring.
5. If existing baseline water quality data identified in Step 4 is not available for the relevant bore(s), a representative baseline groundwater sample is to be collected prior to the stimulation activity.

One sample is to be collected from each relevant bore and is to be analysed for the analytical suite detailed in Table 2, Section 5.

It is important to note that restrictions to sampling such as land access or surface equipment present at the bore (such as pumps) may occur. Where sampling cannot be undertaken due to land access, physical restrictions or insufficient water, baseline water quality may be extrapolated from relevant surrounding bores.

UNCONTROLLED IF PRINTED

Santos

3.0 Stimulation Fluid and Flowback Monitoring

Monitoring of stimulation fluids during the stimulation activity (at sufficient frequency) is to be conducted in order to characterize the quality and quantity of source water, stimulation fluid and flowback.

Given the process of well perforation and stimulation it is not considered viable or practical to collect a representative water sample from the well prior to stimulation. Representative water quality data for the well to be stimulated may be extrapolated from relevant surrounding wells or storage ponds.

3.1 Stimulation Water Source Sampling

Source water to be used for stimulation activities is to be sampled prior to the commencement of the stimulation operations.

One source water sample is to be collected per stimulation activity and is to be analysed for the analytical suite detailed in Table 3, Section 5. For locations where water is regularly sourced, frequency of source water sampling may be reduced to one sample every 10 stimulation activities, i.e. 10% of stimulation activities.

3.2 Stimulation Fluid Sampling

Stimulation fluids must not include restricted stimulation fluids as prescribed by the *Environmental Protection Act 1994* (i.e. BTEX) or polycyclic aromatic hydrocarbons or products that contain polycyclic aromatic hydrocarbons in concentrations above the reporting limit as prescribed in the respective EA.

Service providers must provide confirmation (i.e. laboratory analysis, statutory declaration), that restricted stimulation fluids are not present in the stimulation fluid pad volume prior to the stimulation activity being undertaken. Service providers must record fluid pad volume.

One stimulation fluid sample per stimulation activity on each well is to be taken from the pad volume prior to the addition of the slurry volume and analysed for the analytical suite detailed in Table 3, Section 5. For stimulation activities where fluid chemicals and target formation geology are consistent across a stimulation program, frequency of fluid sampling may be reduced to one sample every 10 wells, i.e. 10% of stimulation activities.

3.3 Flowback Sampling

Post stimulation activities, a representative flowback sample is to be collected when flowback is recovered at surface. Flowback volume(s) must be recorded to ensure 150 percent of the volume of stimulation fluids used in the stimulation event have been extracted from the stimulated well, to the extent practicable.

A flowback or produced water sample is be collected post stimulation and to be analysed for the analytical suite detailed in Table 4, Section 5. For stimulation activities where fluid chemicals and target formation geology are consistent across a stimulation program, frequency of flowback sampling may be reduced to one sample every 10 wells, i.e. 10% of stimulation activities.

The HFRA indicated the geological Bowen and Surat Basins are structurally separate sedimentary depositional centres with competent aquitards separating the target coal seams from overlying and underlying aquifer systems.. The HFRA concluded that through implementation of best industry practice and Santos management controls, migration to groundwater receptors is not a potentially complete exposure pathway.

UNCONTROLLED IF PRINTED

If an active landholder bore is pumping from an aquifer within 200 metres above or below the target formation(s) and is spatially located within a two (2) kilometre radius from the location of the stimulation initiation point, additional flowback monitoring may be required to enable detection of potential adverse water quality impacts and the potential inter-connection with a non-target aquifer. Monitoring requirements are to be assessed on a case by case basis in consideration of the analytical suite detailed in Table 2, Section 5.

UNCONTROLLED IF PRINTED

Santos

4.0 Post-Stimulation Groundwater Bore Monitoring

Where relevant bores have been identified in Section 2, post-stimulation groundwater monitoring is to be undertaken at the following frequencies:

- monthly for the first six (6) months subsequent to the stimulation activities being undertaken; then
- annually for the first five (5) years subsequent to the stimulation activities being undertaken or until analytes and physico-chemical parameters are not detected in concentrations above baseline bore monitoring data on two (2) consecutive occasions.

Groundwater from relevant bores is to be analysed for the analytical suite detailed in Table 2, Section 5.

UNCONTROLLED IF PRINTED

Santos

5.0 Analytical Testing

The HFRA identifies the following environmental values (EVs) of groundwater for the Project Area:

- Groundwater Dependant Ecosystems (GDEs) and springs ;
- drinking water supply;
- stock watering;
- crop irrigation;
- farm supply/use;
- primary contact via recreation activities;
- aquaculture;
- industrial use; and
- cultural and spiritual activities.

Water/stimulation fluid sampling parameters provided in Table 2, Table 3, and Table 4 are considered appropriate for assessing the risks to the abovementioned EVs and to detect potential adverse impacts to water quality from stimulation activities. The standard laboratory limits of reporting (LOR) for analytes presented in Tables 2, 3 and 4 are acceptable for the purposes of evaluating monitoring data and assessment of the risk to the EVs of groundwater identified in the HFRA. The standard LOR for the identified parameters are provided as Attachment C.

Samples are to be collected in general accordance with the Queensland Government *Monitoring and Sampling Manual* and appropriate guidelines as required by Santos EQ EAs.

All samples will be analysed at National Association of Testing Authorities (NATA) accredited laboratories.

Table 2 – Baseline Groundwater Bore Sampling Parameters[1]

Physical Parameters	Ions	Metals (T&D)	Alkalinity	Dissolved Gases and Others
pH (field and laboratory)	Calcium	Aluminium	Total alkalinity as CaCO3	Total recoverable hydrocarbons (TRH)
	Chloride	Arsenic		
Temperature (field only)	Fluoride	Barium	Bicarbonate as CaCO3	Methane[2]
	Magnesium	Beryllium		Carbon dioxide (field)[2]
Electrical conductivity (field and laboratory)	Potassium	Boron	Carbonate as CaCO3	Hydrogen sulphide[2]
	Sodium	Cadmium		Benzene
	Sulphate	Chromium	Hydroxide as CaCO3	Toluene
		Cobalt		Ethylbenzene
Dissolved Oxygen (field only)	Sodium Adsorption Ratio (SAR)	Copper	Total hardness as CaCO3	Ortho-xylene
		Iron		Para-and Meta-xylene
		Lead		Total Xylene
		Manganese		Naphthalene
		Mercury		Phenanthrene
Total dissolved solids (laboratory only)		Molybdenum		Benzo[a]pyrene
		Nickel		Sodium Hypochlorite and Sodium Hydroxide (measured as chlorite)
		Selenium		
		Silver		
		Strontium		Formaldehyde
		Tin		Ethanol
		Uranium		Gross Alpha
		Vanadium		Gross Beta
		Zinc		

[1] Refer Baseline Assessment Guideline

[2] Where the presence of dissolved gases is detected in the field (via the use of a multi-parameter gas detector), a dissolved gas sample must be collected through a flow-through cell, or if not practicable then in accordance with methods outlined in section 7.2 of Groundwater sampling and analysis – A Field Guide (Sundaram, et al., 2009).

UNCONTROLLED IF PRINTED

The concentration of PAHs or restricted stimulation fluids detected in monitoring per Section 3.2 and Table 3, is not measured in relation to source water . The restrictions on PAHs and/or restricted stimulation fluids apply to stimulation fluid (concentrate) prior to being mixed with water (source water). As such the concentration of PAH or restricted stimulation fluids in the source water is to be subtracted from the stimulation fluid analytical results.

Table 3 – Source Water and Stimulation Fluid Sampling Parameters

Physical Parameters	Ions	Metals (T&D)		Alkalinity	Dissolved Gases and Others
pH (field[1] and laboratory)	Calcium	Arsenic	Manganese	Total alkalinity as CaCO3	Volatile organic compounds (VOC)
Temperature (field only[1])	Chloride	Barium	Mercury	Bicarbonate as CaCO3	Polycyclic Aromatic Hydrocarbons (PAH) – Super Ultra trace (0.005µg/L – 0.02µg/L)
Electrical conductivity (field[1] and laboratory)	Fluoride	Boron	Nickel	Carbonate as CaCO3	
	Potassium	Beryllium	Lead	Hydroxide as CaCO3	Total recoverable hydrocarbons (TRH)
Total dissolved solids (laboratory only)	Magnesium	Cadmium	Selenium	Total hardness as CaCO3	Total Organic Carbon

6.0 Roles and Responsibilities

Santos personnel are responsible for the environmental performance of their activities, for complying with relevant approval/permit requirements and for ensuring that all environmental objectives associated with the work are achieved.

All Santos personnel and contractors must also be mindful of:

- Environmental Authority requirements as stipulated in the EQ EAs;
- the General Environmental Duty (GED) as outlined in section 319 of the *Environmental Protection Act 1994* (EP Act),

Roles, responsibilities and accountabilities specific to Stimulation Activities are defined as per SMS Compliance.

A summary of responsibilities for the Stimulation Impact Monitoring Program is provided in Table 5.

Table 5 – Roles and Responsibilities

Responsible Person	Responsibility
Santos Drilling and Completions Manager	Manage Drilling and Completion activities in accordance with Santos Management Systems (SMS)
Principal Environmental Adviser / Team Leader	Implement Stimulation Impact Monitoring Program
	Maintain management systems, processes and procedures
	Ensure SIMP data is recorded and maintained in Santos data management system (EQuIS)
	Implement monitoring outlined in the SIMP
	Perform water quality data review as required
	Schedule assurance audits to ensure compliance with the EAs
	Manage reporting in accordance with EAs
Santos Drilling and Completions Team Leader	Implement the Stimulation activities and processes as per this document
	Maintain records in accordance with the SIMP
	Manage procedures for Stimulation activities
	Manage staff and contractor compliance with the SIMP
All Employees and Contractors	Comply with EHS legal obligations and other requirements that are applicable to Santos' operations and activities.

Santos

7.0 Evaluation and Review

7.1 Implementation

The implementation and effectiveness of this monitoring program and associated plans and procedures will be regularly assessed to ensure:

- Santos is demonstrating compliance with legal and landholder obligations;
- the overall monitoring strategy remains relevant and up to date; and
- the plan and procedures adequately manage the respective environmental issue.

Effectiveness can be assessed by a number of methods as shown in Table 6.

Table 6 – Methods to Assess Legal and Procedural Effectiveness

Assessment Tool	Description
Checklists – Santos Compliance Management System	Checklists, developed to reflect legal and procedural requirements / outcomes will be used by individual Santos assets/departments to assess and manage compliance. The results of the checklists will be evaluated for common non-conformances that may be resolved through procedural change or by implementing another measure or process.
Audits	Conduct internal and/or third party audits to formally assess the level of compliance with both regulatory requirements and with Santos procedures. Audit outcomes are used to develop corrective actions, which may include changes to procedures.
Review of Incidents	A review of internal incidents, near misses or hazards will be undertaken to identify recurrences of similar incident types. This may highlight a requirement for a change in an existing procedure, require the development of a new procedure or by implementation of another measure or process to address the recurring issue.
Review of Data	Analyse all relevant data collected for negative and/or common trends that may be prevented by procedural changes or by implementing another measure or process.

7.2 Review

The SIMP is a living document and the performance of the SIMP shall be reviewed at least every five years or sooner if any of the following occur:

- the plan is not adequately managing identified issues;
- legislative requirements change; and/or
- the area(s) of activity changes.

Similarly, the plan may also be reviewed on an ‘as needs’ basis:

- in the case that there are significant changes to conditions at any site; and/or
- changes to standard limit of reporting for relevant analytes.

As a minimum the review shall take into consideration monitoring frequency, locations, changes to water qualities and/or quantities as a result of Santos’ forward plan of operations.

Reviews and changes to the SIMP are to be communicated to relevant Santos personnel.

1. Introduction

Santos and its joint venture partners are proposing a new gas field development located in central-eastern Queensland to supply natural gas to commercial markets. The proposed development will be known as the 'Santos Roma Phase 7-7B-SD20 Development' (the Project).

1.1. Overview

The Project will involve the progressive construction, operation, decommissioning and rehabilitation of up to 24 coal seam gas (CSG) wells, gas and water gathering flowlines and access track infrastructure in petroleum exploration tenure Authority to Prospect (ATP) 2053 (the Project Area). The Project Area is located in central-eastern Queensland, approximately 5 kilometres (km) east of the regional town of Wallumbilla. The regional location of the Project Area is shown in Figure 1.

The Project footprint located in the Project Area will cover approximately 66 hectares (ha) of land. Petroleum exploration activities undertaken by the Santos in the Project Area to date include the drilling and completion of 5 CSG appraisal wells and construction of associated infrastructure in 2022-2024. These activities are authorised under existing approved Queensland Environmental Authority (EA) 0002052. The existing 5 wells form part of the proposed 24 CSG wells.

CSG and water produced from the Project Area will be sent to existing approved centralised gas and water storage / processing and gas compression facilities located on adjacent Santos owned and operated petroleum tenures. Petroleum activities on adjacent tenures are authorised under existing EPBC Act approvals for the Gladstone Liquified Natural Gas Field Development Project (GLNG GFD) (EPBC Numbers 2008/4059 and 2012/6615) and EAs EPPG00898213 and EPPG00662213. No gas compression or water treatment facilities are proposed to be constructed or operated within the Project Area, and no significant water storage structures will be constructed or operated within the Project Area. Where required, prefabricated water storage tanks (concrete panel tanks or similar) will be assembled for water storage.

The Project will include the following components (but not limited to):

- well leases (typically 1.25 ha for single wells and 3 ha for multi-wells);
- water / gas gathering lines, trunklines and pipelines (typically 20 – 35 metres (m) wide);
- roads and access tracks (typically 10 – 15 m wide);
- other supporting infrastructure:
  - temporary water storage tanks;
  - temporary workers camps;
  - power and communications lines; and
  - other incidental and ancillary petroleum activities required to support the authorised activity.

Santos has developed a preliminary disturbance footprint (PDF) for the project to locate infrastructure to avoid disturbance to Matters of National Environmental Significance (MNES) and other environmental values. The PDF is displayed in Figure 2. The PDF was developed following multiple ecological surveys, field scouting, and desktop planning revisions to avoid impacts to MNES / other environmental values. The process for locating infrastructure, developing the PDF, and defining environmental constraints is described in the Roma Phase 7-7B-SD20 Development Environmental Protocol for Constraints Planning and Field Development Constraints Protocol (Constraints Protocol). The Constraints Protocol was informed by ecological surveys undertaken in 2022-2024 (refer to the *Roma Phase 7-7B SD20 Development Matters of National Environmental Significance Ecological Assessment Report* (Boobook, 2025)).

Design iterations as a result of these surveys and planning assessments are shown in Figure 3. Proposed infrastructure has largely been located in cleared agricultural land. No disturbance to Threatened Ecological Communities (TEC) is proposed. Any minor changes to the disturbance footprint or infrastructure locations would be subject to the requirements of the Constraints Protocol.

Well development will be phased to optimise gas production to meet Santos' gas supply obligations and opportunities. Once operational, gas produced from the Project will supply commercial markets.

Once completed and connected to gas and water gathering infrastructure, operational wells will operate continuously on a 24-hour basis for an anticipated operational life of 30-50 years. Progressive decommissioning and rehabilitation of activities and infrastructure will occur over the life of the Project, thereby reducing disturbance areas for the duration of operation, until final decommissioning and rehabilitation at end of project life.

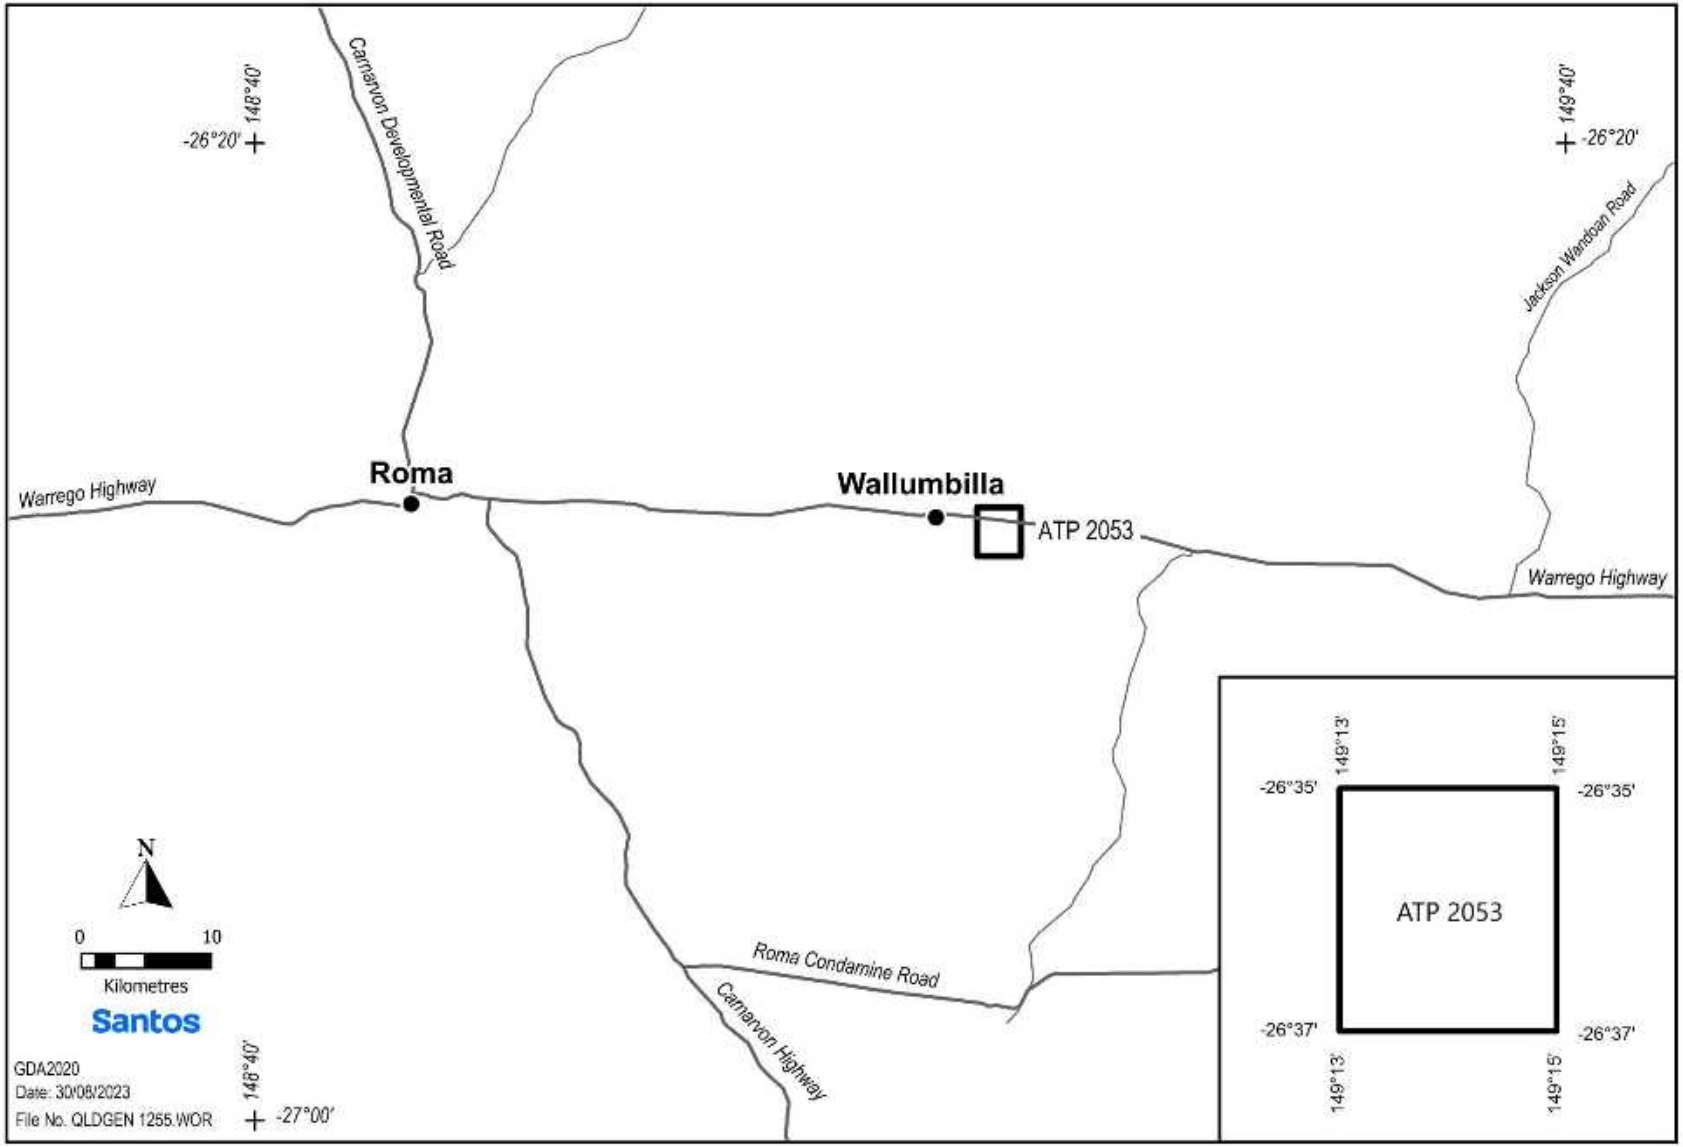

Figure 1: Santos Roma Phase 7-7B-SD20 – Project Area (ATP 2053)

Figure 2: Santos Roma Phase 7-7B-SD20 – Preliminary Disturbance Footprint

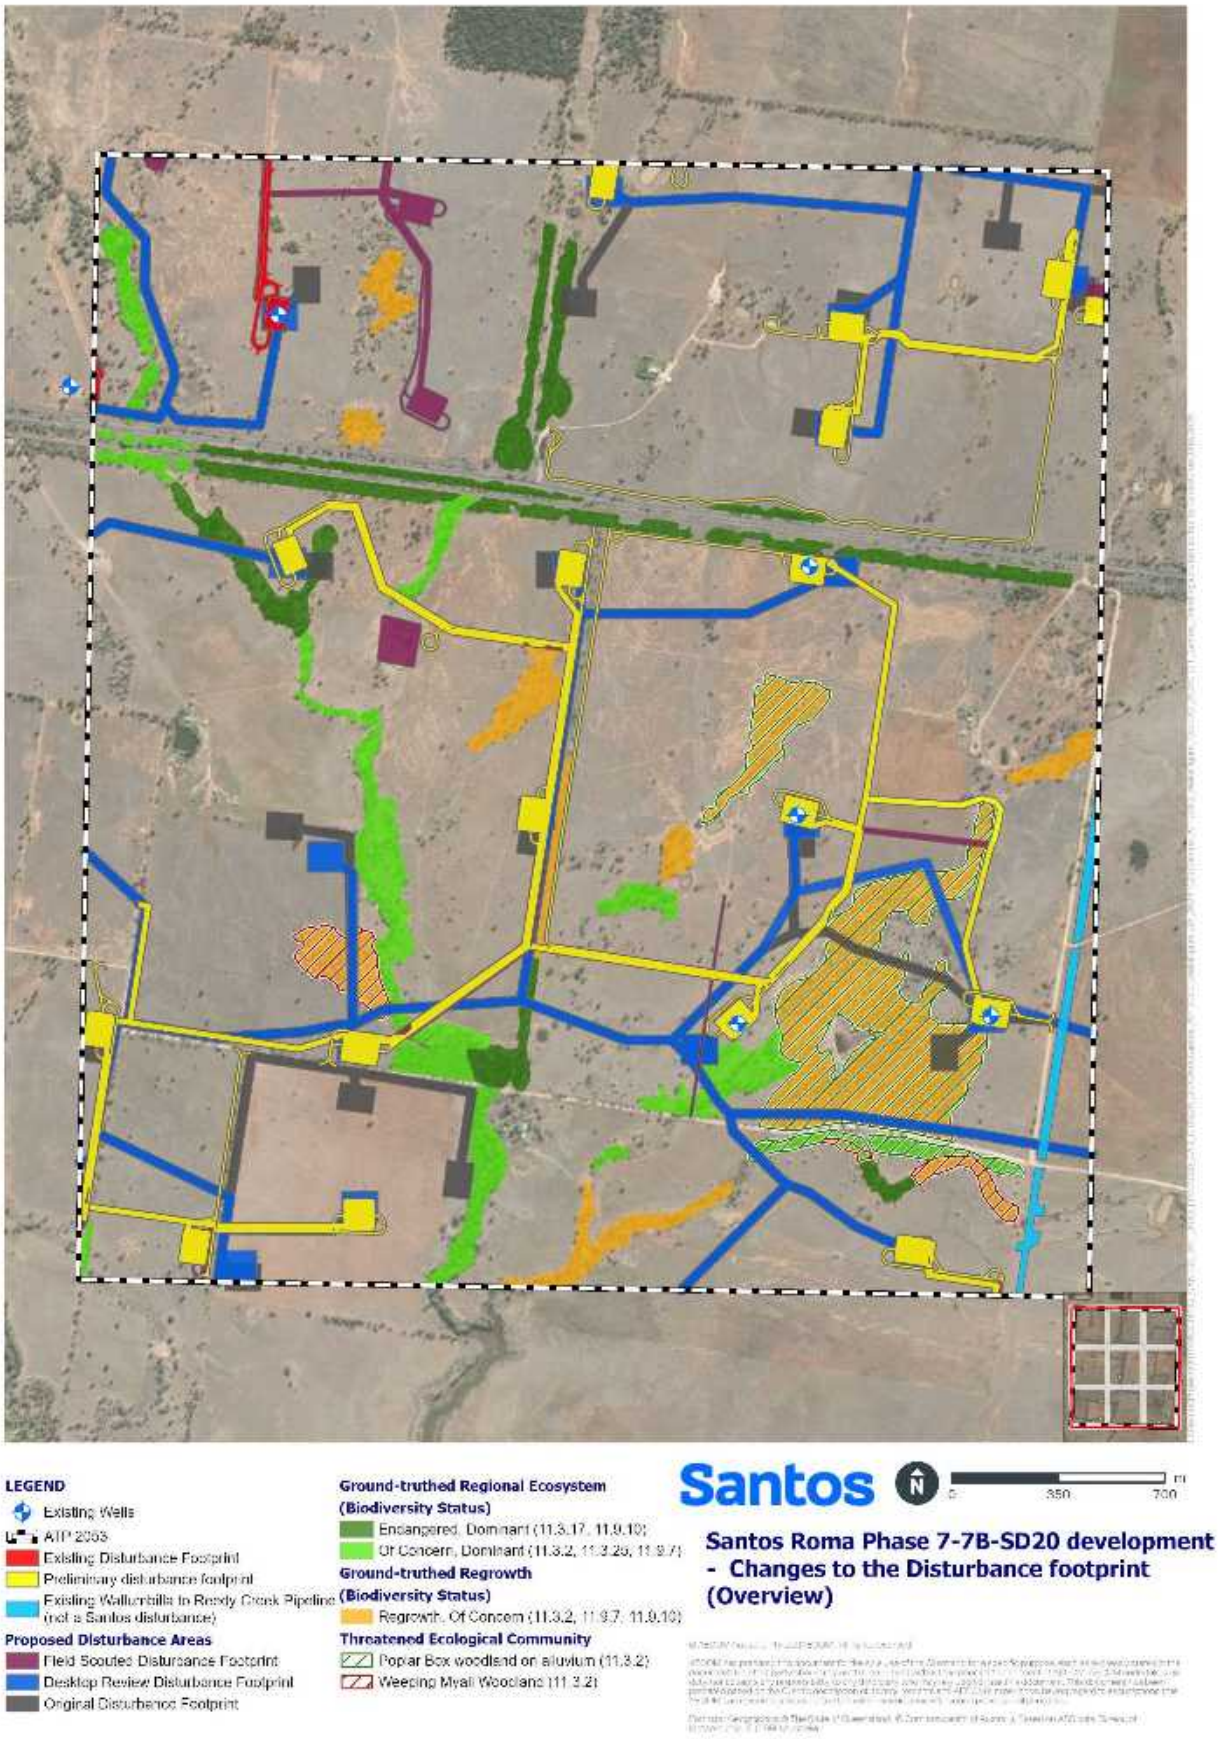

Figure 3: Santos Roma Phase 7-7B-SD20 – Disturbance footprint iterations

1.2. Purpose and scope

This Environmental Management Plan (EMP) has been developed to:

- provide a structured high-level approach to the management of environmental issues over the life of the Project;
- meet the requirements of the *Environment Protection and Biodiversity Conservation Act 1999* (Cth) (EPBC Act) and *Environmental Protection Act 1994* (QLD) (EP Act) (that being the conditions of the relevant EA), industry guidelines and other regulatory requirements;
- provide appropriate environmental management measures and controls to be implemented to avoid, minimise and mitigate environmental impacts; and
- document the environmental outcomes for the Project.

Effective implementation of this EMP and associated environmental control plans (ECPs) will ensure the Project meets regulatory and conditional requirements in a systematic manner with the aim to continually improve environmental performance.

Santos plans to convert the current exploration tenure for the Project Area (ATP 2053) from an ATP to a new Petroleum Lease (PL). Santos will need to apply for new a PL, granted under Chapter 2 of the Queensland *Petroleum and Gas (Production and Safety) Act 2004* (P&G Act) to replace the existing ATP. To authorise petroleum production activities on the new PL, Santos will also need to apply for a new EA under the EP Act. This EMP has been written to consider likely conditions of the new EA, however it will be revised or updated once the new EA is granted to ensure it complies with any additional conditions.

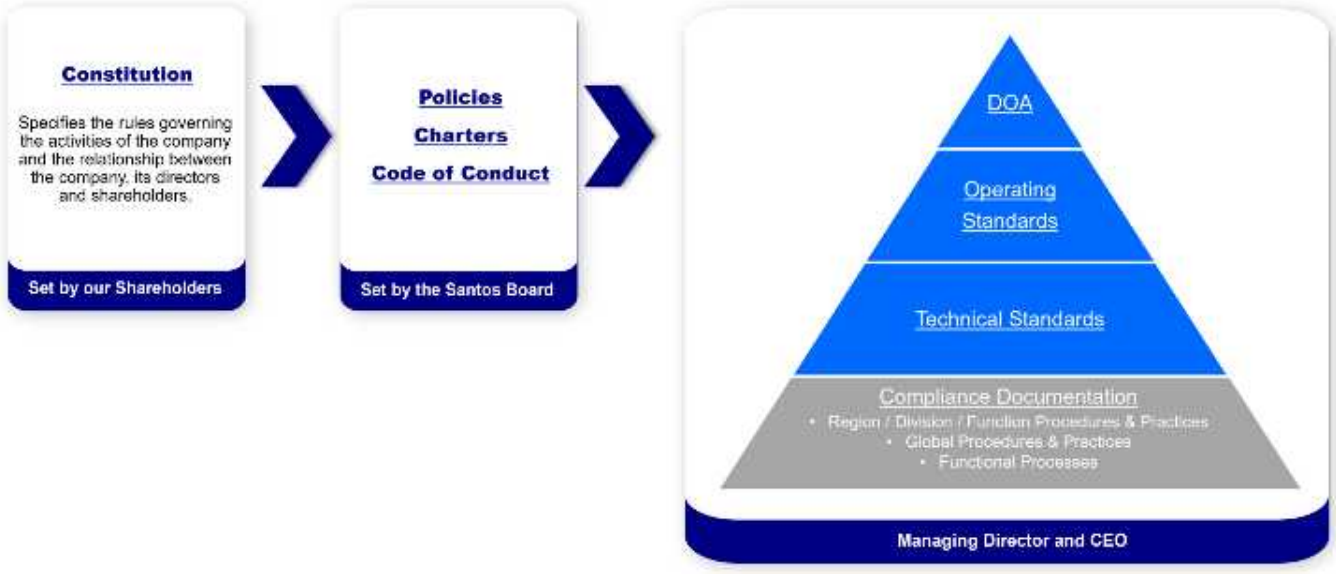
This EMP will be revised or updated from time-to-time to align with regulatory requirements. Revised versions of the EMP will be made available upon request to DCCEEW or as otherwise required under conditions of a regulatory approval, whether under the EPBC Act or any other applicable legislation.

2. Environmental Management Framework

2.1. Environmental policy

Santos has an Environment, Health and Safety (EHS) Policy which makes commitments relating to environmental responsibilities in managing the impact of our operations. The Santos EHS policy is attached in Appendix 1.

2.2. Santos Management System



Santos will use its company-wide Santos Management System (SMS) to provide a structured framework for environmental and safety practices across Santos' activities and operations and is based on industry and Australian Standards (AS).

The SMS comprises four key parts that underpin the EHS framework and describe requirements such as organisation structure / Delegation of Authority (DOA), operating and technical standards, and compliance documentation for meeting the objectives of Santos' EHS policies. These are:

- **Delegation of Authority:**
  - the Santos Board delegates specific decision authorities to the Chief Executive Office, who in turn delegates specific authorities to members of management. These authorities are set out in the Santos DOA.
- **Operating Standards:**
  - consisting of several operating standards structured around key business activities. Compliance with the operating standards is mandatory.
- **Technical Standards**
  - detailed technical requirements or specifications that must be achieved in a consistent manner and must be followed.
- **Compliance Documentation:**
  - procedures and practices developed by and for a specific Region, Division, or Function to comply with Operating and Technical Standards.

This EMP has been developed to align with the SMS. The structure of the SMS and other system elements is depicted in Figure 4. The SMS is maintained in electronic form on Santos' central server and is accessible to all employees and contractors.

Figure 4: Santos Management System

2.3. Objectives, targets and performance indicators

The SMS operating standards require annual EHS objectives and targets to measure and drive continuous improvement in EHS, process safety, and performance across Santos.

Santos has developed lead and lag indicators for both environment and safety performance across all its assets. This enables Santos to set improvement goals and targets for continual improvement in environmental and safety performance.

Specific objectives and performance indicators have been developed for each environmental aspect and are included in Section 6.1.

2.4. Legislative requirements

Santos manages compliance with significant legal obligations in accordance with SMS operating standards, which set down requirements to ensure obligations are identified, communicated, accessible and kept up to date to achieve compliance. The standard and accompanying procedure require Santos to record the following information for each significant compliance obligation using an appropriate compliance tool:

- the requirements of the obligation and its status;
- person responsible; and
- source documents.

Non-compliances are reported internally and, if not resolved within a reasonable timeframe, escalated for appropriate resolution. Further information is available in Section 5.4.

As operator of the Project Area, Santos must comply with State and Commonwealth legislation applicable to the Project (as detailed in Sections 2.4.1 and 2.4.2), including relevant regulatory approvals / authorisations, permits and other requirements as listed in Table 1.

2.4.1. State legislation

The principal state legislation regulating petroleum and gas activities for the Project is the *Petroleum and Gas (Production and Safety) Act 2004* (Qld) (P&G Act). The principal state environmental legislation is the EP Act and associated regulation and protection policies. The EP Act introduces the "*General Environmental Duty*" (as

described in Section 319 and 320, chapter 7), which specifies that a person must not perform their duties in a manner which will cause, or is likely to cause, environmental harm unless the person takes all reasonable and practical measures to prevent or minimise the harm.

Petroleum exploration, appraisal and production testing activities are currently authorised to occur in the Project Area under the requirements of the EP Act via the existing Queensland Environmental Authority (EA) 0002052. Santos and all contractors undertaking petroleum activities within the Project Area must comply with the conditions of the EA, to meet their respective obligations under the EP Act.

Further, as discussed in Section 1.2, to enable commercial gas production activities within the Project Area, a new PL will need to be applied for and granted under the requirements of Chapter 2 of the P&G Act to replace the existing ATP. Further, to authorise commercial gas production activities in the PL, a new EA under the EP Act will also need to be applied for and granted.

2.4.2. Commonwealth legislation

The EPBC Act is the principal environmental legislation administered by the Commonwealth Government. It provides a legal framework to protect and manage, among other matters, nationally and internationally important flora, fauna, threatened ecological communities and heritage places defined under the EPBC Act as MNES.

The EPBC Act requires the principles of ecologically sustainable development to be considered for a new development proposal if that proposal is likely to a result in a significant impact on the environment.

Table 1: Applicable legislation

Name	Administering Authority	Specific Considerations
Commonwealth		
Environment Protection and Biodiversity Conservation Act 1999 (Cth) (EPBC Act)	Department of Climate Change, Energy, the Environment and Water (DCCEEW)	The EPBC Act establishes a process for environmental assessment and approval of proposed actions that have, will have or are likely to have a significant impact on MNES or on Commonwealth land. Under the EPBC Act, a referral to DCCEEW is required if the Project has the potential to cause a 'significant impact' on MNES. The Constraints Protocol will direct the siting of infrastructure and activities to avoid and minimise impacts to MNES that have the potential to occur within the Project Area. Further, a Roma Phase 7-7B-SD20 Development *Significant Species Management Plan* (SSMP) has been prepared to mitigate impacts on a threatened ecological community (TEC) or species (EPBC listed) habitat from the Project.
Native Title Act 1993 (Cth) (NT Act)	National Native Title Tribunal	The NT Act regulates recognition and protection of native title. Indigenous Land Use Agreements (ILUA) are in place.
State		
Aboriginal Cultural Heritage Act 2003 (Qld) (ACH Act)	Department of Treaty, Aboriginal and Torres Strait Islander Partnerships, Communities and the Arts, Queensland Government (DTATSIPCA)	The ACH Act provides recognition, protection and conservation of cultural heritage in Queensland and outlines duty of care obligations for issues compromising Indigenous heritage. Santos engages Traditional Owners and implements measures to protect Aboriginal cultural heritage including the development of a Santos Cultural Heritage Management Plan (CHMP) and implementing a Find Stop Notify Manage procedure.
Biosecurity Act (Qld) 2014 and its subordinate legislation	Department of Agriculture and Fisheries (DAF) – Biosecurity Queensland	Santos and all persons onsite must meet their General Biosecurity Obligation (GBO). This means taking all reasonable and practical steps to prevent biosecurity risks or events such as invasive weed and animal introductions.

Name	Administering Authority	Specific Considerations
Environmental Protection Act 1994 (Qld) (EP Act) and its subordinate legislation	Department of Environment, Tourism, Science and Innovation (DETSI)	The EP Act is the overarching environmental regulatory framework for governing the environmental management of resource activities in Queensland. Prior to the granting of a PL under the *Petroleum and Gas (Production and Safety) Act 2004* (see below), DETSI must grant an Environmental Authority (EA) that authorises resource activities subject to conditions to protect environmental values including acoustic, biodiversity, land, air, surface water, groundwater and wetlands. Petroleum exploration and production testing activities are currently authorised to occur in the Project Area under the requirements of EA 0002052. To enable future commercial gas production activities within the Project Area, a new EA to authorise petroleum production activities will need to be applied for and granted under the requirements of the EP Act. Further to the above, under the requirements of the EP Act: • all persons must implement all reasonable and practicable measures to prevent environmental harm (i.e. General Environmental Duty) • material or serious environmental harm must be reported to the DETSI • controls must be implemented for prescribed water contaminants (e.g., soil and sediment, concrete washout, fuel / oil etc.) • wastes must be managed to prevent environmental harm. Regulated waste must only be carried by licensed transporters and disposed of at appropriately licensed waste receiving facilities; and • contaminated land must be managed in accordance with State and National guidance to protect human health and the environment.
Environmental Offsets Act (Qld) *2014* (EO Act)	DETSI	Under the EO Act an environmental offset is defined as an activity undertaken to counterbalance a significant residual impact on a prescribed environmental matter, including endangered or of concern regional ecosystems (REs), riparian vegetation, connectivity areas, wetlands and watercourses and protected wildlife habitat.
Fisheries Act 1999 (Qld) (Fisheries Act)	DAF	The Fisheries Act regulates and controls waterway barrier works and marine plants. Where works within mapped waterways constitute waterway barrier works, works are to comply with the departments code for Accepted development requirements (ADR) for operational work that is constructing or raising waterway barrier works, including any temporary works. Works that cannot comply with this code are considered assessable development requiring development approval (DA) under the *Planning Act 2016*. The Project Area intersects the following waterways all associated with Washpool Creek: • 8 high impact waterways • 1 moderate impact waterway; and • 10 low-impact waterways.

Name	Administering Authority	Specific Considerations
Nature Conservation Act 1992 (Qld) (NC Act) and its subordinate legislation	DETSI	The primary purpose of the NC Act is to conserve biodiversity by protecting wildlife and its habitat. Permits are required under the NC Act for interfering with protected wildlife and their habitat requiring DETSI approval of a species management plan or other mitigation measures. Additional permits are required for clearing protected plants requiring DETSI approval of an impact management plan for the clearing and offsets for the species if required. Where wildlife listed under the *Nature Conservation (Animals) Regulation 2020* (Qld) or the *Nature Conservation (Plants) Regulation 2020* (Qld) are proposed to be disturbed, relevant NC Act management, assessment and approval requirements will apply. Requirements for managing fauna including the responsibilities of fauna catchers and spotters during clearing and construction activities are documented in the Project's Significant Species Management Plan.
Petroleum and Gas (Production and Safety) Act 2004 (Qld) (P&G Act)	Department of Natural Resources and Mines, Manufacturing, and Regional and Rural Development (DNRMMRRD)	The P&G Act facilitates and regulates activities associated with the safe exploration, development and production of petroleum and gas resources in Queensland. Petroleum tenure granted by the DNRMMRRD under the P&G Act relevant to the Project include ATP, PL and Petroleum Pipeline Licence (PPL). Prior to commencing commercial gas production activities within the Project Area, a PL to authorise petroleum production activities will need to be applied for and granted under the requirements of the P&G Act.
Planning Act 2016 (Qld) (Planning Act)	Department of State Development, Infrastructure and Planning (DSDIP)	The Planning Act establishes an efficient, effective, transparent, integrated, coordinated, and accountable system of land use planning, development assessment and related matters that facilitates the achievement of ecological sustainability. Activities outside of the area of a petroleum tenure (e.g., depots) will require assessment and approval under the Planning Act, including any DA for operational works.
Queensland Heritage Act1992 (Qld)	DETSI	The Queensland Heritage Act (QH Act) operates in tandem with the ACH Act and the *Torres Strait Islander Cultural Heritage Act 2003* (Qld) to protect Queensland's cultural heritage. The act creates a framework to protect places or objects of cultural heritage significance for aesthetic, architectural, historic, scientific, social or technological reasons. The principal mechanism through which the Act operates is the 'Queensland Heritage Register', which is administered by DETSI. The Project Area does not intersect any heritage places listed by the Queensland Heritage Register'.
Regional Planning Interests Act 2014 (Qld) (RPI Act)	DSDIP	The RPI Act provides a level of protection for agricultural land from impacts associated with development and resource activities in Queensland. These protections seek to manage the impact of resource activities and other regulated activities on areas of regional interest; and support coexistence of resource activities with other activities, including highly productive agricultural activities. The RPI Act identifies and protects areas of regional interest throughout Queensland. Under the RPI Act and associated statutory regional plans, areas are classified as 'areas of regional interest' in order to recognise their unique characteristics from a land use perspective. Key areas of regional interest relevant to resource development are identified as Priority Agricultural Areas (PAAs), Strategic Cropping Areas (SCAs), and Strategic Environmental Areas (SEAs). For a resource activity to be undertaken on an area of regional

Name	Administering Authority	Specific Considerations
		interest, in addition to other approvals, a resource company is required to have a Regional Interest Development Approval (RIDA), or an exemption prior to the activity being undertaken. Where activities are proposed in areas of regional interest, they must comply with the requirements of the RPI Act.
Vegetation Management Act 1999 (Qld) (VM Act) and its subordinate legislation	DNRMMRRD	The VM Act regulates the clearing of vegetation in Queensland in a way that allows for sustainable land use, conserves remnant vegetation, ensures land clearing does not cause land degradation, prevents loss of biodiversity, and maintains ecological processes. Further, the Act regulates the clearing of vegetation in a way that reduces greenhouse gas emissions. The purpose of the VM Act is to primarily regulate the clearing of native vegetation on freehold and leasehold land, however its requirements and definitions are linked to several other environmental Queensland environmental Acts, Regulations, and other legislative instruments including Guidelines and Environmental Authorities.
Water Act 2000 (Qld) (Water Act) and its subordinate legislation	DNRMMRRD	The Water Act provides a framework for the planning, allocation and use of surface water and groundwater in Queensland, including regulating major water impoundments (e.g. dams and weirs) and extraction through pumping for irrigation and other uses. The Project Area is located within the Surat Cumulative Management Area (CMA) and will be assessed by the Office of Groundwater Impact Assessment (OGIA) in the Underground Water Impact Report (UWIR) for the Surat CMA. Section 370 of the Water Act requires an UWIR be prepared for approval. The Surat UWIR assesses the cumulative groundwater impacts from resource operations in the Surat and Southern Bowen basins. OGIA prepared the first Surat UWIR in 2012 and updated it in 2016, 2019 and 2021. The UWIR identifies responsible tenure holder obligations under the Water Act that include 'make good' agreements, undertaking baseline assessments and implementing the water management strategy and the spring impact management strategy. Further, water licences under the Water Act may be required for other activities (e.g. licence to take water from a bore) associated with the Project.
Waste Reduction and Recycling Act 2011 (Qld) (WRR Act) and its subordinate legislation	DETSI	The WRR Act promotes resource recovery through End of Waste (EOW) codes, including EOW Code *Irrigation of Associated Water (including CSG produced water),* EOW Code *Associated Water (including CSG produced water)* and EOW Code *CSG Drilling Mud.*

3. Existing Environment

The Project Area is located approximately 5 km east of the regional town of Wallumbilla in central Queensland in the Maranoa Regional Local Government Area (LGA). This Project Area is located in the southern extent of the Brigalow Belt Bioregion (BRB).

3.1. Land use

The Project Area is predominantly rural land characterised non-remnant derived grasslands dominated by introduced pastoral grasses with occasional native trees and shrubs. The area is used largely for agricultural development, primarily cattle grazing. The Project Area is comprised of predominantly non-remnant vegetation that is generally disturbed and fragmented as a result of land use practices (Boobook, 2025).

The agricultural land uses of the region coexist with existing petroleum, energy and mining activities. Existing permits overlapping the Project Area include:

- EPC 1763 held by Wanbei Coal Electricity International Mining (Australia) Pty Ltd;
- EPG 2034 held by Within Energy Pty Ltd;
- Wallumbilla to Reedy Creek Pipeline (Petroleum Pipeline Licence (PPL) 2023) held by APA Reedy Creek Wallumbilla Pty Ltd; and
- a powerline easement crossing the northern portion of the Project Area held by Ergon Energy.

Two State-controlled roads are in the vicinity of the Project Area, including the Warrego Highway running east to west through the northern half of the Project Area, and Wallumbilla South Road located approximately 3 km west of the Project Area, providing efficient access for local and heavy vehicle traffic.

In the wider local area, a number of State Forests (SF) occur within 20 km of the Project Area, including Inglebogie, Yuleba and Wallabella SF, which are located approximately 15-20 km east, east and south of the Project Area, respectively.

3.2. Topography

This is a landscape of low relief comprising a broad floodplain with meandering streamlines flanked by slightly elevated areas. Ground elevations within the Project Area range from approximately 300 m to 350 m Australian Height Datum (AHD). Beyond the Project Area, to the east, an abrupt north-south trending plateau rises up to 50 m above the surrounds, forming the Grafton Range.

3.3. Climate

The climate of the Project Area is classified as subtropical with hot, wet summers and moderately dry, cold winters. Mean maximum temperatures range between 34.6°C in the summer months and 20.4°C in the winter months (Bureau of Meteorology station 043091, Roma Airport) (Bureau of Meteorology, 2024). Mean minimum temperatures range between 21.1°C in the summer months and 3.7°C in the winter months. The highest rainfall occurs during December to February, with an average highest rainfall of 75.2 mm in December, the lowest rainfall occurs during June to September with a lowest average rainfall of 24.9 mm in August.

The average annual evaporation in the vicinity of the Project Area is between 2,000 millimetres (mm) and 2,400 mm. The highest evaporation occurs during the summer months (average monthly pan evaporation 300 mm), while the lowest evaporation occurs during the winter months (average monthly pan evaporation 80 mm) (Bureau of Meteorology, 2024).

3.4. Regional catchment and surface water quality

The Project Area is located within the Bungil Creek catchment of the Maranoa-Balonne Rivers Basin (WQ4222) as described by the Environmental Protection (Water and Wetland Biodiversity) Policy 2019 (DESI, 2023). The Maranoa–Balonne Basin is a subset of the broader Condamine-Balonne catchment of the Murray-Darling Basin. Environmental values and water use associated with the Bungil Creek catchment include aquatic ecosystems, irrigation, farm supply / use, stock water, aquaculture, human consumption, primary recreation, secondary recreation, visual recreation, drinking water, industrial use and cultural, spiritual and ceremonial values. No High Ecological Value (HEV) waters are mapped within the Project Area.

While the Project Area generally has a uniform low elevation, ranges in the surrounding region include the Great Dividing Range to the north, Grafton Range to the west, and the Dulacca Range to the south-east. Most watercourses in the Project Area are ephemeral. There are no major watercourses mapped within the Project footprint, only one watercourse mapped within the Project Area, the closest major watercourses include:

- Washpool Creek: is a minor creek, which originates 5km north of the Project and flows through the Project before joining Wallumbilla Creek 2 km south of the Project;
- Wallumbilla Creek: originates 16 km northwest of the Project and flows south – southwest close to the township of Wallumbilla. The creek continues to flow south before reaching the Balonne River confluence downstream of Yuleba Creek, 54 km south of the Project; and
- Middle Creek: is a tributary of Wallumbilla Creek, which originates 15 km northwest of the Project and flows south between the township of Wallumbilla and the Project before joining Wallumbilla Creek 2 km west of the Project.
- Yuleba Ck (consists of SO 1-5 tributaries) is identified by the *Qld Water Act 2000* as a major watercourse and flows for approx. 187 km from near the Great Dividing Range before joining the Balonne River 45 km south of Yuleba. Yuleba Ck flows predominately south, close to the township of Yuleba, located 13 km east of the Project Area and joins the Balonne River, 46 km southeast of the Project Area.

Other minor, unnamed watercourses occur within the Project Area, almost all of which drain into one of the watercourses listed above.

The Sustainable Rivers Audit 2 for rivers within the Murray-Darling basin (Murray–Darling Basin Authority, 2012) found that the Condamine Valley, which includes the region around the Project Area, had an overall poor ecosystem health rating. The physical form of the Condamine Valley river system was rated as being in moderate condition, characterised by enlarged channels and evidence of widening and channel bed degradation. The cause of this condition was not specified.

According to assessment (Queensland Government, 2024), there are no wetlands of High Ecological Significance (HES) or HEV within or immediately adjacent to the Project Area, with the nearest mapped HEV wetland located approximately 39 km south-west of the Project Area.

There are no active springs mapped within 30 km of the Project Area. There is a low confidence of mapped terrestrial groundwater-dependent ecosystems (GDE) within and near the Project Area. There are no known or mapped subterranean GDEs or groundwater-dependent spring ecosystems located within the Project Area.

There are two registered groundwater bores located in the Project Area, these bores are recorded as Registered bore Numbers (RNs) 123195 and 208460 in the Groundwater Database - Queensland, which are sub-artesian bores for private water supply.

3.5. Regional geology

The regional geology of the Project Area comprises sediments from the Early Cretaceous to Quaternary age Surat Basin. Stratigraphic units of relevance to the Project Area include:

- quaternary alluvial systems within majority of the Project Area;
- early cretaceous age mudrock along the mid-eastern border of the Project Area; and

- fine grained sedimentary rock north-eastern corner of the Project Area.

Land zones are categories that describe the major geologies, the associated landforms and geomorphic processes in Queensland, and are a critical component of the RE classification scheme. The land zones identified within the Project Area using state mapping (Queensland Government, 2023) are detailed in Table 2.

Table 2: Land zones occurring within the Project Area

Land zone	Description as per Wilson & Taylor (2012)
3	Recent Quaternary alluvial systems, including closed depressions, paleo-estuarine deposits currently under freshwater influence, inland lakes and associated wave built lunettes. Excludes colluvial deposits such as talus slopes and pediments. Includes a diverse range of soils, predominantly Vertosols and Sodosols; also with Dermosols, Kurosols, Chromosols, Kandosols, Tenosols, Rudosols and Hydrosols; and Organosols in high rainfall areas.
4	Tertiary-early Quaternary clay deposits, usually forming level to gently undulating plains not related to recent Quaternary alluvial systems. Excludes clay plains formed in-situ on bedrock. Mainly Vertosols with gilgai microrelief, but includes thin sandy or loamy surfaced Sodosols and Chromosols with the same paleo-clay subsoil deposits.
9	Fine grained sedimentary rocks, generally with little or no deformation and usually forming undulating landscapes. Siltstones, mudstones, shales, calcareous sediments, and labile sandstones are typical rock types although minor interbedded volcanics may occur. Includes a diverse range of fine textured soils of moderate to high fertility, predominantly Vertosols, Sodosols, and Chromosols.

3.6. Regional ecology

The BRB bioregion is characterised by *Acacia harpophylla* (brigalow) forests and woodlands on clay soils (Sattler & Williams, 1999). Other ecosystems that are widespread throughout the bioregion include eucalypt forest and woodland, grassland, dry rainforest, cypress pine woodland and riparian communities (Sattler & Williams, 1999).

The majority of the Project Area has been cleared of native vegetation to form non-remnant derived grassland dominated by introduced pastoral grasses with occasional native trees and shrubs. Areas of remnant and regrowth native vegetation occur as irregular, discontinuous corridors along streamlines or as small, isolated fragments. River Red Gum (*Eucalyptus camaldulensis*) dominates riparian woodland along the banks of larger streams, while Poplar Box (*E. populnea*) dominates floodplain woodlands (Boobook, 2025).

The likelihood of occurrence of threatened flora, fauna, Threatened Ecological Communities (TECs), migratory fauna, fish and gastropod species listed under the EPBC Act within the Project Area are listed in Table 3. No threatened flora were identified to have potential to, or are likely, to occur within the Project Area.

Refer to the *Roma Phase 7-7B SD20 Development Matters of National Environmental Significance Ecological Assessment Report* (Boobook, 2025) for further information on the ecology of the Project Area.

Table 3: Likelihood of occurrence of MNES within the Project Area

MNES	EPBC Act Status	NC Act Status	Likelihood of Occurrence[1]
Threatened Ecological Communities			
Poplar Box Grassy Woodlands on Alluvial Plains TEC	Endangered	-	Known
Weeping Myall Woodlands	Endangered	-	Known
Birds			
Sharp-tailed sandpiper (*Calidris acuminata*)	Vulnerable, Migratory	Special Least Concern	Potential
Glossy black-cockatoo (eastern) (*Calyptorhynchus lathami lathami*)	Vulnerable	Vulnerable	Potential
Latham's snipe (*Gallinago hardwickii*)	Vulnerable, Migratory	Special Least Concern	Potential
White-throated needletail (*Hirundapus caudacutus*)	Vulnerable, Migratory	Vulnerable	Likely
Australian painted snipe (*Rostratula australis*)	Endangered	Endangered	Potential
Migratory Birds			
Fork-tailed swift (*Apus pacificus*)	Migratory	Special Least Concern	Likely
White-throated Needletail (*Hirundapus caudacutus*)	Migratory, Vulnerable	Vulnerable	Likely
Common Sandpiper (*Actitis hypoleucos*)	Migratory	Special Least Concern	Potential
Sharp-tailed Sandpiper (*Calidris acuminata*)	Migratory	Special Least Concern	Potential
Pectoral Sandpiper (*Calidris melanotos*)	Migratory	Special Least Concern	Potential
Latham's Snipe (*Gallinago hardwickii*)	Migratory, Vulnerable	Vulnerable	Potential
Mammals			
Koala (*Phascolarctos cinereus*)	Endangered	Endangered	Potential
Reptiles			
Yakka skink (*Egernia rugosa*)	Vulnerable	Vulnerable	Potential
Grey snake (*Hemiaspis damelii*)	Endangered	Endangered	Potential

Notes: EPBC Act 'Marine' listed species, and species unlikely to be present within the Project Area, have been excluded from Table 3. Likelihood of occurrence determination made in Boobook 2025.

4. Project Activities

4.1. Gas field infrastructure

4.1.1. Wells

Santos proposes to drill and operate up to 24 CSG production wells in the Project Area.

A well lease will be constructed to accommodate drilling, well completion equipment and support services. Typically, well construction will involve a drill rig and other equipment including storage for fuel, chemicals, drilling fluids, produced water and raw water supply. An operational production well lease will generally include gas and water metering, separation and filtering equipment, electrical and control systems and water and gas pipeline connections.

Well locations will be selected based on proximity to the subsurface target location and with consideration to environmental, cultural heritage, landholder and access constraints on the surface. Locating and developing a new well and supporting infrastructure will also take into account and ensure compliance with relevant environmental legislation and Federal and State government approvals.

Hydraulic fracture stimulation will be used to complete all wells (where required). On well completion, a pump will be installed to depressurise the coal seam and facilitate gas production. Well construction will involve the use of drilling muds, and hydraulic fracturing fluids where hydraulic fracturing stimulation is required (refer to Section 4.2 for further detail). Produced water and waste drilling muds, hydraulic fracturing fluids will be generated and managed in accordance with Section 4.3.4.

CSG production wells will be designed, constructed and decommissioned in accordance with the "*Code of Practice for the construction and abandonment of coal seam gas and petroleum wells, and associated bores in Queensland Version 2*" (the Code). The Code outlines mandatory requirements and good practice to reduce the risk of environmental harm. Production wells will be designed to:

- prevent any interconnection between target hydrocarbon-bearing formations and aquifers;
- ensure that gas is contained within the well and associated pipework and equipment without leakage;
- ensure zonal isolation between different aquifers is achieved;
- not introduce substances that may cause environmental harm; and
- production wells will not be installed within 90 metres (m) of a landholder bore.

Well leases will be constructed for each well to create a stable working platform suitable for safely undertaking drilling, and completions and well operations. The lease incorporates safe access and areas for the drilling rig, generators, fuel, chemical, casing and pipe storage, and associated portable buildings. Each well pad is also designed for subsequent operations like hydraulic stimulation generally incorporates the following standard features:

- a compacted and stable drilling rig hard stand area;
- tanks for management and disposal of drill cuttings and the recirculation of water into the mud system;
- an access road or track with clear entry and exit points for vehicles;
- mobile wastewater treatment systems for the disposal of ablutions waste from well site offices and accommodation;
- water storage tanks or ponds for drilling and / or hydraulic fracturing water and flowback fluid; and
- proppant and chemical storage for drilling and / or hydraulic fracturing operations.

The size and layout of the well lease will vary depending on a number of factors such as the number of wells to be drilled (multi-well leases), the size and type of drilling rig, the number of hydraulic stimulation stages, the need for on lease water storage, the program for completion of the well(s) and the surrounding environment / topography.

The lease size required to accommodate a single petroleum well is typically 1 to 1.25 ha. Minimum disturbance leases (consisting of matting placed on the ground to create a hardstand surface) would be used where topography and vegetative cover allows. Minimum disturbance leases can be less than one ha. Where additional area is needed to accommodate infrastructure such as a water tank, single well leases may be up to 1.5 ha in size. Well leases located on native slopes exceeding 4% require cut and fill construction techniques, and these areas will require leases greater than 1 ha in size.

Multi-well leases may be necessary to maximise gas recovery, reduce overall disturbance associated with multiple single leases, and / or accommodate landholder requirements. These may be up to a maximum 3 ha in size, resulting in a larger footprint per lease area but a reduced footprint per well.

Well lease construction methods vary depending upon the land system and soil type on which the well is to be drilled. Typically, topsoil with rootstock and vegetation is cleared and stockpiled for use later in restoration. Material sourced from borrow pits is imported where required to construct the lease pad, access roads and associated infrastructure. Borrow material is watered and rolled to achieve adequate compaction, provide a stable and trafficable surface and reduce dust. The risk of erosion is managed through the well pad design (i.e. surface water run-on and run-off) and engineered management controls. Considerations for siting and constructing well leases and associated infrastructure include:

- selection of non-sloping well leases is preferable (this minimises the requirements for cut and fill or importation of borrow material to level the site);
- employment of additional management controls in sensitive areas such as floodplains and proximity watercourses (where required);
- constructing erosion control measures where appropriate (i.e. diversion banks or berms);
- capping of sensitive terrain to preserve the underlying soils where required;
- avoiding environmentally sensitive and restricted areas and ensuring compliance with terms of the Santos Cultural Heritage Management Plan (CHMP); and
- minimising disturbance of native vegetation and fauna habitat.

Where practicable, minimum disturbance leases may be used as an alternative to traditional lease construction.

4.1.2. Access tracks

Construction of typical access roads (typically 10 - 15 m wide) will be required to accommodate heavy and light vehicles associated with project activities. Wherever practicable, existing access tracks will be upgraded for use, and new access roads will be co-located with gas and water gathering (and electrical and communications infrastructure) corridors wherever practicable to reduce the overall construction footprint.

Access tracks are required for construction activities. Where practicable, existing access tracks would be upgraded for use and new access tracks would be co-located with gas and water gathering (and electrical and communications infrastructure) corridors to reduce the overall construction width required. Co-located linear infrastructure corridors may be wider than 20 - 35 m where several services are co-located, and they typically do not exceed greater than 40 m total width, other than when several services are co-located.

Typically, bed level crossings are used for access tracks. Design and construction vary depending on the land system, expected frequency of use, traffic loadings and safety requirements. Where required they are constructed to withstand heavy and light vehicles associated with the activities and would typically be 10 - 15 m in width.

Access track crossings would be designed to comply with Queensland's existing framework for "waterway barrier works" under the *Planning Act 2016* (Qld), which is administered by DAF; only "accepted development" which

complies with specific standards may be carried out without a permit from the DAF. These standards include (but are not limited to):

- development work minimises impacts to waterways and fish habitat through the following actions:
  - minimise disturbance to the instream bed and banks e.g. use geofabric as a work base;
  - if it is necessary to remove vegetation, aim to cut vegetation no lower than ground level and leave the root in the ground to aid in stabilisation. If deep excavation is required during construction the roots may only be removed within the construction footprint area;
  - minimise the area of land disturbed or compacted;
  - ensure the least volume of soil or sediment is disturbed;
  - limit the use of machinery within waterways;
  - use machinery no greater than the capacity required for the purpose;
  - implement sediment and erosion protection measures; and
  - undertake works at times that minimise disruption to fish migration and fish habitat.
- impacts on water quality are to be minimised by undertaking the works to the standard set out in the current version of the Best Practice Erosion and Sediment Control, published by the International Erosion Control Association (IECA), Australasia (and in accordance with relevant EA conditions).
- for any part of the waterway bed or banks adjacent to the works that has been altered by the waterway barrier works, the site is restored and / or rehabilitated so that as a minimum:
  - stability and profiles of the bed and banks are re-instated to natural stream profiles and stability upon completion of the works;
  - the waterway bed is retained with natural substrate or reconstructed with substrate comparable to the natural substrate size and consistency; and
  - site conditions allow the rapid re-establishment of native vegetation and cover or native species are replanted to re-establish the natural plant community.

4.1.3. Gas and water gathering network

A construction right-of-way (RoW) approximately 20 - 35 m wide will be required for standard gathering line / pipeline construction including the excavation of a trench, pipeline laying, backfilling the trench, and reinstatement of the RoW.

Santos will utilise new and existing water and gas gathering lines / pipelines to transfer produced gas and water from the proposed CSG wells to existing approved water and gas processing facilities. These facilities are located on adjoining Santos owned and operated tenures in the broader Roma Gas Field. Gathering infrastructure RoW corridors are typically 20 - 35 m in width for individual services. As discussed in Section 4.1.2, where practicable, access tracks will be co-located with gas and water gathering (and electrical and communications infrastructure) corridors to reduce the overall construction width required. Co-located linear infrastructure corridors may be wider than 20 - 35 m where several services are co-located, and they typically do not exceed greater than 40 m total width, other than when several services are co-located.

During the field development planning process, Santos will assess stabilisation risks for pipeline watercourse crossings to inform crossing design. The assessment considers:

- watercourse cross-section geometry at the crossing location;
- watercourse catchment area; and
- watercourse longitudinal slope (bed slope / channel slope) at the crossing location.

The assigned risk level is a function of cross section geometry and flow erosivity (i.e. crossings with steeper banks and larger catchment areas / greater flow have higher risk levels). The crossing design is chosen based on assigned risk. Standard designs for low, medium and high-risk crossings are appended to this EMP in Appendix 2.

Gathering lines and pipelines would be constructed of high-density polyethylene (HDPE) pipe of 100 - 1000 millimetres (mm) in diameter. Low point drains and high point vents would be installed at intervals along the gathering lines to allow drainage of condensate from gas, and the release of minor entrained gas from produced water as required.

Gas gathering lines would be designed and constructed to comply with Australian Standard *AS/NZS 2885 – Pipelines Gas and Liquid Petroleum* (Standards Australia, 2018) and the Australian Pipeline and Gas Association (APGA) *Code of Practice Upstream PE Gathering Networks – CSG Industry*, *Version 6* (2024).

Gathering lines would be constructed using a combination of conventional earthmoving equipment and specialist pipeline trenching and lifting equipment. Gathering lines would be constructed using a standard construction methodology including:

- clearing and grading;
- trenching and padding;
- pipe stringing, laying and welding;
- backfilling and reinstating natural ground level; and
- installing marker signs as required.

Pipelines would be preferentially built during periods of no stream flow; as such, no impacts to natural stream flows are expected.

Once installed, the construction corridor would be rehabilitated back to the minimum width (termed the 'operational RoW') required for operation and regular inspection of the pipeline. Groundcover would be re-established along the operational RoW.

4.1.4. Other incidental activities

Supporting infrastructure, which may include small temporary workers camps (less than 2 ha), power and communications lines (co-located with gas gathering lines and pipelines) and other incidental petroleum activities such as borrow pits and laydown areas (less than 1 ha).

A small, temporary camp site may be required to provide accommodation for drilling, completions and associated support personnel. Camp sites are located within proximity to well leases to minimise travel related risks. Construction methods for camps are similar to those employed for laydown areas. The camp site location is flexible and will be constructed in an area where disturbance of native vegetation, particularly woody vegetation can be avoided or minimised. The camp location will also take into consideration landholder requirements, such as the potential for noise and dust generation and other operational hazards such as traffic. The camp will include a sewage treatment plant and associated irrigation area.

Other ancillary infrastructure and incidental petroleum activities required to support the construction activities for the Project may include:

- laydown, stockpile, storage and vehicle cleaning areas;
- storage tanks;
- power and communication lines;
- borrow pits;
- fencing;
- environmental monitoring equipment and management controls;

- geophysical, geotechnical, geological, topographic, cadastral and ecological surveys; and
- external infrastructure, such as transport, energy supply, water supply and communications.

4.2. Well drilling and completions

4.2.1. Site set up

The well lease needs to provide a stable working platform suitable for safely undertaking drilling and associated activities such as hydraulic fracturing and well workover (i.e. well maintenance) operations. The lease area provides adequate space for the drilling and hydraulic fracturing vehicles and equipment, generators, fuel and chemical storage, casing and pipe storage and associated portable buildings. The well lease area generally incorporates the following standard features:

- a compacted and stable hard stand area;
- an access road or track with clear entry and exit points for vehicles;
- mobile wastewater treatment systems for the disposal of ablutions waste from well site offices and accommodation;
- water storage tanks or ponds for hydraulic fracturing make up water and flowback fluid; and
- proppant and chemical storage for drilling and / or hydraulic fracturing operations.

4.2.2. Drilling

Wells would be constructed in accordance with the Code. The Code mandates that the design basis for wells must:

- consider casing setting depths that take into account aquifer and production zone locations;
- provide for installation of pressure control equipment (PCE) based on risk assessment, e.g. Blowout Preventor (BOP) equipment to American Petroleum Institute (API) standard 53;
- use appropriate casing weight and grade with appropriate casing running procedures. This includes consideration for casing corrosion risk and connection suitability;
- use appropriate well design and construction materials;
- use appropriate casing centralisation;
- use engineered cement slurries with both appropriate and effective cement placement techniques;
- ensure all fluids produced from the well travel directly from the production zone to the surface without cross contamination; and
- ensure they are constructed, maintained and abandoned in such a manner that it can be demonstrated there are two verified well barriers between a hydrocarbon bearing or abnormally pressured formation and the surface.

Drilling fluids and additives used during drilling activities will be used in accordance with the mandatory requirements and good practice guidelines outlined in the Code as well as the Safety Data Sheets (SDS) provided with each fluid / additive. With relation to drilling fluids, the mandatory requirements include:

- drilling fluids must be selected and managed to ensure all manufactured products used during well procedures are in accordance with the manufacturer’s recommendations and relevant SDS; and
- the name, type and quantity of each chemical used on each well throughout the life of the well must be recorded.

Good industry practice for drilling includes:

- drilling fluid should be a carefully monitored and controlled mixture designed to achieve best drilling results and ensure efficient removal of formation cuttings;
- control formation pressures;
- minimise damage to formations;
- petroleum tenure holders should ensure that the drilling fluid selected is appropriate for the well design to manage any locally experienced drilling problems and the geological conditions likely to be encountered;
- the use of biodegradable substances in the drilling fluid is preferred;
- the source of water for all well procedures (drilling, completion, workover and abandonment) should be recorded for future well monitoring purposes;
- products should be chosen, stored, and used at concentrations that minimise the risk of causing environmental harm;
- personnel, including contractors, should be aware of the environmental impact and emergency spill procedures for the products and substances in use on site; and
- petroleum tenure holders should use established, effective drilling practices to achieve a stable, uniform and, as far as possible, in-gauge hole.

During drilling, fluid is pumped through the inside of the drill string to the drill bit and back up the outside of the drill string to lift drill cuttings out of the hole. The drilling fluid / drill cuttings are then channelled into tanks where the drill cuttings are separated from the drilling fluid, and then drilling fluid is recycled down hole in a continuous process. Drilling fluids are also typically recycled onto other wells in a multi well scenario. Casing, which is concentric steel pipe, is installed into the well and cemented in place to provide the structural integrity and well integrity barriers for the life of the well. A typical drilling rig layout and lease and access roads required for drilling operations is shown in Figure 5.

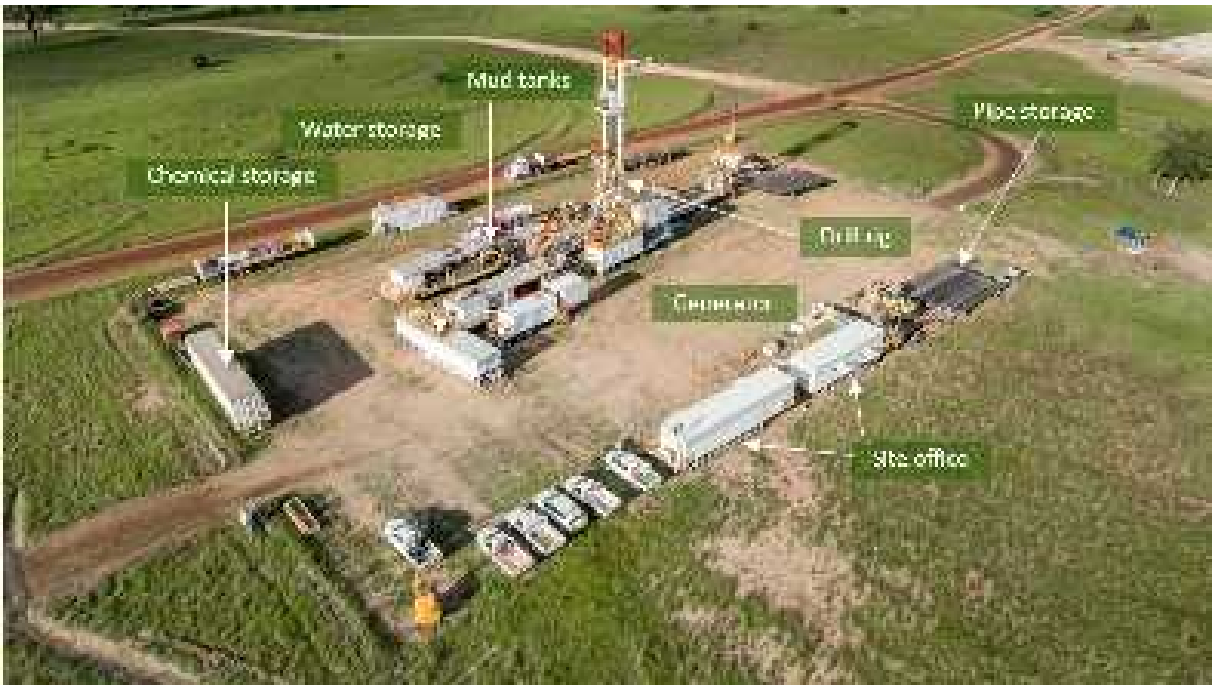


Figure 5: Example of well lease and drilling rig

Wells are drilled to such a depth as to reach the gas formation targets through a series of ‘hole sections’. Each hole section serves a specific purpose for well construction and well integrity as outlined below.

1. A shallow Conductor Hole Section may be drilled and cased to stabilise shallow surface sediments from the drilling of subsequent drilling phases (i.e. it prevents the loose soils from caving into the borehole). A conductor casing string is installed by exception and only if required based on local conditions for well construction purposes.
2. The Surface Hole Section is drilled and cased to achieve regulatory requirements for isolating shallow aquifer systems (if present) and to stabilise the well for subsequent hole sections. The hole section is drilled with drilling fluid that exerts a higher hydrostatic pressure on the rock face, than what is present naturally in the rock pore space, ensuring formation fluids do not enter the wellbore. The surface casing is cemented in place from bottom to top to ensure effective pressure isolation of shallow aquifers (if present) from deeper hydrocarbon bearing zones encountered in subsequent hole sections. Finally, it is pressure tested to simulate well life design specifications.
3. After the surface casing is installed, a Blowout Preventer (BOP) is installed onto the well at surface to provide a second barrier along with the drilling fluid. At the commencement of drilling the next hole section (i.e. after approximately 3m of new hole drilled), a Leak Off Test (LOT) or Formation Integrity Test (FIT) is conducted on selected representative wells to determine the rock strength in the local area. This will ensure the well is drilled without risk of the rock failing due to exerted pressure.
4. The Production Hole Section is drilled to intersect formation targets and is drilled to a depth below the lowest hydrocarbon bearing target. The hole section is typically drilled with drilling fluid that exerts a higher hydrostatic pressure on the rock face, than what is present naturally in the rock pore space, ensuring formation fluids do not enter the wellbore.
5. Open hole logging may be performed after the production hole section has been drilled and prior to the production casing being run. Wireline logging operations for Santos are undertaken by a number of different industry recognised specialist service companies. Different energy sources are lowered into the well via wireline including density, neutron, acoustic and electrical logging tools. Calculations based on the received signals are undertaken to evaluate the different parameters of the formation such as porosity, permeability, rock type and hydrocarbon saturation.
6. After the production hole is drilled and logged, production casing is installed to the total depth of the wellbore, cemented in place and pressure tested. The purpose of the production casing is to provide hydraulic isolation between the hydrocarbon reservoirs and all other overlying formations, to contain the pressurised fluid used to hydraulically stimulate the target zones, and to provide effective wellbore integrity for well production. The steel casing is manufactured and certified to strict Quality Assurance / Quality Control (QA / QC) standards and installed in a configuration specific for each well.

4.2.3. Casing and cementing

Casing design scenarios are modelled through specialist software to simulate the design loads for collapse, burst, tensile failures, and tri-axial failures observed during the operational, stimulation and production phases. Results of this analysis direct the selection of casing grade and weight. All casing is tested by Santos and the contractor using specific Quality Assessment and Quality Control (QA / QC) procedures prior to installation to ensure compliance with the Santos engineering and regulatory specifications.

After each hole section is drilled, the steel casing is cemented in place. The correct composition, volume and placement of cement is the construction aspect that is most important for well integrity. The cement serves two purposes – it provides protection and structural support to the casing while also providing zonal isolation between different formations, including aquifers (if present). The cement and required additives are high quality materials produced specifically for oil and gas operations with the materials selected designed to address the specific conditions of a particular well.

Santos and the cementing contractor must ensure the cementing material and equipment is adequate to achieve the well design objectives and ensure effective isolation. Prior to pumping the cement, it must be lab tested against the engineering design and actual downhole conditions such as temperature. The cement is tested using specific QA / QC procedures and includes the following:

- slurry density;
- thickening time;
- fluid loss control;
- free fluid;
- compressive strength development;
- fluid compatibility (cement, mix fluid, mud);
- sedimentation control;
- expansion or shrinkage characteristics of the set cement;
- static gel strength development; and
- mechanical properties.

Cased hole logs may be run on selected wells as required inside the cemented casing to validate the quality and integrity of the cement sheath bond to the casing and to the formation. Typically, these logs include:

- gamma ray - measures naturally occurring gamma radiation to characterise the rock or sediment in a borehole;
- casing collar locator - a magnetic device that detects the casing collars; and
- cement bond log - an acoustic device used to measure the properties of the cement sheath and the quality of the cement bond between the casing and the formation.

The cement bond log is an acoustic device that can detect cemented or non-cemented casing. It works by transmitting a sound or vibration signal into the casing, and then recording the amplitude of the arrival signal. Casing that has no or poor-quality cement surrounding it (i.e. free pipe) will have large amplitude acoustic signal because the energy remains in the pipe and isn't transmitted to the formation. Casing that has a good cement sheath (fills the annular space between the casing and the formation and effectively couples the two) will have a much smaller acoustic amplitude signal as the energy is absorbed by the formation due to effective acoustically coupling.

Santos uses experienced contractors to identify the key features of the cement quality to ensure the integrity of the cement seal for each casing pipe sheath. If cement is not of sufficient height or quality and deemed by the operator to be unsafe for continued operations, hydraulic stimulation will not proceed until it can be effectively remediated.

4.2.4. Hydraulic fracture stimulation

Due to the characteristic of the geological formations located within the Project Area, all proposed CSG wells will require hydraulic fracturing to produce commercially viable gas volumes / rates.

This process has been used extensively in the petroleum industry since 1947. Santos has successfully used this technique on wells in the Cooper Basin for over 50 years. Santos is currently performing the process in many basins around Australia, including for CSG wells within Santos' approved GLNG (EPBC No. 2008/4059), GFD (EPBC No. 2012/6615) and Towrie (EPBC No. 2021/8979) projects in the Surat Basin.

Hydraulic fracture stimulation is not part of the drilling process but is a completion technique applied after the well is drilled and is typically performed on newly installed production wells. The intent of hydraulic stimulation is to place highly conductive channels into the target reservoir that increase the permeability of the coal seam immediately adjacent to the well and improve flow of groundwater and gas into the well bore. Production wells may be subject to multiple fracturing events over their operational life.

The stimulation process involves injecting hydraulic fracturing fluids (water, sand / proppant and minor chemical additives) at high pressure into a cased wellbore. It is usually conducted over a number of intervals along the

production zone of the well. The proppant keeps the fractures open once the pump pressure is released which improves the productive potential of the well.

Hydraulic fracturing is a predominantly physical process in which hydraulic pressure is applied to a fluid to increase the effective permeability of the formation rock. The process creates narrow pathways (fractures) in the target formation to improve its ability to transmit gas back to and then out of the well.

After a pre-fracturing assessment and hydraulic fracturing design, onsite activities include site setup, perforation of the well casing and cement into discrete targeted sections of the cased bore (to access most viable gas bearing formation), injection of hydraulic fracturing fluid and flowback of the injected fluid. These processes are described in the following sections.

4.2.5. Pre-fracturing assessment and design

Operators investigate the subsurface conditions, including hydrogeological and mechanical properties of the target and surrounding geological units, to design the hydraulic fracturing program to strategically identify and reduce the possible risks involved (IESC, 2014).

To understand the geological formation and priorities for the hydraulic fracturing program, key aspects of subsurface characterisation (Beckwith, 2010) include:

- describing all geological units;
- assessing target formation permeability;
- analysing subsurface distribution of stresses and faults; and
- assessing fluid loss characteristics.

The hydraulic fracturing program is designed after the subsurface characterisation is complete. Part of this design is the prediction of fracture growth within the target zone. Specific hydraulic fracture simulation software is used to predict the geometry of fractures (fracture length, conductivity and height), while the orientation is determined from the in-situ stress field (IESC, 2014). Typical inputs to numerical models include volume and properties of the fluid and proppant, closure stress, pressures within pores, permeability, mechanical properties and layer geometry.

A number of considerations influence the final design for each stimulation treatment, including:

- depth and thickness of the formation target;
- lithology of formation target and bounding layers;
- minimum and maximum horizontal stress across all layers (target and bounding);
- thickness of the seals above and below the target reservoir formation;
- porosity and permeability of the formation;
- pore fluid saturations (percentage of formation pore volume occupied by oil, gas or water);
- pore fluid properties (e.g. density, water salinity);
- well performance data, including flow rates, formation pressure and produced fluid properties;
- formation boundaries (as identified from seismic data);
- bulk rock density, elastic properties and compressibility;
- natural fracture networks; and
- stress field analysis to determine the maximum principle stress direction and the minimum principle stress direction.

4.2.6. Well perforation

Holes are created in the well casing pipe at locations which align to the centre of the coal seams targeted for gas production (these are referred to as 'perforations'). A section of the casing pipe typically less than one metre long is selected for perforation to allow the well to discretely access the coal seam. They are generally aligned slightly below the midpoint of the coal seam being fractured to accommodate the tendency for upward propagation of the fracture (in the direction of least stress).

The perforations, or holes, are created by blasting a jet of water or fine sand / water mix at high pressure at the pipe wall or using small explosives. The perforations penetrate the steel casing and the cement grout layer, and into the coal seam by up to half a metre.

4.2.7. Acid injection

If the coal seam cleats[1] are found to be naturally filled with calcite mineral (calcium carbonate) then a diluted acid mix is injected through the perforation holes into the coal seam to dissolve the calcite away prior to hydraulic fracturing. This is found to be necessary in less than 10% of CSG wells only. It is carried out after completion of the well casing and directly prior to hydraulic fracturing operations, typically completed by the fracturing spread.

The selected coal seam can be pressurised with a 15% solution of hydrochloric acid (with preservatives), with typical volumes pumped of approximate 1 cubic metre (m^3). Hydraulic fracturing can then be carried out.

4.2.8. Hydraulic fracturing fluid

Hydraulic fracturing fluid generally consists of three parts: base fluid (the largest constituent by volume), additives and proppant. Base fluid (water) and proppant (sand) make up around 99% of the hydraulic fracturing fluid, with additives making up the remaining 1%. The purpose of the proppant is to keep the fractures open once the pump pressure is released which improves the productive potential of the well. Each chemical additive serves a specific, engineered purpose such as:

- viscosity: gelling agents and crosslinkers are added to the water to provide viscosity to enable the proppant material such as sand or ceramic beads to be transported down the well and into the created fractures;
- breakers: added to reduce the viscosity of the fluid when flowing back the well, enhancing recovery of fracturing fluid and additives to surface;
- friction reduction: to reduce the force required to pump the fluid, friction reducers are added, making the fluid more 'slippery' and easier to pump at the high pressures and rates required to create the fracture network;
- biocide: biocides or disinfectants are added to reduce the amount of naturally occurring microbes or organisms present in the water which can impact fluid stability and also to ensure they will not enter and contaminate the reservoir;
- scale and corrosion: scale and corrosion inhibitors are added to prevent deposition of mineral scales and to prevent corrosion of the steel casing or tubing; and
- surface tension: surfactants or surface tension modifiers are added to assist the back flow of fluids from the formation.

The chemicals used in hydraulic fracturing (and drilling) are subject to a chemical risk assessment process (under the *Roma Phase 7-7B-SD20 Development Chemical Risk Assessment Framework* (CRAF) (Santos, 2025a)).

4.2.9. Stimulation process

A number of steps are involved in the hydraulic stimulation process to pump the designed fracture treatment. These include:

[1] Coal seams have natural fractures, known as cleats. Cleats act as a major transport system for gas and water flow within a coal seam.

- Diagnostic Fracture Injection Test (DFIT) to validate and update the proposed stimulation design. This involves injecting a small volume of water, shutting down the surface pumps and monitoring pressure decline to evaluate near wellbore entry friction, fracture gradient, fluid leak off, and minimum horizontal stress. This stage is typically only performed in the exploratory/ appraisal stages of development, or until localised fracture characteristics are defined;
- drift run to check there are no obstructions in the wellbore;
- in the case of Plug and Perforation stimulation conveyance method, perforation of stimulation stage one (deepest stage) to gain access to the reservoir from the wellbore;
- in the case of coiled tubing stimulation conveyance method, all stimulation stages are perforated before the fracturing crew and equipment arrive at the wellsite;
- main stimulation treatment consisting of pad volume injection, slurry stage injection(s) with increasing proppant concentrations, and flush stage to displace last slurry stage through the perforations and into the fracture;
- mechanical isolation of the completed fracture stimulation stage;
- perforate the next stage to be hydraulically stimulated and repeat the processes above until the final fracture stimulation stage is completed;
- remove all mechanical isolation devices by milling out the mechanical isolations; and
- flowback well to clean up fracture stimulation fluids and monitor hydrocarbon production.

Hydraulic stimulation operations typically take 1 to 2 days to complete at a CSG well. Hydraulic fracture stimulation initial fluid flowback may occur for a period of 1 to 30 days, depending on the reservoir and clean up profile before being connected into gathering network.

4.2.10. Injection and isolation of hydraulic fracturing fluid

Once the well has been perforated in the depth interval that is to be hydraulically fractured, fluid injection is performed.

Hydraulic fracturing fluid is injected into the well at the surface through the wellhead. The perforation zones are isolated by either a coiled tubing unit with packers, a bridge or frac plug set by a wireline operator, or by a baffle and ball-drop system.

Following isolation of the perforated zone, injection of fluid commences. The hydraulic fracturing fluid is forced into fractures and remains within the target reservoir. The bore design and construction, comprising multiple physical barriers such as cement and steel casing, ensure that the hydraulic fracturing fluid does not come into contact with overlying strata, including aquifers. The integrity of these barriers is tested before hydraulic fracturing activities are undertaken.

The injection pressure, injection rates, slurry volumes, fluid viscosity, additive concentrations and proppant concentration are monitored in real-time during each injection. Downhole pressure information is also recorded and reviewed during the hydraulic fracture stimulation operation. Down-hole pressures are calculated based on wellhead pressure, fluid density, casing diameter and the depth to the target formation. When a coiled tubing unit is used as part of the operation pressure is monitored: inside the casing above the top packer of the tool, inside the coiled tubing delivering the fluid and inside the wellhead at surface.

Once the entire hydraulic fracturing operation is complete for a well, a completions rig or coiled tubing unit will generally mill out the bridge plugs or baffles that were installed for the hydraulic fracturing operation, to clear them from the well.

4.2.11. Return of injected fluid and water (flowback)

Once the injection process is complete, the internal pressure of the rock formation typically causes fluid to return or “flowback” to the surface through the gas well. Flowback fluid contains the dissociation or broken-down products of the injected chemicals plus naturally occurring geogenic compounds.

The volume of the injected fluids which is recovered as flowback is variable depending on the formation, treatment execution, and fluid type used. Immediately after stimulation, typically 0% to 20% of the stimulation volume is recovered within a few days of the completion of the fracturing operation. The well then continues to flowback once connected into the gathering network, where often >100% of the stimulation volume is recovered.

The flowback water is typically temporarily stored tanks before treatment for reuse or disposal.

4.2.12. Flowback fluid management

The recovered fluid, or flowback, may be treated and stored for reuse in the next hydraulic fracturing event. Flowback fluid unable to be reused would be disposed of at a licensed facility or transferred to one of Santos’ engineered treatment facilities for treatment and management under existing approvals for those facilities.

4.2.13. Wells

Once completed and connected to gas and water gathering infrastructure, wells would operate continuously on a 24-hour basis. Operating wells would be monitored and controlled remotely. The wells would also have automated shutdown systems in the event of non-routine operating conditions. As per the requirements outlined in the P&G Act, the volume of produced water will be monitored and recorded and provided to the DNRMMRRD in accordance with statutory obligations.

Ongoing activities at well sites during operations would include routine inspections and maintenance of wellhead infrastructure. Maintenance activities would include repair or replacement of downhole pumps and pump components, clearing of blockages from within the wells that may be limiting production capacity, and other actions as necessary to improve production efficiency.

Well maintenance activities usually require the use of a workover rig (which is smaller than a drilling rig) and are contained within the fenced lease area for the well.

4.2.14. Completions and connections

At the end of the clean-up phase, a workover rig would be required to install the production tubing and associated completion equipment such as packers, nipple profiles, tubing hanger, and the production tree, in preparation for connecting the well for inline production flow.

Production from each well is controlled with a metering skid which includes features such as overpressure protection, flow rate control, well safety shut-in, pressure and temperature monitoring.

After the drilling, stimulation, completion and connection activities are complete, the well lease is transitioned towards the operational phase which involves:

- backfilling the well conduits
- removal of drilling and completions equipment and waste; and
- pumping out additional water from the turkey’s nest (if installed) and removing the liner or removal of the temporary storage tank.

4.3. Production Operations

4.3.1. Wells

Once completed and connected to gas and water gathering infrastructure, wells will operate continuously on a 24-hour basis for an anticipated 30 - 50 years.

An operational production well lease will generally include gas and water metering, initial gas and water separation and filtering equipment, electrical and control systems, and water and gas pipeline connections (and tanks where on site water storage is required).

Operating wells will be monitored and controlled remotely. Each well has an automated shutdown system in the event of non-routine operating conditions.

Ongoing activities at well sites during operations will include routine inspections and maintenance of wellhead infrastructure. Maintenance activities will include repair or replacement of downhole pumps and pump components, clearing of blockages from within the wells that may be limiting production capacity, and other actions as necessary to improve production efficiency.

Well maintenance activities usually require the use of a CSG well workover rig (which is smaller than a CSG well drilling rig) and are contained within the established lease area for the well.

4.3.2. Gas processing

Gas produced from the Project Area is planned to be transferred to the existing Roma Hub Compressor Station 2 (R-HCS-02) located on PL 314 via new and existing gas gathering infrastructure.

R-HCS-02 and PL 314 are owned and operated by Santos. Petroleum activities located on PL 314 (including compression) are authorised be EA EPPG00898213 and EPBC Act Approvals 2008/4059 and 2012/6615. In the future, gas from the Project Area may potentially be processed elsewhere, subject to environmental approvals.

4.3.3. Gathering lines and pipelines

Gas and water gathering lines and pipelines will be monitored, inspected, and maintained during operation. This may include inspection of low point drains and high point vents as part of routine field maintenance activities, and vegetation slashing within operational RoWs.

4.3.4. Produced water management

The Project peak produced water forecast is estimated at 0.24 Mega L/day in 2028. The majority of produced water generated from the Project is proposed to be transferred to existing approved water storages and treatment facilities located adjacent to the Project Area, namely on PLs 314 and 315, via new and existing water gathering infrastructure. Produced water is then proposed to be transferred to existing approved water treatment facilities located on PL 314, where the water will be processed through a fines and sludge removal facility before being further processed, or bypassed around, the Roma Reverse Osmosis Plant (ROP) to meet re-use criteria in accordance with Qld End of Waste Code Irrigation of Associated Water (ENEW07546918). The Roma ROP is located approximately 25 km northwest of the Project Area.

Adequate water and brine storage and treatment capacity has been assessed by the WMP to be available on adjacent tenures to manage peak water and brine production from the Project. Further, Santos have established procedures to prevent uncontrolled discharge of produced water (i.e. restriction of production by “turning down” or “shutting-in” wells). In future, produced water from the Project Area may be processed or sent elsewhere, subject to relevant approvals.

4.3.5. Waste management

Drilling fluids would be contained on the well lease in tanks during drilling and then either re-used (or recycled and reused) at another well site or disposed of offsite at a licenced waste management facility. Residual drilling

material (RDM) would be stored in tanks during drilling and then, if agreed with the landholder, may be disposed of on-site in accordance with EA conditions, where:

- RDM meets approved quality criteria, and the mix-bury-cover method is used; or
- RDM is certified by a suitably qualified third party as being of acceptable quality for disposal to land by a proposed method, and that environmental harm will not result from the proposed disposal.

The potential risk to MNES receptors from application of RDM to land has been assessed to be low given the following:

- EA conditions adequately regulate land application techniques and a methodology to avoid environmental harm has been developed by a suitable qualified third-party
- the physical and chemical properties of the RDM is largely benign (The Project's CRAF, Santos, 2025a)
- potential application areas will be remote from surface water receptors, and surface watercourses are ephemeral; and
- there is large vertical separation of groundwater receptors from surface activities.

Although no environmental receptors are predicted to be at risk of being impacted from application of RDM, assessments and monitoring will occur to demonstrate that environmental outcomes have been achieved. Assessments and monitoring will include:

- sampling and characterisation of the RDM; and
- soil samples to characterise baseline conditions of each representative soil type within the Project Area for which land application of RDM is proposed.

Alternatively, RDM may be transferred by road to existing approved waste management facilities on adjoining tenures, or to another licensed waste facility for management.

Further, early warning, trigger thresholds and limits for managing the risk of adverse impacts to surface water and groundwater resources from the beneficial reuse of produced water or from land application of RDM is provided in Section 6.1.

4.4. Decommissioning and Rehabilitation

Santos will undertake rehabilitation in accordance with the *Santos Roma Phase 7-7B-SD20 Development Rehabilitation Monitoring Plan* (RMP) (Santos, 2025b).

4.4.1. Wells and well pad rehabilitation

Santos has developed a catalogue of standardised construction designs that focus on long-term stability for the operational life of the well, generally greater than 20 years. Using standardised designs Santos achieves consistent and high-quality execution whilst minimising future disturbances. Where standard designs are deemed not fit for purpose, site-specific designs are developed.

All wells are monitored throughout operations using a risk-based inspection and maintenance program. Santos has a standardised well inspection program, whereby every well lease is inspected on a planned / scheduled basis. Inspections target a range of environmental aspects / criteria for assessment. Maintenance works are scheduled by the civil works team based on priority / severity of maintenance issue.

When a well comes to the end of its productive life or if the well is drilled and deemed uneconomic to move to the 'complete' phase, a decision is made to decommission the well. The primary objective of well decommissioning is to isolate hydrocarbon and water bearing formations and eliminate migration pathways (between the reservoir, other formation / aquifers and surface). Wells earmarked for decommissioning are subject to individual evaluation to determine the most appropriate decommissioning program.

Perforated hydrocarbon zones are isolated with cement plugs and / or bridge plugs and cement bond logs (CBL) used and assessed to ensure that the cement behind the production casing is adequate to avoid migration pathways. If isolation is not evident behind the production casing following CBL integrity checking, the casing will be perforated and squeezed (with cement) to effect isolation. An additional cement plug is placed in the surface casing prior to cutting off the well head below ground level.

Consideration of the following is taken into account when plugging and decommissioning the well:

- isolate all formations that have hydrocarbon shows;
- isolate formations with different pressure regimes;
- set plugs across intermediate casing shoe (if present) to minimise the potential for cross flow between aquifer systems and hydrocarbon bearing intervals;
- set plugs across surface casing shoe; and
- at the surface set a plug in the well prior to cutting off the surface casing bowl.

Final rehabilitation of the well and lease area would include removing the well head, surface infrastructure and fencing; capping the well; filling in pits; respreading topsoil (after preparation) and revegetating the site to match its pre-disturbance vegetation type. Infrastructure that is useful to the landowner (for example pits or hardstand areas) may be handed over to the landowner in accordance with EA conditions.

4.4.2. Gathering line and pipeline RoW rehabilitation (following installation)

Gathering line and pipeline RoWs are cleared, gathering and pipelines installed, and the trench and RoW is reinstated in quick succession.

This methodology reduces exposure of unprotected subsoils, preserves topsoil characteristics e.g. structure, native seed bank etc, and minimises potential impacts from significant rainfall events.

As per relevant EA conditions, gathering line and pipeline trenches must be backfilled, and topsoils reinstated within three months after pipe laying.

RoW reinstatement is undertaken to ensure the following:

- a stable landform;
- re-profiled to a level consistent with surrounding soils;
- re-profiled to original contours and established drainage lines; and
- vegetated with groundcover which is not a declared pest species, and which is established and growing.

In addition, RoWs (including ancillary infrastructure i.e. temporary laydowns) are reinstated immediately following pipeline construction (typically within 3 months or in accordance with EA conditions) with considerations made for a range of factors including Erosion and Sediment Control (ESC), soil amelioration, fertiliser and seeding. These considerations are applied to ensure timely (within 6 months) revegetation of the pipeline RoW.

Santos has standardised watercourse reinstatement designs that are assigned to crossings based the site-specific risk profile (refer to standard watercourse designs drawings in Appendix 2). Watercourses are assessed as part of the planning phase and designs advised for each crossing based on several inputs e.g. soil type, catchment, modelled flows, bank profiles. There are five key options for reinstatement, three standard reinstatement designs (low, medium and high), a fourth site-specific design and a fifth where standard pipeline reinstatement is deemed adequate.

4.4.3. Gathering line and pipeline decommissioning

At the cessation of production, gas and water gathering lines and pipelines are isolated from the wellhead and other connection points i.e. risers and tie-in locations. Once isolated, gathering lines are drained/purged, vented and capped in accordance with the *Australian Pipeline Industry* (APIA) *Code of Environmental Practice - Onshore*

Pipelines (Revision 5) (2022) or applicable code in place at the time of decommissioning. Subsurface components of the gathering network are drained / purged, cleaned and left in-situ, and the RoW is then rehabilitated in accordance with relevant EA conditions. Subsurface pipelines proposed to be abandoned in-situ will be decommissioned in such a way to ensure that ground subsidence and the risk of contamination of the soil or groundwater is minimised. Further, where there is a potential risk of collapse or subsidence, consideration will be given to filling the abandoned pipeline with an inert substance e.g. filling the pipeline with cement to mitigate collapse at road crossing locations.

4.4.4. Access tracks

Access tracks and roads no longer required for petroleum activities will be initially offered to the underlying landholder as an asset. Any access tracks and roads unwanted by the landholder will be rehabilitated.

Access tracks would be rehabilitated or handed over to the landowner in accordance with relevant EA conditions (and State requirements i.e. in accordance with DETSI Guideline *Petroleum activities Transferring petroleum infrastructure to landholders Versions 2.01 - ESR/2020/5403*). If rehabilitation is required, rehabilitation will include removal of any gravel, ripping, levelling and re-profiling to reinstate natural contours of the land (including any watercourses) and revegetating to match the surrounding land-use. For unsealed roads and tracks the key techniques to minimise erosion and damage are good shaping (camber, elevation etc.) and good drainage. These techniques are imbedded in the standardised construction designs.

Watercourse crossings are assessed as part of the early planning phase and designs advised for each crossing based on several inputs e.g. soil type, catchment, modelled flows, bank profiles. In some instances, the standardised design is deemed unsuitable, and a site-specific design will be developed.

When planning for roads, considerations are made for existing and / or proposed adjacent infrastructure. Where construction occurs alongside adjacent infrastructure, the erosion and sediment controls marry into both pieces of infrastructure so as to not cause unwanted drainage or erosion impacts from one to the other i.e. surface waters are controlled across the entire disturbance footprint.

Roads will undergo routine maintenance grades throughout the life of the infrastructure. These will typically follow high vehicle traffic and / or wet weather. In addition to the routine maintenance, any unforeseen issues are captured and stored within a central database for priority maintenance.

4.5. Water Management and Monitoring

4.5.1. Groundwater monitoring

The groundwater monitoring requirements for petroleum tenure holders within the Surat CMA are provided as part of the UWIR Water Monitoring Strategy (WMS) which establishes baseline trends, identifies any changes within or near petroleum development areas or locations of interest and informs future improvement of groundwater modelling.

Santos under the *Water Act 2000* (QLD) developed and implemented a WMS as stipulated in the UWIR for the Surat CMA. This comprises of groundwater monitoring at over 150 monitoring locations throughout the Surat CMA. Revisions of the UWIR may amend the WMS according to the improved understanding and certainty of groundwater risks. Further, Santos undertakes baseline assessments for relevant water bores in accordance with the requirements of the Baseline Assessments Guideline (ESR/2016/1999) and *Water Act 2000* (QLD).

4.5.2. Water supply

Preference would be given to the use of non-potable water supplies for washdown, dust suppression and construction activities where economically and practically feasible.

Santos would only extract water from constructed wetlands and other farm dams for construction purposes with the permission from the landholder when water supplies are abundant. No specific monitoring of water quality within the constructed wetland is proposed given Santos' minimal use.

4.5.3. Water management

Water management will be undertaken in accordance with this EMP which has been developed to meet the requirements of the Queensland government's *CSG Water Management Policy 2012* (DESI, 2023). The *CSG Water Management Policy* guides operators in managing CSG water to comply with their EA requirements and encourages the beneficial use of CSG water in a way that protects the environment and maximises its productive use as a valuable resource.

Portable tanks used to temporarily hold produced water on site will be designed and constructed in accordance with relevant Australian Standards.

4.5.4. Produced water monitoring

Produced water quality will be monitored in accordance with the EMP, *Stimulation Impact Monitoring Program*, and as required by relevant EA conditions and the EoW Code *Irrigation of Associated Water (including coal seam gas water)* (ENEW07546918).

4.5.5. Surface water monitoring

Turbidity monitoring will be carried out during the construction and maintenance of linear infrastructure crossings of watercourses to ensure water release limits specified in relevant EA conditions are complied with. However, in accordance with EA conditions, Santos preferentially undertakes construction and maintenance of linear infrastructure crossings of watercourses during periods of no or very low flows.

4.6. Bore management

The *Water Act 2000* outlines requirements for make good obligations of a resource tenure holder for a bore located in immediately affected areas. Tenure holders must carry out a bore assessment and enter into a make good agreement with the bore owner if the bores are located within an immediately affected area. The UWIR assigns bores to tenure holders located within immediately affected areas.

Santos will comply with make good agreements required in future updates of the UWIR and undertake bore assessments as required as a result of make good obligations. Any required bore assessments will be undertaken in accordance with the Queensland government's *Bore Assessment Guideline* (ESR/2016/2005). If it is determined through the bore assessment that a bore has, or is likely to have, an 'impaired capacity' the make good agreement must provide details on the make good measures to be undertaken by the resource tenure holder to 'make good' the impact. Santos will comply with the *Bore Assessment Guideline* and any make good agreements that are determined to be required for the Project Area.

5. Implementation of EMP

This EMP will be implemented by Santos from the commencement of site mobilisations until completion of Project activities.

5.1. General environmental duty

All persons have a responsibility for their own environmental performance and compliance with the "*General Environmental Duty*" as described in section 319 and 320, chapter 7 of the EP Act:

All Santos staff, contractors, and subcontractors, are required to:

- comply with all requirements of environmental legislation;
- comply with specific requirements of the relevant EA and associated approvals / licences;

- undertake all activities in accordance with the agreed management plans, procedures, work method statements and safe work method statements (SWMS);
- ensure they are aware of the contact person regarding environmental matters;
- report any activity that has resulted in, or has the potential to result in an environmental incident or non-compliance;
- participate in investigations and undertake corrective actions (where required) to reduce or remediate environmental harm or to prevent the re-occurrence of an incident; and
- ensure they attend any environmental training provided.

5.2. Roles and responsibilities

Santos will be responsible for the implementation of environmental management procedures and mitigation measures contained in the relevant EA and its conditions, any EPBC Act decision / approval and conditions, and this EMP. All employees and contractors will meet the requirements of these documents.

Responsibility for a particular piece of infrastructure, such as a well lease, will depend on the phase of development and activities being carried out on the infrastructure at the time.

SMS operating standards and related procedures require all role levels at Santos to have an applicable role description which defines responsibilities and accountabilities including those relating to environmental and safety compliance.

Please see below the roles and responsibilities of personnel.

5.2.1. Project Director

The Project Director is responsible for:

- ensuring the SMS operating standards and EMP are established and implemented effectively throughout the life of the Project to achieve legislative compliance and acceptable standards for safety, health and environment performance;
- providing appropriate training to foster awareness of risks, ensure implementation of relevant controls and maintain acceptable standards of health, safety and environmental performance;
- encouraging all personnel to maintain acceptable standards of health, safety and environmental work practices and foster awareness of health, safety and environmental matters; and
- encouraging all incidents, events and other concerns to be reported and ensuring appropriate feedback on proposed corrective actions.

5.2.2. Construction Manager

The Construction Manager will be responsible for:

- preparation, review and approval of environmental documentation (including management plans, procedures and work instructions) prior to commencement of work;
- incorporation of key environmental aspects and associated impacts in the ECPs to maintain safety, quality and environmental standards to the highest level across the works;
- overall planning, coordination and control of the Project from inception to completion;
- maintaining safety, quality and environmental standards to the highest level across the works;
- environmentally acceptable work methods and practices and proper operation and maintenance of plant and equipment to maintain safety, quality and environmental standards to the highest level across the works;

- leading and managing all aspects of each site on a daily basis to ensure all personnel implement and adhere to the requirements of this EMP;
- promoting environmental awareness of all personnel on site;
- ensuring construction activities are undertaken in accordance with the requirements of the EMP including timely planning and effective communication;
- ensuring potential hazards are identified, risk-assessed and control measures are planned and implemented in consultation with all relevant personnel; and
- participating in environmental incident and non-conformance report investigations and ensuring that any proposed corrective and preventative action effectively implemented.

5.2.3. Environment Adviser

The Environmental Advisor is responsible for:

- ensuring that all relevant environmental approvals and permits are in place for the scope of work, prior to commencing construction activities;
- assurance for implementation and effectiveness of environmental controls and reporting required to achieve legislative compliance;
- reviewing performance against environmental objectives and performance indicators;
- reviewing implementation of ECPs to effectively minimise the potential impact to the environment as a result of construction activities;
- undertaking periodic assurance inspections to review suitable control measures were implemented in line with commitments in this EMP and provide feedback to improve ongoing implementation;
- ensuring all environmental monitoring activities and processes occur as required;
- assist in the review of environmental control measures to assess their ongoing applicability and effectiveness;
- assist all staff and contractors engaged to work on site are appropriately inducted and trained in the environmental issues and controls relevant to the Project, and provide assurance function for the following tasks:
  - being the principal source of functional environmental expertise available to Santos personnel;
  - facilitate environmental reporting requirements for the duration of the Project;
  - facilitate reporting of significant environmental incidents internally and externally (as required by regulator); and
  - participating in environmental incident and non-conformance report investigations and ensure that any proposed corrective and preventative action effectively implemented.

5.2.4. Contractors and subcontractors

All Santos contractors, and subcontractors, are required to:

- comply with legislative requirements, conditions of approval, including EA and EPBC Act conditions and other permits;
- undertake all activities in accordance with the agreed management plans, procedures, work method statements and SWMS;
- report any activity that has resulted in, or has the potential to result in an environmental incident or non-compliance;

- participate in investigations and undertaking corrective actions (where required) to reduce or remediate environmental harm or to prevent the re-occurrence of an incident; and
- attend any environmental training provided.

5.3. Inductions and training

The SMS operating standard defines expectations for ensuring employees, contractors and visitors have the necessary knowledge and skills to conduct their activities safely, in an environmentally responsible manner and without damaging plant and equipment.

All personnel working or visiting a Santos site or premise must complete the appropriate EHS inductions. Training and induction records are maintained for staff and contractors.

The following levels of induction are required:

Applicable Personnel	Induction Requirements
Santos personnel and contractors working on Eastern Queensland assets	Level 2 Onshore Induction Level 2 Environment, Health and Safety induction for Eastern Queensland
Santos personnel and contractors working in Eastern Queensland operational sites	Level 3 Site-Specific induction for staff and contractors attending the field Land Access - QLD induction Biosecurity Management at Santos
If working or driving in the field	Heat Stress training Safe Driver Training

Level Two inductions are maintained by a delegate of the sites / premises and provide information on the location's significant EHS hazards and controls implemented to minimise risk as well as the location's generic emergency response protocols. The Level Two induction is available on-line.

Level Three inductions are maintained by a delegate of the location / activity and provide information on significant EHS hazards and controls implemented to minimise risk as well as site-specific emergency response protocols. The Level Three Induction is specific to the field location.

5.3.1. Environmental awareness training

Santos and contractors must facilitate employees and subcontractors to undergo environmental awareness training through a site induction prior to the commencement of construction activities. The environmental awareness training will cover significant environmental aspects, actual or potential impacts associated with the construction activities (e.g. flora & fauna management, erosion and sediment control, waste management and hydrocarbon and chemical management) and environmental management processes, controls and onsite responsibilities.

5.3.2. Pre-start meetings

Pre-start meetings with site personnel will be convened throughout construction activities. The meetings will detail work planned for the day and cover weather forecast, site conditions, recent environmental issues / incidents and future environmental requirements to be planned / scheduled and responsibility assigned.

5.3.3. Toolbox talks

As a minimum toolbox talks will be conducted on a monthly basis, to discuss construction relevant environment matters and will be attended by staff, contractor personnel and sub-contractors. Additional site toolbox talks may also occur in the field with specific crews and may cover topics outlined for specific tasks, or as identified by the Construction workers themselves. Environmental toolbox topics may include, but are not limited to, Santos's legislative commitments, contractual requirements, emergency spill response an incident management, soil

management and erosion and sediment control, flora and fauna, water, dust, fuel and chemical management. All records of such toolbox talks and attendees register must be kept on file for auditing purposes.

5.4. Incidents and emergencies

Santos has developed the operating standards and procedures relating to incident and crisis management. These documents require a risk-based emergency and crisis management framework be in place which includes:

- a tiered response and management structure with defined criteria and authority levels for enacting each level of response;
- emergency preparedness and response plans based on credible scenarios and risks where required by legislation;
- sufficient equipment, facilities and trained personnel available to enact plans;
- scheduled emergency and crisis preparedness activities; and
- review of findings from exercises and actual events to identify learnings and opportunities for improvement.

All incidents including environmental incidents, non-conformance events and complaints are recorded electronically and managed through the Santos Incident Management System (IMS) in EHS Toolbox.

EHS incidents and near misses are investigated in order to identify the causal factors and associated underlying systemic weaknesses (root causes). The process to determine the correct level of incident investigation is outlined in the relevant SMS Operating Standard.

The DETSI Pollution Hotline will be notified by the relevant environmental advisor within 48 hours of becoming aware of various prescribed incidents including, but not limited to:

- unauthorised significant disturbance to land;
- unauthorised release of contaminants above thresholds described in the EA; and
- potential or actual loss of well integrity.

Depending on the risk, and in addition to the contractors investigation (if involved), environmental incidents may be investigated by Santos in accordance with Santos' incident investigation process.

Upon completion of the investigation, the findings and recommendations will be distributed to relevant personnel force via daily prestart meetings. Where lessons are learnt from the investigation or current procedures are identified as being ineffective or inadequate, the EMP or other pertinent documentation will be revised to include the improved procedures or requirements.

In the event a contractor performing works on behalf of Santos is involved in an environmental hazard, near miss or incident, the Santos Construction Manager must be notified. Where an environmental incident occurs, verbal notification to the Santos Construction Manager must be given as soon as possible. An incident response report is to be completed by the contractor detailing the incident itself and all identified corrective and preventative actions. Where incidents are classified as moderate or higher a more detailed investigation is to be completed with a final report provided to Santos. All reporting must be completed in accordance with the requirements and timeframes outlined in the relevant operating standard.

5.5. Complaints management

Santos records and manages responses to complaints within a Stakeholder Relationship Management System (SRMS). All complaints received are recorded in the SRMS and assigned a Complaints Handling Officer to manage the complaint. The Complaints Handling Officer is responsible for ensuring the complaint is adequately investigated, gathering facts and information to inform a recommended course of action and communicating with the complainant. All complainants are responded to verbally and then in writing with an appropriate plan to

address the complaint including remedial action if necessary. Once the complaint has been resolved Santos checks whether the complainant is satisfied. It is only then that the complaint is closed out.

All complaints received by any contractor performing works on behalf of Santos must be referred to the Santos Construction Supervisor and Environmental Advisor as soon as practicable.

5.6. Monitoring, inspections, audits and corrective actions

The Santos *Risk Management, Investigation and Assurance Operating Standard* (Standard) outlines the requirements to provide assurance that EHS systems and processes are effectively implemented, fit for purpose and are meeting relevant statutory requirements. The key assurance levels of the Standard are summarised below:

- **Level one** assurance activities performed by frontline leadership, must be conducted to ensure that front-line controls are in place and operating effectively for the management of risk; and compliance with controls is monitored and maintained.
- **Level two** assurance must be performed by management and senior management on planned basis and within defined timeframe must occur to confirm effectiveness of level one assurance and must also establish an escalation mechanism to receive reports on any material or systemic control failures or weaknesses.
- **Level three** assurance must only be conducted by independent internal parties (Functions / Divisions) and external third parties, such as the statutory financial external audit or other independent audits commissioned by Santos. This includes annual internal audit plans approved by the Audit & Risk Committee of the Board.

Assurance must be built into processes, including Core Business Processes, at appropriate intervals rather than leaving to the end of the process. Control improvement actions arising from assurance activities must be recorded, monitored, and tracked to completion. Lookbacks must be conducted for transactions approved by the Board as identified by the Managing Director and CEO.

Monitoring will be carried out in accordance with relevant EA conditions and EPBC Act approval conditions (once granted), and other relevant environmental approvals / permits.

5.6.1. Environmental inspections

Inspections will be documented on a checklist that will record whether the performance requirement for each item was achieved, and corrective actions required to achieve the performance requirement. Where the non-conformance does not present a significant risk of environmental harm, and can be corrected promptly, the corrective action will be closed out on the checklist. Where the risk of environmental harm is more significant and / or the corrective action cannot be undertaken promptly, the action will be recorded in the corrective action register.

The corrective action process consists of the following steps:

- identification of a problem (failure or deficiency);
- root cause analysis to identify causes and determine solutions;
- decision as to the appropriate action;
- application and documentation of corrective or preventative action; and
- follow-up and evaluation.

Corrective actions in relation to environmental management may arise from:

- recommendations and outcomes of incident investigation reports, including investigations into incidents, near misses and non-compliances;
- reviews of monitoring results indicating that performance requirements are not being met and / or that trends indicate that environmental degradation may be occurring;
- checks and inspections (note that minor corrective actions identified through checks and inspections will generally be resolved on the spot);
- identification of hazards or improvement opportunities;
- audit recommendations; and
- complaints.

5.6.2. Internal (Santos) assurance inspections

Site inspections will be conducted regularly by Santos during active works. Inspections will be carried out to assess activities against compliance requirements set out in this EMP, EA conditions and EPBC Act approval conditions (once granted), and other relevant environmental approvals / permits.

Additional environmental inspections will be carried out to monitor work practices and conformance to the EMP requirements and any relevant overarching legislative criteria. Non-conformances identified will be issued to the contractor through the relevant contractual communication mechanism for action e.g. Site Instruction.

5.6.3. Contractor and subcontractor inspections

Environmental monitoring and inspections must be undertaken by contractor personnel to ensure compliance against applicable legislation and EMP requirements. All inspection and monitoring data is to be made readily accessible and available to Santos.

Inspections must be conducted, documented and results provided to relevant Santos personnel. Areas identified as requiring corrective and preventive action must be raised within the Contractor's management system and relevant contractor personnel issued corrective actions for close out. This process must be managed by the Contractor.

Inspections must be carried out by the Contractor regularly throughout the construction period to adequately address inherent environmental risks present throughout construction.

5.6.4. Plant and equipment inspections

Prior to mobilising plant to site, a pre-mobilisation plant checklist, including environmental checks is to be completed by the contractor. Prior to arrival at the site, a declaration regarding the weed status of all plant and mechanical equipment is to be made, by completing a Vehicle Hygiene Report. All plant, including tracked or wheeled mechanical equipment is to be inspected on arrival at the site and before commencing construction work.

Additionally, plant operators must conduct their own daily inspections and routine maintenance checks throughout construction.

5.7. Reporting and record keeping

This EMP and all associated, documents and registers will be controlled documents subject to unique document identifiers and version control. Corrective actions will be tracked on a register / database to ensure that updates on the status of corrective actions are available to managers and supervisors.

Other documentation and records to be retained will include:

- incident investigation reports;
- remedial actions taken following incident reports;

- completed site checklists;
- records of training and induction;
- audit reports;
- records of waste removal including waste tracking certificates; and
- all monitoring records.

Reporting will be carried out in accordance with relevant EA conditions and EPBC Act approval conditions (once granted), and other relevant environmental approvals / permits.

All records and data required to be maintained by relevant approval conditions will be retained as specifically required, or for a minimum of 5 years.

6. Environmental Management

6.1. Environmental objectives and performance outcomes

Table 4 identifies environmental objectives and performance indicators (and compliance requirements) for each environmental aspect in the Project Area.

Planning, Objectives and Targets aim to be:

- quantified and measurable;
- realistic and achievable;
- focused on continual improvement;
- consistent with, and related to, Santos's Environment Policy and management standards;
- periodically reviewed and, if required, revised; and
- performance indicators will be reviewed as part of the EMP review.

Table 4: Environmental objectives and performance indicators (and compliance requirements)

Aspect	Objectives	Performance indicators (and compliance requirements)
Water resources	• avoid or minimise impacts to groundwater and surface water values. • avoid or minimise impacts to the physical integrity, fluvial processes and morphology of watercourses and wetlands. • for ephemeral watercourses, undertake works as a priority during periods with no flow to very low flow. • erosion and sediment control devices maintained and fit for purpose as required. • no water contamination by wastes, hydrocarbons or other chemicals used during petroleum activities that result in serious or material environmental harm. • implementation of (as applicable): – Constraints Protocol (Santos, 2025c). – Code of Practice for the construction and abandonment of petroleum wells and associated bores in Queensland Version 2 QLD, Australia (DNRME, 2019) (The Code). – Roma Phase 7-7B-SD20 EPBC Act Water Resource Impact Assessment Report (WRA) (KCB, 2025). – relevant EA and EPBC Act decision conditions (once granted) – Roma Phase 7-7B-SD20 CRAF (Santos). – EOW Irrigation of Associated Water (including coal seam gas water) (ENEW07546918); and – no production wells installed within 90m of a landholder bore.	• erosion and sediment controls are implemented. • no release of produced water to surface waters. • turbidity monitoring undertaken in accordance with relevant EA conditions. • works involving significant disturbance near watercourses and wetlands are in accordance with relevant EA conditions. • impacts to existing groundwater bores are managed in accordance with 'make good' provisions in the *Water Act 2000*. • produced water utilised onsite in accordance with relevant EA conditions / EOW ENEW07546918. • compliance with (as applicable): – Constraints Protocol. – The Code. – WRA. – EA and EPBC Act decision conditions (once granted). – CRAF. – EOW ENEW07546918; and – no production wells installed within 90m of a landholder bore.

Aspect	Objectives	Performance indicators (and compliance requirements)
Soil and land resources	• avoid or minimise adverse impacts to the quality and stability of soils. • reinstate and rehabilitate authorised disturbances to a safe, stable and non-polluting landform suitable for its intended ongoing land use. • avoid or minimise adverse impacts to the quality and stability of soils. • ground disturbance minimised as far as practicable. • no soil contamination by wastes, hydrocarbons or other chemicals used during petroleum activities that result in serious or material environmental harm. • implementation of: – RMP. – Constraints Protocol. – The Code. – WRA. – EA and EPBC Act decision conditions (once granted); and – this EMP.	• erosion and sediment controls are implemented. • release of contaminants to land (including treated sewage effluent and RDM) is in accordance with EA conditions. • fuels and chemicals are stored in accordance with relevant Australian Standards. • produced water utilised onsite in accordance with EA conditions / EOW ENEW07546918. • significantly disturbed land is rehabilitated to a safe, stable and non-polluting landform suitable for its intended ongoing land use. • compliance with: – RMP. – Constraints Protocol. – WRA. – The Code. – WRA. – EA and EPBC Act decision conditions (once granted); and – this EMP.
Flora and fauna	• avoid or minimise impacts to terrestrial and aquatic ecosystems and associated flora, fauna and habitat of state (Matters of State Environmental Significance) and national significance (MNES). • avoid or minimise habitat loss and fauna mortality. • a suitably qualified Fauna Spotter / Catcher will be present during vegetation clearing activities where required; and fauna found to be present within areas to be cleared shall be managed, removed and / or relocated by the Fauna Spotter / Catcher where appropriate, and in accordance with the requirements of this EMP and the SSMP. • hollow logs (located on ground) within disturbance areas retained and shifted to adjacent undisturbed areas where practicable. • measures implemented to reduce risks to fauna from earthworks, vegetation clearing, and entrapment in excavations in accordance with the SSMP. For example, checking open trenches for trapped fauna, use of hessian bags, trench ladders, ramps, sticks, ropes (or similar) to assist trapped fauna escape / survive until they are removed by a Fauna Spotter / Catcher.	• compliance with: – EA and EPBC Act decision conditions (once granted). – Constraints Protocol (including post-EPBC Act approval authorised disturbance limits); and – SSMP.

Aspect	Objectives	Performance indicators (and compliance requirements)
	• active work areas, pits, and other areas hazardous to fauna and stock must be fenced or covered to prevent access. • implementation of: – EA and EPBC Act decision conditions (once granted). – Constraints Protocol (including post-EPBC Act approval authorised disturbance limits); and – SSMP (Santos, 2025d).	
Weeds and pests	• to prevent the introduction, and spread, of invasive weeds and pest animals to the Project Area. • all reasonable and practicable measures will be taken to prevent the introduction, and spread, of invasive weeds and pest animals to the Project Area. • implementation of: – EA and EPBC Act decision conditions (once granted); and – this EMP.	• no introduction of invasive weeds or animals that are classified as Prohibited or Restricted Matter by the Biosecurity Act to the Project Area as a result of authorised activities. • valid weed hygiene certification maintained at all times for vehicles, plant, machinery and equipment. • compliance with: – EA and EPBC Act decision conditions (once granted); and – this EMP.
Rehabilitation	• all significantly disturbed areas caused by petroleum activities are to be rehabilitated to be non-polluting, stable, re-profiled to have contours consistent with surrounding land, surface drainage lines re-established, topsoil reinstated, and groundcover and vegetation is to be consistent with surrounding vegetation cover and species richness. • significantly disturbed areas that may be of value as an asset to the underlying landholder (i.e. access tracks) will be offered to the landholder prior to rehabilitation commencing. Any significantly disturbed areas unwanted by the landholder will be rehabilitated.	• significantly disturbed land is rehabilitated to a safe, stable and non-polluting landform suitable for its intended ongoing land use. • significantly disturbed land is rehabilitated to meet the final rehabilitation criteria specified in the Project's RMP and EA, or otherwise be handed over to the landholder.
Noise	• protect noise environmental values within and around the Project Area.	• noise emissions are avoided, reduced and mitigated wherever practicable. • noise emissions generated by petroleum activities do not exceed relevant noise nuisance limits stipulated by the EA, other than where an alternative arrangement is in place. • noise emissions do not cause environmental nuisance at a sensitive place, other than where an alternative arrangement is in place. • noise complaints are investigated, monitored and resolved in accordance with environmental nuisance monitoring requirements of the EA. • compliance with:

Aspect	Objectives	Performance indicators (and compliance requirements)
		– EA and EPBC Act decision conditions (once granted).
Air	• protect air environmental values and around the Project Area.	• air emissions are avoided and reduced wherever practicable. • dust emissions are adequately suppressed i.e. via road watering. • air quality complaints are investigated, monitored and resolved in accordance with the environmental nuisance monitoring requirements of the EA. • compliance with: – EA and EPBC Act decision conditions (once granted). – Air quality objectives (measured at a sensitive receptor) prescribed by Schedule 1 of the Environmental Protection (Air) Policy 2019.
Hazardous Substances	• to minimise the risk of environmental contamination or harm by correctly storing, handling, using, recycling and disposing of hazardous substances.	• all chemicals, oil and fuel must be labelled, handled, stored and effectively contained, and transported in accordance with relevant Australian Standards and Australian Dangerous Goods Code (ADG Code). • register and SDS for all hazardous substances available on site. • spill kits available on site and maintained. • no uncontrolled release of chemicals, oil or fuel is to occur to the environment.
Liquid and solid waste	• minimise generation of waste and avoid or minimise impacts associated with waste generation and storage. • apply the waste management hierarchy and principles based on waste avoidance, reduction, reuse, recycling, treatment and disposal. • implementation of: – CRAF. – EOW ENEW07546918. – EA and EPBC Act decision conditions (once granted). – waste transport and tracking requirements under the EP Act.	• produced water used in accordance with EA conditions and EOW ENEW07546918. • produced water that cannot be beneficially reused in the Project Area is transferred to existing waste management facilities on adjoining tenures for management and beneficial reuse in accordance with the EA conditions and EOW ENEW07546918. • general and regulated waste is separated and managed in accordance with the requirements of the EP Act. • land application of RDM is in accordance with EA conditions. • regulated waste is transported by a person who holds the appropriate authority under the EP Act. • waste tracking certificates and / or log books are maintained as required under the EP Act. • odour or other complaints relating to waste management are investigated, monitored and resolved in accordance with the relevant nuisance monitoring requirements of the EA.

Aspect	Objectives	Performance indicators (and compliance requirements)
Plant and equipment	• ensure plant and equipment are operated and maintained to minimise environmental impacts / noise and air emissions/ incidents. • ensure plant and equipment are cleaned to minimise weed spread and comply with landholder agreement requirements.	• plant and equipment maintained in accordance with the manufacturer's recommendations. • daily pre-start checks completed for all plant and equipment. • weed hygiene certificates available for all applicable plant and equipment. • all access to private property must be in accordance with landholder agreements.
Stimulation activities	• avoid or minimise impacts to groundwater, surface water and aquatic ecology environmental values. • manage stimulation activities to minimise the risk of adverse environmental impacts. • implementation of a stimulation impact monitoring program in accordance with EA conditions.	• stimulation activities do not negatively affect water quality, other than that within the stimulation impact zone of the target gas producing formation. • a stimulation impact monitoring program is implemented in accordance with the EA conditions. • stimulation activities do not cause a connection of the target gas producing formation and another aquifer. • a stimulation risk assessment is carried out for wells prior to stimulation in accordance with relevant EA conditions.
Community and social	• avoid or minimise adverse impacts on community and social values. • implementation of: – Santos Social Impact Management Plan (SIMP) (Santos, 2012).	• consultation with directly and indirectly affected stakeholders is undertaken. • minimal community complaints are made and those received are effectively resolved. • emergencies and other incidents are infrequent and managed effectively to ensure limited impacts on the community. • implementation of relevant initiatives and actions in the SIMP.
Cultural heritage	• avoid impacts to known places of cultural heritage value. • avoid or minimise impacts to unknown places of unknown heritage value. • no unauthorised harm to areas or items of cultural heritage value at the site. This includes both indigenous and non-indigenous cultural heritage values. • implementation of: – Santos Cultural Heritage Management Plan (CHMP) (Santos, 2009).	• comply with requirements of the CHMP. • correct procedures are followed in event an item of cultural heritage significance is found. • no avoidable loss or disturbance of items or areas of cultural value due to Santos' activities. • no valid complaints related to impacts on cultural heritage from the local community or traditional owners.
Traffic	• minimise impacts on the road network and infrastructure. • ensure safe operation of vehicles and machinery by Santos and maintain road user safety for all.	• Santos safe driving programs are implemented (including training and use of In Vehicle Monitoring Systems (IVMS)).

Aspect	Objectives	Performance indicators (and compliance requirements)
		• comply with Queensland Department of Transport and Main Roads (DTMR) and Maranoa Council road construction, use and permit notification requirements i.e. road corridor permit, road works approval.
Environmental emergency preparedness and response	• minimise the potential for environmental emergencies and be able to respond effectively in the event of an environmental emergency.	• spill kits available and maintained. • daily pre-start checks completed for all plant and equipment. • plant and equipment maintained in accordance with the manufacturer's recommendations. • undertaking of regular inspections, maintenance and integrity checks. • regular monitoring of weather and fire conditions. • fire controls in place for hot works. • no burning of wastes on site. • site tidy and maintained at all times. • smoking only in designated areas. • emergency response procedures in place. • compliance with: – EA and EPBC Act decision conditions (once granted).

6.2. Environmental control plans

The following section comprises the ECPs, which have been developed to document site-specific environmental management measures to be implemented throughout development of the Project.

The ECPs have been developed to achieve ongoing environmental compliance with regulatory requirements and ensure implementation of best practice environmental management strategies.

A brief summary of each ECP is available in Table 5.

Table 5: Environmental Control Plans

ECP	Key Content
1. Construction site management	Measures for general construction site management to minimise risks to environmental values from site establishment through to demobilisation and handover
2. Soil resource management	Management measures to minimise the risk of degrading soil resources during construction works. Includes consideration of erosion and sediment control, contaminated land and acid sulfate soils
3. Water resource management	Management measures to minimise the risk of degrading the quantity and quality of water (surface water and groundwater) resources during construction works
4. Flora and fauna management	Measures to protect the flora and fauna of the local area during construction works
5. Weed and pest management	Measures to reduce the risk of invasive plant and animal introduction and spread at the site or onto surrounding lands
6. Air, vibration, light and noise management	Measures to reduce the risk of environmental harm from air, light, vibration and noise emissions during construction works
7. Liquid and solid waste management	Measures to manage regulated, general and recyclable wastes from the construction works in accordance with the waste management hierarchy
8. Cultural heritage management	Measures to protect the cultural heritage values of the site and surrounding area
9. Hazardous substances use and management	Measures for hazardous substance storage, handling, use and disposal to minimise the risks of environmental contamination
10. Plant and equipment management	Measures for the maintenance and operation of plant and equipment during construction to minimise the risk of environmental harm
11. Environmental emergency preparedness and response	Measures to minimise the impacts of the three environmental emergencies that could reasonably be expected to occur at the site at some time: major chemical spill (fuel), dangerous weather events (heavy rainfall / flooding / cyclone) and bushfire.

Table 6: ECP 1 – Construction site management

ECP 1 – Construction Site Management		
Aspect		
The development has the potential to have an adverse impact on environmental values.		
Key References		
• *Environmental Protection Act 1994.*		
Potential Impacts		
• adverse impact to surrounding environmental values from construction activities.		
Management Actions	**Responsibility**	**Timing**
General		
Works will not be undertaken outside the limits of the approved plans of development.	Construction Manager	At all times
The limits of works will be clearly marked or communicated to all personnel to minimise the potential for disturbance to environmental values outside the approved development area.	Construction Manager / Environment Advisor	Prior to starting works in each area
All personnel will receive training in project-related environmental awareness as part of site induction.	Construction Manager	Prior to starting on site
Environmental exclusion zones established where necessary prior to works commencing in the surrounding area to ensure environmental or cultural heritage values (including MNES values) are protected.	Environment Advisor	As required
No unauthorised entry or works by personnel, vehicles, plant or equipment in environmental exclusion zones.	All personnel	At all times
No stockpiling or storage of any materials, plant or equipment in environmental exclusion zones.	All personnel	At all times
Environmental controls will be installed prior to the relevant activity / task commencing and maintained for the duration of its use.	Construction Manager	As required
All environmental plans, policies, procedures and other relevant information will be communicated, implemented and made available to all personnel.	Construction Manager	As required
Fuel and oil storage tanks will be self-bunded and not stored adjacent to watercourse.	Construction Manager	During site planning
Refuelling will not occur in close proximity of a watercourse	Construction Manager	During site planning
Monitoring	**Responsibility**	**Timing**
Routine site inspections.	Construction Manager	Dependent on activity levels / work schedules
Rainfall based site inspections.	Construction Manager	Prior to and following significant rainfall
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Environment Advisor / Construction Manager	At all times
Reporting	**Responsibility**	**Timing**
Near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Corrective Action		
Near misses and incidents in relation to construction site management will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 7: ECP 2 – Soil resource management

ECP 2 – Soil Resource Management		
Aspect		
Construction activities have the potential to impact soil resources on or adjoining the construction site.		
Key References		
• *Environmental Protection Act 1994.* • *National Environmental Protection (Assessment of Site Contamination) Measure 1999 (amended in 2013).* • International Erosion Control Association (IECA) *Best Practice Erosion and Sediment Control 2008.*		
Potential Impacts		
• soil contamination from poor waste management, use of chemicals (namely hydrocarbons) and plant and equipment maintenance (spills and leaks of hydrocarbons). • erosion (loss of soil resource). • altered geological setting. • change to landform. • degradation of soil resources. • unauthorised / accidental release to land. • temporary reduction in land available for agriculture.		
Management Actions	**Responsibility**	**Timing**
Erosion and Sediment Control		
Erosion and sediment control will be managed so as to: • erosion: minimise the area and duration of soil exposure. • sediment: sediment controls to be suited to soils, climate and catchment size. • drainage: divert clean runoff around disturbed areas and convey drainage in a non-erosion manner.	Construction Manager	As required
Erosion and sediment controls will be installed prior to the start of ground disturbing works and maintained until the area of disturbance has been stabilised.	Construction Manager	As required
Progressive rehabilitation / reinstatement of significant disturbances in accordance with relevant EA conditions.	Construction Manager	As required.
Soil Contamination Prevention and Management		
Notify DETSI of any Notifiable Activities that are to be undertaken at the site.	Environment Advisor	Prior to undertaking a Notifiable Activity
Works will be excluded from areas where soil contamination is encountered that presents a risk of actual or potential material or serious environmental.	Environment Advisor	As required
The construction will be managed and designed in accordance with ECP 1: Construction Site Management to minimise the risk of soil contamination.	Construction Manager	At all times
Liquid and solid wastes will be managed in accordance with ECP 7: *Liquid and Solid Waste Management* to minimise the risk of soil contamination.	Construction Manager / Environment Advisor	At all times
Hazardous substances (including fuel) will be used and managed in accordance with ECP 9: *Hazardous Substances Use and Management* to minimise the risk of soil contamination.	Construction Manager / Environment Advisor	At all times
Plant and equipment maintenance will be undertaken in accordance with ECP 10: *Plant and Equipment Management* to minimise the risk of soil or water contamination.	Construction Manager	At all times

ECP 2 – Soil Resource Management		
Soil and water contamination from emergency situations will be minimised by implementing ECP 11: *Environmental Emergency Preparedness and Response*.	Environment Advisor	At all times
If soil contamination presenting a risk of material or serious environmental harm is encountered at the site or occurs during construction, it will be investigated, and appropriate management / remediation strategies and notification requirements developed and implemented.	Construction Manager / Environment Advisor	At all times
The Project's RMP will be implemented to meet the final rehabilitation requirements required under the EA. This Plan may be updated when the EA is issued or amended from time to time.	Construction Manager / Environment Advisor	During and post construction activities
Monitoring	**Responsibility**	**Timing**
Site inspections.	Environment Advisor	Dependent on activity levels / work schedules
Rainfall based site inspections.	Environment Advisor	Prior to and following significant rainfall
Soil contamination testing (if required).	Environment Advisor	As required
Reporting	**Responsibility**	**Timing**
Near misses or non-compliances with Performance Targets for soil resource management will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Damage to or maintenance required by ESC measures will be reported to the Construction Manager.	All personnel	Within 24 hours
Corrective Action		
Near misses and incidents in relation to soil resource management will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 8: ECP 3 – Water resource management

ECP 3 – Water Resource Management		
Aspect		
Construction activities have the potential to impact water resources (surface water or groundwater) on or adjoining the construction site.		
Key References		
• *National Environmental Protection (Assessment of Site Contamination) Measure 1999 (amended in 2013).* • IECA *Best Practice Erosion and Sediment Control* (IECA, 2008). • *Monitoring and Sampling Manual Environmental Protection (Water) Policy 2009* (DESI, 2018). • *Environmental Protection Act 1994.*		
Potential Impacts		
• aquifer depressurisation resulting in change in groundwater flow paths and storage, decline in groundwater levels / pressure in bores and reduced supply to groundwater users, and reduced stream baseflow for groundwater dependent watercourses or springs. • subsidence altering groundwater flow paths and aquifer storage or causing ground surface displacement and altering surface water flow paths. • changes to groundwater quality resulting in degradation of groundwater supply value for beneficial use or groundwater dependent ecosystems. • increased sedimentation (effects on water quality and geomorphology). • erosion of stream banks. • surface water quality impacts. • altered surface water flow regime (risk to overland flow paths, riparian vegetation, terrestrial ecosystems and environmental flow regime).		
Management Actions	**Responsibility**	**Timing**
Surface Water Flow		
Based on the assigned risk, adopt standard crossing designs for low, medium and high-risk crossings (refer to Appendix 2).	Construction Manager	As required
Pipelines will be buried and preferentially built during periods of no flow to very low flow.	Construction Manager	As required
Erosion and Sediment Control		
Erosion and sediment control will be managed so as to: • erosion: minimise the area and duration of soil exposure. • sediment: sediment controls to be suited to soils, climate and catchment size. • drainage: divert clean runoff around disturbed areas and convey drainage in a non-erosion manner.	Construction Manager	As required
Erosion and sediment controls will be staged in line with ground disturbing works and maintained until the area of disturbance has been stabilised.	Construction Manager	As required
Erosion and sediment controls and works undertaken onsite will reference the IECA Best Practice Erosion and Sediment Control principles.	Construction Manager	As required
Minimise area of land disturbed or compacted. Minimise disturbance to instream bed and banks e.g. use geofabric as a work base.	Construction Manager	As required
Limit use of machinery in waterways.	Construction Manager	As required
Progressively reinstating / rehabilitating significant disturbances in accordance with the EA.	Construction Manager	As required

ECP 3 – Water Resource Management		
For any part of the waterway bed or banks adjacent to the works that has been altered by the waterway barrier works, the site is restored and / or rehabilitated so that as a minimum: • stability and profiles of the bed and banks are re-instated to natural stream profiles and stability. • the waterway bed is retained with natural substrate or reconstructed with substrate comparable to the natural substrate size and consistency. • site conditions allow the rapid re-establishment of native vegetation and cover or native species are replanted to re-establish the natural plant community.	Construction Manager	As required
Water Contamination Prevention and Management		
Notify DETSI of any Notifiable Activities that are to be undertaken at the site.	Environment Advisor	Prior to undertaking a Notifiable Activity
The construction will be managed and designed in accordance with ECP 1: *Construction Site Management* to minimise the risk of soil contamination.	Environment Advisor	At all times
Liquid and solid wastes will be managed in accordance with ECP 7: *Liquid and Solid Waste Management* to minimise the risk of water contamination.	Environment Advisor	At all times
Hazardous substances (including fuel) will be used and managed in accordance with ECP 9: *Hazardous Substance Uses and Management* to minimise the risk of water contamination.	Environment Advisor	At all times
Plant and equipment maintenance will be undertaken in accordance with ECP 10: *Plant and Equipment Management* to minimise the risk of water contamination.	Environment Advisor	At all times
Water contamination from emergency situations will be minimised by implementing ECP 11: *Environmental Emergency Preparedness and Response*.	Environment Advisor	At all times
If water contamination that presents a risk of material or serious environmental harm, is encountered at the site or occurs during construction, it will be investigated, and appropriate management / remediation strategies and notification requirements developed and implemented.	Environment Advisor	As required
Where minor volumes of produced water are to be beneficially reused on site, it will be stored in manufactured tanks, that are designed, constructed and operated in accordance with relevant Australian Standards and State regulations.	Construction Manager	As required
No production wells will be installed within 90 m of a landholder bore unless a site-specific assessment determines that a closer distance is appropriate.	Construction Manager	At all times
Well integrity to be verified prior to stimulation to ensure that there is no significant leakage in the casing, tubing or packer and there is no significant movement into another aquifer through vertical channels adjacent to the well bore hole.	Drilling and Completions Manager	Prior to stimulation
Authorised releases in a manner that ensures (unless otherwise authorised): • no damage to vegetation. • no adverse impact to soil quality and structure. • no ponding or runoff to surface waters. • no aerosols or odours. • deep drainage below root zone is minimised. • no adverse impact to the quality of shallow aquifers.	Construction Manager / Environment Advisor	As required

ECP 3 – Water Resource Management		
A 50 m buffer will be maintained between sewage effluent irrigation areas and watercourses, wetlands or significant vegetation and a 100 m buffer from potable water supply or stock drinking water.	Construction Manager / Environment Advisor	At all times
Use of Water Resources		
Preference will be given to the use of non-potable water supplies for washdown, dust suppression and construction activities where economically and practically feasible.	Environment Advisor	During construction planning
Only extract water from constructed wetland and other farm dams for construction purposes with the permission from the landholder and when water supplies are abundant.	Construction Manager / Environment Advisor	As required
Road watering will only be undertaken when necessary to control dust emissions.	Construction Manager / Environment Advisor	As required
Water use for dust suppression and vehicle washing will be minimised as far as practicable.	Construction Manager / Environment Advisor	At all times
Monitoring	**Responsibility**	**Timing**
Routine site inspections.	Construction Manager / Environment Advisor	Dependent on activity levels / work schedules
Rainfall based site inspections.	Construction Manager / Environment Advisor	Prior to and following significant rainfall
Water quality monitoring downstream of works in watercourses to confirm compliance with release limits specified under the EA.	Construction Manager / Environment Advisor	As specified under EA
Water quality testing of contaminated water (if required).	Environment Advisor	As required
Water use in the vehicle wash and for dust suppression will be monitored and recorded.	Construction Manager / Environment Advisor	At all times
Regular inspections, maintenance and integrity checks on produced water storage tanks will be undertaken.	Construction Manager / Environment Advisor	As required
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Construction Manager / Environment Advisor	At all times
Reporting	**Responsibility**	**Timing**
Near misses or non-compliances with Performance Targets or for water management will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Damage to or maintenance required by ESC measures will be reported to the relevant Project Engineer.	All personnel	Within 24 hours
Corrective Action		
Near misses and incidents in relation to water resource management will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 9: ECP 4 – Flora and fauna management

Santos has developed a Significant Species Management Plan (SSMP) (Santos, 2025d) for the Project to guide the management of potential impacts to MNES values located in the Project Area. This SSMP in conjunction with the Constraints Protocol (Santos, 2025c) provides Santos with the tools to systematically identify relevant significant species and implement management measures during the course of conducting petroleum activities in the Project Area. Refer to the SSMP for further information.

ECP 4 – Flora and Fauna Management		
Aspect		
Construction works near or within environmentally sensitive areas		
Key References		
• *Animal Care and Protection Act 2001.* • *Environmental Protection Regulation 2018.* • *Stock Route Management Act 2002.* • *Nature Conservation Act 1992.* • *Nature Conservation (Animals) Regulation 2020 (NCA Regulation).*		
Potential Impacts		
• unnecessary loss of vegetation and habitats. • temporary changes in hydrology which result in vegetation loss. • accidental entrapment of fauna in open voids i.e. excavations and trenches. • mortality from moving vehicles and machinery. • erosion and sedimentation. • light disturbance.		
Mitigation Strategy / Action	**Responsibility**	**Timing**
All clearing must be internally approved and undertaken as per the requirements of the Constraints Protocol and the SSMP.	Principal Contractor / Environment Advisor	Prior to the commencement of any construction activity
Clearing areas should be clearly delineated.[2]	Principal Contractor / Environment Advisor	Prior to the commencement and during any construction activity
Reinforce need to conduct activity in designated and approved areas during site toolbox / induction meetings.	Principal Contractor / Environment Advisor	Prior to the commencement and during any construction activity
A suitably qualified Fauna Spotter / Catcher will be present during vegetation clearing activities where required; and fauna found to be present within areas to be cleared shall be managed, removed and / or relocated by the Fauna Spotter / Catcher where appropriate, and in accordance with the requirements of this EMP and the SSMP.	Principal Contractor / Environment Advisor	Prior to the commencement of and during any construction activity
Hollow logs (located on ground) / potential habitat features within disturbance areas will be retained and shifted to adjacent undisturbed areas where practicable	Principal Contractor / Environment Advisor	Prior to the commencement of any construction activity

[2] Areas can be delineated spatially using GPS technology or physically using visual markers / tape.

ECP 4 – Flora and Fauna Management		
Measures implemented to reduce risks to fauna from earthworks, vegetation clearing, and entrapment in voids. For example, checking on open trench for trapped fauna, use of hessian bags, trench ladders, ramps, sticks, ropes (or similar) to assist trapped fauna escape / survive until removed	Principal Contractor / Environment Advisor	Prior to the commencement of and during any construction activity
Open voids must be fenced or covered where practicable to prevent access or harm to the fauna. Where this is not practicable, the focus should be on regularly checking open voids for entrapped fauna and installing measures to reduce risks to potentially entrapped fauna.	Principal Contractor / Environment Advisor	During construction activities that require open voids
During construction, work areas and open voids will be regularly checked for potentially entrapped fauna.	Principal Contractor / Environment Advisor	During construction activities that require open voids
Open voids will be backfilled as soon as practicable following completion of works.	Principal Contractor / Environment Advisor	As required
Avoid providing artificial food and water sources or shelter within the construction footprint that may attract fauna.	Principal Contractor / Environment Advisor	At all times
Monitoring and Reporting	**Responsibility**	**Timing**
Unauthorised clearing will be immediately communicated to the Site Supervisor and Environmental Advisor.	Principal Contractor	As required
Fauna and stock deaths will be reported in accordance with the Santos SMS reporting procedure.	Principal Contractor	As required
Fauna Spotter / Catcher updates on interactions and reporting will be regularly provided to the Site Supervisor and Environmental Advisor.	Principal Contractor	As required

Table 10: ECP 5 – Weed and pest management

ECP 5 – Weed and Pest Management		
Aspect		
Vehicles, plant, equipment and materials required for construction may introduce invasive weeds or animals to the site.		
Key References		
• *Biosecurity Act 2014.* • DAF (2019) *Vehicle and machinery cleandown procedures.*		
Potential Impacts		
• introduction or spread of invasive weeds or pest animal species.		
Management Actions	**Responsibility**	**Timing**
All site-based personnel will receive General Biosecurity Obligation (under the *Biosecurity Act 2014*) and weed hygiene awareness training. This allows the site-based personnel to be considered a competent and trained person.	Principal Contractor / Environment Advisor	Induction

• all work vehicles, plant and equipment will be inspected and certified as clean by a competent and trained person prior to first entry to the site. This does not apply to road-only vehicles that only use well-formed and maintained tracks and roads on the site that are clear and free of vegetation, have not been contact with invasive plants and only visit the site to deliver materials or perform a particular service (e.g. septic pump out truck).
• if wash down is required, this will be undertaken by a competent and trained person in accordance with DAF (2019) *Vehicle and machinery cleandown procedures*.
• records of weed washdown and certification will be kept in the vehicle at all times and made available to landholders on request and presented to the Santos Site Supervisor upon initial entry to site.
• the certification will remain valid as long as the vehicle/equipment:
  ○ has a current weed hygiene declaration dated within the last 30 days.
  ○ does not travel off sealed roads and well-maintained unsealed roads (other than within the site).
  ○ does not come into direct contact with invasive plants.
  ○ does not operate after coming into direct contact with invasive plants.
  ○ if operating off-road, stays within the designated work area and does not cross a property boundary or other designated boundary.
	Principal Contractor / Environment Advisor	Prior to first entry to site. To be repeated as required

A Weed Hygiene Declaration will be provided by the supplier of all organic materials (soil, sand, mulch, gravel, road base, ballast etc.) brought to site.	Principal Contractor	At the time of delivery
Only registered herbicides to be used in accordance with the *Agricultural Chemicals Distribution Control Act 1966* and regulations.	Principal Contractor	As required
All personnel managing and using pesticides will be appropriately trained and licensed in accordance with the *Agricultural Chemicals Distribution Control Act 1966* and regulations.	Principal Contractor	As required
Should spraying near water be required, only pesticides registered for use near water will be used.	Principal Contractor	As required

ECP 5 – Weed and Pest Management		
Prior to the commencement of activities, personnel undertaking spraying activities will consider the potential impacts of the activities to adjoining properties, livestock, flora, fauna, and sensitive vegetation communities. Personnel will ensure there is confirmation that adjacent land users / holders have been notified of the activity, the appropriate choice of pesticide for the application, wind factor on the day, appropriate methods of targeted spraying, and access to treated plants by livestock.	Principal Contractor	As required
No domestic animals or pets will be brought to site.	All persons	At all times
Putrescible wastes (e.g. food wastes) will be covered to prevent access by vermin and removed regularly from site.	Principal Contractor	At all times
Feeding of wild animals is prohibited.	All persons.	At all times
Pest animal control will only be undertaken by contractors with appropriate permits and licenses.	Principal Contractor	As required
Mud or debris from wheels and bodies of vehicles and equipment will be removed prior to entering public roads or other sealed pavements (by means of vehicle washdown bays).	Site Supervisors	As required
Vehicles will not drive in vegetated areas that are a high risk for weed occurrence if they do not have to, stay on established tracks and roads.	All personnel	At all times
Monitoring	**Responsibility**	**Timing**
Site inspections will include identifying evidence of significant infestations of invasive plants or animals.	Principal Contractor / Environment Advisor	Dependent on activity levels / work schedules
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Environment Advisor / Construction Manager	At all times
Reporting	**Responsibility**	**Timing**
Records of all weed and pest inspections and certification to be kept.	Environment Advisor and drivers and operators.	At all times
Application of any pesticide will be recorded and kept.	Environment Advisor	Within 24-hours of application of pesticide
Near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Copies of all weed hygiene certifications and declarations will be kept on the electronic record management system.	Environment Advisor and drivers and operators	At all times
If Class 1 or 2 restricted matter invasive plants or animals listed under the *Biosecurity Act 2014* are identified as present on site these will be reported to the administrating authority.	Environment Advisor	Within 2 hours of becoming aware of the matter
Corrective Action		
Near misses and incidents in relation to biosecurity will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 11: ECP 6 – Air, vibration, light and noise management

ECP 6 – Air, Vibration, Light and Noise Management		
Aspect		
Air emissions (dust), vibration emissions, light emissions and noise emissions resulting from construction activities may impact amenity at sensitive receptors.		
Key References		
• *Environmental Protection (Air) Policy 2019.* • *Environmental Protection (Noise) Policy 2019.* • *AS 2436-2010 Guide to Noise and Vibration Control on Construction, Demolition and Maintenance Sites.* • *Noise Measurement Manual* (Department of Environment and Science, 2020). • *AS 1055:2018 Acoustics - Description and Measurement of Environmental Noise.* • *Monitoring and Sampling Manual* (DES, 2018) • *AS/NZS 3580.10.1:2016 Methods for Sampling and Analysis of Ambient Air: Determination of Particulate Matter - Deposited Matter - Gravimetric Method.* • *AS/NZS 4282-2023 Control of the Obtrusive Effects of Outdoor Lighting/*		
Potential Impacts		
• reduction in noise amenity. • noise nuisance to sensitive receptors. • reduction in air quality. • generation of dust and fine particulates causing nuisance to sensitive receptors. • light nuisance to sensitive receptors.		
Management Actions	**Responsibility**	**Timing**
Dust, vibration, light and noise management awareness training will be provided as part of the site induction.	Construction Manager / Environment Advisor	Induction
No unnecessary use of horns or other audible signals on mobile plant or equipment.	All personnel	At all times
No unnecessary revving or idling of engines on mobile and stationary machines and shut down any equipment not in use.		
Use of manually adjustable or ambient noise sensitive or ‘squawker’ type reversing alarms on plant and vehicles.		
Use silenced generators where possible.	Construction Manager	At all times
Maintain all vehicles, plant and equipment to reduce the potential for noise emissions.	Drivers and operators	Manufacturer specifications
Ensure trucks, trailers and loads are secured to minimise dust (from load), rattling and other noise emissions when on public roads.	Drivers and operators	At all times
Site speed limits to be implemented and monitored through the IVMS.	All personnel	At all times
Vehicles limited to a reduced speed limit on unsealed roads and haulage routes to reduce dust impacts.	Construction Manager	At all times
Suppress dust emissions from road surfaces with water or chemical dust suppressants.	Environment Advisor	As required
All outdoor lighting designed, built and operated in accordance with *AS/NZS 4282 – 2023 Control of the Obtrusive Effects of Outdoor Lighting*.	Construction Manager	At all times
Do not direct high-beam lighting on vehicles into sensitive receptors.	All personnel	At all times
Progressively rehabilitating significant disturbances where possible.	Construction Manager	As required
Design and operation of flares and vents to be in accordance with petroleum legislation and Australian Standards.	Construction Manager	As required
Landholders or residents of any adjacent sensitive places will be advised of planned works prior to the commencement of activities.	Environment Advisor	As required
Comply with noise nuisance limits stipulated by the EA.	All personnel	At all times
Monitoring	**Responsibility**	**Timing**

ECP 6 – Air, Vibration, Light and Noise Management		
Where required: • noise monitoring will be undertaken by a Suitably Qualified Person (SQP) in accordance with the *Noise Measurement Manual* (D) and *AS 1055:2018 Acoustics – Description and Measurement of Environmental Noise*. • vibration monitoring will be undertaken by SQP in accordance with *AS 2436-2010 Guide to Noise and Vibration Control on Construction, Demolition and Maintenance Sites*. • dust monitoring will be undertaken by SQP in accordance with the *Monitoring and Sampling Manual (*DES, 2018*)* and *AS/NZS 3580.10.1:2016 Methods for Sampling and Analysis of Ambient Air: Determination of Particulate Matter – Deposited Matter – Gravimetric Method*. • illumination (light) monitoring will be undertaken by SQP in accordance with the *AS/NZS 4282-2023 Control of the Obtrusive Effects of Outdoor Lighting*.	SQP and Environment Advisor	Monitoring will be conducted if a written request is made by a regulatory authority or investigate a complaint of nuisance
Site inspections will include inspection of noise, dust, light and vibration controls.	Construction Manager / Environment Advisor	Dependent on activity levels/ work schedules
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Environment Advisor	At all times
Reporting	**Responsibility**	**Timing**
Monitoring results will be provided to the regulatory authority within 10 business days of the completion of nuisance-based monitoring.	Environment Advisor	As required
Near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.6 of the EMP.	All personnel	As required
Corrective Action		
Near misses and incidents in relation to noise, dust, light and vibration management will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 12: ECP 7 – Liquid and solid waste management

ECP 7 – Liquid and Solid Waste Management		
Aspect		
Management of solid and liquid wastes generated by Santos's construction activities.		
Objective		
• to minimise environmental harm to environmental values (land, air quality, surface water and groundwater) by managing all wastes correctly and minimising waste disposal where practicable. • minimise generation of waste and avoid or minimise impacts associated with waste generation. • apply the waste management hierarchy and principles based on waste avoidance, reduction, reuse, recycling, treatment and disposal.		
Performance Targets		
• wastes correctly segregated and stored. • no onsite waste disposal or burning of wastes. • all wastes transported by appropriately licensed waste transporters to licensed waste facilities. • all waste tracking documents and receipts retained for 5 years. • concrete washout restricted to designated areas. • monthly waste statistics recorded and reported. • produced water will be beneficially reused in accordance with EA conditions and the EOW *Irrigation of Associated Water (including coal seam gas water)* (ENEW07546918). • produced water that cannot be beneficially reused will be transferred to existing water / waste management facilities located on adjoining tenures for management and beneficial reuse in accordance with EA conditions or EOW *Irrigation of Associated Water (including coal seam gas water) (ENEW07546918).* • general and regulated waste is separated and managed in accordance with the requirements of the EP Act. • land application of RDM is in accordance with the EA conditions. • regulated waste is transported by a person who holds the appropriate authority under the EP Act. • waste tracking certificates and / or log books are maintained as required under the EP Act. • odour or other complaints relating to waste management are investigated, monitored and resolved in accordance with the environmental nuisance monitoring requirements of the EA.		
Key References		
• *Waste Reduction and Recycling Act 2011* (and Regulation). • *Environmental Protection Regulation 2019.*		
Potential Impacts		
• generation of variety of waste types. • excessive waste generation from inefficient use of resources, and improper management or storage of wastes generated by petroleum activities. • associated environmental impacts of waste generation and management.		
Management Actions	**Responsibility**	**Timing**
The site will be kept in a clean and tidy state at all times.	All personnel	At all times
All personnel will receive waste management awareness training as part of the site induction.	Environment Advisor	Induction
No wastes will be disposed of or burnt at the site.	All personnel	At all times
Wastes will not be stored in environmental exclusion zones.	All personnel	At all times
Wastes will be segregated correctly.	All personnel	At all times
General waste and recycling bins (with lids) will be provided within and near amenities.	Environment Advisor	At all times
Covered bins / skips will be provided for general and recyclable wastes to prevent windblown litter, access by birds / vermin, odour emissions and rainfall ingress.	Environment Advisor	At all times
Regulated Waste (e.g. waste oil, washbay wastewater and blackwater from amenities) will only be removed from site by a Regulated Waste contractor.	Environment Advisor	As required
Wastes will only be transported by appropriately licensed waste transporters to licensed waste facilities.	Environment Advisor	At all times

ECP 7 – Liquid and Solid Waste Management		
Excess batched concrete and concrete washout wastes will be managed in accordance with the relevant SWMS.	Construction Manager	As required
All waste or excess materials (e.g. ballast, sleepers etc), other than waste that has been or will be lawfully reused onsite in accordance with the waste management hierarchy, will be removed from site at the completion of works.	Construction Manager	Prior to demobilisation
Soil or water that is contaminated by an emergency will be managed in accordance with ECP 2: *Soil Resource Management* and ECP 3: *Water Resource Management.*	Environment Advisor	As required
Stimulation flow back fluids will be managed, contained and recycled / reused in accordance with regulatory requirements.	Drilling and Completions Team / Construction Manager	As required
When applying RDM to land: • select suitable locations. • design and control application area size and rates to avoid run-off. • visual monitoring to avoid run-off. • apply adaptive management of application rates and RDM quality.	Drilling and Completions Manager	As required.
All sites will be kept free from litter.	All personnel	At all times
Green waste may be used on site for both rehabilitation and sediment and erosion control.	Environment Advisor	As required
Monitoring	**Responsibility**	**Timing**
Site inspections will include assessment of waste management practices.	Construction Manager / Environment Advisor	Dependent on activity levels / work schedules
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Construction Manager / Environment Advisor	At all times
Implementation of a stimulation impact monitoring program, in accordance with EA conditions, which will require monitoring of stimulation fluids and flow back waters.	Drilling and Completion Manager / Environmental Advisor	As required
All waste records will be provided to the Environment Advisor on a monthly basis or upon request.	Construction Manager / Environment Advisor	As required
Reporting	**Responsibility**	**Timing**
Near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
All waste-tracking forms and waste disposal receipts will be managed in accordance with Section 5.7 of the EMP and recorded in the Waste Management Register.	Construction Manager / Environment Advisor	Duration of project
Records of all wastes generated will be retained and the quantities and management strategy reported in the monthly environmental report.	Construction Manager / Environment Advisor	Monthly
Corrective Action		
Near misses and incidents in relation to waste management will be investigated in accordance with Section 5.6 of the EMP to identify necessary corrective actions for implementation.		

Table 13: ECP 8 – Cultural heritage management

ECP 8 – Cultural Heritage Management		
Aspect		
Construction works near or within areas of cultural heritage value.		
Key References		
• *Cultural Heritage Act 2003* Duty of Care Guidelines. • *Aboriginal Cultural Heritage Act 2003 and Torres Strait Islander Cultural Heritage Act 2003* Guidelines for the discovery, handling, and management of human remains. • Santos *Cultural Heritage Management Plan* (CHMP) (Santos, 2009).		
Mitigation Strategy / Action	**Responsibility**	**Timing**
Cultural heritage awareness and duty of care training provided to all personnel in the site induction and as required by the CHMP.	Construction Manager / Cultural Heritage Advisor	Induction
Undertake all works with a cultural heritage duty of care.	All personnel	At all times
Environmental exclusion zones established where necessary prior to works commencing in the surrounding area to ensure cultural heritage values are protected on site.	Construction Manager / Cultural Heritage Advisor	As required
No unauthorised entry or works by personnel, vehicles, plant or equipment in environmental exclusion zones.	Construction Manager / All personnel	At all times
No stockpiling or storage of any materials, plant or equipment in environmental exclusion zones.	All personnel	At all times
In the event that an item of cultural heritage significance is found, works in the immediate vicinity would cease and further action would be taken in accordance with the CHMP.	Construction Manager / Cultural Heritage Advisor	Immediately in response to a find
If human remains are found: • immediately cease all works on site • notify in accordance with relevant procedure and CHMP.	Construction Manager / Cultural Heritage Advisor	Immediately in response to a find
Monitoring	**Responsibility**	**Timing**
Site inspections will include inspection of cultural heritage management measures.	Construction Manager / Cultural Heritage Advisor	Monthly
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Construction Manager / Cultural Heritage Advisor	At all times
Reporting	**Responsibility**	**Timing**
All cultural heritage reporting, and monitoring data will be recorded and kept.	Construction Manager / Cultural Heritage Advisor	Dependent on activity levels / work schedules
Near misses or non-compliances with Performance Targets for cultural heritage will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
If any items that are suspected of being of cultural heritage value are found or if human remains are found, the find will be reported in accordance with Section 5.6 of the EMP.	Construction Manager / Cultural Heritage Advisor	Immediately in response to a find
Corrective Action		
Near misses and incidents in relation to cultural heritage will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 14: ECP 9 – Hazardous substances use and management

ECP 9 – Hazardous Substances Use and Management		
Aspect		
Storage, handling, use and disposal of hazardous substances during construction activities.		
Key References		
• *AS1940-2017 The Storage and Handling of Flammable and Combustible Liquids* • Workplace Health and Safety Queensland's *Managing risks of hazardous chemicals in the workplace Code of Practice* (WHSQ, 2021)		
Management Actions	**Responsibility**	**Frequency**
General		
Hazardous substances awareness training will be provided to all personnel as part of the site induction. This will include a component on spill response and clean-up.	Construction Manager / Environment Advisor	Induction
All SDS will be kept on the intranet and in the chemical storage for all hazardous substances at the site.	Environment Advisor	At all times
A register of hazardous substances will be kept on the electronic record management system.	Construction Manager / Environment Advisor	At all times
All hazardous substances will be stored, handled, used and disposed in accordance with the SDS, manufacturer recommendations and applicable regulatory requirements including AS 1940-2004 The storage and handling of flammable and combustible liquids.	All personnel	At all times
Hazardous substances will only be stored with compatible products (with exceptions where segmentation and distance separation requirements are met).	All personnel	At all times
Hazardous substances will be stored undercover in a bunded area or container. The bund will have the capacity of 110% of the largest container.	All personnel	At all times
Water accumulated in bunds will be removed by a Regulated Waste contractor.	Construction Manager / Environment Advisor	As required
Appropriate fire extinguishers will be provided on site for flammable and combustible chemicals.	Construction Manager	At all times
Appropriate spill kits for the type and quantity of chemicals will be provided and maintained wherever chemicals are stored and used.	Construction Manager / Environment Advisor	At all times
No onsite disposal of chemical wastes.	All personnel	At all times
Spills will be cleaned up immediately using dry methods (not hosing)	All personnel	As required
Only registered herbicides will be used by a licensed weed sprayer in accordance with the *Agricultural Chemicals Distribution Control Act 1966.*	Construction Manager / Environment Advisor	As required
The construction will be managed and design in accordance with ECP 1: Construction Site Management to minimise the risk of contamination associated with hazardous substances.	Construction Manager / Environment Advisor	At all times
Pressure testing of well casing and cement to confirm well integrity and determine the presence / absence of leak potential or significant fluid movement.	Drilling and Completions Team / Construction Manager	As required
Stimulation flow back fluids will be managed, contained and recycled/reused in accordance with regulatory requirements.	Drilling and Completions Team / Construction Manager	As required
Monitoring	**Responsibility**	**Frequency**
Site inspections will include inspection of hazardous substance management measures.	Construction Manager / Environment Advisor	Dependent on activity levels / work schedules
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Environment Advisor	At all times

ECP 9 – Hazardous Substances Use and Management		
Reporting	**Responsibility**	**Frequency**
Near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Corrective Action		
Near misses and incidents in relation for hazardous substance use and management will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 15: ECP 10 – Plant and equipment management

ECP 10 – Plant and Equipment Management		
Aspect		
Incorrect operation of plant and equipment has the potential to adversely impact the environment.		
Management Strategies		
Proactive management strategies to reduce the impacts of plant and equipment include daily pre-start checks, routine maintenance, covering loads of trucks where appropriate, and implementation of weed and pest hygiene measures such as cleaning, inspections and certifications.		
Key References		
• regulatory approval requirements for plant and equipment (Section 2.4)		
Management Actions	**Responsibility**	**Timing**
Daily pre-start checks will be completed on all plant and equipment.	Operators	Daily
Plant and equipment will be maintained in accordance with the manufacturer's recommendations.	Operators	As required
Maintenance and repair works to plant and / or equipment will be undertaken at the workshop. In-field repairs will only occur if the plant or equipment cannot be moved under its own power.	Construction Manager	As required
Spill kits and drip trays and any other necessary controls will be used during maintenance works or repairs to plant and equipment. This applies to the workshop and in-field repairs.	All personnel	As required
Wastes from plant and equipment maintenance undertaken in the workshop or in-field will be in accordance with ECP 7 – Liquid and Solid Waste Management.	All personnel	As required
Refuelling plant and equipment will be in accordance with the relevant SWMS. Suitable containment devices to be in place for refuelling activities involving volumes greater than 50 L.	Refuelling personnel	At all times
No unnecessary revving or idling of engines on mobile and stationary machines and shut down any equipment not in use.	All personnel	At all times
Weed and pest hygiene requirements for plant and equipment (i.e. washdown and certification requirements) are outlined in ECP 5 – Weed and Pest Management.	All personnel	At all times
Ensure trucks, trailers and loads are secured to minimise rattling and other noise emissions when on public roads.	Operators / drivers	At all times
Cover loads of organic materials (soil, gravel, sand, mulch) in trucks and trailers travelling on public roads to and from the site.	Operators / drivers	At all times
Clean tyres of mud before driving on public roads.	Operators / drivers	As required
Monitoring	**Responsibility**	**Timing**
Daily pre-start checks will monitor plant and equipment condition.	Operators	Daily
Plant and equipment management will be monitored as part of monthly site inspections	Environment Advisor	Dependent on activity levels / work schedules
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Environment Advisor	At all times
Reporting	**Responsibility**	**Timing**
Daily pre-start forms will be kept with the plant and equipment.	Operators	At all times
Service records will be retained and made available upon request.	Sub-contractors	At all times
Near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Corrective Action		
Near misses and incidents in relation to plant and equipment management will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

Table 16: ECP 11 – Environmental emergency preparedness and response

ECP 11 – Environmental Emergency Preparedness and Response		
Aspect		
Environmental emergencies at the site may cause harm to people and the natural environment.		
Key References		
• n/a		
Important Information		
The triggers for a spill emergency event are more than 50 litres to ground or any amount of spillage to a watercourse or drain. The region in which the site is located experiences heavy rain and flooding (mainly during the summer months). The area is a low-medium risk for bushfire.		
Management Actions	**Responsibility**	**Timing**
Spills		
All personnel will receive emergency response awareness training as part of the site induction. This will include spill clean-up and fire extinguisher use.	Environment Advisor	Duration of project
Hazardous substances will be managed in accordance with ECP 9: *Hazardous Substance Use and Management*.	All personnel	At all times
Refuelling and servicing of plant and equipment will be managed in accordance with ECP 10: *Plant and Equipment Management*.	Refuelling personnel / Construction Manager	At all times
Appropriate spill kits for the type and quantity of chemicals will be provided and maintained wherever chemicals are stored and used.	Environment Advisor	At all times
Immediately cease any hot works within 30 m of the spill and evacuate all personnel from the area.	All personnel / Construction Manager	Immediately after spill
Spills will be cleaned up immediately (isolate / stop, absorb / clean, dispose of contaminated materials).	All personnel	Immediately after spill if safe
Soil or water that is contaminated by an emergency will be managed in accordance with ECP 2: *Soil Resource Management* and ECP 3: *Water Resource Management.*	Environment Advisor	As required
Heavy Rain, Storms and Flooding		
If heavy rainfall or flooding is forecast, the site will be prepared by: • relocating any mobile plant or equipment to higher parts of the site or away from the site (as required). • removing potential contaminants such as wastes or chemicals from site or ensuring that potential contaminants are protected from rainfall or stormwater flows. • securing loose equipment and materials, ensure bin covers are secure. • ensuring all erosion and sediment control measures have been maintained and are in place.	Construction Manager Advisor	Prior to the event
Bushfire		
Plant and equipment will be maintained to minimise the risk of presenting an ignition source.	Plant operators	As required
Hot works will be undertaken in accordance with the relevant hot work permit requirements and SWMS.	All personnel	During hot works
Fire extinguishers will be provided at the site office, crib rooms, where flammable and combustible liquids are stored and in all vehicles.	Construction Manager / Environment Advisor	At all times
No burning of wastes on site.	All personnel	At all times
Smoking will only be allowed in designated smoking areas. Cigarette bins will be provided at designated smoking areas.	Construction Manager / Environment Advisor	At all times
Monitoring	**Responsibility**	**Timing**
Daily monitoring of forecast weather and fire hazard ratings provided by Bureau of Meteorology. This will be discussed in the daily pre-work brief meeting.	Construction Manager / Environment Advisor	Daily

ECP 11 – Environmental Emergency Preparedness and Response		
Routine and rainfall-based site inspections will determine if hazards are present at the site that could cause an environmental emergency.	Construction Manager / Environment Advisor	Prior to and following significant rainfall
All monitoring, inspection and audit data will be managed in accordance with Section 5.6 of the EMP.	Construction Manager / Environment Advisor	At all times
Reporting	**Responsibility**	**Timing**
Emergencies, near misses or non-compliances with Performance Targets will be reported and managed in accordance with Section 5.4 of the EMP.	All personnel	As required
Corrective Action		
Near misses and incidents will be investigated in accordance with Section 5.4 of the EMP to identify necessary corrective actions for implementation.		

7. EMP Review and Update

This EMP will be reviewed and updated as required by Santos following granting of the new EA and EPBC Act decision and approval conditions.

Updates will reflect changes to processes and procedures, new and / or amended approval conditions, updates to legislation, guidelines and standards, and / or changes to Santos requirements.

Reviews may also be more regularly scheduled (i.e. every 1 to 5 years) or occur in response to matters that affect environmental management (such as incidents, emergencies, changes in site conditions etc).

Appendix 1: Santos EHS Policy

Santos

Environment, Health and Safety

Policy

Our Commitment

Santos is committed to being the safest gas company wherever we have a presence and preventing harm to people and the environment.

Our Actions

We will:

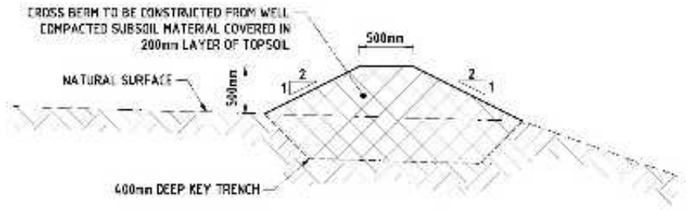
1. Integrate environment, health and safety management requirements into the way we work
2. Comply with all relevant environmental, health and safety laws and continuously improve our management systems
3. Include environmental, health and safety considerations in business planning, decision making and asset management processes
4. Identify, control and monitor risks that have the potential for harm to people and the environment, so far as is reasonably practicable
5. Report, investigate and learn from our incidents
6. Consult and communicate with, and promote the participation of all workers to maintain a strong environment, health and safety culture
7. Empower our people, regardless of position, to "Stop the Job" when they feel it necessary to prevent harm to themselves, others or the environment
8. Work proactively and collaboratively with our stakeholders and the communities in which we operate
9. Set, measure, review and monitor objectives and targets to demonstrate proactive processes are in place to reduce the risk of harm to people and the environment
10. Report publicly on our environmental, health and safety performance

Governance

The Environment Health Safety and Sustainability Committee is responsible for reviewing the effectiveness of this policy.

This policy will be reviewed at appropriate intervals and revised when necessary to keep it current.

Kevin Gallagher



Managing Director and CEO

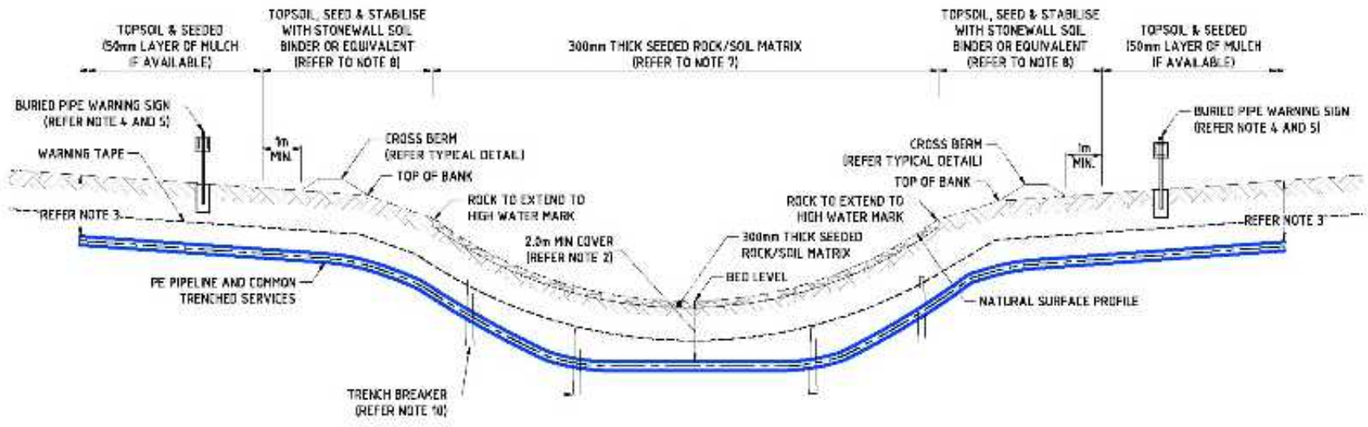
NOTES:



1. REFER TO DWG 0007-650-PLA-0097 FOR GENERAL NOTES.
2. MINIMUM COVER TO BE TAKEN FROM BELOW LOOSE MATERIAL IN DRAINAGE FEATURE BED LIKELY TO BE SCOURED AWAY DURING HIGH FLOW EVENTS.
3. RETURN TO NORMAL DEPTH OF COVER AS PER PROJECT SPECIFIC PIPELINE DETAILED DESIGN.
4. FOR WARNING SIGN REFER TO DWG 1500-050-GAR-0012 AND 1500-050-GAR-0013.
5. BURIED PIPE WARNING SIGNS TO BE LOCATED A MINIMUM OF 3.0m FROM THE TOP OF BANK.
6. INSTALL FINAL BERM ACROSS ROW AT TOP OF THE BANKS. INSTALL ON A MAXIMUM GRADE OF 1.0%. ALL FINAL BERMS TO BE COVERED IN 200mm TOPSOIL. ENSURE BERMS DISCHARGE TO A STABLE LOCATION DOWNSTREAM OF THE WORK SITE (IE. GRASS OR ROCK AREA).
7. FOR FINAL DRAINAGE FEATURE TO HIGH WATER MARK:
   - 7.1 APPLY 300mm THICK LAYER OF SEEDED ROCK/SOIL MATRIX AS PER ORIGINAL SITE CONTOURS. ROCK/SOIL MATRIX TO BE 50% ORIGINAL BED MATERIAL (MIXED WITH SEED) & 50% 200mm RIP RAP ROCK. OR;
   - 7.2 WHERE INSUFFICIENT OR UNSUITABLE ORIGINAL BED MATERIAL EXISTS APPLY SOIL AMELIORANTS (GYPSUM, LIME, DOLOMITE, COMPOST ETC) TO PROVIDE SUITABLE GROWING MEDIUM AS PER SOIL AMENDMENT ADVICE. APPLY 300mm THICK LAYER OF SEEDED ROCK/SOIL MATRIX AS PER ORIGINAL SITE CONTOURS. ROCK/SOIL MATRIX TO BE 50% ORIGINAL BED MATERIAL (MIXED WITH SEED) & 50% 200mm RIP RAP ROCK.
8. FOR FINAL DRAINAGE FEATURE ABOVE HIGH WATER MARK:
   - 8.1 RESPREAD TOPSOIL AS PER ORIGINAL SITE CONTOURS. PROVIDE A MINIMUM OF 200mm TOPSOIL DEPTH. WHERE POSSIBLE, PLACE THE BALANCE OF TOPSOIL FOLLOWED BY THE TOP 50mm OF STRIPPED TOPSOIL. ADD REQUIRED FERTILISER AND SEED. STABILISE WITH STONEWALL SOIL BINDER OR EQUIVALENT. OR;
   - 8.2 WHERE INSUFFICIENT OR UNSUITABLE TOPSOIL EXISTS, APPLY SOIL AMELIORANTS (GYPSUM, LIME, DOLOMITE, COMPOST ETC) TO PROVIDE SUITABLE GROWING MEDIUM AS PER SOIL AMENDMENT ADVICE. RESPREAD AS PER ORIGINAL SITE CONTOURS. ADD FERTILISER AND SEED. STABILISE WITH STONEWALL SOIL BINDER OR EQUIVALENT.
9. SEED TO BE BROADCAST WITHIN TOP 50mm TOPSOIL OR ROCK/SOIL MATRIX. SEED MIX TO TO BE IN ACCORDANCE WITH SEEDING RECOMMENDATIONS.
10. TRENCH BREAKERS SHALL BE INSTALLED AS REQUIRED BY SANTOS SPECIFICATION 'CONSTRUCTION OF POLYETHYLENE GATHERING SYSTEMS' 1515-120-SPC-0008 AND IN ACCORDANCE WITH DRAWING 1500-040-GAR-0001.

Appendix F: Risk Assessment

The environmental risk assessment contained in Section 4.0 was undertaken in accordance with the Santos Management System (SMS) Risk Management Standard. The SMS Risk Management Standard is based on accepted principles and applicable Australian standards. The risk assessment process involves:

- identifying the potential hazards or threats posed by the proposed activities;
- categorising the potential consequences and their likelihood of occurring; and
- using a risk matrix to characterise the level of risk.

Environmental risk assessment is used to differentiate minor acceptable risks from major risks, and to provide a basis for further evaluation and management of major risks. Risks are generally considered acceptable if they fall into the low category without any further mitigation measures, and 'tolerable' if they fall into the medium risk category and are managed to reduce the risk to a level 'So Far As Is Reasonably Practicable' (SFAIRP). Risk reduction measures must be applied to reduce high risks to tolerable levels (see Operational Risk Requirements in Figure 7).

SFAIRP essentially involves making a judgement about whether all reasonably practicable measures are in place to control a potential risk or impact considering the level of consequence and cost, time and resources involved to mitigate it.

Control Measure Identification

Based on identified potential impacts, and the ranking of their unmitigated risk, 'Management Practices' ('Control Strategies') were identified to eliminate, prevent, reduce or mitigate consequences associated with each of the identified potential impacts. Appropriate control strategies were identified from previous activities, current Santos management practices, and through review of best practice techniques across the industry.

Determination of Severity of Consequence

The potential level of impact (consequence) was assessed and assigned in line with potential hazards and receptors, using the 'Santos Environmental Consequence Classification' (see Figure 7) from the Santos Risk Matrix. The consequence level for each risk source is documented in the risk assessment tables in Section 4.0. To describe the severity, scale and duration of potential impacts, six categories of consequence are used (as displayed in Figure 7).

Determination of Likelihood

Likelihood relates to the potential for a consequence to occur. This includes the likelihood of an event occurring and the subsequent potential consequence. This is defined using the Santos Risk Matrix (See Figure 7). To describe the likelihood of a potential environmental consequence occurring, six categories of likelihood are used. The Santos Risk Matrix is then used to characterise the resultant risk into one of five levels.

Determination of Residual Risk

Risk is expressed in terms of a combination of the consequence of an impact and the likelihood of the impact occurring. Santos uses a risk matrix (see Figure 7) to plot the consequence and likelihood to determine the level of risk.

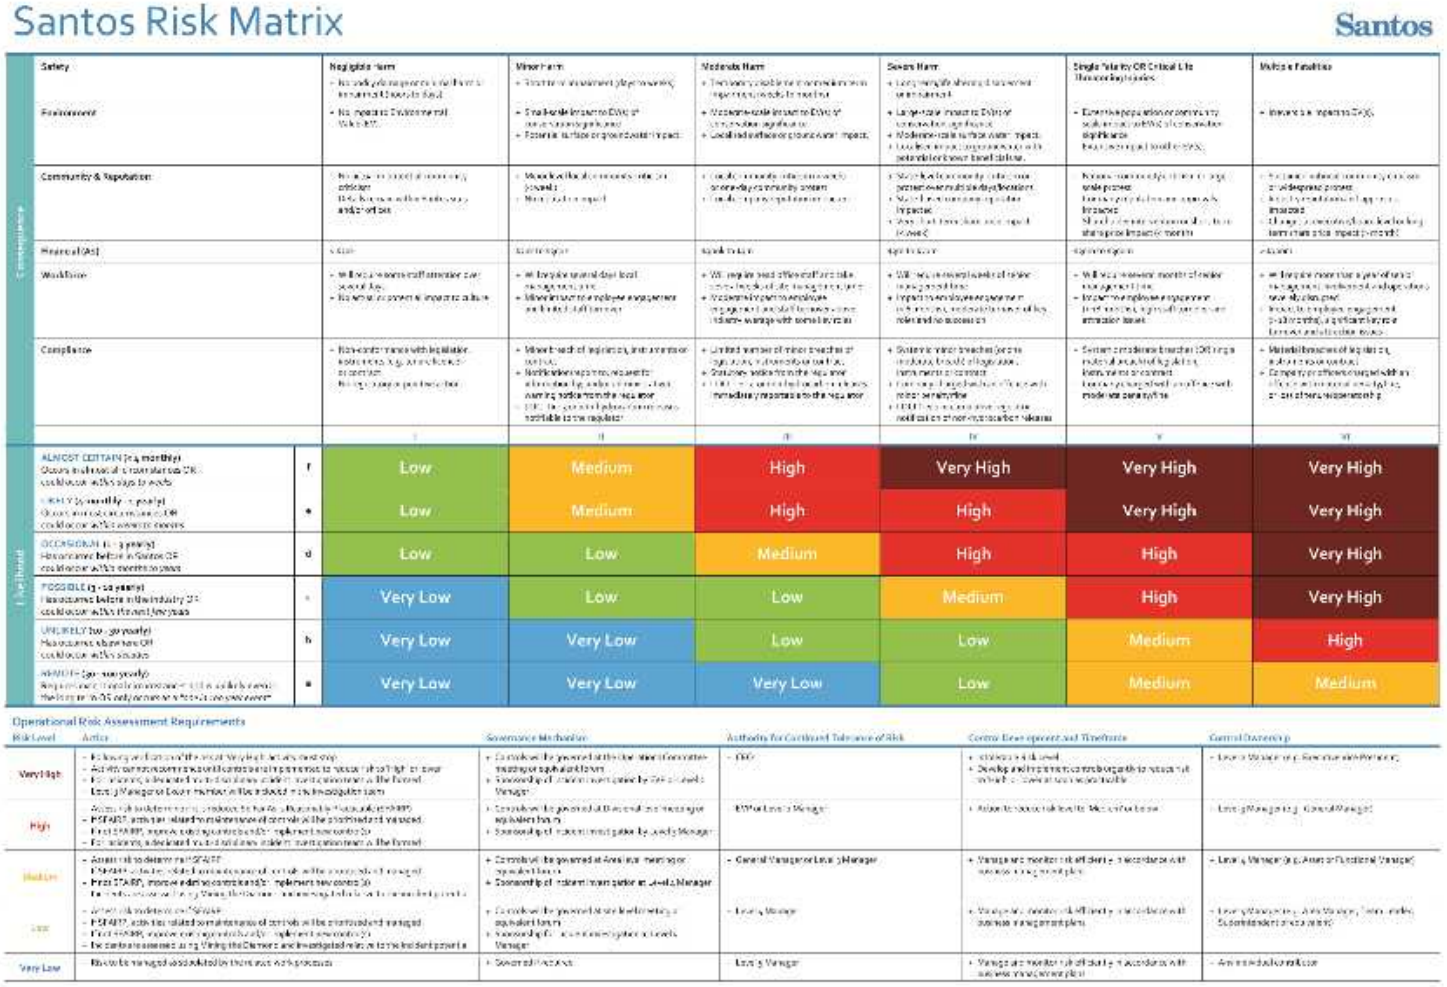

Figure 7: Santos Risk Matrix

Table 33: Environmental Risk Assessment

Identification				Unmitigated Risk			Control Strategies	Residual Risk		
Risk Event / Activity	Relevant EV	Potential Impact	Risk Source	Consequence	Likelihood	Risk		Consequence	Likelihood	Risk
Construction and operation of proposed infrastructure	Land Resources Waste Rehabilitation	Reduction in visual amenity Soil erosion, topsoil loss, inversion and compaction Disturbance to land use and suitability changes Reduction in agricultural productivity Contamination of soil	Infrastructure construction (earthworks activities, including grading and trenching) Vehicle and plant movements Minor spills or leaks of fuels and chemicals from vehicles and equipment Loss of containment Bushfire and flood (natural event) Fire (ignition sources resulting from activities)	III	d	Medium	**General** • Compliance with relevant EA conditions, and all relevant internal and external approvals are in place before work is undertaken. • All disturbance undertaken in accordance with Santos standards. • Industry standards and good industry practices are followed. • Appropriate emergency response plans in place. **Land Resources** • The proposed infrastructure has been designed to be located in pre-disturbed, non-remnant areas or co-located to minimise the area of new disturbance to land and vegetation as much as is reasonably possible (given safety and engineering restrictions). • Surface disturbance will be restricted to the minimum area required to safely carry out activities. • Infrastructure will be located to minimise impacts to drainage patterns, soil, and vegetation. • Sensitive terrain is protected through appropriate construction and maintenance practices. • Management of sensitive areas (e.g. sloped areas) is detailed in scope of works, approval documents and company procedures. • Erosion and sediment control measures in place where appropriate (refer to additional Control Strategies listed under Surface Water). • Following gathering line installation, groundcover will be re-established along the operational RoW. • Any short-term reduction in the availability of existing land use would be offset by commercial agreements between proponents and the property owner. • Vehicle and plant movements: - No unauthorised driving outside of the approved construction area. - Watering of disturbed areas and/or access tracks carried out as required / permitted to reduce dust generation. - Active promotion of appropriate road use behaviours, and the setting of appropriate speed limits for Santos personnel and contractors. - Work scheduled to fit in with landholder's property management activities. • Fire and flood: - Activity planning will consider seasonal conditions and risk of fire and flood. - Water crossings scheduled to take into account seasonal conditions and rainfall / flood likelihood. - Construction activity not undertaken during or immediately prior to flooding. - Personnel are informed on the fire danger season and associated restrictions, and ignition sources are controlled via permit to work. - Measures undertaken to reduce potential impacts of fire and flood where appropriate (e.g. removal of fuels/chemicals/equipment prior to arrival of fire or flood event). • Fuel, oil and chemical storage and handling: - Fuel, oil and chemical storage and handling undertaken in accordance with Australian standards / guidelines (i.e. in bunded areas). - Spill leak and drip trays provided to address minor drips and spills resulting from re-fuelling operations. Spill response equipment and materials kept on site and in operational vehicles (where appropriate). - Maintain a register of incidents and implement corrective actions based on outcome of investigations. - Vehicles and equipment are operated and maintained in accordance with specifications to minimise the potential for a spill or leak (e.g. oil leak or hydraulic hose failure). - Any waste generated during spill clean-up operations will be disposed of in accordance with manufacturer's guidelines and legislative / EA waste management requirements. • Production operations: - Plant and equipment designed, constructed and operated in accordance with Santos Engineering Standards and relevant Australian/International standards.	III	c	Low

Identification				Unmitigated Risk			Control Strategies	Residual Risk		
Risk Event / Activity	Relevant EV	Potential Impact	Risk Source	Consequence	Likelihood	Risk		Consequence	Likelihood	Risk
							- Infrastructure design process to address location and non-location specific threats (e.g. pipeline corrosion) and develop adequate controls to mitigate environmental and public/third party safety risk. - Safety, testing, maintenance and inspection procedures implemented. - Prestart-up checklist prior to commissioning and decommissioning activities. - Pipeline construction integrity verification (e.g. hydro test, or pneumatic test). • Loss of containment: - Infrastructure designed, constructed and operated in accordance with Santos Engineering Standards, relevant Australian/International standards, and relevant EA conditions. - Infrastructure design process to address location and non-location specific threats and develop adequate controls to mitigate environmental and public/third party safety risk. Safety, testing, maintenance and inspection procedures implemented. - Gathering lines designed and constructed to comply with Australian Standards AS2885 – Pipelines Gas and Liquid Petroleum and the APGA Code of Practice For Upstream Polyethylene Gathering Networks-CSG Industry – Version 6 (APGA, 2024). - Pipeline construction integrity verification (e.g. hydro test, or pneumatic test). - Regular monitoring of control systems (e.g. emergency shutdown valves) to ensure that protection levels are adequate. Emergency response training for emergency response personnel. - Loss of containment managed via appropriate Santos incident management system (IMS), and implementation of corrective actions is based on incident investigation. **Waste** - Waste managed in accordance with the *Waste Reduction and Recycling Act 2011* and Waste and Resource Management Hierarchy. - Where practicable, Santos would implement the waste and resource management hierarchy, and reduce risks to EVs from waste storage and disposal, by: o designing activities to incorporate less resource-intensive materials and more efficient processes. o designing contracts which encourage waste avoidance and set waste reduction targets. o identifying and separating waste streams for re-use, recycling, treatment or disposal. o storing waste in appropriate receptacles or designated areas prior to their re-use or collection for recycling, treatment or disposal. o ensuring wastes are removed by transporters which are appropriately licensed or authorised to transport that particular waste type. o ensuring all wastes removed from the site are recycled, treated or disposed of at an appropriately licensed waste facility. o reviewing and auditing waste management practice to confirm legal compliance and identify opportunities for improvement. - Covered bins are provided for the collection and storage of wastes. - Rubbish loads are covered during transport to a licensed waste facility. - On site disposal of residual drilling mud (RDM) undertaken in accordance with mix bury cover method, or alternative method and quality criteria as certified by a suitably qualified third party. - Hydraulic fracturing flowback fluid contained in lined pits or tanks, and removed from site for authorised reuse or disposal upon completion of operations. - In the event of expected flooding, waste will be removed from areas at risk of inundation (where appropriate / safe to do so). - Waste materials and non-essential infrastructure removed from operational areas as soon as reasonably practicable following petroleum activities. **Rehabilitation** - Pipeline trenches are backfilled and topsoils reinstated after pipe laying in accordance with relevant EA conditions. - Gathering line RoWs are re-instated and revegetation commenced after completion of petroleum activities for the purpose of pipeline construction in accordance with relevant EA conditions. - Rehabilitation of significantly disturbed areas undertaken in accordance with relevant EA conditions and rehabilitation criteria. - Areas potentially exposed to contamination will be assessed and remediated as in accordance with relevant EA conditions and rehabilitation criteria.			

Identification				Unmitigated Risk			Control Strategies	Residual Risk		
Risk Event / Activity	Relevant EV	Potential Impact	Risk Source	Consequence	Likelihood	Risk		Consequence	Likelihood	Risk
							- Final rehabilitation of disturbed areas would be undertaken to achieve the final rehabilitation acceptance criteria and relevant EA conditions. - Rehabilitation aims to reshape and stabilise disturbed areas to provide appropriate site conditions to facilitate natural revegetation processes, and will include the following activities (where appropriate): ▪ ripping of areas of compacted soil (except on sensitive soils / environments). ▪ respreading of stockpiled topsoil, vegetation and seed stock (where available) to facilitate natural revegetation. ▪ restoration of natural landform contours.			
Construction and operation of proposed infrastructure	Flora, REs, ESAs, and Flora and Fauna	Damage to and/or loss of native riparian vegetation and habitat Damage to and/or loss of high value flora Introduction and/or spread of weeds, pest plants, animals and pathogens Loss of species population, further endangerment and loss in species diversity Disturbance, injury or loss of fauna	Infrastructure construction (earthworks activities, including grading and trenching) Entrapment in voids (trenches / bell holes / pits) Vehicle and plant movements Fire (ignition sources resulting from activities)	III	c	Low	**General** • Compliance with relevant EA conditions, disturbance limits to MSES/MNES, and all relevant internal and external approvals in place before work undertaken. **Flora, REs and ESAs** • Existing areas of disturbance will be utilised wherever practicable to locate proposed disturbances to minimise habitat fragmentation / disturbance. • All clearing and disturbance must be internally approved via internal Santos approval processes prior to commencement of construction activities. • Areas proposed to be disturbed / cleared shall be clearly delineated (via GPS or visual markers), and the need to conduct the proposed activity in designated and approved areas will be reinforced during site toolbox / induction meetings. • Mature trees will be avoided wherever practicable (and tree limbs will be loped in preference to removing entire trees wherever practicable). • Disturbance in and around ephemeral wetlands will be avoided or minimised wherever practicable, or otherwise preferentially scheduled to occur when the areas are dry, and otherwise in accordance with relevant EA conditions and disturbance limits to MSES/MNES. • Maximum clearance widths for linear and non-linear infrastructure will be in accordance with relevant EA conditions. • Introduction and / or spread of weeds, pest plants, animals and pathogens: - Hygiene protocols implemented as appropriate to minimise the introduction, spread and persistence of weeds, pest plants, animals and pathogens. - Access to and from the site via designated access tracks only. - Vehicle and equipment wash-down when operations have been undertaken in areas of known weed infestations. - Monitor for presence of weeds within the construction area, and where necessary implement control measures. - Ensure that imported material is from an area or source considered to be pest plant/disease free. • Refer to Control Strategies listed under ‘Fire and Flood’ and ‘Vehicle and plant movements’ under Land Resources. **Fauna and Livestock** • A suitably qualified Fauna Spotter / Catcher will be present during woody vegetation clearing activities where required. • Prior to construction activities commencing, the Fauna Spotter / Catcher will survey for the presence of fauna located in or near the proposed disturbance area. • Fauna and significant habitat features will be avoided or relocated outside the proposed disturbance area where appropriate to do so. • Clearing and construction activities will be scheduled to avoid breeding periods, where work delivery schedules are sufficiently flexible to do so. • The period of time that trenches and other excavations are open will be minimised, and open voids will be backfilled as soon as practicable following completion of works. • During construction, open trenches and other open voids will be regularly checked for potentially entrapped fauna. • Open voids must also be fenced or covered wherever practicable to prevent access or harm to fauna and stock. Where this is not practicable, the focus should be on regularly checking open voids for entrapped fauna and installing measures such as escape routes to reduce risks to potentially entrapped fauna. • Pipe string ends will be capped nightly to prevent fauna ingress.	II	c	Low

Identification				Unmitigated Risk			Control Strategies	Residual Risk		
Risk Event / Activity	Relevant EV	Potential Impact	Risk Source	Consequence	Likelihood	Risk		Consequence	Likelihood	Risk
							• Prior to backfilling, trenches and voids will be checked for fauna and any found will be removed. • Refer to additional Control Strategies listed under Vehicle and Plant Movements and 'Fire and Flood' under Land Resources.			
Construction and operation of proposed infrastructure	Surface Water and Wetlands	Disturbance to natural drainage patterns Degradation of downstream water quality from sediment releases / minor spills or leaks of fuels and chemicals (PW / hydrotest water) Damage to and/or loss of native riparian vegetation and habitat Reduction in groundwater quantity and/or availability for other users Contamination of soil and/or watercourses	Drilling and hydraulic stimulation / fracturing activities Production operations Infrastructure construction (earthworks activities including grading and trenching) Vehicle and plant movements Minor spills or leaks of fuels and chemicals from vehicles and equipment Loss of containment Flood (natural event)	IV	c	Medium	**General** • Compliance with relevant EA conditions, and all relevant internal and external approvals in place before work undertaken. **Surface Water** • Appropriate erosion and sediment control (ESC) measures will also be implemented where required to mitigate potential sediment impacts to drainage features. More specifically, Santos will develop site-specific erosion and sediment control plans (ESCP) or implement standard ESCPs for each scope of work e.g. gathering line installation. • RoWs will be constructed to ensure sufficient area is available to construct appropriate erosion and ESC structures (where required). • Santos will only construct in ephemeral wetland areas when they are dry, and linear infrastructure RoWs will be reinstated to their natural landform following construction. • Construction of linear infrastructure within a water course would preferentially be carried out in periods of low or no flow. • Where it is necessary to carry out works in a watercourse during periods of flow, these would be carried out in accordance with the relevant Department of Agriculture, Fisheries and Forestry Waterway Barrier Works Code(s). • Watercourse crossings would be selected at locations where the least impact to riparian flora and fauna will occur (i.e. clearing of vegetation and at narrowest and shallowest locations) where practicable. • Construction or maintenance of linear infrastructure activities in watercourses will comply with the turbidity limit of relevant EA conditions, and water quality monitoring would be carried out downstream of watercourse crossing works where necessary to ensure compliance with water quality limits. • Rehabilitation will commence as soon as reasonably practicable following completion of construction activities, including the restoration of natural landform contours to ensure natural surface water flows are maintained. • Appropriate spill kits would be kept on site and in staff vehicles for use in the event of a spill or leak of hydrocarbons or chemicals, and Chemicals, fuels or other hazardous substances would be stored and managed in accordance with relevant Australian Standard. • Refer to Control Strategies listed under Flora, REs and ESAs, Fire and Flood, Fuel, Oil and Chemical Storage and Handling, and Loss of Containment under Land Resources.	IV	b	Low
Construction and operation of proposed infrastructure	Ground water	Decline in groundwater level / pressure at water bores, reducing water availability and potentially impacting groundwater environmental values Reduction in groundwater head resulting in a reduction of groundwater discharge at	Drilling and hydraulic stimulation / fracturing activities Production (gas and water) operations Well control or well head equipment failure Well casing or cement failure (well integrity failure)	IV	c	Medium	**General** • Refer to general control strategies listed under the Land Resources EV. • Compliance with relevant EA conditions, and all relevant internal and external approvals in place before work undertaken. **Groundwater** • Production wells will be designed, constructed and decommissioned in accordance with the *Code of Practice for the construction and abandonment of petroleum wells and associated bores in Queensland Version 2* (DNRME 2019). • Hydraulic fracturing activities will be undertaken in accordance with the requirements of the Code of Practice (DNRME, 2019), Santos Hydraulic Fracturing Risk Assessment – Santos Eastern Queensland (HFRA) (EHS Support 2021), Eastern Queensland Stimulation Impact Monitoring Program (SIMP) (Santos 2021), Chemical Risk Assessment Framework (CRAF) (Santos, 2025), and the WRA (KCB, 2025). • Drilling and hydraulic fracturing fluids and additives will be used in accordance with the mandatory requirements and good practice guidelines outlined in the Code of Practice (DNRME 2019), CRAF (Santos, 2025), as well as the Safety Data Sheets provided with each fluid / additive. • Drilling and hydraulic fracturing fluids will not contain benzene, toluene, ethyl-benzene and xylene above prescribed levels. No chemicals identified as Persistent, Bio-accumulative and Toxic (PBT) will be used. • The use of biodegradable substances in the drilling and hydraulic fracturing fluid would be preferred where practicable. Products would be chosen, stored, and used at concentrations that minimise the risk of causing environmental harm.	IV	b	Low

Identification				Unmitigated Risk			Control Strategies	Residual Risk		
Risk Event / Activity	Relevant EV	Potential Impact	Risk Source	Consequence	Likelihood	Risk		Consequence	Likelihood	Risk
		spring complexes, potentially causing degradation of GDEs Reduction of baseflow to watercourses, potentially resulting in reduced availability of water to GDEs and reduced water availability to potential users downstream	Minor spills or leaks of fuels, chemicals or other produced fluids Loss of containment Storage and disposal of general waste, chemical and process wastes Vehicle and plant movements				• Personnel, including contractors, would be made aware of emergency spill procedures. • Production wells would be constructed a minimum distance of 90 metres from landholder bores. • Baseline Assessment Plan to consider new landholder bores as required (if applicable depending on bore status). • Refer to Control Strategies listed under Flora, REs and ESAs, Fire and Flood, Fuel, Oil and Chemical Storage and Handling, and Loss of Containment under Land Resources.			
Construction and operation of proposed infrastructure	Air Quality and Noise	Air pollution and localised reduction in air quality Nuisance caused by vibration, noise and dust generation Disturbance to fauna and livestock	Infrastructure construction (earthworks activities including grading and trenching) Vehicle and plant movements Fire (ignition sources resulting from activities) Minor air emissions generated from vehicles and equipment	III	c	Low	**General** • Refer to general control strategies listed under the Land Resources EV. • Fit for purpose equipment. • Conduct regular testing, inspections and maintenance of site equipment. **Air Quality and Noise** • Air and noise emissions will be managed in accordance with controls outlined in Section 4.6.2, including the following processes: – Identification of sensitive receptors during planning. – Landholders consulted as required where activities may affect sensitive receptors and/or agricultural operations. – Systems in place for logging stakeholder / landholder complaints to ensure issues are recorded and addressed as appropriate. – Noise managed in accordance with ‘management hierarchy for noise’ set out in the *Environmental Protection (Noise) Policy 2019* (Noise). – Vehicles, engines and equipment operated and maintained in accordance with manufacturer specifications and planned maintenance systems. – Use of attenuation / suppression devices where required e.g. silencing equipment – Majority of vehicle movements will be limited to daylight hours. – Dust suppression measures carried out where required e.g. road watering. – Refer to control strategies for ‘vehicle and plant movements’ under the Land Resources EV.	II	c	Low

Appendix G: Environmental Objective Assessment and Performance Outcomes

Environmental objectives

The environmental objectives in Schedule 8, Part 3, Division 1 of the EP Reg are based on EVs to be protected, with the exception of the waste objective.

An application should demonstrate how the proposed activity will be managed in a way to achieve these environmental objectives.

Performance outcomes

The assessment tables in Divisions 1 and 2 of the EP Reg also provide performance outcomes to give applicants guidance on how to demonstrate they are meeting the environmental objective. There are usually two performance outcomes.

The first performance outcome is usually the ‘no impact’ option, which makes it clear that if there is to be no impact on an environmental value, then the environmental objective is achieved.

The second performance outcome should be considered when the first is not met. The second performance outcome specifies a series of measures or actions that can be taken to adequately manage the risks the activity poses to the relevant EVs. If an application does not meet either performance outcome for an environmental objective, the application may meet the performance outcome through alternative measures.

Assessment against Schedule 8 (Parts 1 and 2) of the EP Reg (Environmental Objective Assessment and Performance Outcomes) is provided in Table 34 below.

Table 34: Environmental objective assessment

Value / Objective	Performance Outcome - Santos Response
Air	
Environmental objective	
The activity will be operated in a way that protects the environmental values of air.	The intention of this environmental objective is to ensure that any discharges to air, including contaminant releases from point sources, fugitive emissions, and wind borne dust, do not impact on EVs. Consideration should be given to the values as defined in the *Environmental Protection (Air) Policy 2019*. Schedule 8 part 3 of the EP Reg sets identifies the performance outcomes to be achieved that will achieve the Environmental Objective of operating the activity in a way that protects the EVs of air. The Performance Outcomes are: 1. The is no discharge to air of contaminants that may cause an adverse effect on the environment from the operation of the activity; or. 2. All of the following: a. fugitive emissions of contaminants from storage, handling and processing of materials and transporting materials within the site are prevented or minimised b. contingency measures will prevent or minimise adverse effects on the environment from unplanned emissions and shut down and start up emissions of contaminants to air c. releases of contaminants to the atmosphere for dispersion will be managed to prevent or minimise adverse effects on EVs. Schedule 1 of the EPP Air, sets the air quality objectives and indicators to be achieved for each EV. Under the EPP Air, the EVs likely to be affected by the proposed activities includes: • Protecting human health and wellbeing from emissions such as nitrogen dioxide (NO_2) and carbon monoxide (CO)

Value / Objective	Performance Outcome - Santos Response
	• Protecting aesthetic environment from visibility reducing particles such as dust and smoke. Section 4.7 provides an assessment of potential Impacts, mitigation measures and environmental risk assessment of the proposed activities with regard to potential impacts to air EVs (as described in Section 3.9). The proposed activities may result in impacts to air values primarily as a result of: • infrastructure construction; • vehicle and plant movements; • fire (ignition sources resulting from activities); and • minor exhaust emissions generated from vehicles, equipment and machinery. The activity will be operated in a way that protects the EVs of air. Fugitive emissions and releases of contaminants from storage, handling and processing of materials and transporting materials within the site to the atmosphere will be minimised in accordance with mitigation and management measures identified in Appendix F, Table 33 to prevent or minimise adverse effects on EVs. Further, contingency measures will prevent or minimise adverse effects on the environment from unplanned emissions and shut down and start up emissions of contaminants to air. Primary air pollutants generated during the proposed activities would be minor dust and exhaust emissions from operating vehicles, plant and machinery. These sources will be predominantly temporary, occurring only during the construction period. These relatively minor dust and exhaust emissions would remain local to the source, and are unlikely to affect air quality EVs of the broader Project Area provided that mitigation and management measures identified in Appendix F, Table 33 are implemented. There are eleven potential sensitive receptors, including five residences located within the Project Area, and six residences located within approximately 1km of the Project Area boundary. Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to air EVs as a result of the proposed activities are

Value / Objective	Performance Outcome - Santos Response
	classified as 'Low'.
Water	
Environmental objective	
The activity will be operated in a way that protects environmental values of waters.	The intention of this environmental objective is to ensure that any discharges to water do not impact on EVs. Consideration should be given to the values as defined in the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019.* The Performance Outcomes are: 1. There is no actual or potential discharge to waters of contaminants that may cause an adverse effect on an environmental value from the operation of the activity. 2. All of the following— a. the storage and handling of contaminants will include effective means of secondary containment to prevent or minimise releases to the environment from spillage or leaks; b. contingency measures will prevent or minimise adverse effects on the environment due to unplanned releases or discharges of contaminants to water; c. the activity will be managed so that stormwater contaminated by the activity that may cause an adverse effect on an environmental value will not leave the site without prior treatment; d. the disturbance of any acid sulfate soil, or potential acid sulphate soil, will be managed to prevent or minimise adverse effects on EVs; e. acid producing rock will be managed to ensure that the production and release of acidic waste is prevented or minimised, including impacts during operation and after the environmental authority has been surrendered; f. any discharge to water or a watercourse or wetland will be managed so that there will be no adverse effects due to the altering of existing flow regimes for water or a watercourse or wetland; g. for a petroleum activity, the activity will be managed in a way that is consistent with the coal seam gas water management policy, including the prioritisation hierarchy for

Value / Objective	Performance Outcome - Santos Response

	managing and using coal seam gas water and the prioritisation hierarchy for managing saline waste;
	h. the activity will be managed so that adverse effects on EVs are prevented or minimised.
	
	Section 4.5 provides an assessment of potential impacts, mitigation measures and environmental risk assessment of the proposed activities with regard to potential impacts to surface water EVs (as described in Section 3.7).The proposed activities have potential to result in direct and indirect impacts to surface water EVs primarily as a result of:
	
	• drilling and hydraulic stimulation / fracturing activities;
	• production operations;
	• infrastructure construction (earthworks activities including grading and trenching);
	• vehicle and plant movements;
	• minor spills or leaks of fuels and chemicals from vehicles and equipment;
	• loss of containment; and
	• flood (natural event).
	
	Refer to Section 4.5 for a detailed discussion of mitigation measures proposed to be implemented to manage and mitigate potential impacts to water EVs.
	
	Section 14 of the EPP water defines the management hierarchy for surface or groundwater. To the extent it is reasonable to do so, release of wastewater or contaminants to waters must be dealt with in the following order of preference:
	
	• firstly—reduce the production of wastewater or contaminants by reducing the use of water;
	• secondly—prevent waste and implement appropriate waste prevention measures;
	• thirdly—evaluate treatment and recycling options and implement appropriate treatment and recycling;
	• fourthly—evaluate the following options for waste water or contaminants in the order in which they are listed –
	  ○ appropriate treatment and release to a waste facility or sewer;
	  ○ appropriate treatment and release to land;

Value / Objective	Performance Outcome - Santos Response
	○ appropriate treatment and release to surface waters or groundwaters. To meet the objectives under EPP Water, the following will be undertaken: • sediment and erosion control measures (e.g., silt fences, diversion drains) will be developed in accordance with the Best Practice Erosion and Sediment Control guidelines; • progressive rehabilitation to re-establish ground cover and minimise run-off; • construction activities occurring within watercourses will be completed in accordance with proposed EA conditions; • all disturbed areas will then be reshaped and stabilised following trenching and revegetated where required to support natural hydrology and ecological recovery; • effluent released to land will be in accordance with MEDLI; • clean up of unauthorised releases as soon as practicable; • appropriate bunding and clean water diversions; • use of sediment ponds to collect any contaminated stormwater; and • CSG water released to land will be in accordance with the release criteria. Further, proposed EA conditions (refer to Appendix A) limit activities within wetlands, lakes, springs and watercourses, and other 'waters' as defined by the EA. For well pads and other permanent infrastructure close to drainage lines and watercourses, areas will be bunded to contain spills and prevent run-off. Spill kits will be kept on-site, and all staff will follow spill response procedures. Cleared areas will be stabilised, and disturbed land will be rehabilitated after works are complete in alignment with proposed EA conditions and Santos internal procedure documents. Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to surface water EVs as a result of the proposed activities are classified as 'Low'.
Wetlands	

Value / Objective	Performance Outcome - Santos Response
Environmental objective	
The activity will be operated in a way that protects the environmental values of wetlands.	Wetlands are defined in the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* as an area shown as a wetland on the Map of Queensland wetland EVs. The Map of Queensland wetland EVs is a statewide statutory map under the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019*. It identifies wetlands of high ecological significance (HES) and general ecological significance (GES) across the state. This performance outcome is met if the activity will not potentially or actually impact on a wetland. For example, the activity may be located in an area without any wetlands nearby. The map of referable wetlands, available on the DETSI website may be used to identify proximate referable wetlands. There are no referable wetlands, HES or GES wetlands, spring vents, spring complexes or watercourse springs mapped to be located within the Project Area and there will be no potential or actual adverse effect on a wetland as defined by the *Environmental Protection (Water and Wetland Biodiversity) Policy 2019* as part of carrying out the activity. Proposed activities do not include planned direct abstraction from, or discharges to, watercourses. Impacts on surface water users, EVs and spiritual values are not anticipated. Further, proposed EA conditions (refer to Appendix A) limit activities within wetlands, lakes, springs and watercourses, and other 'waters' as defined by the EA, and the activity will be operated in a way that prevents or minimises adverse effects on the EVs of wetlands.
Groundwater	
Environmental objective	
The activity will be operated in a way that protects the environmental values of groundwater and any associated surface ecological systems.	Groundwater is defined in Schedule 19 Dictionary of the EP Reg and means 'underground water'. Surface water is defined in s. 31 of the EP Reg as 'water other than groundwater'. The Performance Outcomes are: 1. Both of the following apply —

Value / Objective	Performance Outcome - Santos Response
	a. there will be no direct or indirect release of contaminants to groundwater from the operation of the activity; b. there will be no actual or potential adverse effect on groundwater from the operation of the activity. 2. The activity will be managed to prevent or minimise adverse effects on groundwater or any associated surface ecological systems. This performance outcome is met if the activity does not involve the intentional injections or release of contaminants to groundwater, and does not involve any activities that might lead to an unintentional release to groundwater, for example, by spillage of contaminants. An activity that could meet performance outcome 1 is an activity that does not involve the handling or storage of any contaminants that may cause an impact on groundwater. If management action or infrastructure is required to manage contaminants, for example secondary containment, then performance outcome 2 is relevant. Section 4.6 provides an assessment of potential Impacts, mitigation measures and environmental risk assessment of the proposed activities with regard to potential impacts to groundwater EVs (as described in Section 3.8). Further, as discussed in Section 3.8, Santos commissioned KCB to undertake a third-party WRA (KCB, 2025) of proposed activities located in the Project Area (attached as Appendix E). Predicted impacts to groundwater as a result of the Project were estimated using the OGIA groundwater model developed for predicting effects on groundwater due to CSG and coal mine development within the Surat Cumulative Management Area (CMA). Refer to Section 4.6 for detailed discussion of mitigation measures proposed to be implemented to manage and mitigate potential impacts to groundwater EVs. Section 14 of the EPP water defines the management hierarchy for surface or groundwater. To the extent it is reasonable to do so, release of wastewater or contaminants to waters must be dealt with in the following order of preference: • firstly—reduce the production of wastewater or contaminants by reducing the use of water; • secondly—prevent waste and implement appropriate waste prevention measures;

Value / Objective	Performance Outcome - Santos Response

	• thirdly—evaluate treatment and recycling options and implement appropriate treatment and recycling;
	• fourthly—evaluate the following options for wastewater or contaminants in the order in which they are listed –
	  ○ appropriate treatment and release to a waste facility or sewer;
	  ○ appropriate treatment and release to land;
	  ○ appropriate treatment and release to surface waters or groundwaters.
	
	All activities with the potential to interact with groundwater will be conducted in line with Santos' internal groundwater management procedures and proposed EA conditions. For linear infrastructure, trenching activities will avoid shallow groundwater areas where practicable. To avoid introducing contaminants to groundwater, fuels, chemical and other hazardous materials will be stored within bunded storage areas and spill kits will be made available. Groundwater monitoring will be undertaken as required by proposed EA conditions and applicable regulatory requirements to verify that groundwater levels and quality are not adversely affected.
	
	For production wells, all well construction will comply with industry standards and Santos' internal design specifications, including casing and cementing to isolate aquifers and prevent inter-aquifer mixing. Permanent infrastructure, including well pads and associated storage areas, will be bunded and designed to contain any spills or leaks, preventing infiltration to underlying groundwater systems. Spill kits and response procedures will be in place at all operational sites.
	
	Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to groundwater EVs as a result of the proposed activities are classified as 'Low'.

Noise	
Environmental objective	

Value / Objective	Performance Outcome - Santos Response
The activity will be operated in a way that protects the environmental values of the acoustic environment.	Sensitive receptors for noise issues are specified in the *Environmental Protection (Noise) Policy 2019.* The Performance Outcomes are: 1. Sound from the activity is not audible at a sensitive receptor. The release of sound to the environment from the activity is managed so that adverse effects on EVs including health and wellbeing and sensitive ecosystems are prevented or minimised. Noise emissions associated with CSG activities are regulated under the EP Act and the subordinate legislation being the *Environmental Protection (Noise) Policy 2019* (EPP Noise) and EP Reg. Section 6 the EPP Noise describes the EVs that are to be protected or enhanced are: • The qualities of the acoustic environment that are conducive to protecting the health and biodiversity of ecosystem • The qualities of the acoustic environment that are conducive to human health and wellbeing, including by ensuring a suitable acoustic environment for individuals to do any of the following: ○ sleep ○ study or learn ○ be involved in recreation, including relaxation and conversation • The qualities of the acoustic environment that are conducive to protecting the amenity of the community. Schedule 8 part 3 of the EP Reg sets the performance outcomes that will achieve the Environmental Objective of operating the activity in a way that protects the EVs of the acoustic environment. These are: 1. Sound from the activity is not audible at a sensitive receptor; or 2. The release of sound to the environment from the activity is managed so that adverse effects on EVs, including health and wellbeing and sensitive ecosystems, are prevented or minimised. If not properly managed, the proposed activities have potential to impact on the EVs for noise by causing environmental harm, including nuisance. Section 14 of the EP Act defines environmental harm as any adverse effect, or potential adverse effect (whether temporary or permanent and of

Value / Objective	Performance Outcome - Santos Response
	whatever magnitude, duration or frequency) an EV and includes environmental nuisance. Section 15 of the EP Act defines environmental nuisance as unreasonable interference or likely interference with an EV caused by: • Aerosols, fumes, light, noise, odour, particles or smoke; or • An unhealthy, offensive or unsightly condition because of contamination; or • Another way prescribed by regulation. Schedule 1 of the EPP noise, sets the acoustic quality objectives at sensitive receptors and the EV to be protected. The acoustic EVs identified for the proposed activities include: • Residential receptors (indoor and outdoor) – daytime, evening and night-time • Commercial and retail activity – when the activity is open for business. Section 4.7 provides an assessment of potential Impacts, mitigation measures and environmental risk assessment of the proposed activities with regard to potential impacts to noise EVs (as described in Section 3.9). The proposed activities may result in impacts to noise values primarily as a result of: • infrastructure construction; • vehicle and plant movements; • fire (ignition sources resulting from activities); and • minor exhaust emissions generated from vehicles, equipment and machinery. The majority of potential noise impacts from the proposed activities would be temporary and limited to the initial construction period. The proposed activities (and potential noise and air quality impacts) are also consistent with those associated with existing petroleum activities authorised by the nearby Backbone EA (EPPG04323316), underlying RSGPA (EPPG00898213) and RSGPAE (EPPG00662213) EAs, and existing land use (pastoral / grazing / cropping activities). Impacts from construction activities are expected to be minimal and of short duration. No blasting is proposed. Section 8 of the EPP Noise outlines the management hierarchy for an activity involving noise that affects or may affect an environmental value to be enhanced or protected under the policy. To the

Value / Objective	Performance Outcome - Santos Response

	extent that is reasonable to do so, the EPP Noise requires that noise emissions must be dealt with in the following order of preference:
	• firstly – avoid noise, for example by locating an industrial activity in an area that is not near a sensitive receptor
	• secondly – minimise the noise in the following order
	  ○ firstly – orientate an activity to minimise the noise for example by facing a part of an activity to minimise the noise
	  ○ secondly – use best available technology to minimise the noise
	• thirdly – manage the noise for example by using heavy machinery only during business hours.
	Section 9 of the EPP Noise outlines the management intent for an activity involving noise that affects or may affect an EV to be enhanced or protected under the policy. To the extent it is reasonable to do so, noise must be dealt with in a way that ensures:
	• the noise does not have any adverse effect, or potential adverse effect on an EV
	• background creep (general gradual increase in the total amount of background noise) in an area or place is prevented or minimised.
	All activities will be undertaken in accordance with the operational and monitoring conditions of the proposed EA conditions. Further, alternative arrangements will be in place for a noise scenario where the permissible sound level is exceeded in accordance with proposed EA conditions. The proposed activities are expected to be undertaken with negligible risk of impacts to surrounding sensitive receptors.
	Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to noise EVs as a result of the proposed activities are classified as 'Low'.

Waste	
Environmental objective	

Value / Objective	Performance Outcome - Santos Response
Any waste generated, transported, or received as part of carrying out the activity is managed in a way that protects all environmental values.	The intention of this environmental objective is to ensure that waste issues are adequately addressed. The Performance Outcomes are: 1. Both of the following apply: a) waste generated, transported or received is managed in accordance with the waste and resource management hierarchy in the *Waste Reduction and Recycling Act 2011*; b) if waste is disposed of, it is disposed of in a way that prevents or minimises adverse effects on EVs. Performance outcome 1 applies to all activities that generate, transport, receive, or dispose of waste. In Queensland waste associated with CSG activities are regulated under key pieces of legislation including: • *Environmental Protection Act 1994* (EP Act) • Environmental Protection Regulation 2019 (EP Regulation) • *Waste Reduction and Recycling Act 2011* (WRR Act) • Waste Reduction and Recycling Regulation 2023 (WRR Regulation) • Coal seam gas water management policy 2012 • Queensland government's coal seam gas brine action plan 2023-2033 • The National Environment Protection (movement of controlled waste between States and Territories) Measure (NEPM) The EP Act aims to protect Queensland's environment while allowing for development that improves the total quality of life, both now and in the future, in a way that maintains the ecological processes on which life depends (being ecologically sustainable development). The WRR Act aims to promote waste avoidance and reduction and to encourage resource recovery and efficiency. Under section 8AA of the WRR Act; • 'Waste' is defined as anything that ○ is left over, or is unwanted by-product from an industrial, commercial or other activity ○ is surplus to industrial, commercial, domestic or other activity generating the waste,

Value / Objective	Performance Outcome - Santos Response
	• however, waste does not include a resource, or a thing prescribed by regulation not to be a waste • waste can be a gas, liquid, solid or energy, or a combination of any of them. Schedule 8 part 3 of the EP Reg sets the performance outcome that will achieve the Environmental Objective that any waste generated, transported or received as part of an activity is managed in a way that protects all EVs. Under this section, both of the following apply: • waste generated, transported or received is managed in accordance with the waste and resource management hierarchy under the WRR Act; and • if waste is disposed of, it is disposed of in a way that prevents or minimises adverse effects on EVs. The NEPM provides a basis for ensuring that controlled wastes which are to be moved between States and Territories are properly identified, transported, and otherwise handled in ways which are consistent with environmentally-sound practices for the management of these wastes. The proposed EA conditions will appropriately govern waste management for the Project, and Santos will implement measures so that waste is managed in accordance with the waste and resource management hierarchy and the waste and resource management principles. **Waste generation** Waste generation will occur throughout construction, operation and decommissioning of each Project activity. The principal waste generating activities from the proposed activities can be broadly classified as the following: • Project construction activities • CSG well drilling • CSG production/extraction • Sewage treatment • Pipeline waste water from low point drains • Activities incidental to construction and operation such as camps • Asset decommissioning and abandonment activities.

Value / Objective	Performance Outcome - Santos Response

	Each of these activities generate a variety of waste products that can be categorised as being one of the following three categories:
	
	• **Regulated waste** – wastes listed schedule 9[3] of the EP Regulation. Regulated wastes are subject to specific storage, transport and Reporting requirements and require careful on-site management due to the hazards associated with them. Regulated wastes may be recyclable or disposable. The EP Regulation also defines 'limited regulated waste'. Up to 10% of the total amount of waste received at a general waste disposal facility in a year can be limited regulated waste. The definition of limited regulated waste includes the following specific regulated waste types:
	  ○ animal effluent and residues, including abattoir effluent and poultry and fish processing waste
	  ○ asbestos
	  ○ food processing waste
	  ○ quarantine waste that has been rendered non-infectious
	  ○ sewage sludge or residue produced in carrying out an ERA to which an environmental authority for sewage treatment applies
	  ○ tyres
	• **General recyclable waste** – wastes that are not regulated and able to be reused, reconditioned, or reprocessed.
	• **General waste** – wastes that are not regulated and cannot be recycled. General disposal waste is comprised of two main waste streams: putrescible (i.e., something that can decay) and non-putrescible.
	
	The specific waste types expected to be generated as part of the Project are listed in Section 3.10.
	
	EVs to that are to be protected or enhanced that can potentially be impacted by waste from the proposed activities include:
	
	• Water – contamination of surface and groundwater can potentially occur if:

[3] https://www.legislation.qld.gov.au/view/html/inforce/current/sl-2019-0155#sch.9

Value / Objective	Performance Outcome - Santos Response
	○ waste is not stored and contained appropriately ○ unauthorised release of contaminants such as brine and untreated CSG water ○ stormwater is not appropriately managed before release ○ unplanned spills of produced water, hydrocarbons, chemicals are not cleaned appropriately ○ effluent is not appropriately treated before releasing to land • Land – contamination of soils can potentially occur if: ○ waste is not stored and contained properly ○ unauthorised release of contaminants such as brine and untreated CSG water ○ stormwater is not appropriately managed before release ○ effluent is not appropriately treated before releasing to land ○ excessive nutrient loading from the treated effluent ○ irrigation of CSG water that does not comply with the release criteria • Health and wellbeing – health and wellbeing can potentially be impacted where: ○ dust, excessive noise, and other airborne contaminants including offensive odours that can cause nuisance at a sensitive receptor ○ waterborne human disease-causing microorganisms in the treated effluent ○ unauthorised release of contaminants such as brine and CSG water • Flora and fauna – Flora and fauna can potentially be impacted if: ○ waste is not stored and contained properly • General aesthetic and amenity – the general aesthetic of the environment can potentially be impacted where: ○ Waste stockpiles are not covered causing litter and dust emissions ○ Waste stockpiles exceed certain heights • Impact on air quality from emissions including dust, GHG, NOx Section 4.8 provides an assessment of potential Impacts, mitigation measures and environmental risk assessment of the proposed activities with regard to potential impacts associated with waste generation, storage, processing and transport. The proposed activities may result in impacts to EVs (as described in Section 3.9) due to the generation of waste, primarily as a result of the storage and disposal of: • general waste; • waste fuels;

Value / Objective	Performance Outcome - Santos Response
	• oils and other chemicals; and • produced fluids and other process wastes. All chemicals and fuels used for the Project will be stored, transported and handled on-site will be effectively contained and where relevant, meet the relevant Australian Standards (e.g. AS 1940:2017 for the storage and handling of flammable and combustible liquids. Further, management of PW, residual drilling materials, hydraulic fracturing stimulation fluids and hydrostatic test water and water from LPDs are specifically discussed in Sections 4.8.1 to 4.8.5. Impacts associated with the generation of waste, primarily as a result of the storage and disposal of waste, have the potential to impact on EVs including on land and biodiversity, visual amenity, soil and water quality and human health. Santos aims to minimise the operational footprint and significant disturbance associated with its activities as far as reasonably practicable. However, potential direct and indirect impacts to EVs resulting from the generation, storage and disposal of waste may include: • reduction in visual amenity; • disturbance, injury or loss of fauna and livestock (i.e. fauna/livestock access to waste/contaminants); • contamination of soil and water resources (groundwater / surface water); • disturbance to land use and land suitability changes; and • reduction in agricultural productivity. Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate that residual risks to EVs due to the generation, storage and disposal of waste as a result of the proposed activities are classified as 'Low'
Land	
Environmental objective	

Value / Objective	Performance Outcome - Santos Response
The activity is operated in a way that protects the environmental values of land including soils, subsoils, landforms and associated flora and fauna.	The intention of this environmental objective includes management of land issues during the operational phase of the activity, as well as rehabilitation of significantly disturbed land once operational activities have ceased. Schedule 8 part 3 of the EP Reg, sets the performance outcomes for achieving the Environmental Objective of carrying out the activity in a way that protects the EVs of land, including soils, subsoils, landforms and associated flora and fauna. The Performance Outcomes are: 1. There is no actual or potential disturbance or adverse effect to the environmental values of land as part of carrying out the activity. 2. All of the following — a. activities that disturb land, soils, subsoils, landforms and associated flora and fauna will be managed in a way that prevents or minimises adverse effects on the environmental values of land; b. areas disturbed will be rehabilitated or restored to achieve sites that are (i) safe to humans and wildlife; and (ii) non-polluting; and (iii) stable; and (iv) able to sustain an appropriate land use after rehabilitation or restoration; c. the activity will be managed to prevent or minimise adverse effects on the environmental values of land due to unplanned releases or discharges, including spills and leaks of contaminants; d. the application of water or waste to the land is sustainable and is managed to prevent or minimise adverse effects on the composition or structure of soils and subsoils. The land EVs of the Project Area are described in detail in Section 3.1, and Sections 4.1 and 4.9 provide an assessment of potential Impacts, mitigation measures, rehabilitation and environmental risk assessment of the proposed activities with regard to potential impacts to land

Value / Objective	Performance Outcome - Santos Response
	EVs. Potential direct and indirect impacts to land resources will be predominantly short-term and associated with the initial limited clearing and construction phases of the project. The proposed activities would result in direct disturbance of land for the construction of well leases, access tracks, gathering infrastructure and other incidental petroleum activities as described in Section 2.2. Proposed disturbance may temporarily reduce the availability of land for agriculture. However, these impacts would be offset by commercial agreements between Santos and relevant property owners. Following completion of the construction phase, large sections of land will begin regenerating to achieve stability and groundcover similar to that of surrounding areas. In accordance with the Land Guideline (ESR/2015/1839), appropriate soil management and rehabilitation practices will be implemented to avoid or mitigate these impacts and to ensure that disturbed land is returned to a stable and non-polluting condition. Section 4.9 provides a detailed description of rehabilitation to be undertaken as part of the proposed activities. Rehabilitation activities should seek to maintain or enhance, and protect the following EVs: • the existing primary land use for agriculture • ecosystem functioning including provision of wildlife habitat and connectivity, and ecosystem services like clean air and water; and • visual amenity of the landscape. Rehabilitation works would aim to meet Rehabilitation Acceptance Criteria under the proposed EA conditions. Rehabilitation and decommissioning of disturbed land areas would occur progressively in accordance with proposed EA conditions. The objective of rehabilitation and decommissioning is to achieve a post development landform that is: • safe for humans, native fauna and livestock • non-polluting; and

Value / Objective	Performance Outcome - Santos Response
	• stable and able to sustain appropriate land use. Disturbed areas such as pipeline RoWs would be stabilised post-construction to ensure the safe and effective operation of assets and to minimise the risk of erosion, soil loss and weed invasion. Stabilisation works would include: • remediating areas of contaminated land resulting from petroleum activities • re-establishing surface drainage lines and re-profiling contours for operational use • establishing a safe landform for humans and livestock in areas of significant cut and fill • reinstating top soil • soil conditioning where required; and • promoting the establishment of groundcover vegetation. Once disturbed areas are no longer required for operations, these would be returned to an appropriate land use in accordance with landholder needs and applicable regulatory requirements. Agricultural land uses and natural areas comprising MSES, ESAs and other forms of vegetation are the two most common pre-disturbance land uses to be rehabilitated. Final rehabilitation of natural areas would be undertaken to achieve the final rehabilitation criteria specified conditions for the proposed EA. Management (control) strategies, risk sources, potential impacts and the level of risk associated with the proposed activities are summarised in Appendix F, Table 33. The results of the risk assessment indicate the residual risk to land resource EVs as a result of the proposed activities is classified as 'Low'.

Appendix H: Eastern Queensland Hydraulic Fracturing Risk Assessment

Statutory Declaration

Resource activities other than mining

Declaration of compliance for written documents

A statutory declaration is a written statement of facts that is sworn or declared under the Oaths Act 1867. *This statutory declaration has been prepared to declare the authority holders compliance with the provisions of the* Environmental Protection Act 1994 *(EP Act) or an environmental authority condition that stipulates the requirement to submit a certified written document to the administering authority.*

Oaths Act 1867

QUEENSLAND
TO WIT

Re: Written documents relating to an environmental authority for a resource activity other than mining under the *Environmental Protection Act 1994.*

Written document: Santos Eastern Queensland Hydraulic Fracturing Risk Assessment – Document # 0007-650-EMP-0044 (7 March 2025)

(Insert type of document, e.g. contingency plan for emergency environmental incidents)

Subject matter: Compliance with Environmental Authorities and conditions as per Section 1.3 for the Environmental Authorities listed in Table 1 of the written document.

(Insert subject matter, e.g. compliance with environmental authority number PEN1001222222)

Authority holder: Santos Ltd

I, Nigel Goulding

(Insert full name of person making this declaration)

of, 3900 Stonewater Drive, Columbus OH 43221

(Insert suburb and city of the person making this declaration)

Declaration of compliance for written documents

in the State of Queensland do solemnly and sincerely declare that:

1. I am a suitably qualified person as defined in the environmental authority; having professional qualifications, training, skills and experience relevant to the subject matter and can give authoritative assessment, advice and analysis relative to the subject matter using the relevant protocols, standards, methods or literature. A copy of my curriculum vitae is Annexure A to this declaration[1];
2. The authority holder has fully complied with the requirements of environmental authority(ies) as per Section 1.0 and conditions of the environmental authority(ies) as per Attachment 1 of the written document.
3. All relevant material has been considered in preparing the Eastern Queensland Stimulation Impact Monitoring Program.
4. The content of the Eastern Queensland Stimulation Impact Monitoring Program is accurate and true.
5. The Eastern Queensland Stimulation Impact Monitoring Program meets the requirements of the environmental authority(ies) as per Section 1.0 and conditions of the environmental authority(ies) as per Attachment 1 of the written document.

And I make this solemn declaration conscientiously believing the same to be true, and by virtue of the provisions of the *Oaths Act 1867*.

1 Introduction

1.1 Preamble

Santos is undertaking the development of conventional and coal seam gas (CSG) resources in the Surat and Bowen Basins of Queensland.

For the purposes of this assessment, the term 'study area' refers to area applicable to this assessment and includes all of Santos' upstream tenures associated with the Santos upstream development areas in Eastern Queensland (EQ) (hereafter referred to as the Santos EQ Project).

Where required, environmental approvals for Santos' petroleum and gas activities have been obtained from the Queensland Coordinator General (CG) and/or the Department of Environment and Science (DES). Environmental Authorities (EAs), issued by DES for specific project areas and/or individual petroleum leases (PLs) and specific exploration and appraisal areas (authority to prospect (ATP)) have also been obtained. These EAs have typically required the development of a risk assessment, prior to the undertaking stimulation activities, to ensure that stimulation activities are managed to prevent environmental harm.

This Hydraulic Fracturing Risk Assessment (HFRA) has been written as a single overarching risk assessment that covers all relevant and site-specific matters for EQ Project. As all wells have the potential to be hydraulically stimulated at one or more point in time, the single HFRA approach is considered appropriate to cover all wells over the Santos EQ Project time-period.

The HFRA addresses the regulatory requirements contained within the current Santos EQ EAs and synthesises the findings of several hydraulic fracturing risk assessments completed to date. The document includes information and assessment on all the hydraulic fracturing fluids currently used by Santos in EQ and provides a framework for inclusion of new tenure and new fluids systems within the risk assessment document as required. The HFRA also describes the process by which hydraulic fracturing is conducted and monitored.

The framework of this HFRA is such that it can be readily applied to all the wells comprising the Santos EQ Project as there are limited differences in the site-specific characteristics of wells within the study area nor differences in the type of stimulation procedures. Where specific characteristics do differ, additional information relating to respective sub-regions has been provided (e.g., climate, geology).

To facilitate the assessment and compilation of risk assessments completed on multiple fluid systems, this document has been organised with project information associated with the setting, geology and hydrogeology of the areas and the risk assessment methodologies and general findings within the body of the text. Information specific to the individual vendor hydraulic fracturing fluid systems and the associated risk assessment results are summarised in separate Appendices. The reader should identify the specific fluid system being utilised and the reference the appropriate risk assessment summary.

1.2 Project Area

This HFRA documents the environmental conditions relevant to the Santos EQ Project which are pertinent to the assessment of potential risks associated with hydraulic fracturing activities. The Santos EQ Project Area and

primary infrastructure relating to this HFRA are shown on

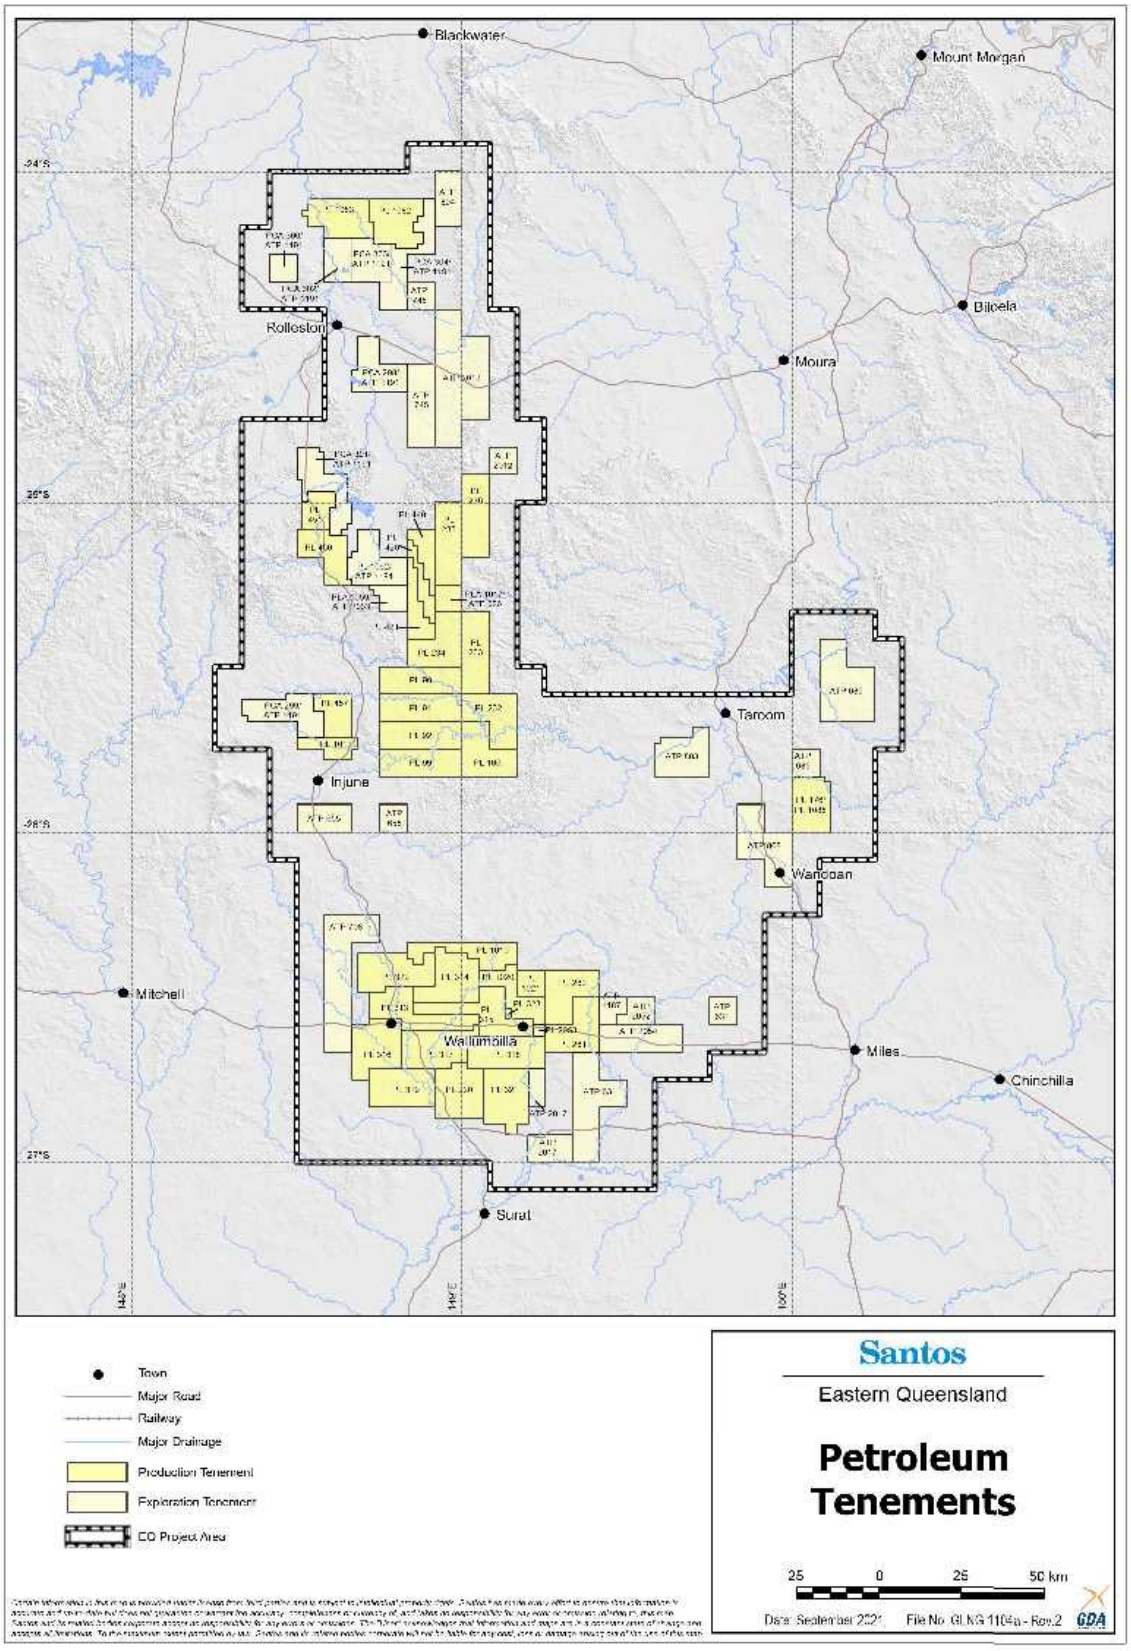

Figure 1, the extent of which is identified as 'Possible Area for Supporting Infrastructure'.

~~The main development areas focus on the Roma Shallow Gas Project Area (RSGPA), Fairview Project Area (FPA), Arcadia Valley Project Area (AVPA), Scotia Project Area (SPA) and Denison Project Area (DPA).~~ These

areas/regions present different geological, hydrological and geomorphological characteristics however the coal sequences and key aquifer units reflect the broader Basin depositional history and geometry. Where specific characteristics do differ, additional information relating to respective sub-regions has been provided. The area lies within the Surat and Bowen Basins, the latter comprising a portion of the Great Artesian Basin (GAB). The area is sparsely developed, and generally comprises rural communities and homesteads that are largely engaged in agriculture, such as livestock grazing.

For the purposes of this assessment, the terms 'study area' and EQ Project Area refer to the areas applicable to this assessment and includes all of the upstream tenures associated with the Santos EQ Project. The EAs (Permit Numbers) and Project Areas covered by this HFRA, include but are not limited to those identified in **Table 1**.

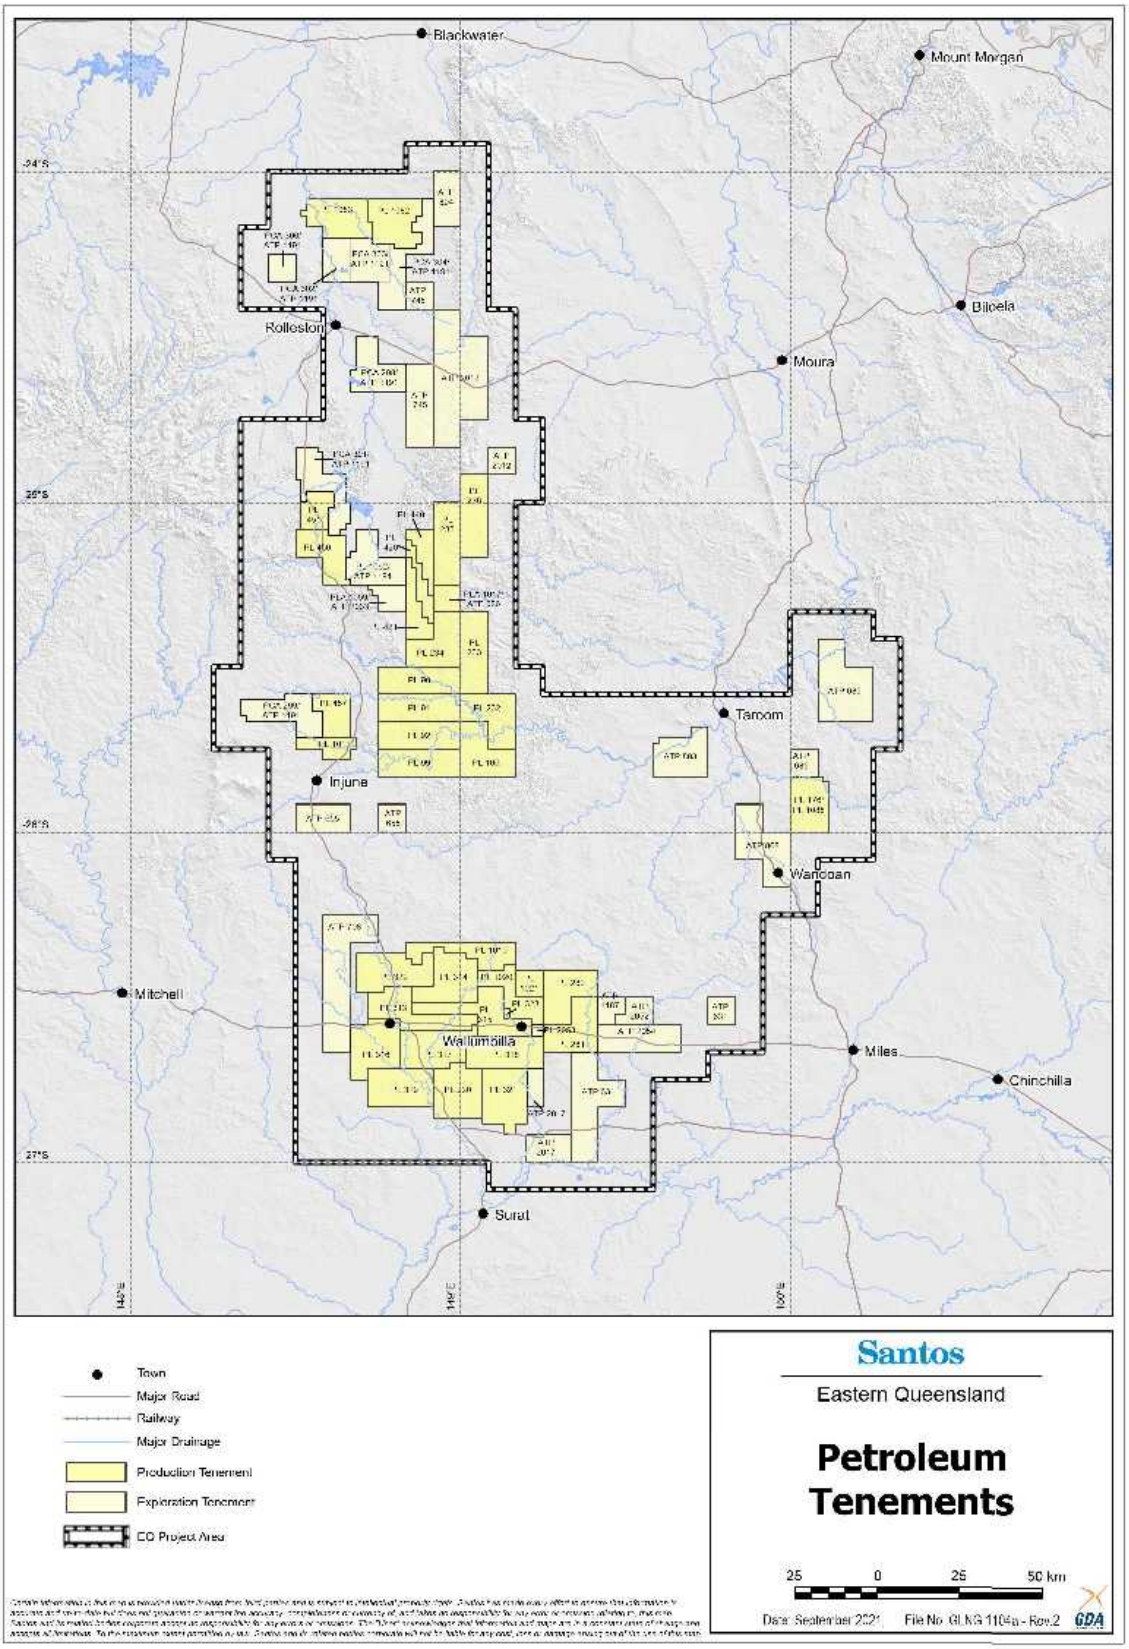

Figure 1. Santos EQ Project Petroleum Tenures

1.3 Environmental Authority Requirements

The EA approval requirements for the Santos EQ Project necessitate the collection and provision of information on hydraulic fracturing. Detailed regulatory requirements contained in these EAs and the sections of this risk assessment where the conditions are met are provided in **Table 2**.

Evaluation of compliance with these requirements must be considered in the context of other approval and regulatory requirements. As described further in **Section 4**, the drilling, completion and hydraulic fracturing is conducted in accordance with the *Code of Practice for the Construction and Abandonment of Petroleum Wells and Associated Bores in Queensland* (version 2 December 2019) [Code of Practice], which is overseen by the Department of Resources (DOR). No well can be drilled or hydraulically fractured without completion of DOR's prescribed process and reporting requirements.

In addition, Santos has key management plans associated with State and Commonwealth Approvals, which determine where wells can be drilled and potentially hydraulically fractured and identify the processes for assessment and management of risk. These key documents include the Environmental Protocol for Constraints Planning and Field Development (Constraints Protocol), which establishes the framework for avoiding or minimising environmental impacts, including the potential for impacts on aquifers, watercourses and springs and other associated management plans to comply with EA requirements.

Further, supporting documents such as the Stimulation Impact Monitoring Plan (SIMP), which is informed by this risk assessment, and associated routine operational monitoring are core components of the risk assessment/management components contained in this document.

Table 2. EA Approval Requirements

Reference[1]	Condition	Section in Risk Assessment
(*)	Prior to undertaking well stimulation activities, a risk assessment must be developed to ensure that stimulation activities are managed to prevent environmental harm	This document.
(*)	The stimulation risk assessment must be carried out for every well to be stimulated prior to stimulation activities being carried out at that well and address issues at a relevant geospatial scale such that changes to features and attributes are adequately described and must include, but not necessarily be limited to	This HFRA has been written as a single overarching risk assessment that covers all relevant and site-specific matters for the Santos EQ Project. As all wells have the potential to be hydraulically stimulated at one or more point in time, the single HFRA approach is considered appropriate to cover all wells over the Santos EQ Project time-period. The framework of this HFRA is such that it can be readily applied to all the wells comprising the Santos EQ Project as there are limited differences in the site-specific characteristics of wells within the study area nor differences in the type of stimulation procedures. Where specific characteristics do differ, additional information relating to respective sub-regions has been provided (e.g., climate, geology).
(a)	a process description of the stimulation activity to be applied, including equipment and a comparison to best international practice	**Section 4** provides a detailed discussion of the processes and monitoring implemented as part of hydraulic fracturing. As documented in **Section 4**, a prescriptive program of requirements for well completion and hydraulic fracturing is provided within the Code of Practice and International Best Practices (American Petroleum Institute Standards) that are used by Santos and Santos' hydraulic fracturing contractors. The ongoing advancements in technology and processes provided by international

Reference[1]	Condition	Section in Risk Assessment
		hydraulic fracturing specialists such as Schlumberger and Halliburton ensure that best practices are continuously being adopted on projects to ensure effective management of potential human health and environmental hazards.
(b)	provide details of where, when and how often stimulation is to be undertaken on the tenures covered by this environmental authority	Hydraulic fracturing can be conducted in any well completed in the Basin to enhance performance. The need for hydraulic fracturing is determined by physical data on the coal sequences, appraisal testing data and the performance data for other wells in the area. As noted in **Section 4.2.1**, a systematic framework of risk assessment must be completed before hydraulic fracturing is proposed and executed in a well. This starts with the siting of wells that are placed away from faults and structures that may be of concern (e.g., areas where fractures do or may have the potential to propagate from the target sequence into overlying aquifers – see **Section 2.5** and **2.6**). Details on how often wells are to be fractured in the area is provided in **Section 4.6** along with the process of notifications and reporting to DNRME (who approves and monitors the proposed activities), which is provided in **Section 4.6.1**.
(c)	a geological model of the field to be stimulated including geological names, descriptions and depths of the target gas producing formation(s)	Information regarding the conceptual geological model is found in the following sections: **Sections 2.5** (Regional and Basin Geology) **Sections 2.6** (Local Geology)
(d)	naturally occurring geological faults	Information regarding the fault systems can be found in the following sections: **Section 2.4.3** **Sections 2.5** (namely: **Section 2.5.4** and **Section 2.5.5**) **Sections 2.6** (namely: **Section 2.6.1.1**, **Section 2.6.2.1**, **Section 2.6.3.1** and **Section 2.6.4.1**) Importantly, information suggests that due to the tectonic setting, the faults and folds are tight and are characteristically not zones of groundwater flow, but rather are hydraulic barriers to flow. They typically compartmentalise the groundwater and restrict free flow across the compartment boundaries. This is generally manifested in water quality and temperature differences between compartments.
(e)	seismic history of the region (e.g., earth tremors, earthquakes)	Seismic history of the region is discussed in **Section 2.4** and **Section 2.5.5**.
(f)	proximity of overlying and underlying aquifers	The proximity of overlying and underlying aquifers to development targets is presented in **Section 3.7**.
(g)	description of the depths that aquifers with environmental values occur, both above and below the target gas producing formation	The description of the depths that aquifers with environmental values occur, both above and below the target gas producing formation is included in **Section 3.7**. This is also visually represented on **Figure 18** to **Figure 20**, **Figure 21** to **Figure 26**, and **Figure 30** to **Figure 35**.
(h)	identification and proximity of landholders' active groundwater bores in the area where stimulation activities are to be carried out	This is presented in **Figure 45** to **Figure 47** and discussed in **Section 3.6**, **Section 3.8** and **Section 3.9**.
(i)	the environmental values of groundwater in the area	**Section 3.6** Presents the Environmental Values of Groundwater **Section 3.8** Proximity to Environmental Values
(j)	an assessment of the appropriate limits of	The hazard and quantitative risk assessments demonstrated that the risk from hydraulic fracturing activities is limited with the implementation of standard

Reference[1]	Condition	Section in Risk Assessment
	reporting for all water quality indicators relevant to stimulation monitoring in order to accurately assess the risks to environmental values of groundwater	management and administrative controls. The fencing of sites (precluding the entry of unauthorised personnel and livestock) and management of initial flow back and produced water limit the potential for any unacceptable impacts within the receiving environment. In this context standard reporting limits for water quality parameters are considered sufficient for stimulation impact monitoring with baseline bore sampling including low level polycyclic aromatic hydrocarbon (PAH) analysis to ensure that the water quality in landholder bores is suitable for potable uses.
(k)	description of overlying and underlying formations in respect of porosity, permeability, hydraulic conductivity, faulting and fracture propensity	**Section 2.6** Faults and geological controls **Section 3.2.2** Aquifer and aquitard hydraulic properties **Section 3.5** Description of formation as well as some local formation properties
(l)	consideration of barriers or known direct connections (between the target gas producing formation and the overlying and underlying aquifers	**Section 3.7** Proximity to overlying and underlying aquifers and coal seams **Section 3.8** Proximity to Environmental Values
(m)	a description of the well mechanical integrity testing program	In accordance with the Code of Practice and International Best Practices, a comprehensive well design, well construction validation and mechanical testing program is implemented to ensure that the wells meet the project requirements and are not subject to mechanical failures that could result in human health or environmental hazards. **Section 4.3** provides a detailed discussion of the well integrity program, including selection of casing materials, logging of the boreholes, well completions, casing and cementing design, and validation testing of the casing and cement.
(n)	process control and assessment techniques to be applied for determining extent of stimulation activities (e.g., microseismic measurements, modelling)	This includes down hole pressure, flow rates and hydraulic fracturing fluid viscosity (if gel based systems are being used), which are described in **Section 4.4.2** and **Section 4.4.3**. This allows the hydraulic fracturing contractor to optimise the performance of the hydraulic fracturing process, and to rapidly identify unexpected pressure changes that could indicate a loss of well or confining layer integrity, and hence trigger a hold point for the hydraulic fracturing operation. Site-specific data are used in combination with models to predict the performance of each hydraulic fracturing event. The use of models as part of the design process (**Section 4.4.1**) is a critical component of the process as actual pressures and flows are compared to the model to determine the performance of the hydraulic fracturing event (including extent). Anomalies are identified as part of the monitoring program and subject to further evaluation and supplemental assessments. Microseismic measurements and testing are rarely used to assess performance.
(o)	practices and procedures to ensure that the stimulation activities are designed to be contained within the target gas producing formation	The practices and procedures for ensuring that stimulation activities are designed and implemented in a manner to contain the fluids to the target formation are discussed in **Section 4.4**. The key components include appropriate design and installation of well casing and cement to ensure effective zonal isolation, robust design practices including modelling using site-specific data to design a safe and effective hydraulic fracturing event (**Section 4.4.1**), extensive monitoring of the hydraulic fracturing event (refer response to (n) above), evaluation of actual versus modelled pressure and flows and assessment of anomalous data . Leveraging the processes contained within the Code of Practice and International Best Practices, Santos and its contractors implement a

Reference[1]	Condition	Section in Risk Assessment
		comprehensive set of procedures to ensure safe implementation of hydraulic fracturing and containment of the fluids within the target formation.
(p)	groundwater transmissivity, flow rate, hydraulic conductivity and direction(s) of flow	**Section 3.3** provides a regional overview and data properties summarised in **Table 6**. **Section 3.5** provides localised data (where available) and these are captured in **Table 8** to **Table 11**. Groundwater flow is captured in **Section 3.2**, **Section 3.3, Section 3.5** and **Figure 42** to **Figure 44**.
(q)	a description of the chemicals used in the stimulation activities (including estimated total mass, estimated composition, chemical abstract service numbers and properties), their mixtures and the resultant compounds that are formed after stimulation	A broad range of fluid systems and chemicals are utilised for hydraulic fracturing activities (see **Appendix A**). Detailed mass balances of the composition of these fluid systems and associated CAS numbers are included in **Appendix C**. In addition, hazard and quantitative risk assessments are included for chemicals and fluid systems in **Appendix C**. The toxicological profiles for individual chemicals consider the resultant breakdown products for each chemical (if relevant) and its associated toxicological properties (**Appendix F** and **Appendix G**).
(r)	a mass balance estimating the concentrations and absolute masses of chemicals (compounds) that will be reacted, returned to the surface or left in the target gas producing formation after stimulation	A mass balance of the chemicals returned to surface is included in **Appendix C** and **Appendix D**. This mass balance, which is supported by Stimulation Impact Monitoring data, indicates that injected chemicals are diluted with formation water and return to surface at concentrations lower than the injected concentrations. High concentrations are initially observed within the first days of pumping but rapidly decline to concentrations less than 10% of the injected concentration. In addition to dilution, other mass loss mechanisms include complexation, bio-decay and hydrolysis. Physical sorption and sorption to the organic carbon of the coals is a major mass loss mechanism for cations and organic molecules with high sorption coefficients. Physical fate and transport modelling (**Section 7.2**) of indicative chemicals has been conducted based on the physical properties of the chemicals and the coal. This has demonstrated that migration of chemicals within the coal sequences is limited.
(s)	an environmental hazard assessment of the chemicals used, including their mixtures and the resultant chemicals that are formed after stimulation including: • toxicological and ecotoxicological information of chemicals used • information on the persistence and bioaccumulation potential of the chemicals used • identification of the stimulation fluid chemicals of potential concern (in stimulation	The approach to the environmental hazard assessment of the chemicals used, including their mixtures and the resultant chemicals that are formed after stimulation is detailed in • **Section 6** (Qualitative Assessment Methodology) • **Section 7** (Exposure Assessment) • **Section 8** (Quantitative Risk Assessment Methodology). The findings of the assessment are discussed in **Appendix C** for each fluid system that has been assessed. In particular: • Toxicological and ecotoxicological information is tabulated for each chemical in the tables provided in **Appendix C** (i.e., see **Appendix C.1**, **Table 1**). • The environmental hazard assessment approach outlined in **Section 6.1** was undertaken to rank the hydraulic fracturing chemicals based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT). PBT findings for each stimulation fluid chemical is provided in **Appendix C** (i.e., see **Appendix C.1**, **Section C2.3**). • Constituents of potential concern based on the findings of the quantitative risk assessment for each fluid system are identified in **Appendix C** (i.e., see **Appendix C.1**, **Section C4**).

Reference[1]	Condition	Section in Risk Assessment
	fluids) derived from the risk assessment	
(t)	an environmental hazard assessment of use, formation of, and detection of polycyclic aromatic hydrocarbons in stimulation activities	As noted in **Section 4.7**, PAHs are not present in any of the chemicals used in hydraulic fracturing and will not be formed from the chemicals used in hydraulic fracturing.
(u)	if used, identification and an environmental hazard assessment of using radioactive tracer beads in stimulation activities	Identification and an environmental hazard assessment of using radioactive tracer beads in simulation activities is discussed in **Section 9.6.**The section summarises the findings of a quantitative risk assessment conducted by EHS Support (2013a) on the use of radiological tracers and perforation balls. The risk assessment is included in **Appendix H**.
(v)	an environmental hazard assessment of leaving stimulation chemicals in the target gas producing formation for extended periods after stimulation	An environmental hazard assessment of leaving stimulation chemicals in the target gas producing formation for extended periods after stimulation is provided in **Section 7.2**.
(w)	human health exposure pathways to operators and regional population	Human health exposure pathways are detailed in **Section 7.1** and **Section 7.3** and tabulated in **Appendix C**.
(x)	risk characterisation of environmental impacts based on the environmental hazard assessment	A quantitative risk assessment was conducted to characterise potential risks of environmental impacts based on the findings of the environmental hazard assessment. The risk characterisation methodology is provided in **Section 8**. The findings of the quantitative risk assessment are detailed for each fluid system in **Appendix C** and summarised in **Section 10**.
(y)	potential impacts to landholder bores as a result of stimulation activities	Fate and transport modelling was conducted to assess the fate and transport of hydraulic fracturing chemicals in the subsurface. Methodology, model assumptions and findings are detailed in **Section 7.2**. Based on groundwater fate and transport modelling, no potentially complete exposure pathways were identified for groundwater.
(z)(1)	the determination of the likelihood of causing interconnectivity and/or negative water quality as a result of stimulation activities undertaken in proximity of each other	It is considered highly unlikely that the activities will cause interconnectivity and/or negative water quality as a result of stimulation activities. The presence of competent aquitards (refer **Section 3**), careful siting of wells (in accordance with the Code of Practice - avoiding areas where fractures or thinning of the aquitards exist), robust casing and cementing design and verification/validation testing (in accordance with the Code of Practice and International Best Practices - as documented in **Section 4.4**) and careful design and execution of hydraulic fracturing prevent the one or multiple hydraulic fractured wells impacting overlying aquifer formations.
(z)(2)	An assessment of cumulative underground impacts, spatially and temporally of the stimulation activities to be carried out on the tenure covered by this environmental authority	An assessment of cumulative underground impacts is provided in **Section 9.7**. Cumulative underground impacts are not anticipated as part of the project based on the controls described within this document. Fracturing will be confined to the target sequences and vertical fracturing into overlying aquifer units will not occur.
(aa)	potential environmental or health impacts which may result from stimulation including but not limited to water quality, air quality	Potential environmental or health impacts which may result from stimulation, including but not limited to water quality, air quality, noise and vibration, are evaluated in **Section 9**. Potential risks associated with noise, vibration and air quality were assessed in the Golder Stage 1 and Stage 2 Hydraulic Fracturing Risk Assessments (2011a). Findings from the assessment are provided in **Section 9.1**, **Section 9.2**, **Section 9.3** and **Section 9.4**.

Reference[1]	Condition	Section in Risk Assessment
	(including suppression of dust and other airborne contaminants) and noise and vibration	Potential environmental or health impacts to water quality are evaluated in **Appendix C**. The assessment concludes that the risks associated with hydraulic fracturing (with implementation of regulatory requirements and Santos controls) is low. Recommendations for risk management consistent with Santos's existing practices have been provided and should be implemented (as required) to ensure potential exposures are incomplete or minimised.

1.4 Risk Assessment Process

Risk assessments provide a systematic approach for characterising the nature and magnitude of the risks associated primarily with environmental hazards and is an important tool for decision-making [Draft guidance for ecological risk assessment provided by the Environment Protection Authority (EPA) Victoria (Gibson et al., 1997) and Environmental Health Risk Assessment, Guidelines for Assessing Human Health Risks from Environmental Hazards (enHealth, 2012)]. It should be emphasised, however, that the risk assessment is only one of the factors that inform decision making in the management of environmental issues.

This report combines qualitative and quantitative risk assessment methodologies to assess the potential risks posed by individual chemicals and the mixtures of chemicals used in hydraulic fracturing. A listing of hydraulic fracturing chemicals assessed by fluid system is provided in **Appendix A**.

The scope of the qualitative risk assessment comprises:

- Issue identification – A description of the current environmental setting (including a description of potential receiving environments and the various factors, which act upon them, including climatic influences), detailed geological and hydrogeological information, gas well integrity and a description of the hydraulic fracturing process, including an identification of the constituents of the hydraulic fracturing fluid.
- Hazard assessment – An evaluation of the environmental hazard of relevant chemical additives in the hydraulic fracturing fluid based on aquatic toxicity, environmental persistence and bioaccumulation.
- Exposure assessment – The exposure assessment comprises of an evaluation of surface and subsurface exposure pathways assessment and mass balance calculation to identify the amount of each chemical additive of the hydraulic fracturing fluid. For the additives selected as chemicals of potential concern (COPCs), fate and transport modelling is used to identify the likely extent of movement from the gas well.
- Risk characterisation – A qualitative evaluation of environmental and human health risk associated with the hydraulic fracturing activities based on the identification of complete exposure pathways and hazard identification.

The quantitative risk assessment builds on the assessment and findings of the qualitative risk assessment, namely quantifying ecological and human health risk for potentially complete exposure pathways.

This risk assessment includes assessments completed over the last eight years for a range of fluid systems and chemicals. The risk assessment approach incorporates revisions to the assessment methodology that have been recommended in national guidance. The initial risk assessment methodology (discussed further in **Section 5**) utilised a risk assessment methodology that aligned with former Australian risk assessment guidelines. This methodology was endorsed in subsequence guidance set forth by the Commonwealth Department of the Environment and Energy (DoEE) (2017).

Subsequent to issuance of this guidance, the Commonwealth developed a more streamlined approach that aligned with other regulatory requirements (Chemical notification, permitting and assessment requirements). These recommendations were incorporated into Categorisation Guidelines (Draft) developed by DoEE, the Northern Territory Hydraulic Fracturing Inquiry and core chemical regulatory guidance developed by the Australian National Industrial Chemicals Notification and Assessment Scheme (NICNAS). The revised approach utilises a tiered assessment framework where quantitative risk assessments are conducted on a chemical-specific basis for higher

hazard chemicals and the risks posed by mixtures evaluated qualitatively. This Hazard and Tiered Risk Assessment approach is discussed further in **Section 5** and is the basis for assessments conducted on chemicals after 1 January 2020.

1.5 Report Structure

Based on the EA requirements and to facilitate the assessment and compilation of multiple fluid systems, the document has been structured with a detailed discussion of the Site setting, hydrogeology and hydraulic fracturing and risk assessment process contained within the body of the report. General findings and recommendations from the risk assessment are also summarised in the document as identified in **Table 3**.

Table 3. Report Structure

Report Section	Content
Section 2	Provides information on the setting and geologic framework within which the hydraulic fracturing activities are being undertaken
Section 3	Evaluates the hydrogeological framework, groundwater resources and the environmental values associated with groundwater and surface water resources in the area
Section 4	Describes the hydraulic fracturing process and documents the integrated nature of well construction and hydraulic fracturing activities. A detailed discussion of the design, implementation and monitoring of hydraulic fracturing activities, in accordance with international best practice, is provided in this section.
Section 5	Describes the risk assessment framework that was implemented by Santos EQ and provides a guide to the process and the remaining chapters
Section 6	Details the methodology, approach and general findings from the Qualitative Risk Assessment
Section 7	Outlines the exposure assessment process and identifies the potentially complete exposure pathways that need to be considered in the Quantitative Risk Assessment
Section 8	Details the methodology, approach and general findings from the Quantitative Risk Assessment
Section9	Assesses the other potential risks associated with hydraulic fracturing including noise and vibration, air quality and the use of alternative proppants and radiological tracers
Section 10	Provides a general overview of the risk assessment findings and guides the reader through the vendor-specific findings, which are provided in **Appendix C** through **Appendix H**.

2 Site Setting and Issue Identification

The information provided in this section addresses the following EA approval requirements: conditions (c), (d), (e) and (k).

2.1 Climate

The climate of the Santos EQ Project Area is inland sub-tropical, with cool a dry winter season (April to September). In general, the year-round climate is dry, with winter months being more arid than summer months (

Table 4). Most of the annual rainfall occurs during the summer months (December and January,

Table 4). Variability in terrain across the project area will contribute to some variability in local climate.

Local climate is described using data observed at eight Bureau of Meteorology (BOM) observation stations. While all available data from the BOM have been considered, not all meteorological variables are recorded at each station; as a result, some data sets are incomplete or different lengths. The Queensland Government provides meteorological variables that are useful for agrometeorological research and modelling called the Data Drill. The meteorological variables in the Data Drill database are derived by interpolating the BOM's station records creating synthetic data calculated for a grid with approximately 5 km surface spatial resolution (http://www.longpaddock.qld.gov.au/silo/).

Based on the Data Drill results, climatic conditions are similar for the development area, although average temperatures and evaporation have a slightly smaller seasonal variability in the Arcadia region, probably reflecting its comparative northern location and proximity to the tropics.

The Denison region experiences the highest average rainfall with approximately 688 millimetres per year (mm/year), then Fairview, Arcadia Valley, Scotia and Roma regions with approximately 630 mm/year, 610 mm/year and 586 mm/year, respectively. While rainfall is similar in winter months across the Santos EQ project area, the regions surrounding Denison, Scotia, Arcadia Valley and Fairview generally experience higher rainfall than the Roma region during summer.

The Santos EQ Project Area is in a portion of Southern Central Queensland where magnitude of rainfall water and evaporation water loss is unbalanced. The Arcadia Valley and Roma regions experience higher evaporation rates, approximately 2,080 mm/year and 2,100 mm/year, respectively, while in Denison and Fairview regions the evaporation rate is approximately 1,930 mm/year and 1,998 mm/year, respectively.

The same spatial distribution can be observed for annual net evaporation, which is lower in the Fairview region (1,370 mm) and higher in the Arcadia valley and Roma regions (1,490 mm and 1,496 mm, respectively). The Roma region experiences the highest variability during the year, with net evaporation ranging between over 190 mm in summer and below 40 mm in winter. Lower seasonal variations occur within the Fairview and Arcadia Valley regions.

Table 4 presents the average minimum and maximum monthly temperatures, the average monthly total rainfall and the total and the average monthly total and net evaporation for the development areas within the Santos EQ Project area. Annual average values are presented for temperature while annual average total amount of rainfall and evaporation are presented in the same table. Maximum values are in red and minimum values in blue.

Table 4. Climate Data within the Santos Eastern Queensland Project Area

2.2 Topography

The general topography of the Santos EQ Project Area is presented on **Figure 2**.

The Great Dividing Range (GDR) traverses the southern part of the Fairview region and the northern part of the Roma region, then trends north north-west to the Buckland Plateau. Notable topographic features within the Santos EQ Project Areas include (URS, 2008):

- Near-level to strongly undulating plateau surface remnants cut by steep-sided ravines and terminating in sandstone escarpments, occurring in the central part of the Santos EQ Project Area including the regions of Denison, Scotia, Fairview and Arcadia Valley.
- Broad areas of low relief undulating terrain and alluvial plains, interrupted by occasional low hills across the southern part of the Roma region.
- Broad alluvial plains and foot slopes of the Arcadia-Comet valley feature extending northward from the northern margin of the Fairview region to the northern limit of the Santos EQ Project Area.

In the northern and central parts of the Fairview and Denison regions, the Precipice Sandstone and Evergreen Formation outcrop resulting in raised plateaus with steep escarpments. The Hutton Sandstone outcrops in the southern parts of the Fairview region with the landscape characterised by rounded hills and in the eastern parts of the SPA. Further south the Orallo Formation and Mooga Sandstone outcrop. The drainage channels have been in-filled with alluvial sediments comprising Quaternary aged sand, gravel and clay.

The topography of the Dension region is dominated by the Taroom Hills geographic region that consists of gently sloping to strongly undulating dissected upland plateau remnants, of mostly broad extent, and that are formed predominantly on sandstone, with very steep ravine slopes and sandstone escarpments (URS, 2008). The area is subject to an array of landforms and soil types, which tend to vary with the different sections of the area.

The Roma region is generally characterised by flat to gently undulating terrain, with a gradual slope towards the southwest. The Bungil and Wallumbilla Formations give rise to typically flat topography in the southern part of the region where large areas of poorly consolidated Tertiary sandstone and conglomerate unconformably overlay the Wallumbilla Formation. The drainage channels have been in-filled with alluvial sediments comprising Quaternary sand, gravel and clay throughout the Santos EQ Project Area.

The eastern portions of the Roma region include gently undulating plains and short segments associated with low hills and ridges; developed on weathered sandstones and shales. The Yuleba area is characterised by undulating plains to scarps and low hills developed mainly on coursed grained, quartzone sandstones and poorly weathered sediments. The Struan Area includes undulating plains to low hills and escarpments developed predominantly on quartzone sandstones. Coogoon includes gently undulating plains and short slopes associated with ridges and crests and developed on weathered sandstones and old sandy alluvia. Maranoa Region contains flat plains, which have been developed on sandy alluvia.

In the far northern reaches of the Santos EQ Project Area, the Arcadia Valley region has been in-filled with Cainozoic sandy sediments, which are overlain by Quaternary aged alluvial deposits along the drainages. Steep cliffs on either side of the valley typically comprise of the Permian aged Clematis Sandstone or Moolayember Formation.

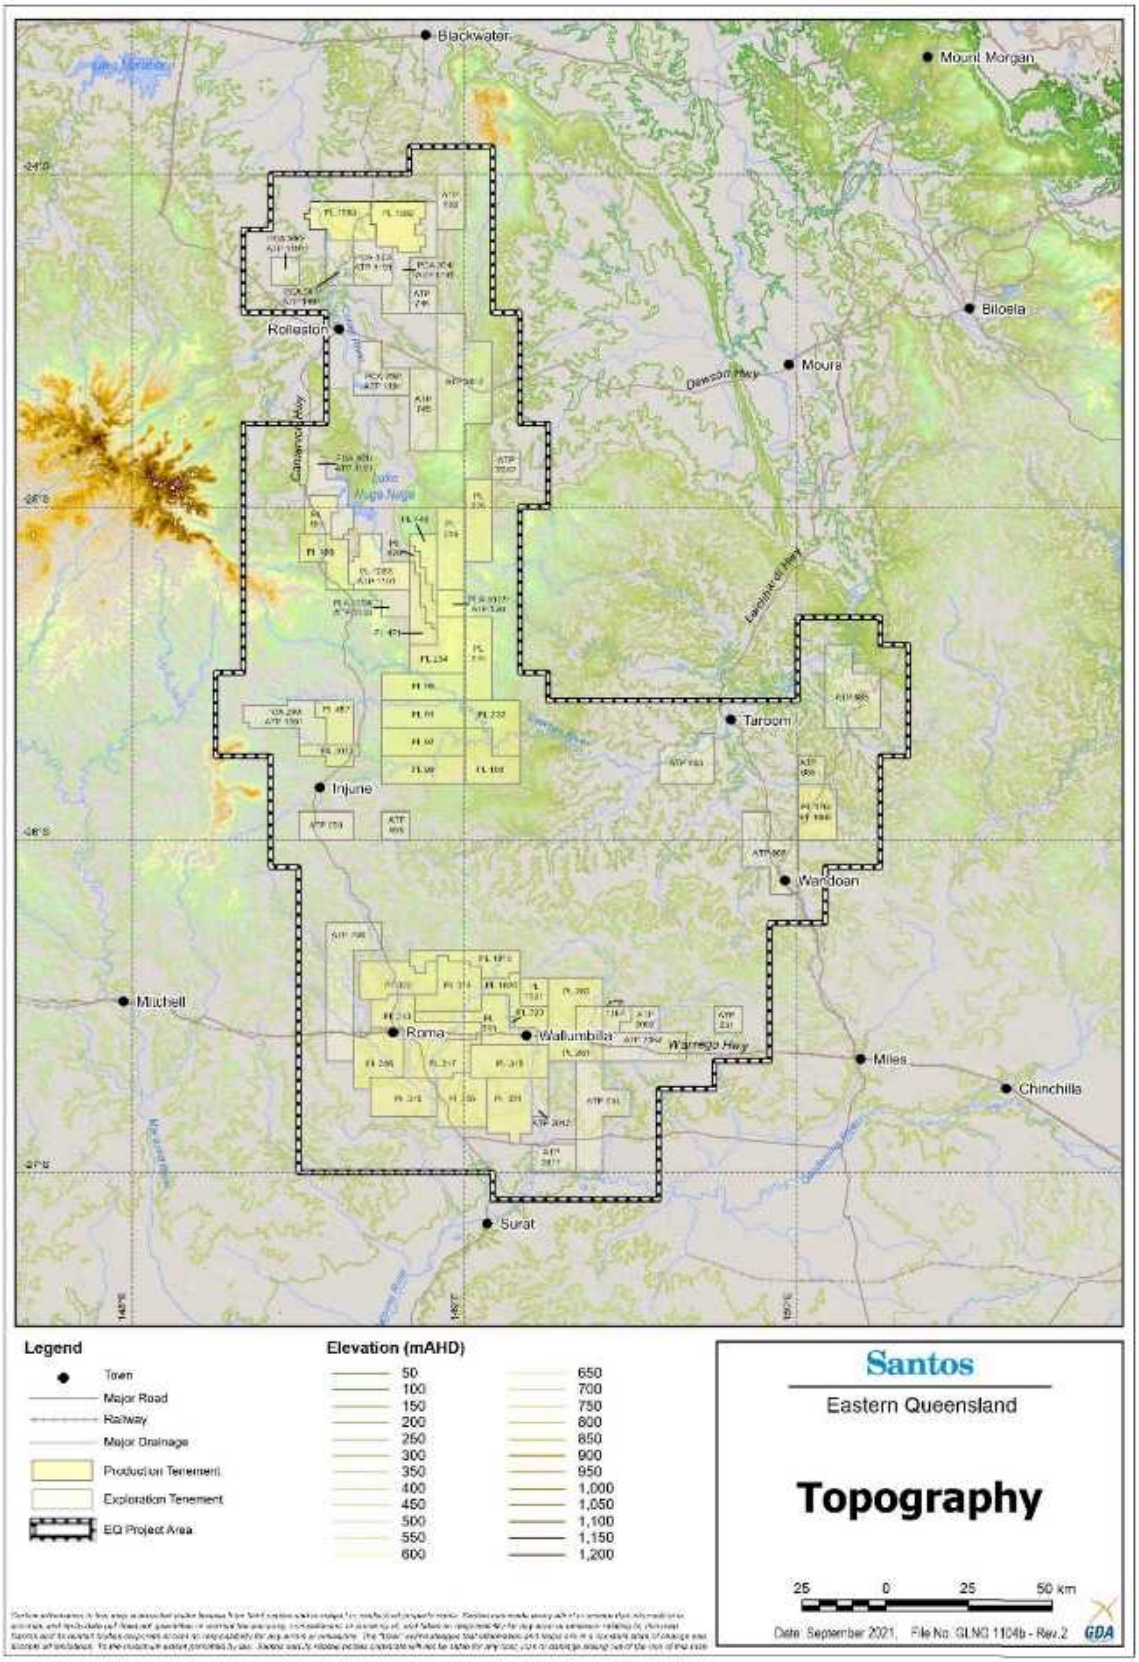

Figure 2. Topography

2.3 Hydrology / Surface Water

Due to the large study area, as well as the relative environmental homogeneity across these extensive basins, the contextual setting for analysis of the existing environment was constrained to six major sub- catchments:

- Fitzroy River Basin
  - Comet River
  - Lower Dawson River
  - Upper Dawson River.
- Condamine-Balonne River Basin
  - Dogwood Creek
  - Upper Balonne River Tributaries
  - Amby Creek (tributary of Maranoa River).

The sub-catchments were delineated based on the catchments depicted in the relevant Water Resource Plan (WRP) Maps (Fitzroy Basin WRP, 2011; Condamine and Balonne WRP, 2004), to enable straightforward identification of environmental values on a sub-catchment scale.

The Condamine-Balonne Catchment is in the Murray Darling Basin, which eventually discharges to the Great Australian Bight in South Australia. The Dawson River and Comet River catchments are located in the Fitzroy Basin, which discharges into the Pacific Ocean near Rockhampton.

The Fitzroy River Basin in Central Queensland is the largest coastal catchment in eastern Australia, covering an area of approximately 142,000 km^2, consisting of six sub-catchments: Nogoa, Comet, Mackenzie, Isaac-Connors, Dawson and Lower Fitzroy.

Many of the rivers and streams in the study area are ephemeral and characterised by high variations in duration and volume of flows due to highly variable rainfall and runoff and high evaporation rates. Prolonged base flow occurs only in wetter years in most streams.

The northern area of the study area (within the Arcadia Valley region) is located in the central-eastern portion of the Comet River catchment (

Figure 3). The Fairview region is located in the southern section of the Fitzroy River Basin in the upper reaches of the Dawson River catchment (

Figure 3). The southern area is located in the upper reaches of the Condamine-Balonne catchment (**Figure 4**). The main surface water system in the Scotia region is Bungaban Creek as well as sections of the Dawson River (

Figure 3). Further detail on each project area (including DPA) is presented in **Section 2.3.1** to **Section 2.3.4**.

2.3.1 Fairview and Arcadia Valley Region

The main plateaus with the Fairview region are referred to as the Fairview and Springwater Plateaus. The entire Springwater Plateau and the south side of the Fairview Plateau drain southward into Hutton Creek, while the northern half of the Fairview Plateau drains north into Baffle Creek and the Dawson River (

Figure 3). The irrigation program is located on those plateaus. In the downstream reaches of Hutton Creek, grazing, forestry and cropping are widespread. A number of water storages and weirs are located on the Dawson River from Taroom downstream and are used for irrigation and recreational purposes, supporting regional industry and urban communities.

The Upper Dawson River catchment area contains extensive but largely ephemeral or intermittent stream networks. The Dawson River downstream of Dawson's Bend is the exception as it is perennial, maintained by significant spring flows arising from the riverbed and adjacent to the stream. A number of springs are located near

the outcrop areas of the Hutton Sandstone, many within the boundaries of the Fairview region (

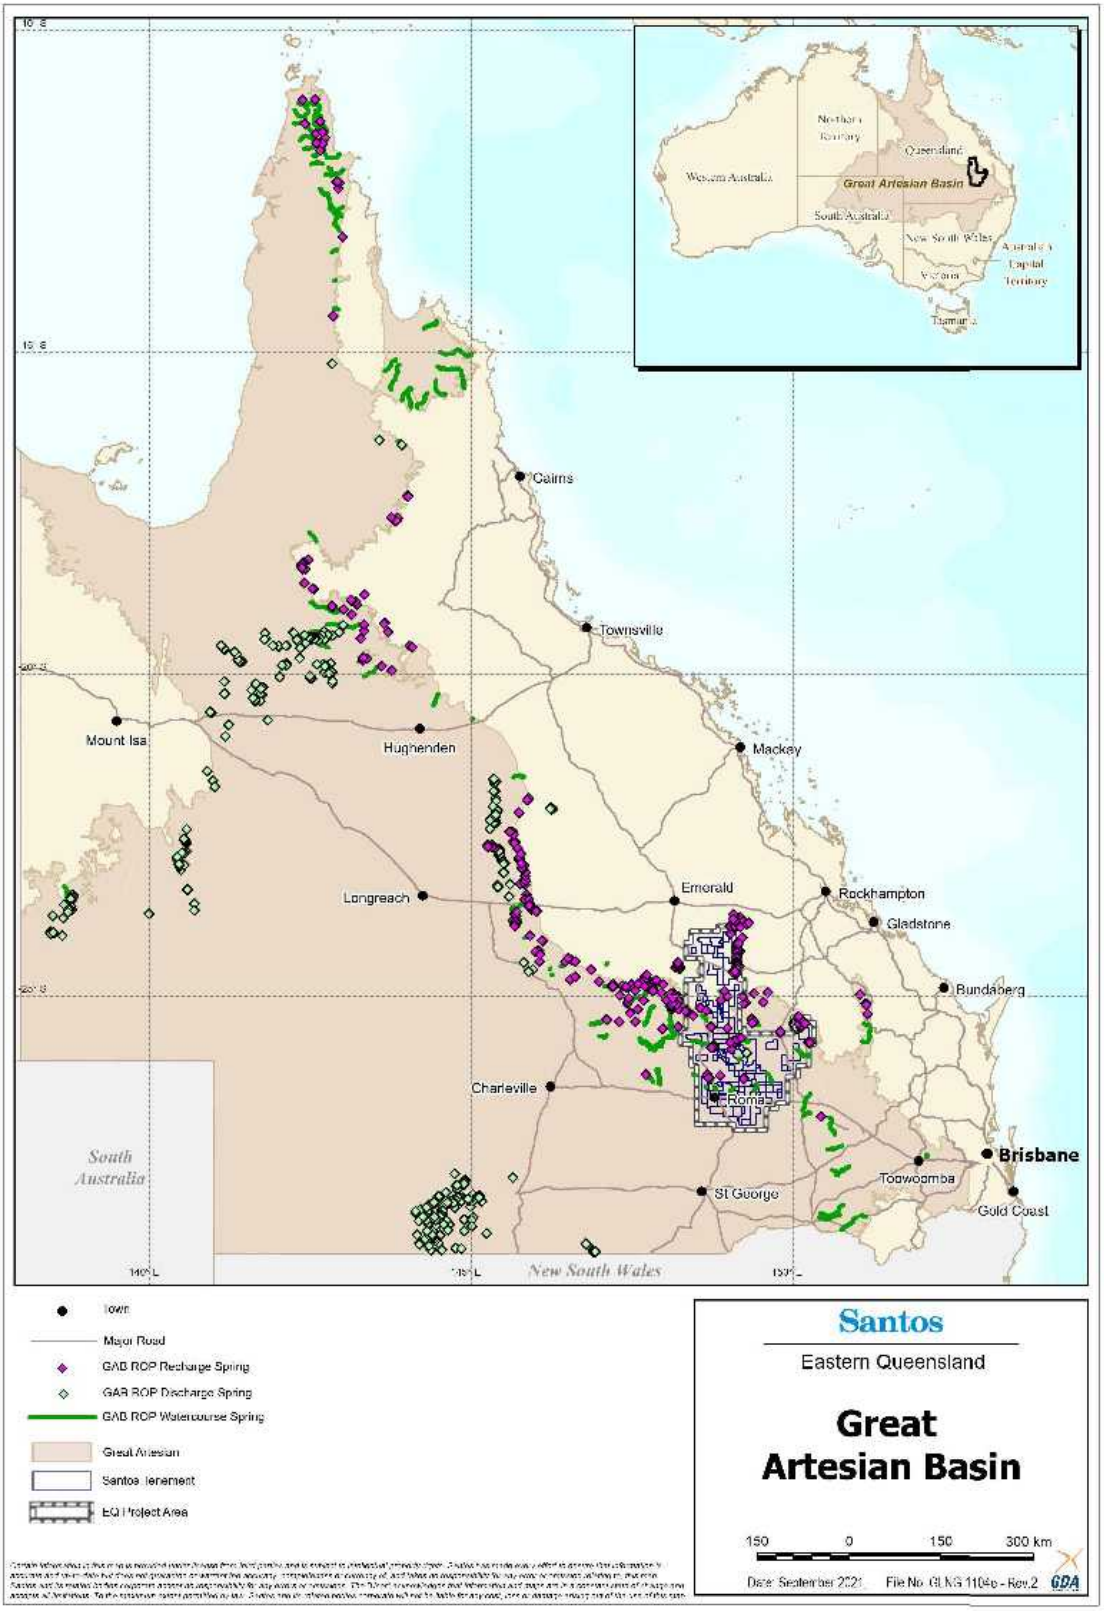

Figure 6). There are several springs located within the Precipice and Gubberamunda Sandstone outcrop areas, also considered to be recharge zones of the GAB.

High ecological environments (HEV) areas identified within the portions of the Upper Dawson River catchment and located inside the Fairview and Arcadia Valley region using the Queensland (EHP) Geographic Information System (GIS) database included:

- Presho Forest Reserve (HEVa2147)
- Presho State Forest (HEVa2146)
- Belington Hut State Forest (HEVa2145)
- Stephenton State Forest (HEVa2144)
- Beilba State Forest (HEVa2142)
- Forrest State Forest
- Doonkuna State Forest (HEVa2141)
- Lake Murphy Conservation Park (HEVa2149) – close to ROB02 monitoring site
- Carraba Conservation Park (HEVm2142)
- Cooaga State Forest (HEVa2159)
- Barakula State Forest (HEVa2159)
- Mundell State Forest (HEVa2160)
- Cherwondah State Forest (HEVa2158)
- Gurulmundi State Forest (HEVa2157)
- Juandah State Forest (HEVa2156)
- Hinchley State Forest (HEVa2155)
- Dinoun State Forest (HEVa2152)
- Mount Organ State Forest (HEVa2154)
- Emu State Forest (HEVa2151)
- Combabula State Forest (HEVa2153)
- Woodduck State Forest (HEVa2150)

A total of 670 wetland areas (encompassing approximately 79,150 ha) were identified within the Upper Dawson River catchment, using the Queensland Wetland Classification Method. The wetlands are predominantly riverine or floodplain swamps with grass, sedge and herb vegetation. Around 30% of the wetlands, classified as lacustrine wetlands, are artificial or modified (e.g., farm dams, irrigation channels). Less than 10% of the identified wetlands consist of swamps containing Melaleuca and Eucalypt tree species. The largest area of wetland appears to be concentrated within the Beilba State Forest (centred on Hutton Creek). There are no nationally or internationally significant wetlands scheduled within this sub-catchment.

The northern and western most portions of the Arcadia Valley region lie within the Comet River Catchment area. The Comet River Catchment area extends west of the Lower Dawson River catchment, encompassing the townships of Springsure and Fernlees in the west and Comet in the northern extent within the larger Fitzroy Basin.

The main tributaries on the Comet River on the western side of the catchment are the Sandhurst, Springsure, Meteor and Minerva Creeks, all flowing south to north. On the eastern side of the Comet River are the Sirius, Humboldt, Rockland, Christmas Creeks and the Brown River. The Comet and Nogoa River confluence forms the Mackenzie River at the township of Comet.

High ecological environment areas identified within the portions of the Comet River catchment using the Queensland Department of Environment and Heritage Protection (DEHP) GIS database included:

- Shotover State Forest (HEVa2127)
- Humboldt National Park (HEVm2126)
- Western portion of Expedition State Forest (HEVa2171)

- Expedition National Park (HEVm2141)
- Nuga National Park (HEVm2124

A total of 127 wetland areas (encompassing approximately 10,557 ha) have been identified within the Comet River catchment, using the Queensland Wetland Classification Method. Whilst the wetlands are predominantly classified as lacustrine, they are also listed as being artificial/modified (features such as dams or irrigation channels). Some sub-coastal floodplain wetlands consisting of grass, sedges and herbs (and occasionally Melaleuca and Eucalypt species), classified as palustrine wetlands, are also present (approximately 13% of identified features). The largest areas of wetland appear to be within Shotover State Forest in the north and Expedition National Park in the south. There are no nationally or internationally significant wetlands scheduled within this sub-catchment.

2.3.2 Denison Region

The Denison region (which includes the DPA) lies wholly within the Fitzroy River Basin. The northern and central sections form part of the catchment area of the Comet River, which is a major tributary of the Fitzroy River.

Several tributaries of the Comet River, as well as the Comet River itself, flow in a northerly direction and include the Brown River, Carnarvon Creek, Arcadia Creek, Meteor Creek and Clematis Creek. The tributaries of the Comet River are ephemeral and typically experience periods of no flow for over 50 percent of time.

The southern section of the Denison region lies within the upper catchment area of the Dawson River, which is also a major tributary of the Fitzroy River. Tributaries of the Dawson River that flow through the southern tenures include Baffle Creek, Hutton Creek and Injune Creek. These creeks rise in the Great Dividing Range that separates this river system from the catchment area of the Maranoa River, which is part of the Balonne-Condamine River Basin. These tributaries of the Dawson River tend to be deeply incised streams flowing through sandstone areas of the Great Dividing Range, and consequently have sustained base flows, unlike the tributaries of the Comet River catchment.

2.3.3 Roma Region

The Roma region (which includes the RSGPA) is located in the upper catchment area of the Murray-Darling Basin (MDB) whereas the Fairview and Arcadia Valley regions are located within the Fitzroy Basin.

The Condamine-Balonne River is a regional river system, which straddles the southern boundary of the southern tenures of the Roma region, generally flowing from east to southwest. This river system contains extensive meandering streams that are largely ephemeral or intermittent. The major streams in the catchment include Yuleba Creek, Wallumbilla Creek, Bungil Creek, Blyth Creek, which discharge to the Balonne River (**Figure 4**), which in turn flows into the MDB.

The Balonne River sub-catchment includes the towns of Toowoomba, Dalby, Roma, Chinchilla and Surat. The topography of the catchment varies from flat near the Balonne River to hilly in the upstream sections. Tributaries include the Maranoa River, which flows southward from the Carnarvon Range into the Beardmore Dam near St George.

Streamflow records are available from two DEHP gauging stations in the Balonne Catchment: Tabers at Bungil Creek (BOM, site 043105, DEHP site 422210) (1966 – Present), and Yuleba Forestry at Yuleba Creek (BOM site: 543008, DEHP site 422219) (1972 – Present). Streamflow records show substantial seasonal variations at each location reflecting their dominant ephemeral nature.

High ecological value (HEV) areas have not yet been scheduled for the Condamine-Balonne River Basin by DEHP.

A total of 476 wetland areas (encompassing around 43,187 ha) have been identified within the across the Upper Balonne Tributaries catchment, using the Queensland Wetland Classification Method. The wetlands are approximately 50% artificial or modified; 20% riverine, and 15% Melaleuca and Eucalypt tree swamps (palustrine wetlands). The remainder of wetland features are generally grass/herb swamps, also classified as palustrine. The largest area of wetland appears to be concentrated along the Balonne River near Yuleba Creek, Bungil Creek, within the Gubberamunda State Forest, and between Bungil Creek and Bungeworgerai Creek. There are no nationally or internationally significant wetlands scheduled within this sub-catchment.

2.3.4 Scotia Region

The Scotia region is located in the upper catchment area of the Dawson River which drains northwards and is a tributary of the Fitzroy River. The main surface water system in the region the Dawson River, Bungaban Creek and Cockatoo Creek. These flow through the northern part of the Scotia block from east to west and onward in a north-westerly direction into the upper catchment of the Dawson River that flows into the Fitzroy River Basin.

The general catchments, streams and rivers in the vicinity of the Scotia region are shown on **Figure 5**.

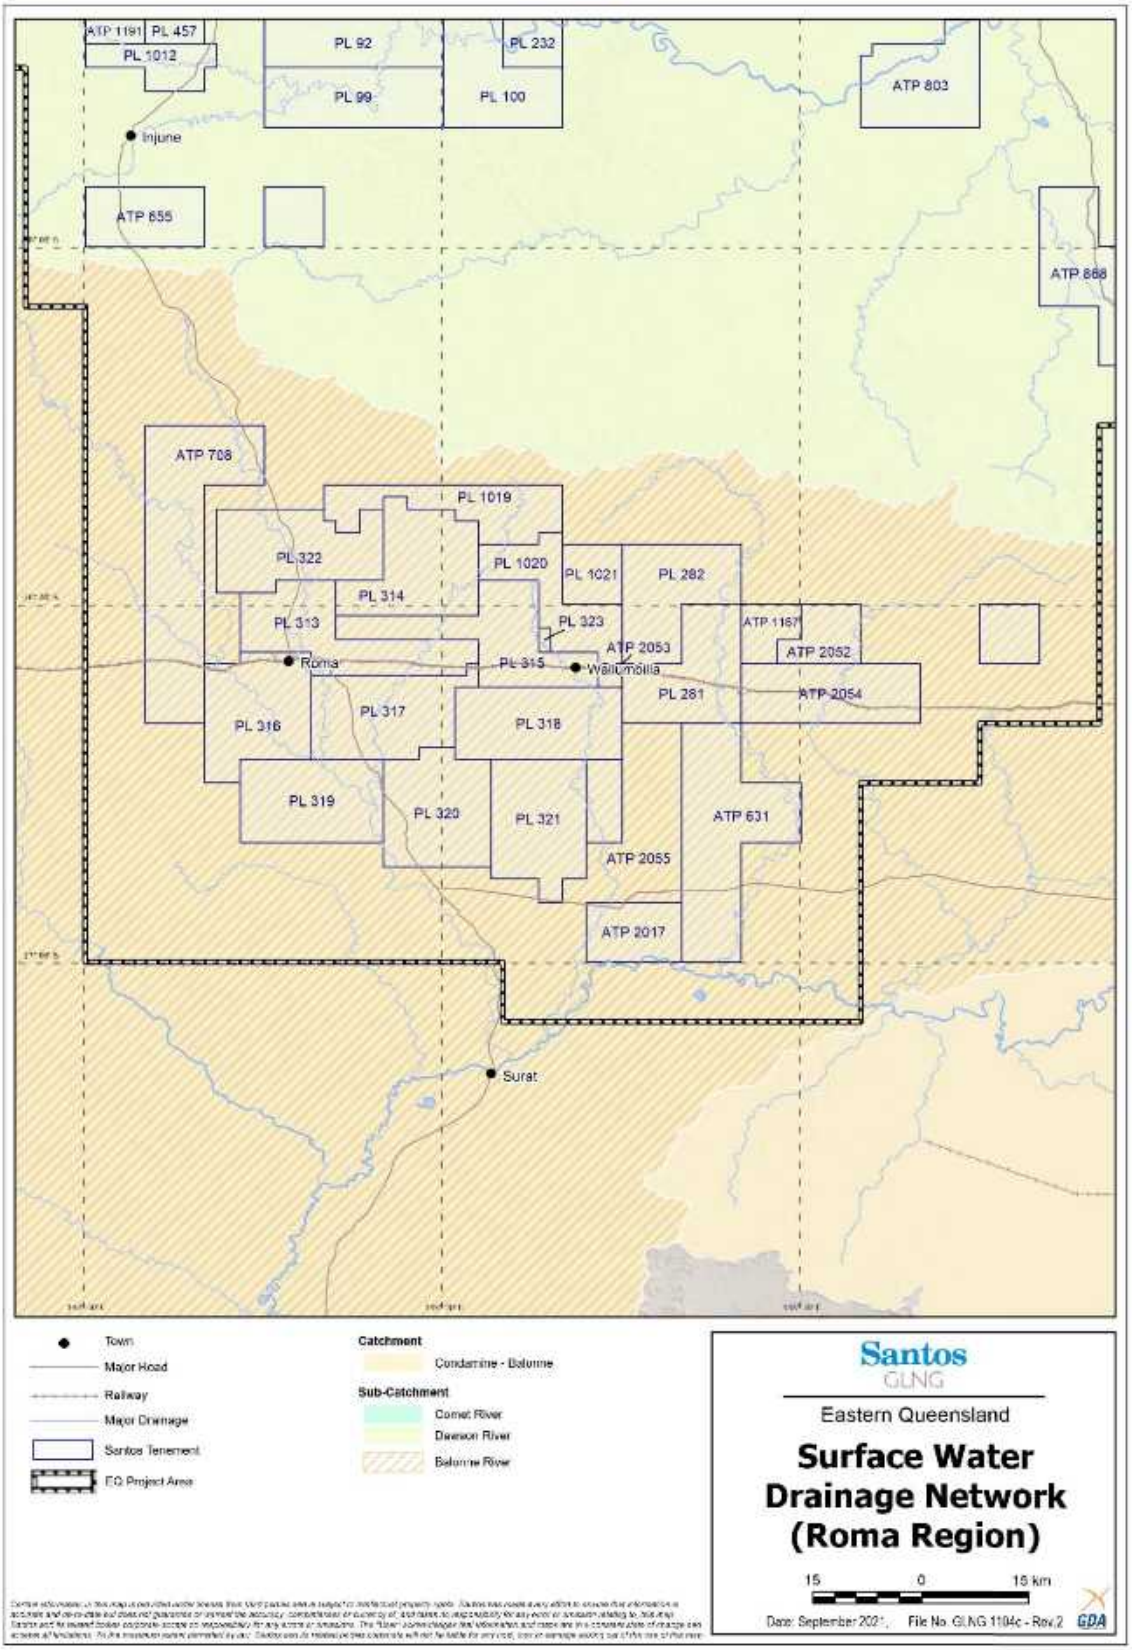

Figure 4. Surface Water Drainage Network (Roma)

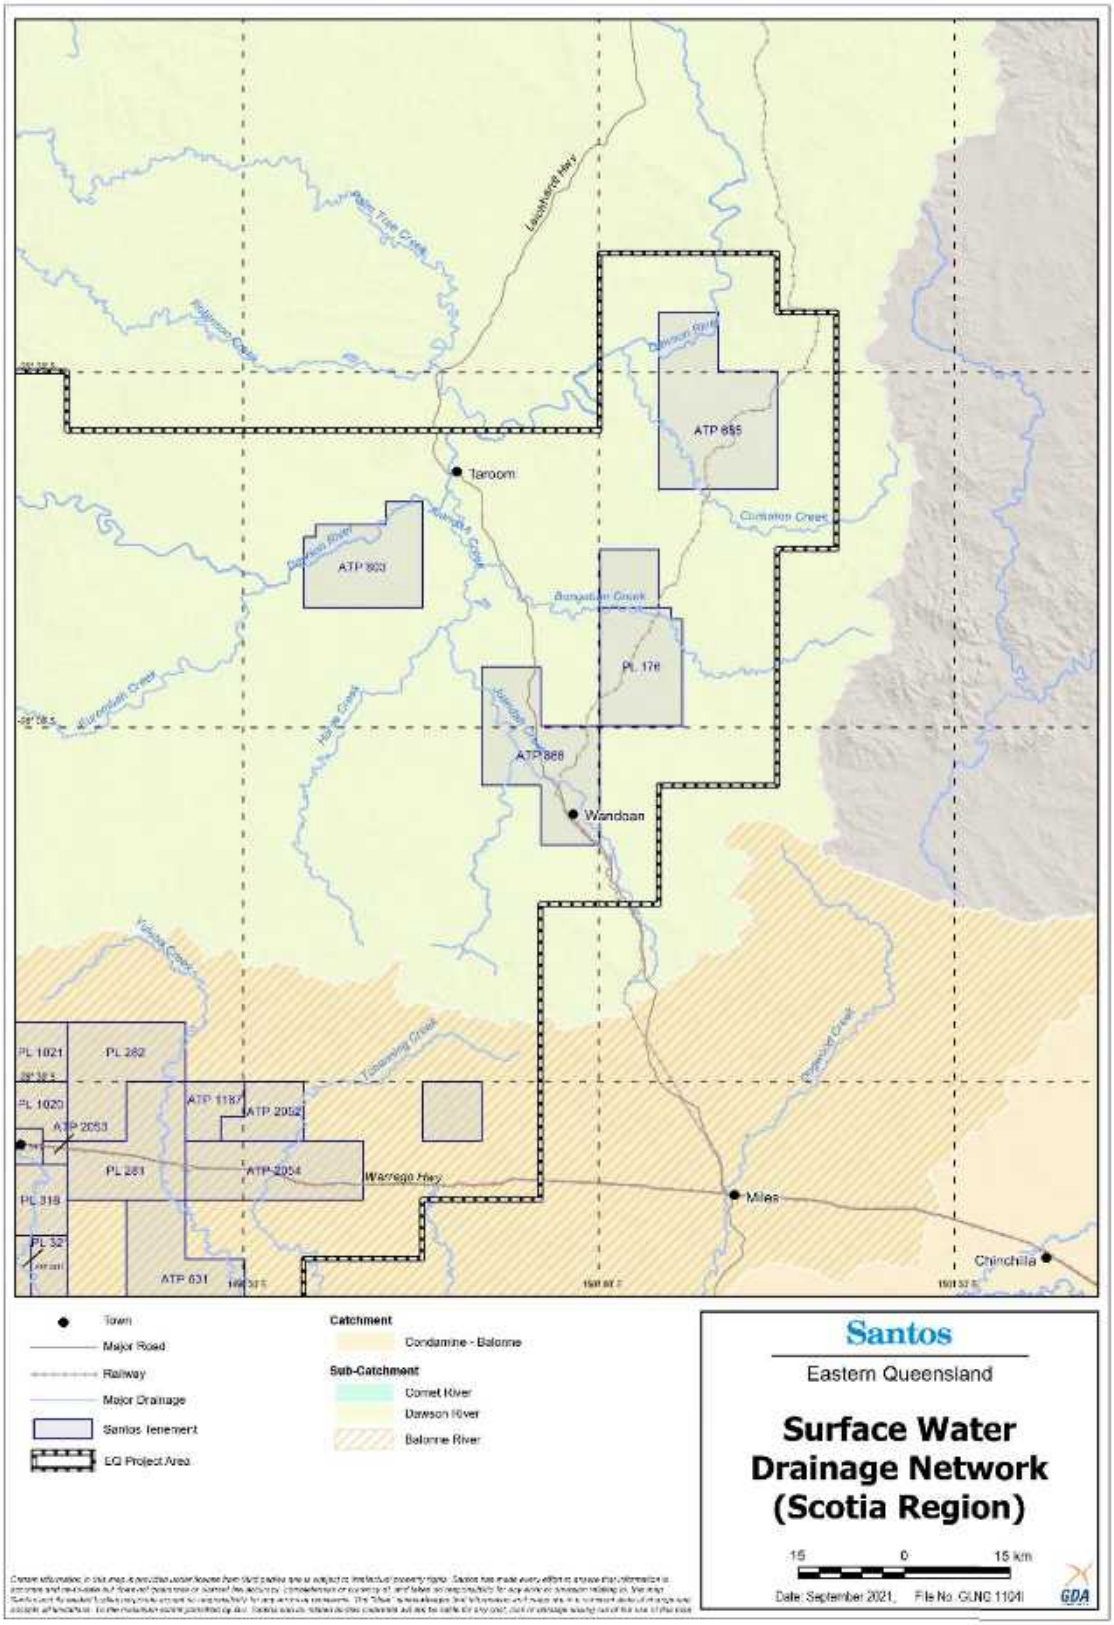

Figure 5. Surface Water Drainage Network (Scotia)

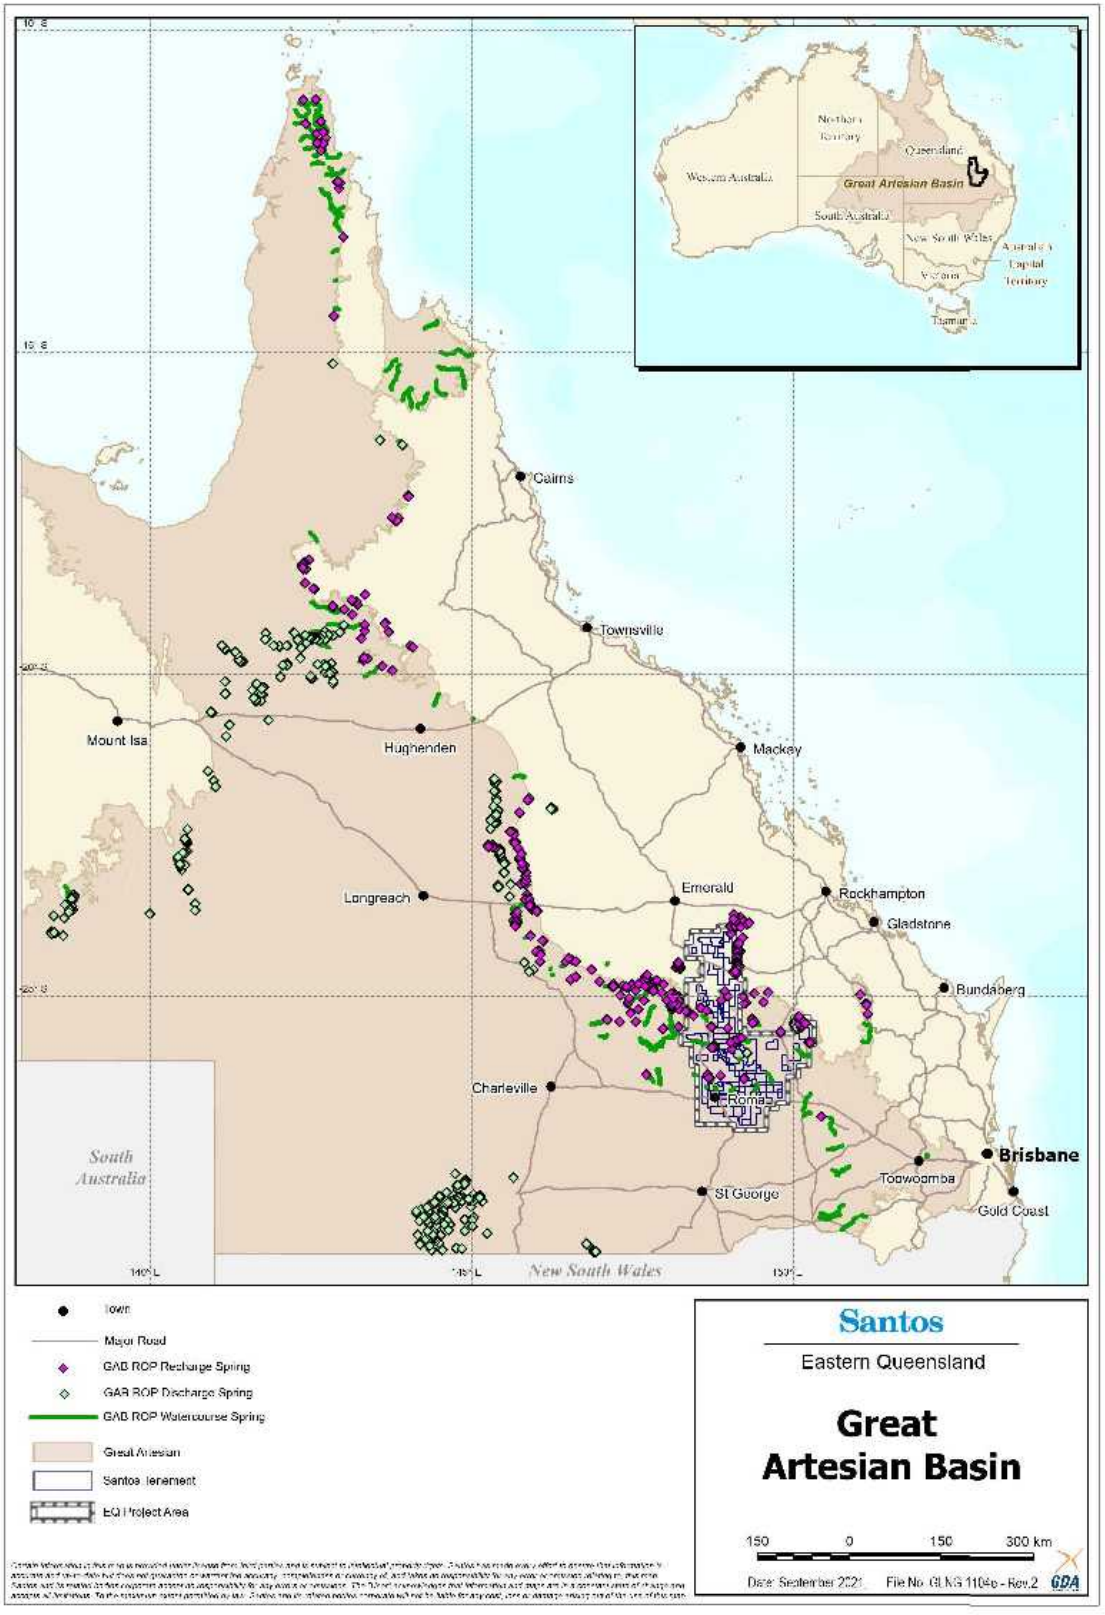

Figure 6. Great Artesian Basin

2.4 Geological Setting

2.4.1 Continental Setting

The Santos EQ Project Area is located entirely within the large, south-dipping Permian to Cretaceous depositional basins of the Bowen Basin and Surat Basin, themselves located within the easternmost location of the GAB extents (

Figure 7).

The GAB is one of the largest artesian groundwater basins in the world. It extends 2,400 km from Cape York in the north to Dubbo in the south. At its widest it is 1,800 km from the Darling Downs to west of Coober Pedy. With an area of over 1.7 million km^2, the GAB underlies approximately one-fifth of the Australian continent.

2.4.2 Stress Field Setting

Australia lies within the Indo-Australian tectonic plate and undergoes an absolute movement of approximately 7 centimetres (cm) per year to the north- north northeast (N-NNE). This is reflected in the N-NNE orientated major horizontal stress field as indicated for the Bowen Basin (**Figure** 8). The minor horizontal stress will be approximately normal (90°) to this, viz. east-east south-east (E-ESE). The horizontal in-situ stress can be relatively high and anisotropic and exceed the vertical stress due to gravity.

The continental geomechanical setting is presented in **Figure 9** and illustrates the tectonic contribution to the regional stress field within continental Australia.

The origin and nature of near surface stress in Australia has been discussed in several publications, for example, Brown and Windsor (1990) and Enever and Lee (2000). The total stress at a point in the Earth's crust (including Australia) is generally considered to be made up of the following components:

- Gravity due to the weight of overburden. Gravity also contributes to the horizontal stress due to the Poisson's effect
- Tectonic component, which could be an active or a remnant tectonic stress, from movement of the earth's plates, and generally impacts the horizontal stress field
- Thermal and physio-chemical effects.

Analysis of stress and rock strength has been undertaken through in-house and contractor (JRS/Helix RDS) services. Borehole studies have utilised image log data, wireline log data, rock strength testing and drilling experience to model the stress variation between geological rock units from surface to the target coal seams, namely, the Walloons and Bandanna Coals of the Surat and Bowens Basins sequences, respectively. The results of these borehole studies are consistent with stress magnitude and orientation produced by broader plate tectonics as indicated on the publicly available Australasian Stress Map (Hillis et al., 1999; Reynolds, 2001).

2.4.3 Tectonic Setting – Faulting and Folding

The regional tectonic setting described above manifests itself in structural features characteristic of a largely compressive environment, in which thrust faulting and folding are dominant. These features are further detailed in **Section 2.5.4** and **Section 2.5.5**. The key consequence of this tectonic setting is that the faults and folds are tight and characteristically not zones of groundwater flow, but rather are hydraulic barriers to flow. They typically compartmentalise the groundwater and restrict free flow across the compartment boundaries. This is generally manifested in water quality and temperature differences between compartments (OGIA, 2020).

2.5 Regional Geology

The geology of the Santos EQ Project Area includes a Jurassic to Cretaceous age sequence of alternating sandstone and siltstone formations associated with the Surat Basin, which unconformably overlies Triassic to late-Permian sedimentary formations of the Bowen Basin (**Figure 10** and **Figure 11**).

The Bowen and Surat Basins are structurally separate sedimentary depositional centres, however they are stratigraphically and hydraulically interconnected (DME, 1997). The Surat Basin is a sub-basin of the GAB (

Figure 7, **Figure 11** and **Figure 36**) . Both the Surat and the Bowen basins contain sandstones, siltstones and mudstones. The sandstones are permeable and include the major aquifers, and the siltstones and mudstones are impermeable and do not contain aquifers.

The basins generally comprise southward dipping synclines, with the Surat Basin formations outcropping or subcropping in the Project Area and the underlying Bowen Basin formations outcropping in the AVPA to the north. A stratigraphic sequence for the study area is presented in **Figure 11** and **Table 5**.

Localised geological cross-section are presented beginning in **Section 2.6.1**, **Figure 18** to **Figure 20**, **Figure 21** to **Figure 26**, **Figure 30** to **Figure 35**. Their transect location is shown in **Figure 10**.

2.5.1 Bowen Basin Geological Setting and Model

The Bowen Basin is an Early Permian to Middle Triassic age basin, which comprises shallow marine and continental clastic and volcanic rocks (**Figure 11**). The Bowen Basin is comprised of two sedimentary depositional centres, namely, the Denison and Taroom Troughs (**Figure 12**). The main structural feature through the Project area is the Comet Ridge, located along the western margin of the Taroom Trough in the southern extent of the Bowen Basin. The Comet Ridge is comprised of mainly Devonian aged rocks and is covered by a relatively thin sequence of gently folded Permian and Triassic rocks, which make up the Bowen Basin.

The oldest formation included in the Bowen Basin stratigraphic sequence is the Reids Dome Beds, a unit of highly variable thickness. The Reids Dome Beds are unconformably overlain by the Early Permian aged formations of the Back Creek Group, which include the Cattle Creek Formation, the Aldebaran Sandstone and a number of other formations (**Figure 11**). The Aldebaran Sandstone is the deepest formation targeted for water supply within the north-western reaches of the Project area, near the town of Emerald. The other formations within the Back Creek Group are generally of a lower permeability. The Back Creek Group is overlain by shale, siltstone, tuff, bentonite and labile sandstone of the Black Alley Shale.

The Black Alley Shale and the Bandanna Formation are included in the Late Permian Blackwater Group. Gas in the Denison, Fairview and Arcadia Valley region is extracted from the coal seams of the Bandanna Formation, at depths of 200 to 1,500 metres below ground level (mbgl). The thickness of the Bandanna Formation is variable throughout the Project area, from approximately 60 to 100 m thick in the Comet Ridge area. Up to six coal seams are defined within the Bandanna Formation with an average coal thickness of approximately 11 to 12 m in the Fairview region, generally thinning northward. However, to the east of the Fairview region, 15.3 m of net coal has been intersected (McClure S. et al., 2008).

The Bandanna Formation is unconformably overlain by the oldest formation of the Triassic aged Mimosa Group, the Rewan Formation (**Figure 11**). This formation is the oldest formation to outcrop within the Arcadia Valley (**Figure 11**). The Clematis Sandstone is a prominent formation in the Arcadia Valley region, forming the steep cliffs of the Expedition Range, and is overlain by mudstone and sandstone units of the Moolayember Formation. The Arcadia Valley has been in-filled with Cainozoic sandy sediments, which are overlain by Quaternary alluvium deposits along the drainages.

The unconformable contact between the Moolayember Formation and the overlying Precipice Sandstone marks the boundary between the Bowen and Surat Basin sequences.

Geological contour maps illustrating the top and thickness of the Precipice Sandstone and the Bandanna Formation are provided in the ‘Groundwater Impact Study’ (Golder, 2010).

2.5.2 Surat Basin Geological Setting and Model

The Surat Basin comprises a sequence of south dipping consolidated Jurassic and Cretaceous sediments. As previously mentioned, the Surat Basin is a sub-basin of the GAB.

Due to compression and erosional processes, the Precipice Sandstone directly overlies, and is in hydraulic connection with, the Bandanna Formation in a limited area of the southwest Fairview region.

The outcrop region of the Precipice Sandstone crosses through the northern part of the Fairview region (**Figure 10**). The younger Surat Basin formations outcrop progressively south through Roma, including the Evergreen Formation, the Hutton Sandstone and Birkhead Formation, the Springbok Sandstone, WCM, Westbourne Formation, the Gubberamunda Sandstone and Orallo Formation.

The final Surat Basin formations that outcrop within the southern reaches of the Santos EQ Project Area include the Mooga Sandstone, and the Bungil and Wallumbilla Formations (Bureau of Mineral Resources, Geology and Geophysics Surficial Geology, 1967).

The WCM are the main gas bearing units within the Surat Basin and are the target formation for gas operations within the Roma area. The thickness of the coal measures in the Roma area ranges from 100 to 460 m, at depths ranging from 170 to 933 mbgl. The coal seams are separated by silty and tight sandstone, which restricts leakage between seams. There is an unconformable contact between the Springbok Sandstone and the WCM. They are considered to be in hydraulic connection (Scott S. et al., 2004).

Note that the Adori Sandstone (referred to in the CG's comments) is a formation of the Eromanga Basin and is not present within the Santos EQ Project Area, with its equivalent in this area being the Springbok Sandstone.

Geological contour maps illustrating the top and thickness of the main Surat Basin aquifers and key Bowen Basin units have been mapped and assessed by Santos EQ and are presented beginning in **Section 2.6.1**, **Figure 18** to **Figure 20**, **Figure 21** to **Figure 26**, **Figure 30** to **Figure** 35. Their transect location is shown in **Figure 10**.

2.5.3 Gas Development Formations

Gas development in the study area targets coal measures within the stratigraphic profiles of both the Surat and Bowen Basins. The Roma area targets the WCM, located within the Surat Basin sequence, while the Bowen Basin coal seams of the Bandanna Formation and Cattle Creek Formation are targeted in the Dension, Scotia, Fairview and Arcadia Valley regions. Descriptions of these formations are provided in the following sections.

2.5.4 Regional Faulting

The southern part of the Santos EQ Project Area is located near the northern margin of the Surat Basin. In this area, the main geological units, including the targeted WCM do not indicate deformation or complex faulted geology. However, the faulting and folding that is recognised in the older subsurface strata is either absent or attenuated in the outcropping Jurassic-Cretaceous sediments. Some features are, however, visible in the outcrop including the Alicker and Eurombah Anticlines, the Hutton- Wallumbilla Fault and several west north-west trending faults.The north-west trending Hutton-Wallumbilla Fault is located west of Roma and is downthrown to the west with a displacement of approximately 450 m in the basement but just 30 m in the overlying sediments. Small north-west

trending faults elsewhere in the Roma region are likely related to the movements that formed the Hutton-Wallumbilla Fault (URS, 2008).

West north-west trending faults also occur in the RSGPA. These faults are likely a result of epeirogenic movements (the gradual uplift or subsidence of the Earth's surface) related to the Surat Basin through the Tertiary period (URS, 2008). These faults have limited or no vertical displacement, but they leave a clearer topographic imprint than the larger faults in the same region due to their younger age.

The major structural feature in the north of the Santos EQ Project Area is Comet Ridge, which comprises mainly Devonian age rocks, and is covered by a relatively thin sequence of Permian and Triassic rocks. The Permian and Triassic sequence of sediments was folded principally during the late Triassic Period, although some of the deformation within the Permian sediments possibly occurred during the period of uplift and emergence in the Lower Permian. Fold axes are generally parallel trending north-west to the Comet Ridge axis. The Permian-Triassic folds are truncated by the erosional unconformity surface on which the Precipice Sandstone was deposited. The overlying Jurassic and Cainozoic rocks are not folded (Golder, 2009).

The central part of the Santos EQ Project Area near Injune is situated between two large reverse fault systems that are oriented approximately north south (**Figure 13**). Immediately to the east of Injune is an anticline, which plunges to the south-southeast and corresponds to a southerly extension of the Comet Ridge in the geological basement. The anticline is complementary to the Mimosa Syncline and runs through the eastern area of the study area near Taroom.

Figure 14 illustrates the structural features in the central and southern part of the Santos EQ Project, which affect the WCM sequence in the Roma Area.

2.5.5 Seismic History of Santos Eastern Queensland Tenements

2.5.5.1 Vulnerability

Earthquakes in Australia are generally caused from the release of built-up stress in the interior of the Indo-Australian plate, which is being pushing north (NNE) and is colliding with the Eurasian, Philippine, and Pacific plates. Geoscience Australia reported that there are on average 200 earthquakes of magnitude 3.0 or more in Australia each year. Earthquakes above magnitude 5.5 occur on average every two years, and those of magnitude 6.0 or more occur approximately every five years.

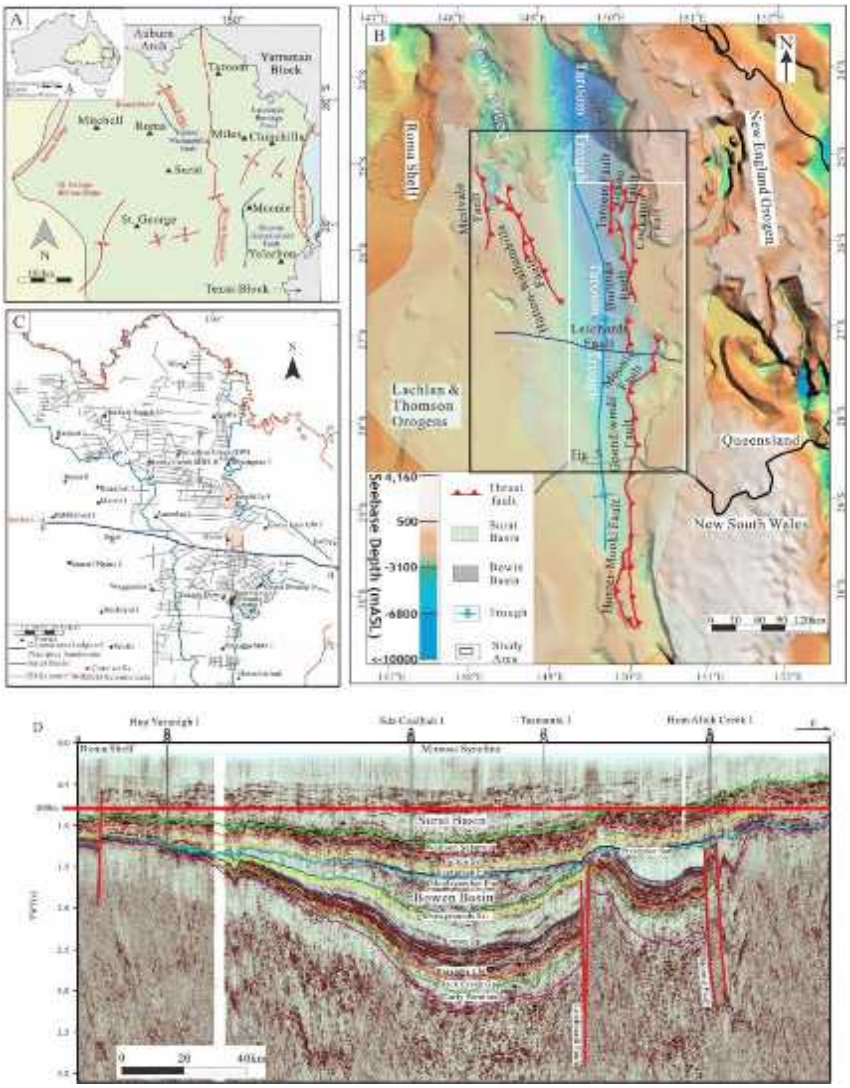
The area of southern central Queensland in the immediate vicinity of the Project tenures is one of the least seismically active areas on Australian continent. The most seismic activity near the Project area is in the Hervey Bay area, approximately 500 km to the east. While more frequent and larger in magnitude earthquakes occur in the Hervey Bay area, little is felt in the area surrounding the tenures. A study performed in the 1990s found that there is a 90% chance that the unitless peak ground acceleration (a term used in civil engineering to estimate forces on structures) will not exceed 0.05 in any 50-year period for this area. This indicates that regardless of the epicentre of any possible earthquake, little ground movement will occur here.

2.5.5.2 Local Historic Faults and Potential Seismic Activity

Figure 10 shows the location of major faults related to the basin structure as mapped by the Geological Survey Queensland 2011 within the Santos EQ Project Area.

Within the Surat Basin and within the Santos EQ project area the only major fault is the north-west trending Wallumbilla Fault which crosses the Roma region and is downthrown to the west with a displacement of ±450 m in the basement but just 30 m in the overlying sediments. Small north-west trending faults elsewhere in this field are likely related to the historic movements that formed the Hutton- Wallumbilla Fault (URS, 2008) (**Figure 13** and **Figure 21**).

Further information on the Hutton-Wallumbilla Fault is discussed below.



Of the other minor faults, the seismic cross-sections presented in **Figure 12**, **Figure 15** to **Figure 17**, **Figure 21,** and **Figure 27** to **Figure 29** illustrate how these fault and fold structures affect the Bowen and Surat Basin sequences. Of note is the deep-seated nature of the basement structures, particularly the faults. These largely do

not penetrate upward beyond the Bowen Basin stratigraphy. The structures are predominantly compressional and do not generally have large fault-throws within the Bowen stratigraphy and negligible throws in the Surat stratigraphy.

The Hutton-Wallumbilla Fault

The Hutton-Wallumbilla Fault (**Figure 16**) is a near-vertical thrust fault dividing the Comet Ridge Platform from the lower Roma Shelf (Green, 1997). The main thrust fault event occurred in the Early Permian during the back-arc extension phase of the Bowen-Gunnedah Basin, which produced a series of graben and half-graben structures along the eastern margin of the Australian continent (Jones & Veevers, 1983). Periods of reactivation have extended the fault through the overlying sediments and have resulted in pervasive en échelon faulting with evidence of reactivation in the near surface (Coote, 1984; Jensen et al., 1964). While the fault system exhibits more than 300 m of displacement in the Bowen Basin, faulting in the Surat Basin is more subdued.

There are several important connectivity features associated with this fault, including the regionally significant Precipice–Bandanna contact zone (OGIA, 2019c). This section, however, will focus on a multidisciplinary case study around a group of springs that are found in the vicinity of the Hutton-Wallumbilla Fault (OGIA, 2015). This site has been selected due to several lines of evidence for structural control on local groundwater dynamics. The Lucky Last and Abyss spring complexes are located approximately 20 km north of Injune (**Figure 17**). OGIA has

undertaken a detailed conceptualisation of these sites as part of a spring wetland conceptualisation project (OGIA, 2015).

*Notes: a) Seismic Line with the Deformation Zone; b) Map Showing the Hutton-Wallumbilla Fault Zone and Spring Locations. Refer to **Figure 16** for location of springs.*

2.6 Local Geology

Conceptual geological model cross-sections through various parts of the Santos EQ Project Area are presented in **Figure 18** to **Figure 20**, **Figure 21** to **Figure 26**, **Figure 30** to **Figure 35** and present an interpretation of the key elements of the Bowen and Surat Basin geology. The locations of these cross-sections are presented on the surface geology map (**Figure 10**).

2.6.1 Roma Region

The Roma region is part of the Surat Basin and are underlain by sedimentary formations associated with the GAB, some of which are recognised as regionally significant aquifers. Jurassic to Cretaceous age sedimentary formations sub-crop and outcrop across the tenures but are predominantly overlain by Quaternary alluvium. A basalt intrusion is present at the Grafton Range towards the north of the Roma area. The gas bearing formation of interest to Santos is the Walloon Coal Measures (WCM) of the Injune Creek Group. **Section 3.5** provides a geological description of each major geological formation underlying the Roma area.

Figure 18 to **Figure 20** shows several cross-sections through the Roma area. These sections were generated using stratigraphy data available in the DEHP groundwater database and from Santos EQ gas well geology logs.

*Note: Refer to **Figure 10** for Cross-Section Location*

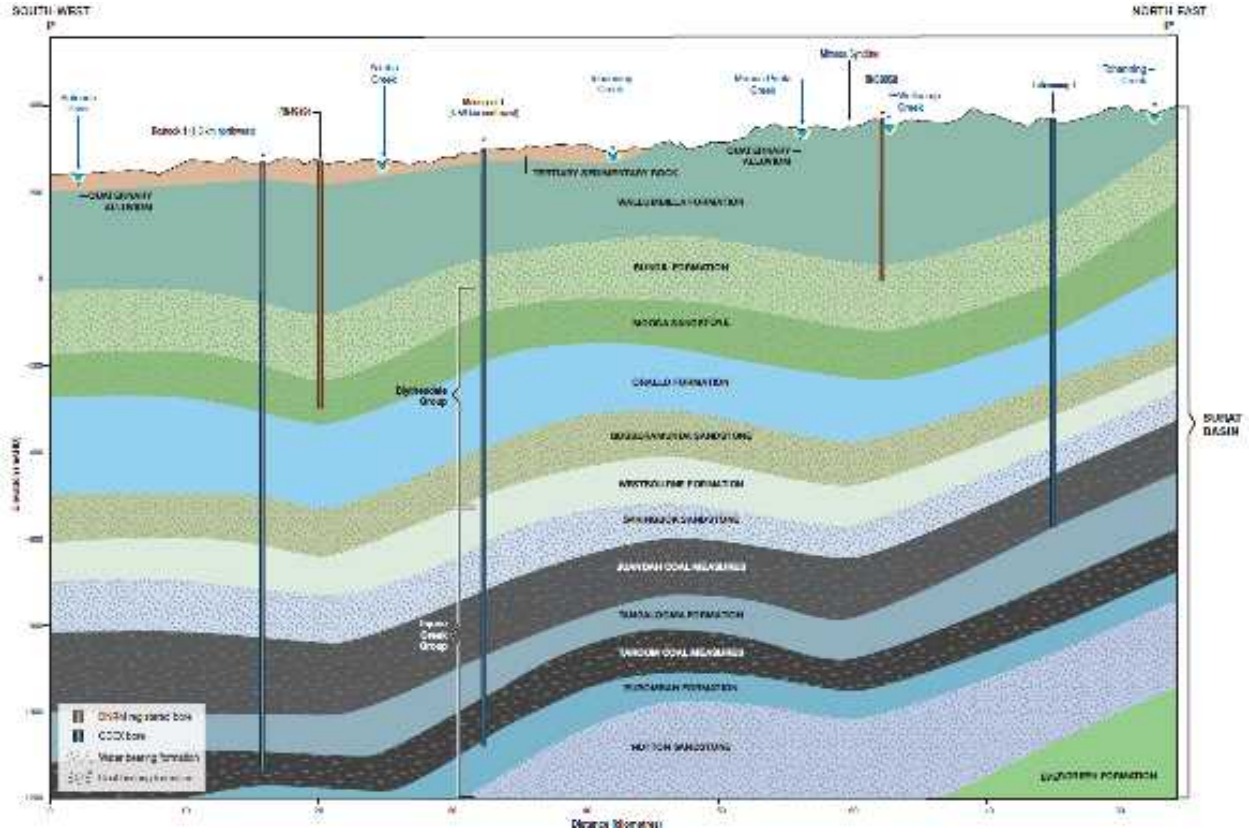

Figure 20. Conceptual Geological Cross-Section Southwest – Northeast

*Note: Refer to **Figure 10** for Cross-Section Location*

2.6.1.1 Faults and Other Geological Controls

The north-west trending Hutton-Wallumbilla Fault crosses the Roma area and is downthrown to the west with a displacement of 450 m in the basement but just 30 m in the overlying sediments (refer to **Figure 21**). Small north-west trending faults elsewhere in the Roma area are likely related to the movements that formed the Hutton-Wallumbilla Fault (URS, 2008). Further detail on the Hutton-Wallumbilla Fault is discussed in **Section 2.5.5.2**.

Other west-northwest trending faults also occur across the Roma area. These faults are likely a result of epeirogenic movements (the gradual uplift or subsidence of the Earth's surface) related to the Surat Basin through the Tertiary period (URS, 2008). These faults have limited or no vertical displacement, but they leave a clearer topographic imprint than the larger faults in the same region due to their younger age.

Importantly in this area, the main geological units, including the targeted Walloon Coal Measures (WCM) do not indicate deformation or complex faulted geology. However, the faulting and folding that is recognised in the older subsurface strata is either absent or attenuated in the outcropping Jurassic-Cretaceous sediments. Some features are, however, visible in the outcrop including the Alicker and Eurombah Anticlines, the Hutton-Wallumbilla Fault and several west north-west trending faults.

In December 2020, the OGIA concluded that the Hutton-Wallumbilla Fault generally do not cause sufficient displacement to juxtapose the Hutton Sandstone and Walloon Coal Measures and as such, the risk of cross-formational flow is low. Furthermore, the report found the other small number of faults that were identified (OGIA, 2020).

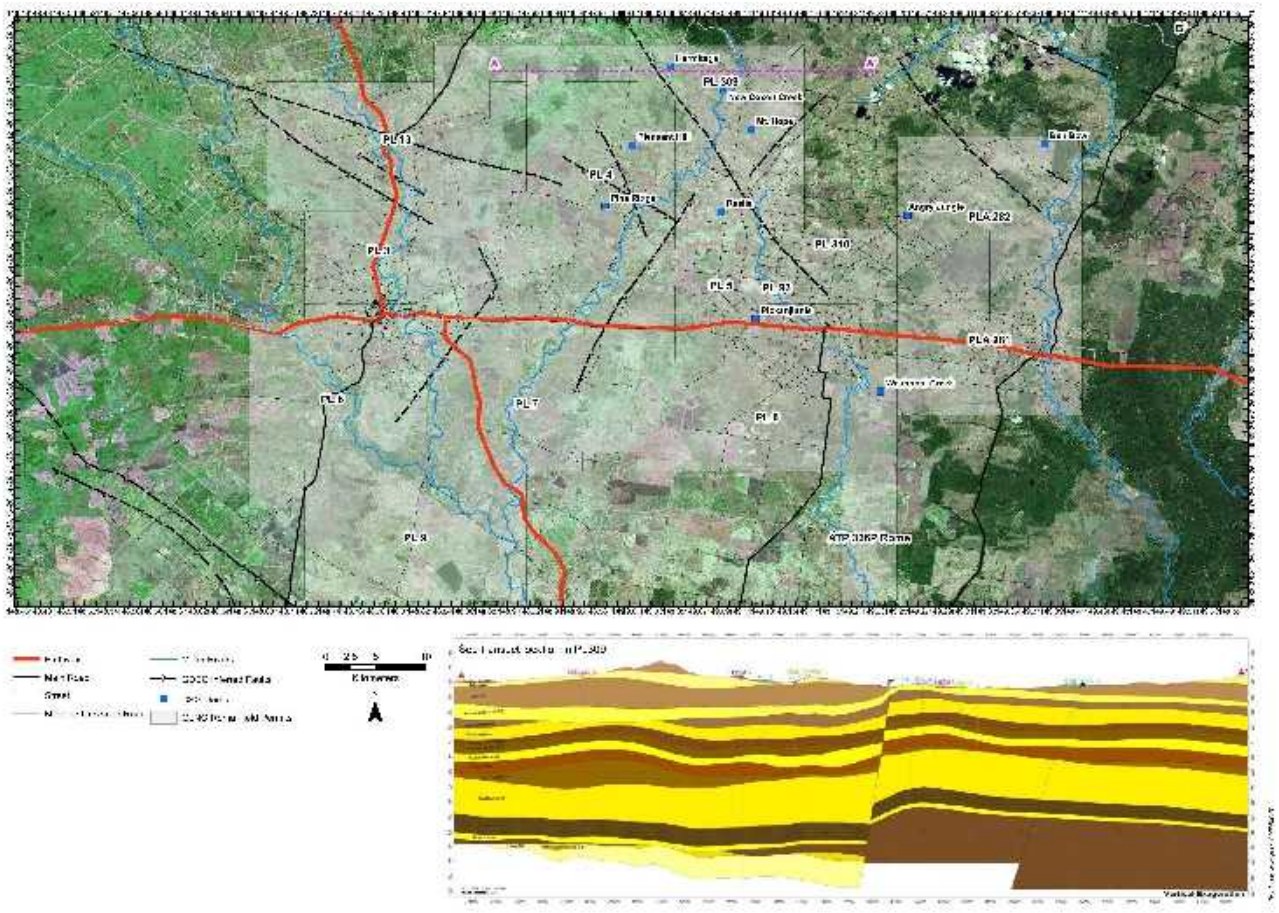

Figure 21. Wallumbilla Fault Cross-Section

2.6.2 Fairview and Arcadia Valley Regions

The Fairview region is directly underlain by the lower GAB formations of the Surat Basin (Hutton, Evergreen and Precipice Sandstone) and the formations of the upper Bowen Basin (Clematis Sandstone). The gas bearing formation of interest in the Fairview region is the Bandanna Formation from the Blackwater Group (Bowen Basin, Late Permian). In the Arcadia Valley region, the main geological units include the Precipice Sandstone, Clematis Sandstone and at depth the Aldebaran Sandstone (the Back Creek Group) in the northern portion of the field.

The Bandanna Formation is unconformably overlain by the oldest formation of the Triassic aged Mimosa Group, the Rewan Formation. This formation is the oldest formation to outcrop within the Arcadia Valley. The Clematis Sandstone is a prominent formation in the Arcadia Valley CSG field, forming the steep cliffs of the Expedition Range, and is overlain by mudstone and sandstone units of the Moolayember Formation. The Arcadia Valley has been in-filled with Cainozoic sandy sediments, which are overlain by Quaternary alluvium deposits along the drainages.

Due to compression and erosional processes, the Precipice Sandstone directly overlies, and is in hydraulic connection with, the Bandanna Formation in a limited area of the southwest Fairview region. The unconformable contact between the Moolayember Formation and the overlying Precipice Sandstone forms the boundary between the Bowen and Surat Basins.

Section 3.5 provides a geological description of each major geological formation underlying the Fairview and Arcadia Valley region **Figure 21** to **Figure 26** shows several cross-sections through the Fairview and Arcadia Valley region. These sections were generated using stratigraphy data available in the DEHP groundwater database and from Santos EQ gas well geology logs.

2.6.2.1 Faults and Other Geological Controls

Fairview Region

The Fairview area is situated between two reverse fault systems that are oriented approximately north south (Santos, 2008) (**Figure 27** and **Figure 28**). The north-west trending Hutton-Wallumbilla Fault (refer to **Section 2.6.1.1**) runs to the west of FPA. The Fairview area is located within an anticline, which plunges to the south-southeast and corresponds to a southerly extension of the Comet Ridge in the geological basement. The anticline is complementary to the Mimosa Syncline, located to the east of the FPA.

Both the anticline and syncline were developed through the Permian and Triassic periods. In the anticlinal structure there are subsidiary minor folds, but after the period represented by the unconformity at the base of the Jurassic aged Precipice Sandstone, folding on the pre-existing axes has been slight. The warping and minor faulting of the Jurassic succession may be related to the compaction of the underlying thick sequence of Permian and Triassic sediments.

Arcadia Valley Region

The major structural feature in the Arcadia Valley is the Comet Ridge, which comprises mainly Devonian age rocks, and is covered by a relatively thin sequence of Permian and Triassic rocks. The Permian and Triassic sequence of sediments within the Arcadia Valley was folded principally during the late Triassic Period, although some of the deformation within the Permian sediments possibly occurred during the period of uplift and emergence in the Lower Permian.

Fold axes are generally parallel (**Figure 29**), trending north-west, through the area designated as Comet Ridge. The amplitude of folding on the Comet Ridge is small and the axes are short and sinuous. The Permian-Triassic folds are truncated by the erosional unconformity surface on which the Precipice Sandstone was deposited. The overlying Jurassic and Cainozoic rocks are not folded.

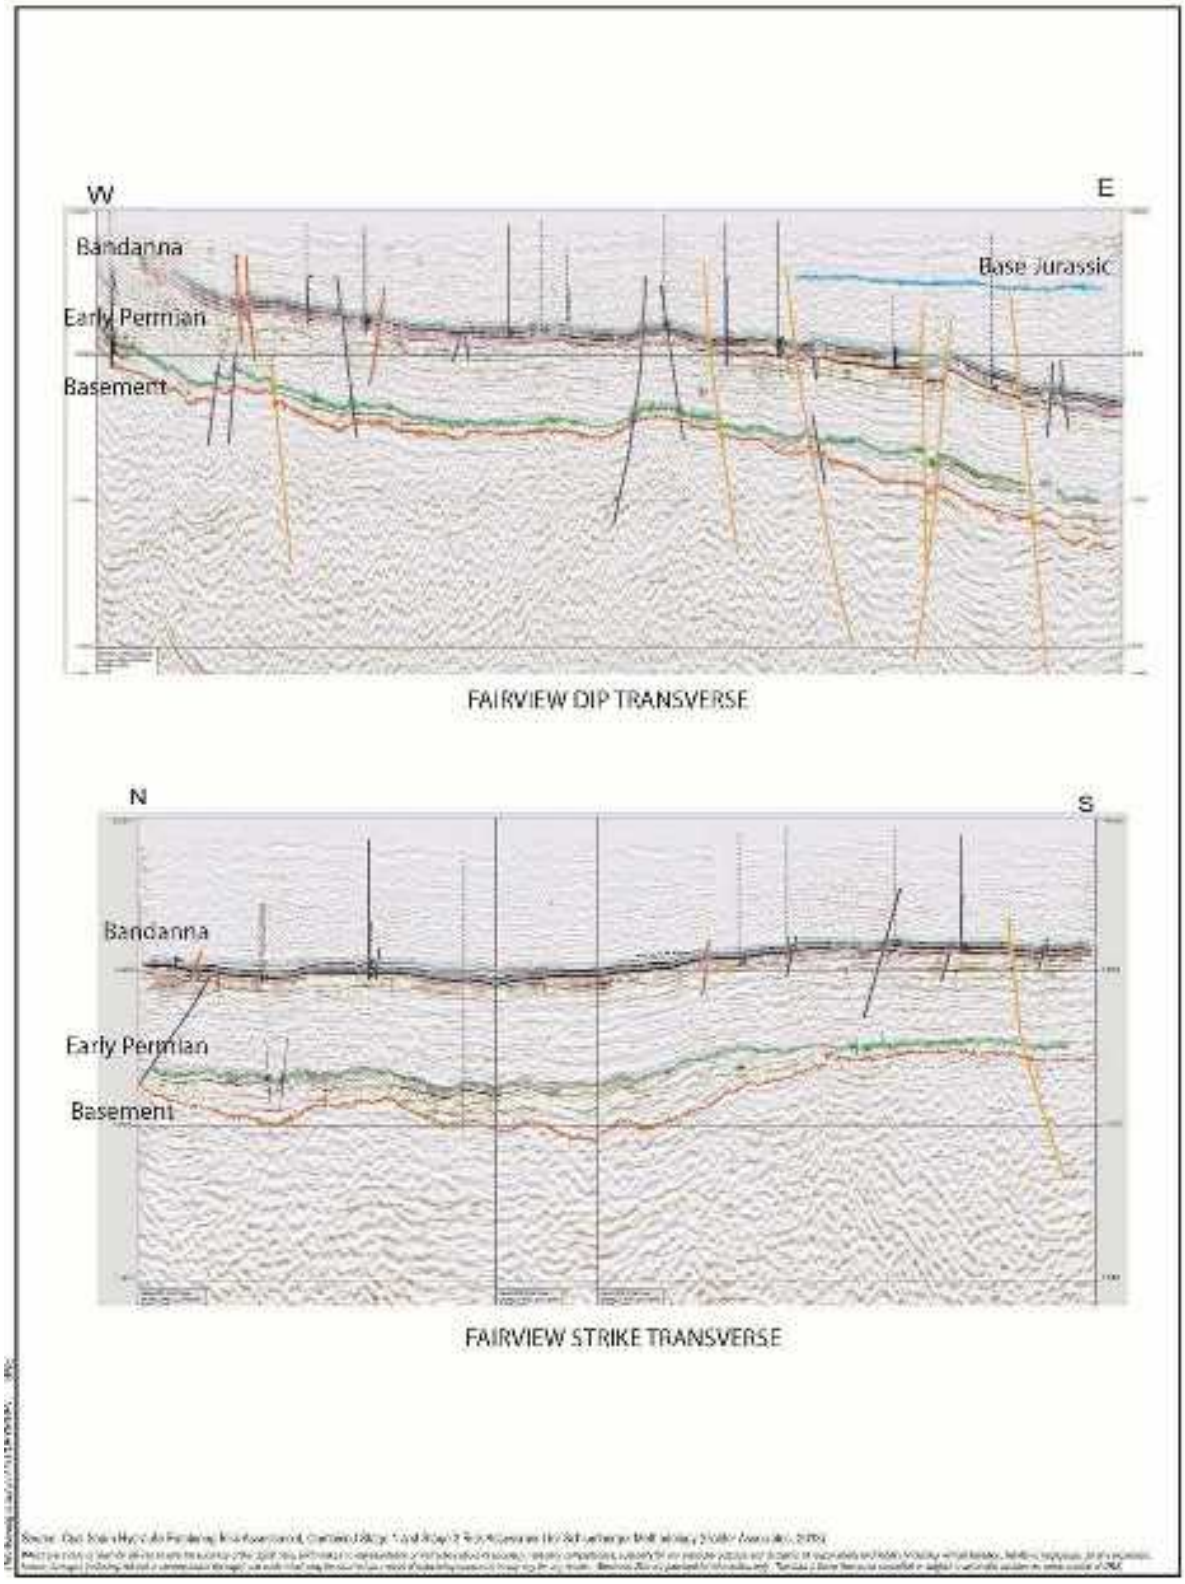

Figure 27. N – S Seismic Section for Fairview Showing Fold and Fault Structure Penetrations

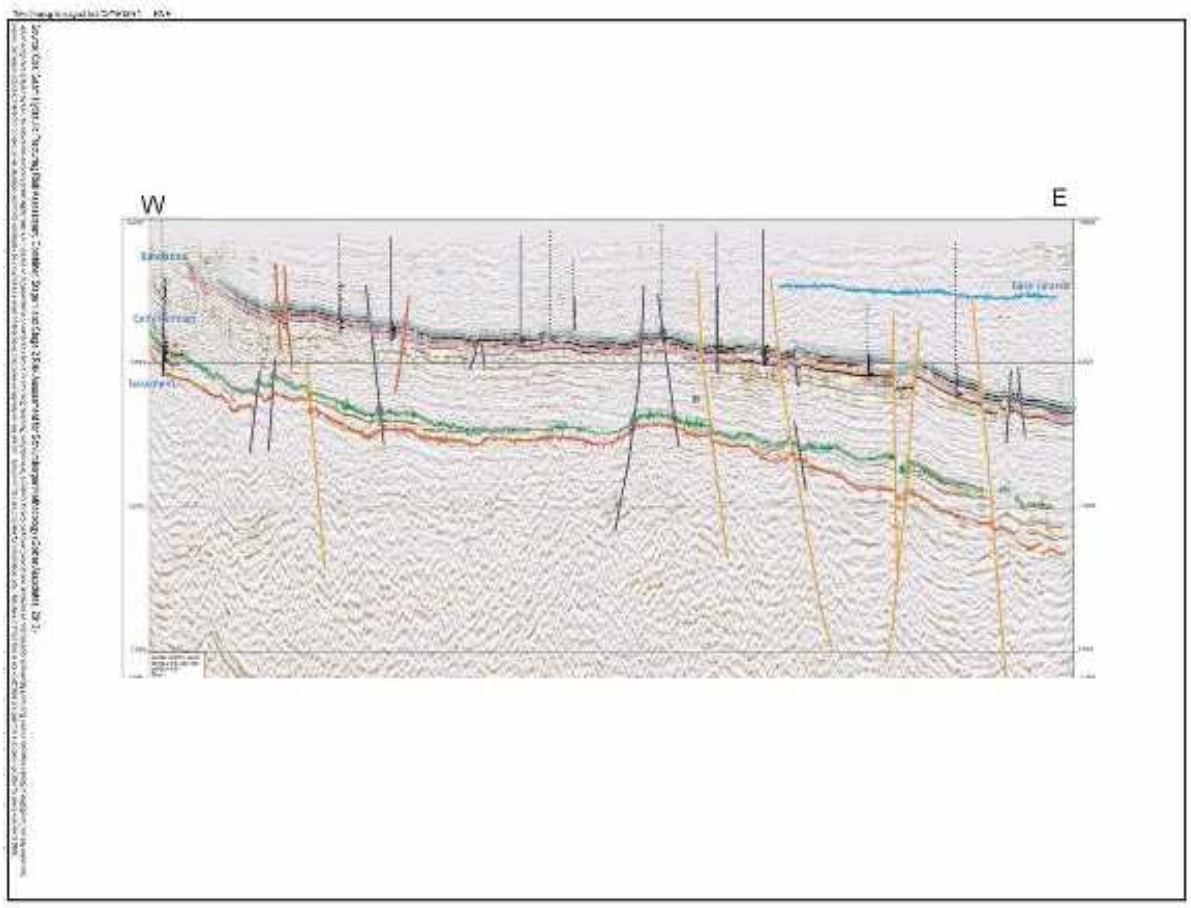

Figure 28. N – S Seismic Section for Fairview Dip Traverse Showing Fold and Fault Structure Penetrations

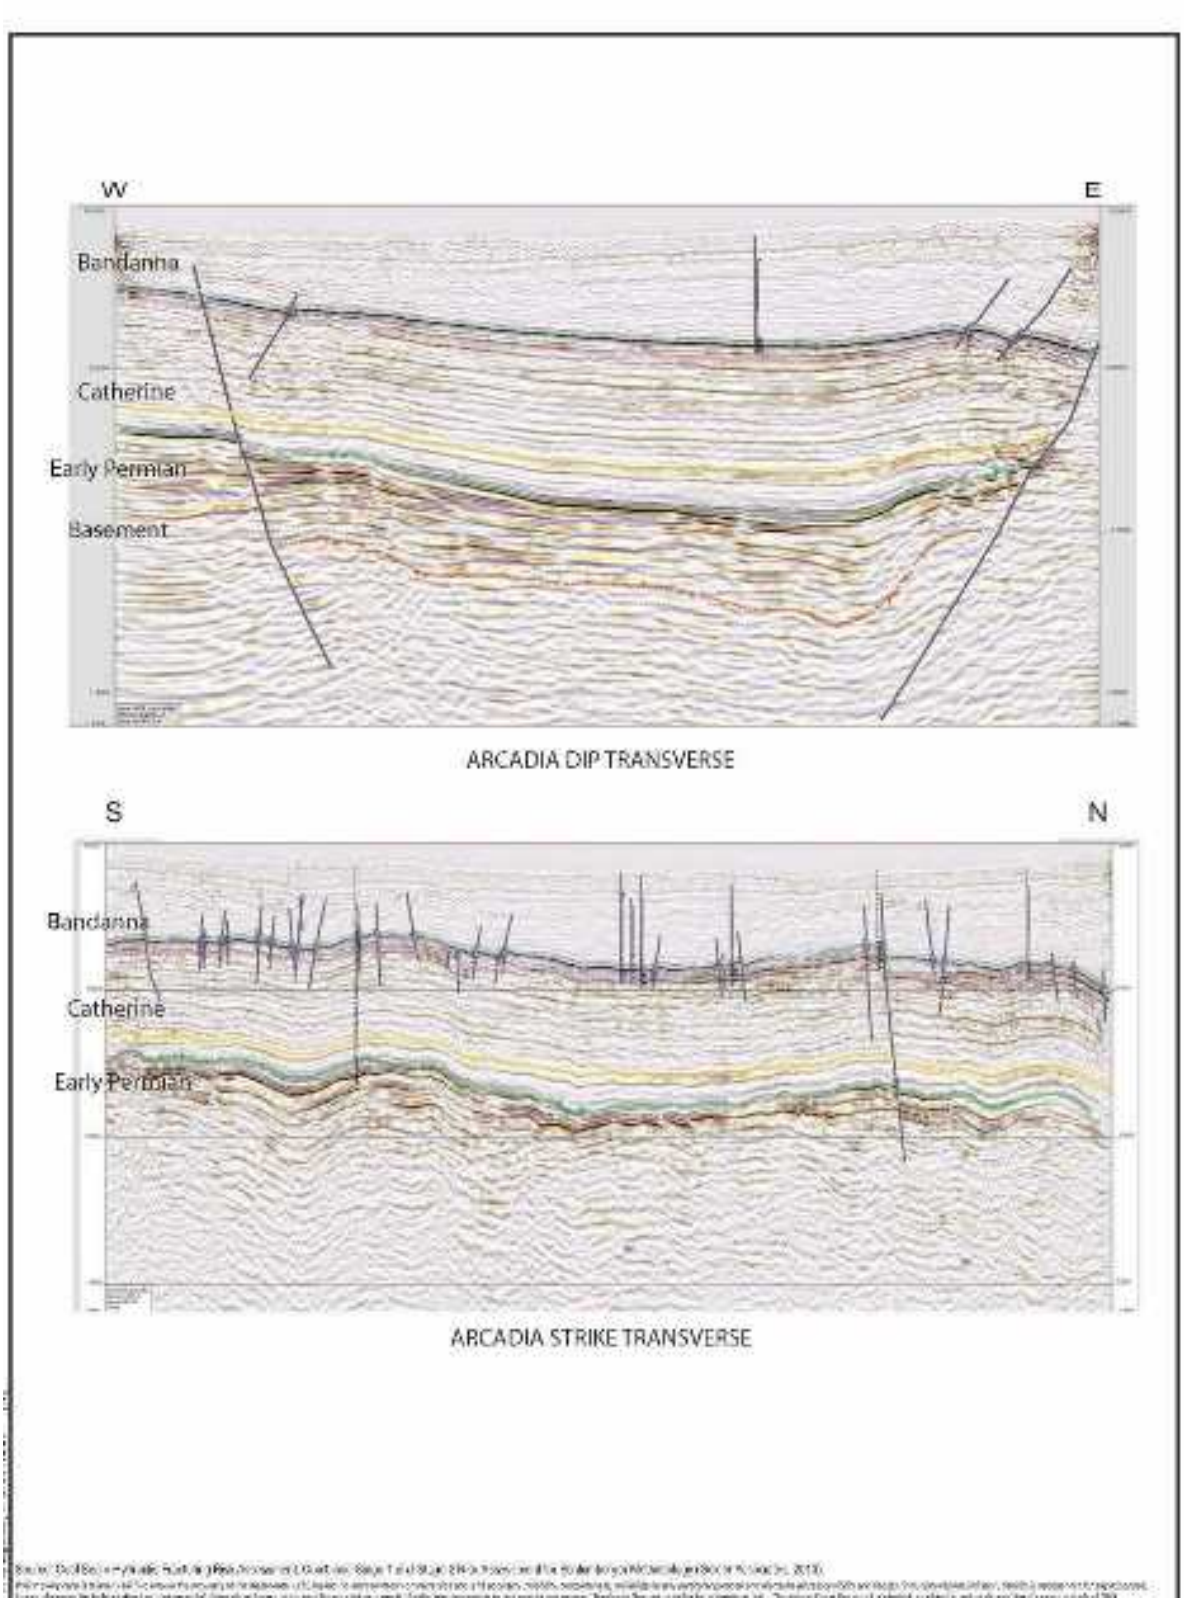

Figure 29. N – S Seismic Section for Arcadia Showing Fold and Fault Structure Penetrations

2.6.3 Denison Project Area

ATP 1191 (and associated tenures) partially capture the Denison Trough and Comet Ridge structural features of the Bowen Basin in Queensland. The Bowen Basin is a deep, elongate, sedimentary trough that extends north-south for 1,100km and covers an area of approximately 160,000km^2 from the townships of Collinsville in Central Queensland to Moree in northern New South Wales. The basin is an asymmetric retro-arc foreland basin containing Early Permian to Middle Triassic sediments. The basin is bounded to the east by a regionally extensive thrust fault system (referred to as the Burunga-Leichhardt Fault in Queensland) and is partially overlain by the Jurassic-Cretaceous Surat Basin sequence.

The Denison Trough is an elongate sedimentary sub-basin, approximately 300 km by 50 km, located along the central western margin of the Bowen Basin. The Denison Trough consists of a series of interconnected N-S to NW-SE trending inverted graben and half graben thrust ramp anticlines separated by broad structural lows. The Comet Ridge is a north-south trending regional basement high which separates the Denison Trough from the Taroom Trough, the main structural depocenter of Bowen Basin.

Figure 30 shows the stratigraphic cross-sections through the Denison region.

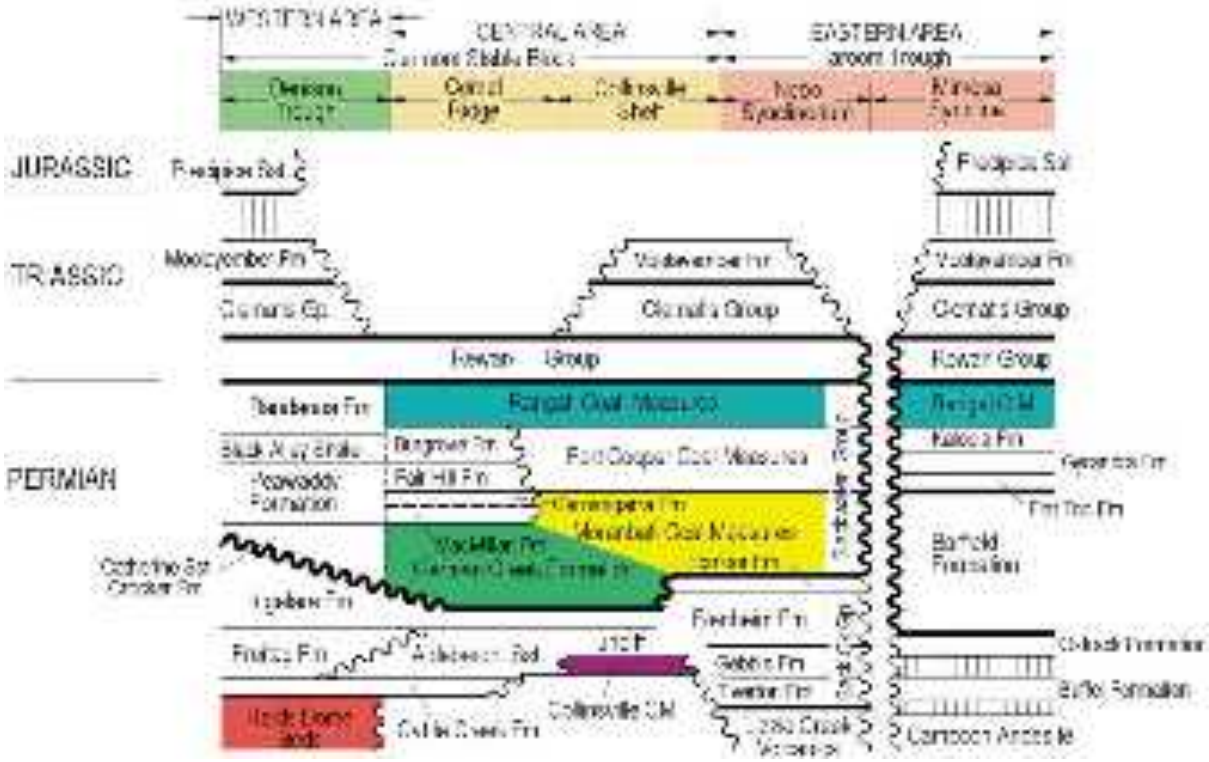

Figure 30. Stratigraphy of the Denison Trough

Source: Modified from Beeston, 1986

2.6.3.1 Faults and Other Geological Controls

The Denison Trough is not known for being seismically active. A search of Geoscience Science Australia Earthquake Mapping Tool (Geoscience Australia, 2019) for earthquakes greater than or equal to a magnitude 2.0 since 1900 showed no history of earthquakes within the Project Area. The closest earthquake identified from this search was a magnitude 3.2 earthquake near Blackwater, Queensland in June 2013.

2.6.4 Scotia Region

The Scotia region lies within the overlap area of the Early Permian to Middle Triassic aged Bowen Basin which contains shallow marine and continental clastic and volcanic rocks, and the south dipping consolidated Jurassic and Cretaceous sediments of the Surat Basin.

The Jurassic age Injune Creek Group outcrops across the majority of the Scotia region. In the Queensland Department of Environment and Resource Management (DERM) groundwater database the Birkhead formation of the Injune Creek Group is the main stratigraphic descriptor used. The Hutton Sandstone, underlying the Injune Creek Group in the Surat Basin sequence, outcrops over the north-eastern portion of the Scotia Project Area. Alluvium is present along the course of the Bungaban Creek in the far north of the Scotia area.

Within the Scotia region the Upper Baralaba Formation is the main coal-bearing unit. This is equivalent of Late Permian Bandanna Formation elsewhere in the Bowen Basin (Santos, 2011). The surface geology in the Scotia region and surrounding area is shown in **Figure 10**. Detailed stratigraphy of the formations present in the Scotia region is presented in **Figure 31** to **Figure 35**.

2.6.4.1 Faults and Other Geological Controls

While no major currently or potentially active faults exist near the Scotia region, there are two (2) minor unnamed faults that could affect the broader area. Regarding part (e) of the draft EA conditions, the historic and currently active structural zones (structural faults or discontinuities) are at sufficient distance and depth (horizontal separation and vertical depth) to not pose a threat of re-activation by stimulation activities proposed for Scotia, nor are the capacities to permit water flow likely to be enhanced by such activities.

3 Hydrogeology, Groundwater Resources and Environmental Values

The information provided in this section addresses the following EA approval requirements: conditions (f), (g), (h), (i), (k), (l), (p) and (z)(1).

3.1 Regional Hydrogeology

The Santos EQ Project Area is located entirely within the large, south-dipping Permian to Cretaceous depositional basins of the Bowen Basin and Surat Basin (see **Figure 36**). The Bowen and Surat Basins are structurally separate sedimentary depositional centres; however, they are stratigraphically interconnected (DME, 1997). The Surat Basin is a sub-basin of the GAB, one of the largest artesian groundwater basins in the world.

Table 5 provides an overview of the relevant hydrogeological units of interest within each sub-Santos EQ Project Area.

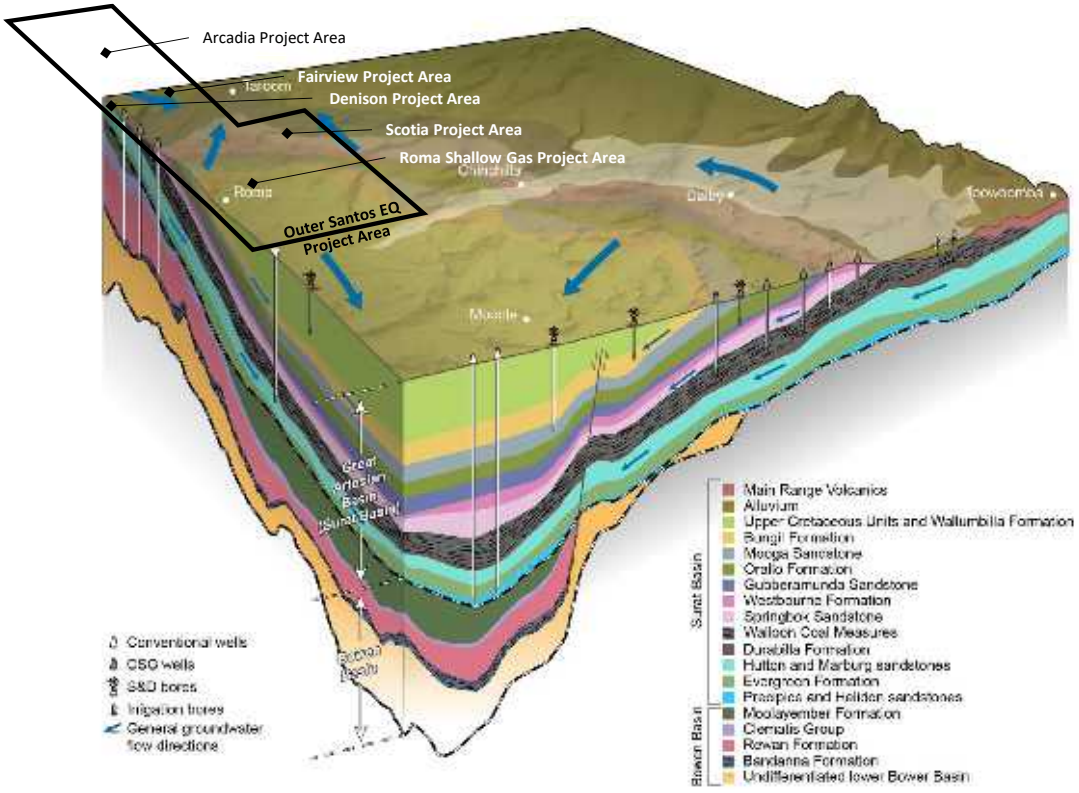

Figure 36. Hydrogeological Units within the Surat and Bowen Basin

3.1.1 Bowen Basin

The Bowen Basin (refer to **Figure 36**) is an Early Permian to Middle Triassic basin, which contains shallow marine and continental clastic and volcanic rocks. The Bowen Basin is comprised of two sedimentary depositional centres: the Denison and Taroom Troughs (refer to **Figure 12**). The main structural feature through the Project area is Comet Ridge, located along the western margin of the Taroom Trough in the southern extent of the Bowen Basin. Comet Ridge is comprised of mainly Devonian aged rocks and is covered by a relatively thin sequence of gently folded Permian and Triassic rocks, which make up the Bowen Basin.

The oldest formation included in the Bowen Basin stratigraphic sequence is the Reids Dome Beds, a unit of highly variable thickness. The Reids Dome Beds are unconformably overlain by the Early Permian aged formations of the Back Creek Group. The Aldebaran Sandstone (a member of the Black Creek group) is the deepest formation targeted for water supply within the north-western reaches of the Project area, near the town of Emerald.

Gas in the Fairview and Arcadia Valley CSG fields is extracted from the coal seams of the Bandanna Formation, at depths of 500 to 1,000 m below ground level (mbgl). The thickness of the Bandanna Formation is variable throughout the Project area, from approximately 60 to 100 m thick in the Comet Ridge area (McClure S. et al., 2008).

3.1.2 Surat Basin

The Surat Basin, (**Figure 36**) is a sub-basin of the GAB and comprises a sequence of south dipping consolidated Jurassic and Cretaceous sediments. The outcrop region of the Precipice Sandstone crosses through the northern part of the Fairview region, in the north of the Santos EQ Project Area. The younger Surat Basin formations outcrop progressively south through Roma, including the Evergreen Formation, the Hutton Sandstone and Birkhead Formation, the Springbok Sandstone, Walloon Coal Measures, Westbourne Formation, the Gubberamunda Sandstone, Orallo Formation Mooga Sandstone, and the Bungil and Wallumbilla Formations.

The Gubberamunda Sandstone and to a lesser extent the Mooga Sandstone are targeted for water supply within the region around Roma and along with the deeper Hutton and Precipice Sandstone as source aquifers for several EPBC Springs (Santos, 2012).

The Walloon Coal Measures (WCM) are the main gas bearing units (coal seams) within the Surat Basin and are the target formation for CSG operations within the Roma region. The thickness of the coal seams in Roma region ranges from 100 to 460 m, at depths ranging from 170 to 933 mbgl.

Historically conventional oil and gas wells were completed into the lower portions of the Evergreen formation and the underlying Precipice Sandstone and in some areas into the deeper Showground Sandstone unit. The upper portions of the Evergreen Formation form the capping aquitard and contains gases within these units.

Table 5. Hydrogeology within Santos EQ Project Area

Basin	Stratigraphy	Unit / Aquifer / Aquitard	Type	Relevant Regions refer to Figure 9					Description
				Arcadia Valley	Fairview	Roma	Denison	Scotia	
Bowen Basin	Rewan Group	Clematis/ Showgrounds Sandstone	Major Aquifer	✓	✓		✓		Medium to coarse grained quartzose to sub labile, micaceous sandstone, siltstone and mudstone and granule to pebble conglomerate
		Rewan Formation	Aquitard	✓	✓		✓	✓	lithic sandstone, pebbly lithic sandstone, mudstone and minor pebble conglomerate.
		Bandana Formation	Coal Seams	✓	✓		✓	✓	Sandstones, siltstone, shale, mudstone, coal, tuff and conglomerate with a thickness of up to 250 m. The total coal seam thickness within the Bandanna Formation is generally less than 10 m, up to six individual coal seams can be identified
Surat	Blythesdale Group	Bungil Formation	Minor Aquifer			✓			Glauconitic, labile to quartzose sandstone, siltstone mudstone. Carbonaceous in part.
		Mooga Sandstone	Major Aquifer			✓			Well-bedded to cross-bedded quartzose to labile sandstone, in part clayey, calcareous, pebbly: mudstone; minor conglomerate at base.
		Orallo Formation	Aquitard			✓			Very fine to medium grained, cross-bedded, lithic to lithic sub-labile sandstone, calcareous or clayey; siltstone and mudstone, carbonaceous in part; clay, some bentonite; minor coal.
		Gubberamunda Sandstone	Major Aquifer			✓			comprises fluviatile sandstone, minor conglomerate siltstone and mudstone.
	Injune Creek Group	Westbourne Formation	Aquitard			✓			alternating sequences of mudstone and lithic sandstone with minor siltstone and coal in the upper portions and thinly bedded siltstone and low permeability sandstone in the lower portions
		Springbok Sandstone	Minor Aquifer			✓		✓	Clayey lithic to very lithic sandstone with localised calcareous deposits and interbedded with carbonaceous mudstone and siltstones
		Walloon Coal Measures						✓	Thin-bedded, claystone, shale, siltstone, lithic and sublithic arenites, coal seams and partings. The Walloon Coal Measures can be mapped as having the following recognisable formations: Upper Walloon Formation (aquitard); Macalister Coal Seams (aquifer/aquitard); Juandah Sandstone (aquifer); Lower Jundah Coal Measures (aquifer/aquitard); Tangalooma Sandstone (aquifer); and Taroom Coal Measures (aquifer/aquitard).

Basin	Stratigraphy	Unit / Aquifer / Aquitard	Type	Relevant Regions refer to Figure 9					Description
				Arcadia Valley	Fairview	Roma	Denison	Scotia	
		Euromba h Formatio n	Aquit ard	✓	✓	✓		✓	Siltstone and mudstone
	Bundamb a Group	Hutton Sandston e	Major Aquif er		✓	✓		✓	Very fine to medium grained sandstone with interbedded argillaceous to arenaceous siltstones
		Evergree n Formatio n	Aquit ard		✓	✓		✓	very fine, quartzose sandstone
		Boxvale Sandston e	Aquit ard		✓	✓		✓	Very fine-grained sandstone with interbedded siltstones
		Precipice Sandston e	Major Aquif er		✓	✓	✓	✓	Sandstone and conglomerate at its base

3.2 Regional Groundwater Flow

Both the Surat and Bowen Basin aquifers are primarily recharged by rainfall infiltration and leakage from streams into outcropping sandstone. The formations are located mainly on the eastern margins of the basins and along the western slopes of the Great Dividing Range.

Regional groundwater flow is from the topographically higher recharge areas around the basin margins towards the lowest parts of the basins in the southwest (refer to

Figure 37) however within the Scotia region an easterly flow is observed towards the Dawson River. In the Arcadia Valley region, the direction of groundwater flow is generally west to east, following the dip of the Clematis Sandstone under the Moolayember Formation.

The rate at which groundwater flows depends on the permeability and thickness of the aquifer, and the lateral hydraulic gradient of each unit. The greatest groundwater velocities are estimated in the high permeability units such as the Precipice Sandstone, Hutton Sandstone and Mooga Sandstone, and the lowest flow rate estimated in the WCM.

Table 5 presents a summary of hydrogeological units underlying the Santos EQ Project Areas. A greater description of the key hydrogeological units is further provided in **Section 3.5**.

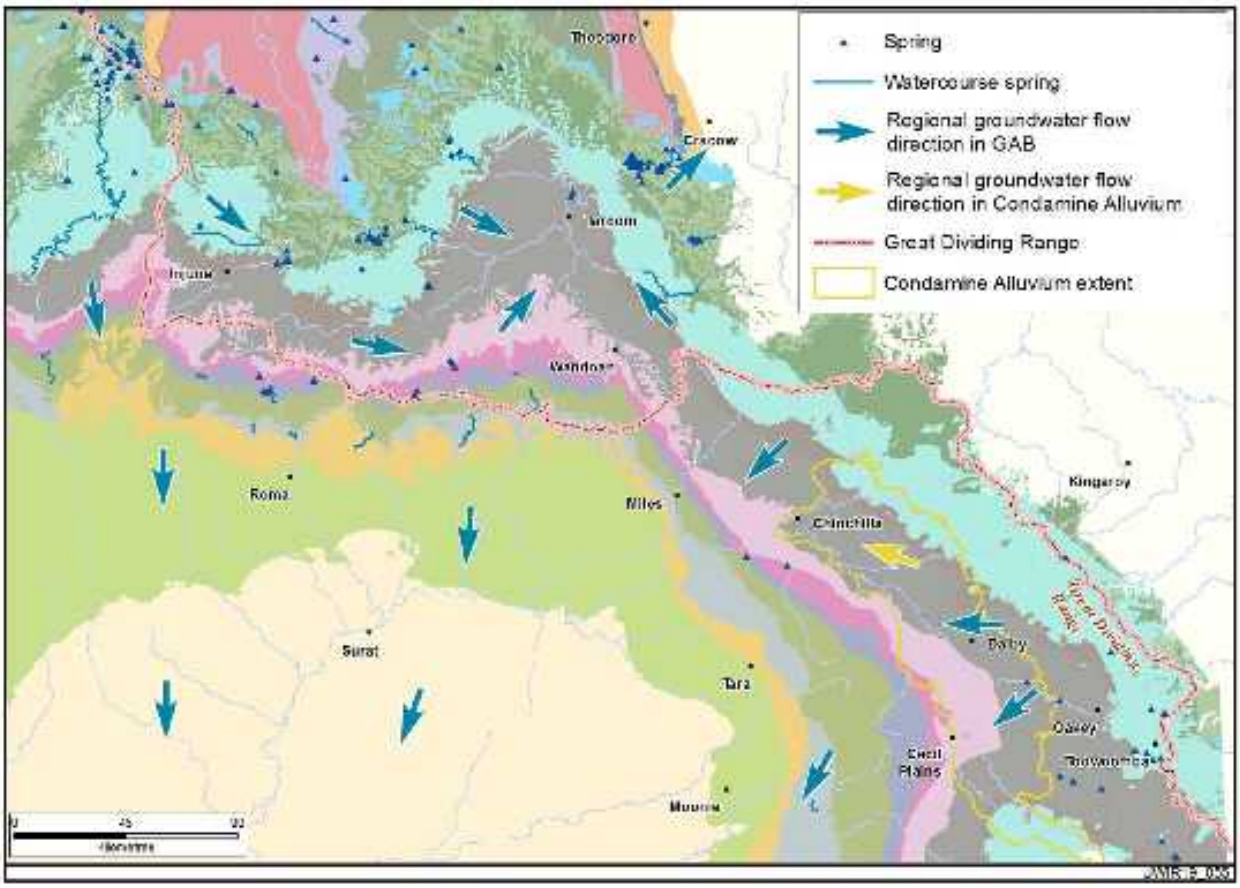

Figure 37. Representation of the Main Groundwater Systems in the Surat CMA (after UWIR 2019)

3.2.1 Recharge / Discharge

Groundwater–surface water interactions occur across the Santos EQ project area in a variety of forms including:

- Discharge of groundwater to streams (watercourse or baseflow springs).
- Recharge of groundwater systems via leakage from streams.
- Interaction between streams and associated alluvial groundwater resources.

The most significant interaction in the Santos EQ project area is discharge of groundwater to streams by watercourse springs. Discharge also occurs via bores where groundwater is extracted for stock and domestic supply, and to a lesser extent, agriculture.

The GAB aquifers are recharged by infiltration (rainfall), and leakage from streams into outcropping sandstone formations, mainly on the eastern margins of the GAB along the western slopes of the GDR. Regional groundwater flow is from the topographically higher recharge areas around the basin margins towards the lowest parts of the basin in the southwest. The Scotia, Roma and Fairview regions are located over outcrop regions of the water-bearing formations in Surat Basin, which are the part of the 'intake beds' of the GAB.

3.2.2 Aquifer and Aquitard Hydraulic Properties

Several flow and pressure test have been carried out on bores in the area of interest to determine the transmissivity for the water producing aquifers. Hydraulic parameters were defined from static recovery tests (over 240 tests) within and around the Santos EQ Project Area and exploration tests.

The hydraulic parameters characterising the formations are presented in **Table 6**. The data presented in the table are based on field measurements and an extensive literature review.

Table 6. Summary of Key Hydrogeological Properties and Uses for Major Aquifers

Unit / Aquifer / Aquitard	Median K [B,C] [max - min] (m)	Porosity	Transmissivity [A] (m2/d)	specific yield (Sy), Storativity (S)	Average Yield (L/s)
Rewan Formation	1.0E-3 (1.0E-5 – 2.0)	No data	No data	Sy = 0.11(1) S = 1.0x10^{-5} to 2.1x 10^{-6}	No data
Bandana Coal	1.0E-4 (1.0E-7 – 2.0)	No data	No data	Sy = 0.01(1) S = 5.0x10^{-5} - 5.1x 10-6	No data
Deep Bandanna	7.5x 10^{-3} – 2.25x10^{-} 2	No data	No data	Sy = 0.05 Ss = 4.0x10^{-6}	No data
Mooga Sandstone		10% - 30%	50	S = 5x10^{-3}	0.6 – 6 (Av 1.7)
Orallo Formation	5.0E-1 (1.0E-5 – 5.0)	10% - 30%	50	S = 5x10^{-3}	Up to 35 (Av 1.3)
Gubberamunda Sandstone	5.0E-1 (1.0E-7 – 10)	10% - 30%	50	S = 5x10^{-3}	4.6 for high yield bores
Westbourne Formation	No data	10% - 30%	150	S=5x10^{-3}	No data
Walloon Coal Measures	1.0E-4 (10E-11 – 20)	<1% coal; 10% - 30% others	50	Ss = 5x10^{-4} Sy = 5x10^{-6}	1.1
Eurombah Formation	0.14	No data	6.8	No data	No data

3.3 Regional Groundwater Quality

Groundwater in the Surat and Bowen Basin are used for a range of purposes, predominantly for agricultural use followed by the stock and domestic (S&D) use. For the last 10 years, a significant proportion of extraction has evolved through development of the CSG industry (KCB, 2016). This is however 'associated water' produced primarily from the target formations being exploited for gas, which are relatively lesser used for water supply.

Groundwater quality from the Department of Natural Resources and Mines (NRM) bores in the Santos EQ Project Area was assessed based on identified groundwater management units (GMUs, refer to **Figure 38**) and major aquifers (**Table 7**). Groundwater chemical data in the NRM database has been collected over a period of 30 years with most data collected between 1980 and 1999. The quality of available water quality data cannot be verified, they are presented in **Table 8**.

Figure 39 compares total dissolved solids (TDS) concentrations in groundwater from all groundwater management units/formations in the Santos EQ Project Area currently undergoing development. Water salinity varies from fresh to saline with TDS values ranging between 51 and 12,955 mg/L. The majority (71%) of the groundwater samples are classified as fresh with TDS values less than 1,000 mg/L and approximately 23% as slightly brackish with TDS values between 1,000 and 3,000 mg/L. Brackish waters with TDS concentrations between 3,000 mg/L and 10,000 mg/L are less common and contributed 6% of groundwater samples collected.

Salinity is spatially presented in **Figure 40**. Several brackish and saline groundwater types were identified in the northern portion of the Project area, to the north-west and north-east of the Arcadia Valley. Brackish groundwater was observed in Tertiary and volcanic formations surrounding the Arcadia Valley, in the Bowen Basin area, particularly in bores completed in the Bandanna Formation, and in alluvium. In addition, TDS concentrations in the Blackwater Group were close to the brackish/saline boundary (approximately 8,700 mg/L).

The distribution of brackish waters in the Surat Basin, appears to increase to the southeast in several groundwater management units. TDS values exceeding 5,000 mg/L were reported for Mooga Sandstone and Bungil Formation bores.

A Piper Diagram of all groundwater samples within the Santos EQ Project Area is presented as **Figure 41** The red line represents conservative (non-reactive) mixing of fresh water and seawater. The position of the markers away from the conservative mixing line is an indication of a geochemical reaction.

3.4 Hydrogeological Context of Gas Development

During gas extraction, the target coal seams are depressurised by extracting groundwater from the coal seams to enhance the release of gas from the coal. During this process, significant inward vertical hydraulic gradients are induced between the coal seams and the overlying and underlying aquifers (i.e., towards the coal measures from which gas is extracted). This is predicted to result in some inter-aquifer transfer of groundwater from the adjacent aquifers (and aquitards) into the coal seams. The extent of inter-formational flow depends on the hydrogeological and stratigraphic relationship between the coal seams and adjacent aquifer units. In other words, the amount of this flow depends what type of layers, aquifer or aquitard layers, which encase the coal seams. Almost exclusively, aquitard layers overlie and underlie the target coal seams for gas extraction. An exception occurs where the Springbok aquifer comes into contact with the upper Walloon coal seams in the Surat Basin stratigraphy.

The establishment of inward hydraulic gradients during gas extraction has important implications with respect to the fate and transport of injected hydraulic fracturing fluids within the coal seams, as it significantly limits the potential for vertical migration of the fluids to adjacent aquifers developed for water supply. This is discussed in further detail in subsequent sections of this report.

3.5 Local Hydrogeology

3.5.1 Roma Region

3.5.1.1 Hydrogeological Units and Groundwater Flow

The Roma region is contained within the areal boundaries of the Surat GMA 19 (**Figure 38**). The main aquifer units in terms of groundwater development within RSGPA include:

- Mooga Sandstone
- Gubberamunda Sandstone
- Springbok Sandstone
- Hutton Sandstone
- Precipice Sandstone.

The main confining units within RSGPA include:

- Orallo Formation
- Westbourne Formation
- Moolayember Formation
- Evergreen Formation

Localised cross-sections of the main hydrogeological formation underlying the Roma area are shown on **Figure 18** to **Figure 20** with a localised hydrogeological description provided below. The location of each cross-section transect is show on **Figure 10**. Local hydrogeological discussion on each major unit present within the Roma region is provided below. **Table 9** provides a summary of formation hydraulic properties within the Roma region.

Table 9. Summary of Formation Hydraulic Properties within the Roma Region

Formation	Type	Horizontal K (min) m/day	Horizontal K (max) m/day	Vertical K (min) m/day	Vertical K (max) m/day	Minimum Porosity (%)	Maximum Porosity (%)
Wallumbilla Formation	Minor Aquifer	0.038[a]	0.060[b]	0.1[b]	0.1[b]	-	-
Bungil Formation	Minor Aquifer	0.040[b]	0.4[a]	0.004[b]	0.152[c]	-	-

Mooga Sandstone

The Mooga Formation grades upward into the Bungil Formation and occurs between the Nebine and Kumbarilla Ridges within the Surat Basin (Exon, 1976). It comprises fluvial quartzose to sublabile sandstone with thinly inter-bedded dark grey mudstone and siltstone of swampy origin. The sandstone is thin but persistent throughout the Surat Basin and it partially outcrops in the north and east of the Roma CSG field.

Orallo Formation

The Orallo Formation occurs east of the Nebine Ridge, 120 km west of the Roma CSG field, and acts as a confining bed for the Gubberamunda Sandstone. It comprises lithic sandstone, siltstone and mudstone deposited dominantly in swamps and as overbank deposits (Exon, 1976). The formation thickness varies from 140 to 270 m, averaging 200 m and is not present on the Nebine Ridge where the Mooga Sandstone rests directly on the Gubberamunda Sandstone. Recharge to the minor aquifers in this formation occurs in the northern and eastern margins of the Surat Basin.

Gubberamunda Sandstone

Gubberamunda Sandstone outcrops in a thin band just north of the Roma area. These outcrops are considered to be part of the recharge area for these aquifers. Five springs are mapped in the Gubberamunda sandstone. Groundwater levels (and the direction of flow) is presented in **Figure 42**.

The general water quality within the Gubberamunda Sandstone can be described as fresh, and is NaCl dominant (URS, 2009) with the average total dissolved solids (TDS) of 760 mg/L.

Westbourne Formation

The Westbourne Formation has very low permeability and underlies the Gubberamunda Sandstone. It comprises alternating sequences of mudstone and lithic sandstone with minor siltstone and coal in the upper portions and thinly bedded siltstone and low permeability sandstone in the lower portions. This formation reaches a thickness of greater than 60 m in the Roma area and was deposited in a low energy fluvial and marginal-marine environment. These sediments outcrop in the northern part of the Surat Basin (Exon, 1976 ref. URS, 2011).

Springbok Sandstone

Over the Roma region, the Springbok Sandstone is continuous, but its hydraulic conductivity is highly variable. At some locations it is an important aquifer and in others it is highly compacted and has very low permeability. Therefore, the Springbok Sandstone hydraulic characteristics vary, and the formation can be divided into a lower and an upper Springbok. The lower Springbok is a poor aquifer of low hydraulic conductivity associated to the deposition of volcanic ash. As a result, the sandstone contains clay minerals with dominance of smectite which significantly lowers its permeability and porosity characteristics (QWC, 2012). Where there is localised unconformable contact between the lower Springbok Sandstone and the upper coal beds of the Walloon Coal Measures they are considered to be in hydraulic connection (Scott S. et al., 2004).

The Springbok Sandstone underlies the Westbourne Formation and unconformably overlies the Walloon Coal Measures. The Springbok Sandstone was deposited by streams in small channels which eroded into the uppermost siltstones of the Walloon Coal Measures and occasionally into its coal seams. This has resulted in direct contact of the Springbok Sandstone with the CSG producing coal layers within the Walloon Coal Measures in some areas. In other areas, the Springbok is separated from the producing coal layers by low permeability sediments of the upper part of the Walloon Coal Measures.

Groundwater levels (and the direction of flow) is presented in **Figure 42**.

Walloon Coal Measures

The Walloon Coal Measures are a member within the Injune Creek Group and are the main gas bearing unit of the Surat Basin. At the Basin scale, the Walloon Coal Measures are considered an aquitard, although in some places they function as an aquifer. The coal seams are generally the more permeable units.

The thickness of the formation is 100 to 460 m in the Roma area. It comprises siltstone and silty sandstone and relatively small intervals of coal (approximately 10%) which were deposited by swamps or lakes and sluggish streams (Exon, 1976). The geology is generally complex.

The Walloon Coal Measures can be mapped as having the following recognisable formations:

- Upper Walloon Formation (aquitard);

- Macalister Coal Seams (aquifer/aquitard);
- Juandah Sandstone (aquifer);
- Lower Jundah Coal Measures (aquifer/aquitard);
- Tangalooma Sandstone (aquifer); and
- Taroom Coal Measures (aquifer/aquitard).

Associated water (AW) at Roma region is expected to range in salinity (TDS) from 200 mg/L to 5,000 mg/L with groundwater levels (and the direction of flow) is presented in **Figure 43.**

Hutton Sandstone

The Hutton Sandstone consists of very fine to medium-grained sandstone with interbedded argillaceous to arenaceous siltstones. It tends to be the thickest aquifer in the Surat Basin. It is a major GAB aquifer but has many tight (low permeability) zones. The Hutton Sandstone has an upper and lower upwards fining sequence. The base of the upper is generally more sand-rich and the most productive for groundwater. The highly permeable zones tend to be thin whilst the rest of the sequence has a large storage capacity and contributes to formation transmissivity.

The groundwater flow direction in the Hutton Sandstone is south to south-east. This differs from the general south-west groundwater flow direction observed for the other hydrogeological units of the GAB and is thought to demonstrate a low level of connectivity between the Injune Creek Group and the Hutton Sandstone (Golder, 2011a).

Groundwater levels (and the direction of flow) is presented in **Figure 44**.

Precipice Sandstone

The Precipice Sandstone is a major aquifer of the GAB comprised of sandstone and conglomerate at its base. Sediments were deposited in a fluvial environment in braided river systems. Regionally, the Precipice Sandstone is approximately 80 m thick and mostly hydrologically isolated from the Hutton Sandstone by the Evergreen Formation. Regionally, groundwater flows in an easterly direction within the Precipice Sandstone in the Development area. The average total dissolved solids (TDS) is 1,216 milligram per litre (mg/L) and the average pH is 7.7 (Parsons Brinckerhoff, 2014).

The Precipice Sandstone in the Roma region is considered to be hydraulically discontinuous. There are limited groundwater bores in the Precipice in the Roma region. The Precipice Sandstone is characterised by a dome structure or pockets. Each pocket is formed by high permeability sediments, which have been found to contain natural gas; these pockets do not contain any groundwater and have been characterised as dry petroleum reservoirs. The sediments of the Precipice Sandstone surrounding these pockets are characterised by low to very low permeability and are considered to be largely an aquitard. The domes of The Precipice Sandstone have and continue to be exploited for methane gas production.

Groundwater levels (and the direction of flow) is presented in **Figure 44**.

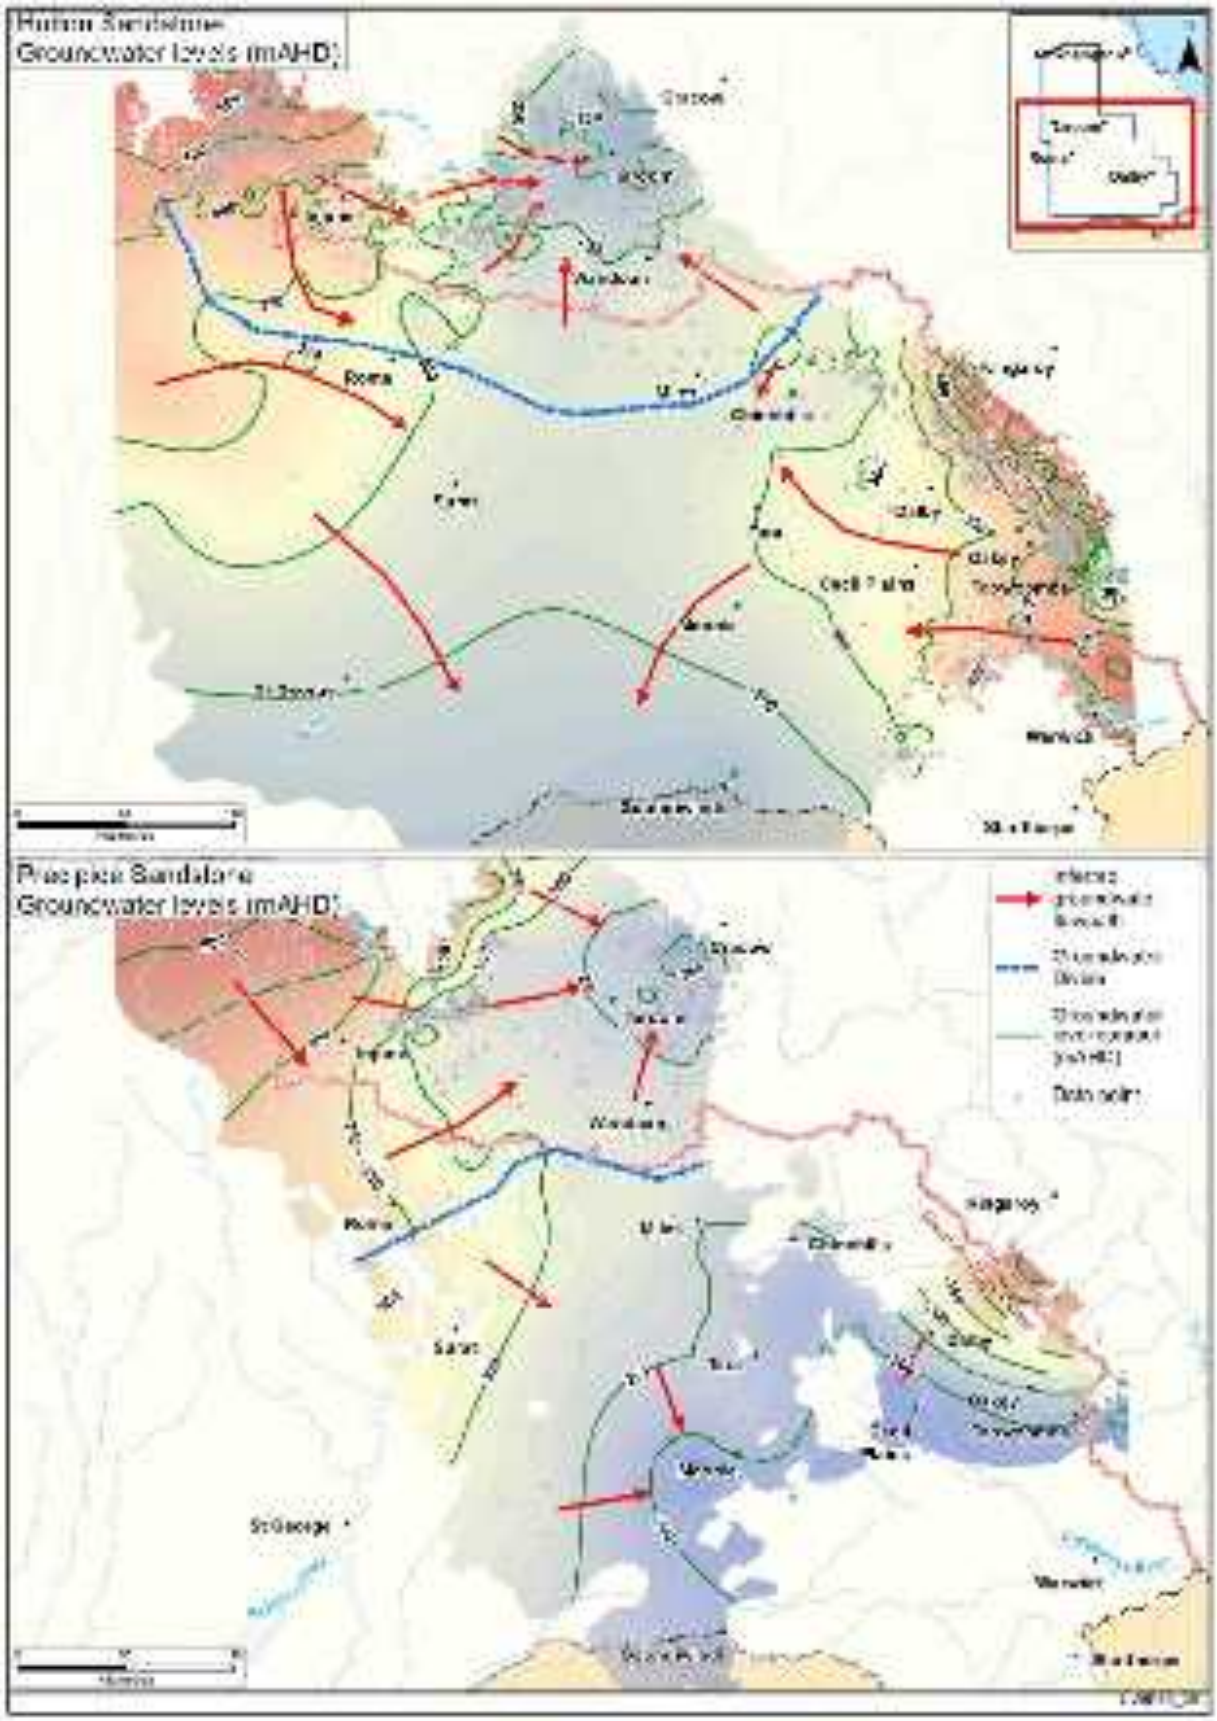

Figure 44. Interpreted groundwater Flow Directions – Hutton Sandstone and Precipice Sandstone (after UWIR 2019)

3.5.2 Fairview Region

3.5.2.1 Hydrogeological Units and Groundwater Flow

The Fairview region is directly underlain by the lower GAB formations of the Surat Basin namely:

- Hutton Sandstone
- Evergreen Formation
- Precipice Sandstone and the GAB formations of the upper Bowen Basin, namely:
  - Moolayember Formation, and
  - Clematis Sandstone

The gas bearing formation of interest to Santos EQ is the Bandanna Formation from the Blackwater Group (Bowen Basin, Late Permian) as well as the Early Permian Cattle Creek Formations.

Localised cross-sections of the main hydrogeological formation underlying the Fairview region are shown in **Figure 21** to **Figure 24** with a localised hydrogeological description provided below. The location of each cross-section transect is show in **Figure 10**. Local hydrogeological discussion on each major unit present within the Fairview region is provided below.

Hutton Sandstone

The Hutton Sandstone outcrops across most of the Fairview region and is unsaturated in many areas. Despite the Hutton Sandstone being considered a major water resource aquifer, across the Fairview region, the Hutton Sandstone is not a reliable groundwater source due to its discontinuous distribution and generally poor water quality.

Groundwater levels and the direction of flow is presented on **Figure 44**.

Precipice Sandstone

Within the Fairview region, the Precipice Sandstone provides good aquifer potential and generally produces higher yielding supplies of potable sub-artesian water when compared to other areas. A number of 'recharge springs' for the Hutton and Precipice Sandstone are present within the Fairview region. The narrow outcropping area can be considered as the northern borderline of the Surat Basin, being the oldest and deepest formation of this basin.for the Hutton and Precipice Sandstone are present within the Fairview region. The narrow outcropping area can be considered as the northern borderline of the Surat Basin, being the oldest and deepest formation of this basin.

Groundwater levels (and the direction of flow) is presented on **Figure 44.**

Clematis Sandstone

The Clematis Sandstone is not present in the Fairview region where it is considered to be undifferentiated from the Rewan Formation (an aquitard) but can be found on the flanks of the region where it can produce good supplies of potable groundwater. Also within the region, the alluvial deposits associated with larger streams can provide supplies of groundwater from shallow depths.

Low permeability formations include the Evergreen and Moolayember Formations, both of which have little potential for water use in the area.

According to information available from DEHP (Foster, 2007), alluvial deposits within the Fairview region have enhanced groundwater potential due to relatively high hydraulic conductivity. Aquifers associated with the sedimentary rocks within the hills of the 'kipper catchments' have lower yields and groundwater quality may be saline due to the depositional nature of the rocks and the reduced rainfall recharge.

Salinity of groundwater within the in the Clematis Sandstone does not vary greatly, with measurements between 131 and 1,260 microsiemens per centimetre (µS/cm) at 47 locations (Santos, 2012).

Rewan Formation

The groundwater abstracted from the Rewan Formation is generally saline, with EC measurements ranging from 4,200 and 27,500 µS/cm.

Bandana Formation

The Bandana coal seams are the only materials with appreciable permeability; groundwater flow is dependent on the permeability of the individual coal seams and their vertical and lateral interconnection (Santos, 2102). It is likely that the permeability of the coal seams of the Bandanna Formation within the deepest areas of the Bowen Basin is so low that groundwater flow does not occur. There is limited groundwater extraction from this formation and groundwater quality is variable.

3.5.3 Arcadia Valley

3.5.3.1 Hydrogeological Units and Groundwater Flow

The Arcadia Valley region are located entirely within the Bowen Basin. The target formation for gas production is the Bandana Formation.

The main aquifer units in terms of groundwater development within Arcadia valley region include the Clematis Sandstone. The main confining units include the Moolayember Formation and Rewan Formation. Many bores are also completed in shallow Tertiary sediments, basalts and alluvium deposits. The Rewan Formation acts as effective hydraulic barrier (aquitard), although a few low yielding stock and domestic bores are also completed within this formation.

Localised cross-sections of the main hydrogeological formation underlying the AVPA are shown in **Figure 25** to **Figure 26** with a localised hydrogeological description provided below. The location of each cross-section transect is show in **Figure 10**. Local hydrogeological discussion on each major unit present within the Arcadia Valley region is provided below.

Cross-section presented in **Figure 26** is characteristic of the central and southern part of region. To the north the formations are shallower and form a monocline, the Precipice Sandstone is not present anymore; the Clematis Sandstone is present to the east corresponding with the National Park and the ranges. A very thick Rewan Formation prevents any direct contact between the Bandanna Formation and the Clematis.

Clematis Sandstone

In the Arcadia Valley region the lower to middle Triassic age Clematis Sandstone is generally unconfined to semi-confined and consists of sandstone, siltstone and mudstone units deposited by fluvial processes. In some areas where it is overlain by the Moolayember Formation, water pressures in the Clematis Sandstone are artesian and there are many springs located along the Clematis-Moolayember boundary to the northeast, following the Arcadia Valley sandstone cliff walls.

The Clematis Sandstone conformably overlie the relatively impermeable Rewan Formation, as such there is limited hydraulic connection between this unit and underlying aquifers, including the Bandana Formation.

Rewan Formation

The Rewan Formation is considered to be a low permeability confining aquitard, the Formation confines the underlying Bandanna Formation. It is comprised of lithic sandstone, pebbly lithic sandstone, mudstone and minor pebble conglomerate.

Bandana Formation

The Bandana Formation contains the target coal measures within the Fairview, Denison and Arcadia Valley region. It is comprised of sandstones, siltstone, shale, mudstone, coal, tuff and conglomerate with a thickness of up to 250 m. The total coal seam thickness within the Bandanna Formation is generally less than 10 m, up to six individual coal seams can be identified (Santos, 2012). The formation outcrops to the northern boundary of the Surat Cumulative Management Area.

3.5.4 Denison Region

3.5.4.1 Hydrogeological Units and Groundwater Flow

The main aquifer units in terms of groundwater development within Denison region include:

- Precipice Sandstone.
- Clematis Group

The main confining units within DPA include:

- Rewan Formation
- Moolayember Formation

Localised cross-sections of the main hydrogeological formation underlying the Denison region is shown in **Figure 30** with a localised hydrogeological description provided below. The location of each cross-section transect is show in **Figure 10**. Hydraulic conductivity data and storage data for the hydro stratigraphic units relevant to the Denison region are summarised in **Table 10** and **Table 11** respectively. These localised values are based on the following sources of information:

- Site-specific permeability data for the Rangal Coal Measures from modular formation dynamics tester (MDT) and drill stem test (DST) testing and from calibration of reservoir models to water production data for pilot wells;
- Calibrated numerical groundwater models where their model boundary overlaps aquifers relevant to the Project Area;
- Rolleston Coal Mine Expansion Environmental Impact Statement (EIS) (Glencore, 2013);
- Arrow Bowen Basin EIS (Ausenco-Norwest, 2012);
- Surat Cumulative Management Area Underground Water Impact Report (CMA UWIR) (OGIA, 2016);
- Surat Cumulative Management Area Underground Water Impact Report, October 2019 (OGIA, 2019a); and
- Surat Cumulative Management Area Groundwater Modelling Report October 2019 (OGIA, 2019b).

Notes:
min = minimum value
max = maximum value

Moolayember Formation

In the Denison region, the Moolayember Formation is a minor discontinuous aquifer, but regionally acts as an aquitard. The aquifer is not high yielding and water quality is often poor (QWC, 2012a). The Moolayember Formation consists of micaceous lithic sandstone and siltstone. (Parsons Brincherhoff, 2014) consider the Moolayember Formation as an aquitard based on its low permeability and considerable thickness.

Clematis Sandstone

The Clematis Sandstone is a discontinuous aquifer across the Denison region. Further detail on the Clematis Sandstone in presented in **Section 3.5.3.1**.

Rewan Formation

Further detail on the Rewan Formation in presented in **Section 3.5.3.1**.

Back-Creek Group

The Back-Creek group is underlain by various sedimentary units of Permian age, none of which are recognised aquifer units. The Black Alley Shale conformably underlies the Rangal Coal Measures (Bandana Formation equivalent) and is in turn conformably underlain by the Mantuan Beds and Peawaddy Formation. These units consist of mudstone, siltstone, tuff and sandstone. These units are regarded as relatively impermeable units confining earlier successions of the Back-Creek Group, most significantly the Upper Aldebaran Sandstone. An unconformity separates the Upper Aldebaran Sandstone from the Lower Aldebaran Sandstone, the Cattle-Creek Formation (which contains targeted coal measures) and the Reids Dome Beds, which are considered the basement of the Bowen Basin.

In the study area, the Black Alley Shale is understood to be at least 200 m in thickness below the base of the Rangal Coal Measures (Bandana Formation equivalent).

3.5.5 Scotia Region

3.5.5.1 Hydrogeological Units and Groundwater Flow

The Scotia region is located within the Surat Basin, 32 km (west) from its border with the underlying Bowen Basin, both of which comprise part of the Great Artesian Basin. The main aquifer units in terms of groundwater development within the region include:

- Hutton Sandstone.
- Precipice Sandstone.

The main confining units within DPA include:

- Eurombah Formation.
- Evergreen Formation.

Localised cross-sections of the main hydrogeological formation underlying the SPA are shown in **Figure 31** to **Figure 35** with a localised hydrogeological description provided below. The location of each cross-section transect is show in **Figure 10**. Local hydrogeological discussion on each major unit present within the SPA is provided below.

Injune Creek Group

The Injune Creek Group (likely Eurombah Formation) outcrops across the Scotia region and are considered to be recharge area for the identified aquifers within the group.

Regional groundwater flow is from the topographically higher recharge areas around the basin margins towards the lowest parts of the basins in the southwest. Regionally, the aquifers of the Surat Basin discharge to springs located to the south and west of the project area. The aquifers also discharge to artesian or sub-artesian water abstraction bores installed across the region into Surat Basin aquifers.

The primary direction of groundwater flow through most units is from north-east to south, moving from their outcrop areas and following the downward formation dip.

The rate of groundwater flow is dependent on the permeability and thickness of the aquifer and the lateral hydraulic gradient for each unit.

Hutton Sandstone

The Hutton Sandstone outcrops over the north-eastern portion of the Scotia region. Beneath the Hutton Sandstone the Evergreen Formation acts as a confining bed.

A north-westerly to northerly direction of groundwater flow is observed in data for the Hutton Formations units (refer to **Figure 44**). This is contrary to the regional picture of flow from outcrop areas in the northeast towards the south, following the formation dip. The suggested northerly trend in groundwater flows may also represent a degree of connection to overlying units or to the outcrop to the north and the upper Dawson River catchment (especially in the Hutton Sandstone).

Groundwater levels (and the direction of flow) is presented in **Figure 44**.

In the Hutton Sandstone, approximately half of the 11 bores contain a qualitative description of water quality such as potable, suitable, or salty. Occasionally conductive measurements are quoted, within the “Strata Log” field, rather than the “Field Water Quality” field. Conductivity values are present for two bores with values of 810 and 2400. Units are not quoted, but as these are field water quality values, they are assumed to be microsiemens (µS/cm).

Precipice Sandstone

The Precipice Sandstone underlies the Evergreen Formation. A major unconformity is present at the base of the Precipice Sandstone. This unconformity represents the boundary between the younger Jurassic age Surat Basin sequence and the older Permian-Triassic sequences of the Bowen Basin beneath.

The nearest surface outcrop of the Precipice formation occurs in the north-eastern part of the region. In this location several recharge springs are found and these are located along the Dawson River in ATP685 where the Precipice Sandstone outcrops (**Figure 47**).

Groundwater levels (and the direction of flow) is presented in **Figure 44**.

3.6 Environmental Values of Groundwater in the Project Areas

The EP Act defines an EV as a quality or physical characteristic of the environment that is conducive to ecological health, public amenity or safety, or another quality of the environment identified or declared to be an EV under an environmental protection policy or regulation.

In the context of the UWIR, the relevant policy is the Environmental Protection (Water) Policy 2009 (Water EPP). The Water EPP identifies specific EVs that are to be protected with

corresponding water quality objectives (WQOs). Under the Water EPP, all Queensland waters, including groundwater, have identified EVs and WQOs. In relation to groundwater, EVs in the Santos EQ Project Area include:

- Human use: consumption or use of groundwater for a range of purposes including aquaculture, recreation (e.g., waterholes), industrial, cultural and spiritual values.
- Aquatic ecosystem: groundwater aquifers, GDEs such as groundwater inflows to rivers (baseflow) and springs, and terrestrial GDEs.

3.6.1 Human Use Environmental Value

The Human use EVs considered by this study are as follows:

- Drinking water;
- Primary, secondary and visual recreational use;
- Irrigation, stock watering and other agricultural uses;
- Aquaculture use;
- Industrial use; and
- Cultural and spiritual values.

One of the main primary uses of groundwater in the area are for stock watering and domestic use with water primarily sourced from the sandstone aquifers of the GAB. The environmental values for groundwater within the Santos EQ Project Area is summarised below in Table 12.

Table 12. Groundwater Environmental Values

Environmental Values	AVPA	FPA	RSGPA	SPA	DPA
Protection of aquatic ecosystem (springs and GDEs)	✓	✓	✓	✓	✓
Primary contact recreation (e.g., swimming) – springs and pools	✓	✓	✓	✓	✓
Drinking water supplies	✓	✓	✓	✓	✓
Crop irrigation	✓	✓	✓	✓	✓
Stock watering	✓	✓	✓	✓	✓
Farm supply/use	✓	✓	✓	✓	✓
Aquaculture (e.g., red claw, barramundi)	-		✓	✓	✓
Industrial use (including manufacturing plants, power generation)	-	✓	✓	✓	✓
Protection of cultural and spiritual activities	✓	✓	✓	✓	✓

3.6.1.1 Groundwater Usage from the GAB

The location of groundwater users across the Santos EQ Project Area are shown in **Figure 45** to **Figure 47**. The majority of these bores access groundwater from 5 primary groundwater systems in the Santos EQ Project Area:

- Alluvial Unconfined Systems (usually associated with valleys and floodplains)
- Mooga Sandstone
- Gubberamunda Sandstone
- Hutton Sandstone
- Precipice Sandstone.

These are described in greater detail in **Section 3.5** . Modelled groundwater associated impacts associated with CSG activities is presented in Chapter 7 of the UWIR 2019.

In RSGPA, groundwater is used for domestic (potable) consumption and stock watering purposes and is derived predominantly from the Mooga and Gubberamunda Sandstone aquifers with contributions also from sandy intervals from the Orallo Formation. The Mooga and Gubberamunda Sandstone aquifers provide the sole source of groundwater supply for urban purposes for Roma and towns in the surrounding area (Mitchell).

The Springbok Sandstone aquifer does not constitute a viable water resource in the Roma region due to its discontinuity and general low hydraulic conductivity. The WCM may be sourced by some farmers in the Surat Basin, however in the Roma region; it is very deep, of low hydraulic conductivity and/or poor water quality.

The Hutton Sandstone underlies the WCM and is relatively undeveloped in the Roma area due to its depth. Whilst the current entitlements and use are very small for the Hutton Sandstone proximal to the Roma region, future extraction needs to be monitored as this aquifer extends beyond the Roma region and it is often used in these more distant locations.

Saturated groundwater from the Hutton, Precipice and Clematis Sandstone units in the Scotia and Fairview region are generally suitable for potable use; however, some bores exceed guideline levels for sodium, total dissolved solids and fluoride. Groundwater from these formations is also generally suitable for irrigation and stock watering use, due to having low sodium and salinity hazard.

Groundwater from the gas wells in Fairview region (Bandanna Formation) is generally unsuitable for potable use due to elevated sodium, chloride, total dissolved solid, fluoride and iron. It can be used for irrigation if treated. Groundwater from these wells is marginally suitable for stock watering, with the limiting factors being elevated concentrations of fluoride, copper, aluminium, lead and selenium above guideline values.

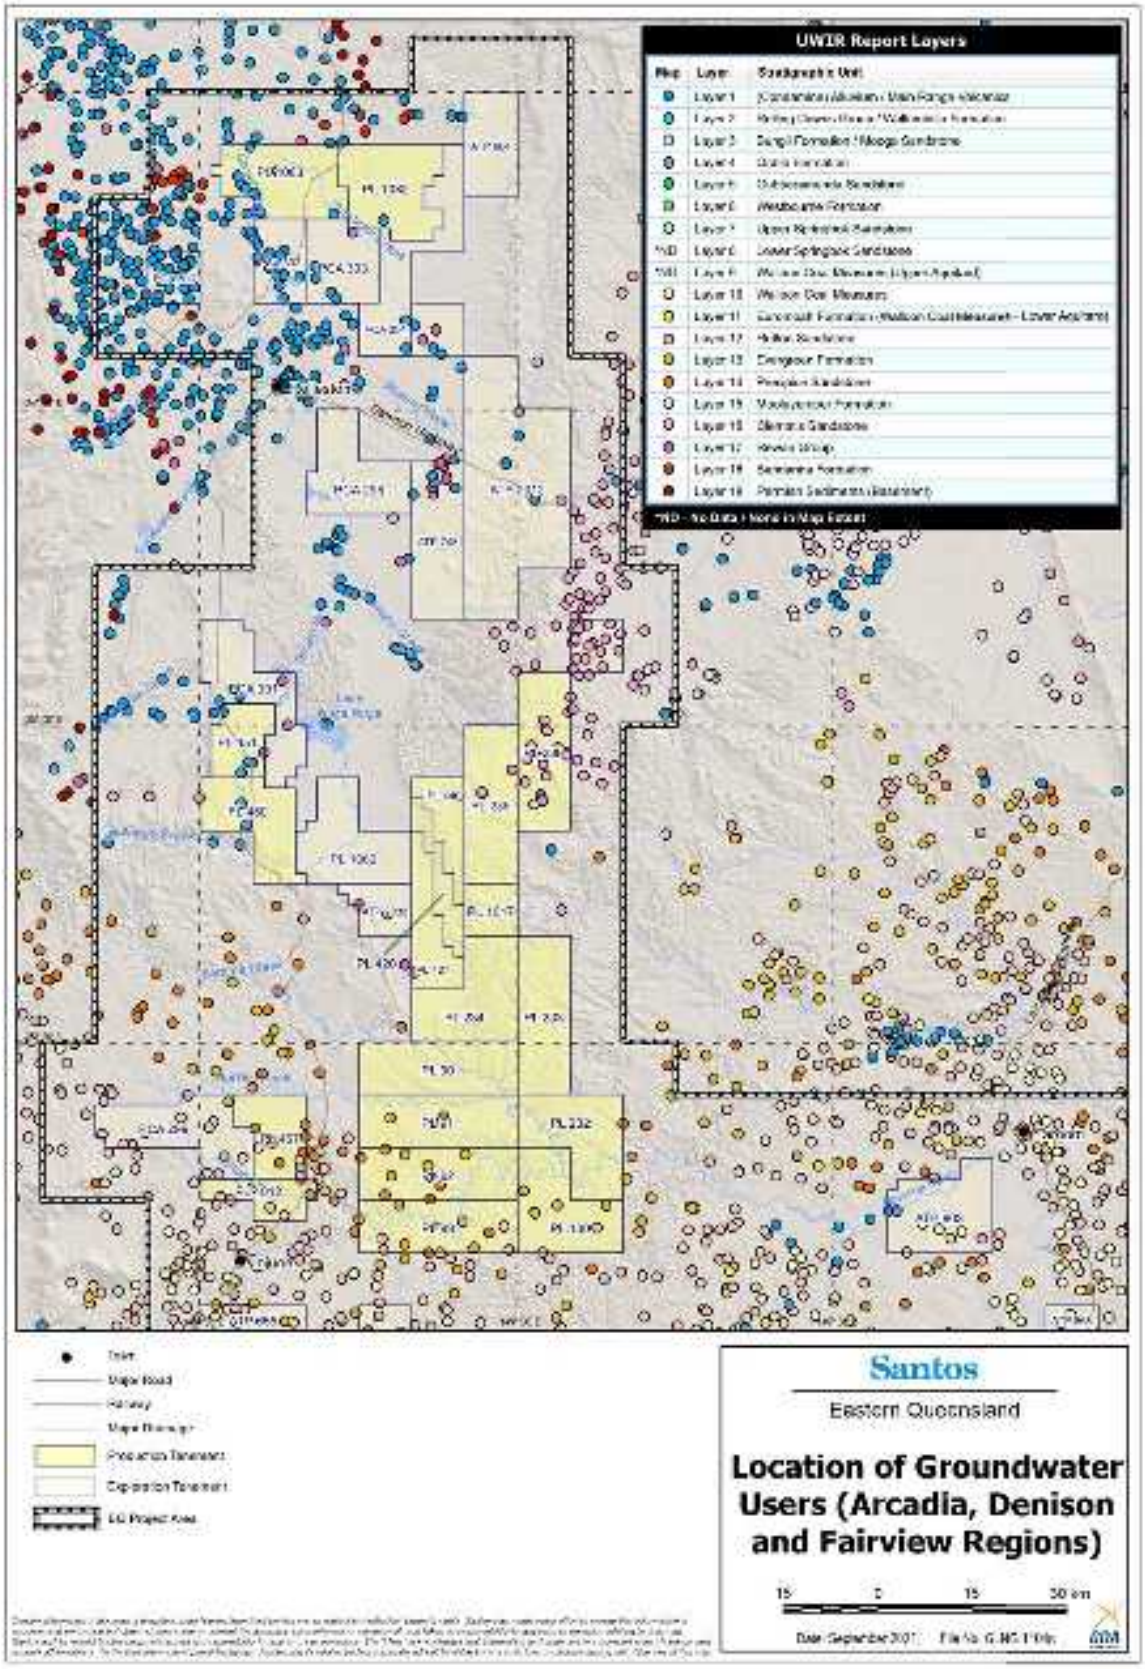

Figure 45. Location of Groundwater Users (Fairview, Arcadia Valley and Denison Region)

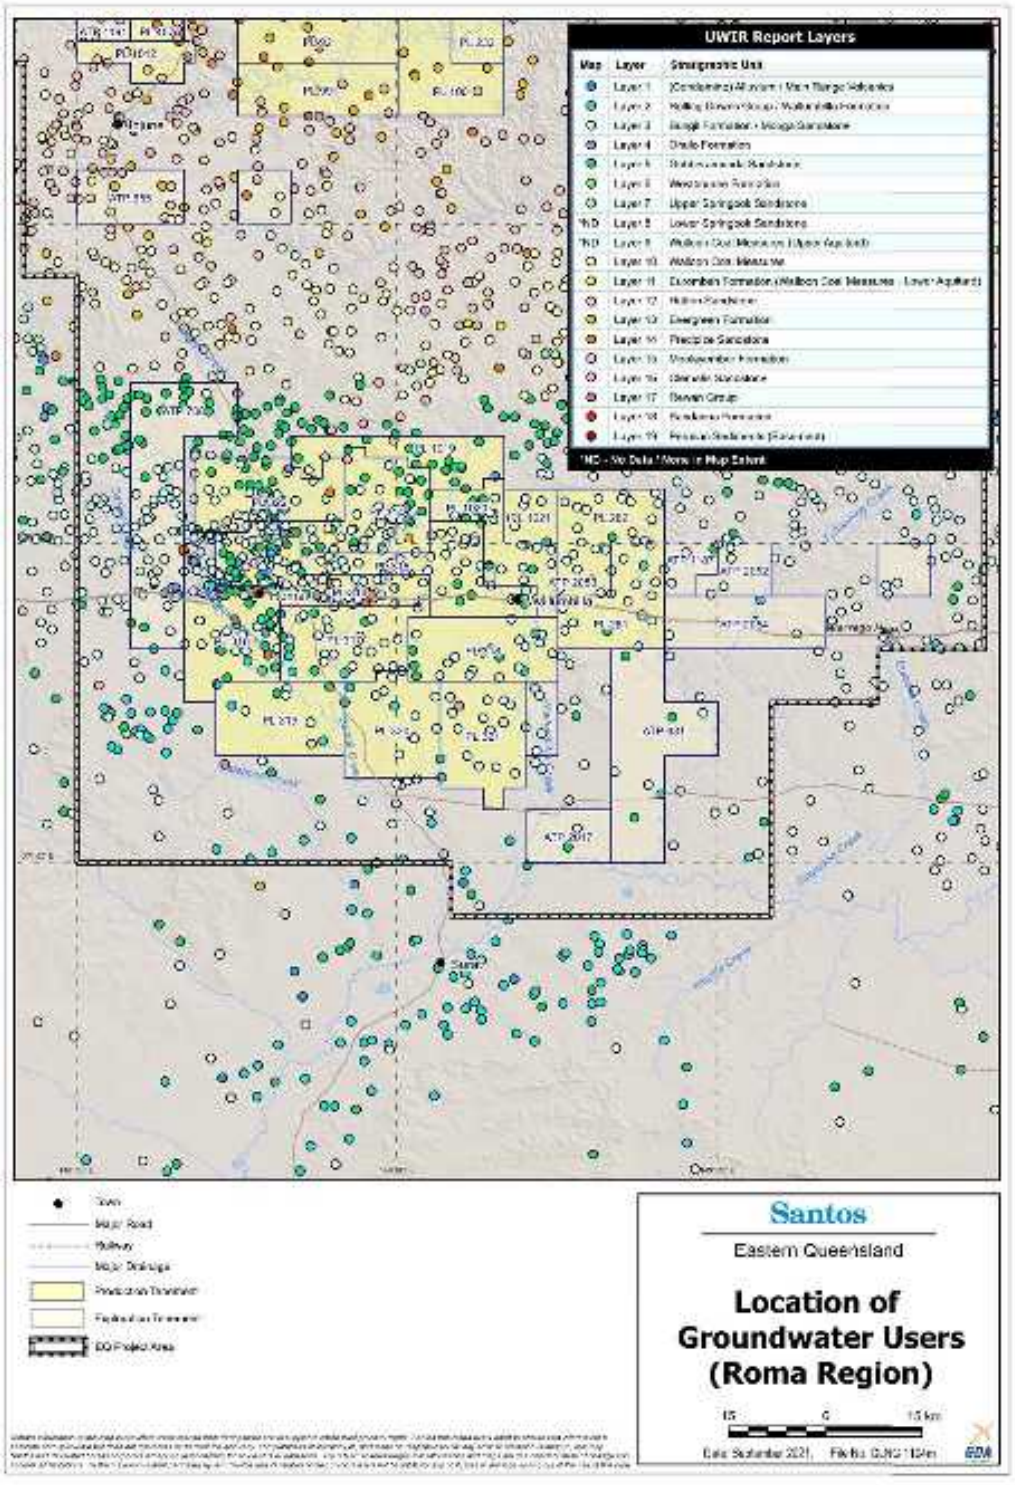

Figure 46. Location of Groundwater Users (Roma Region)

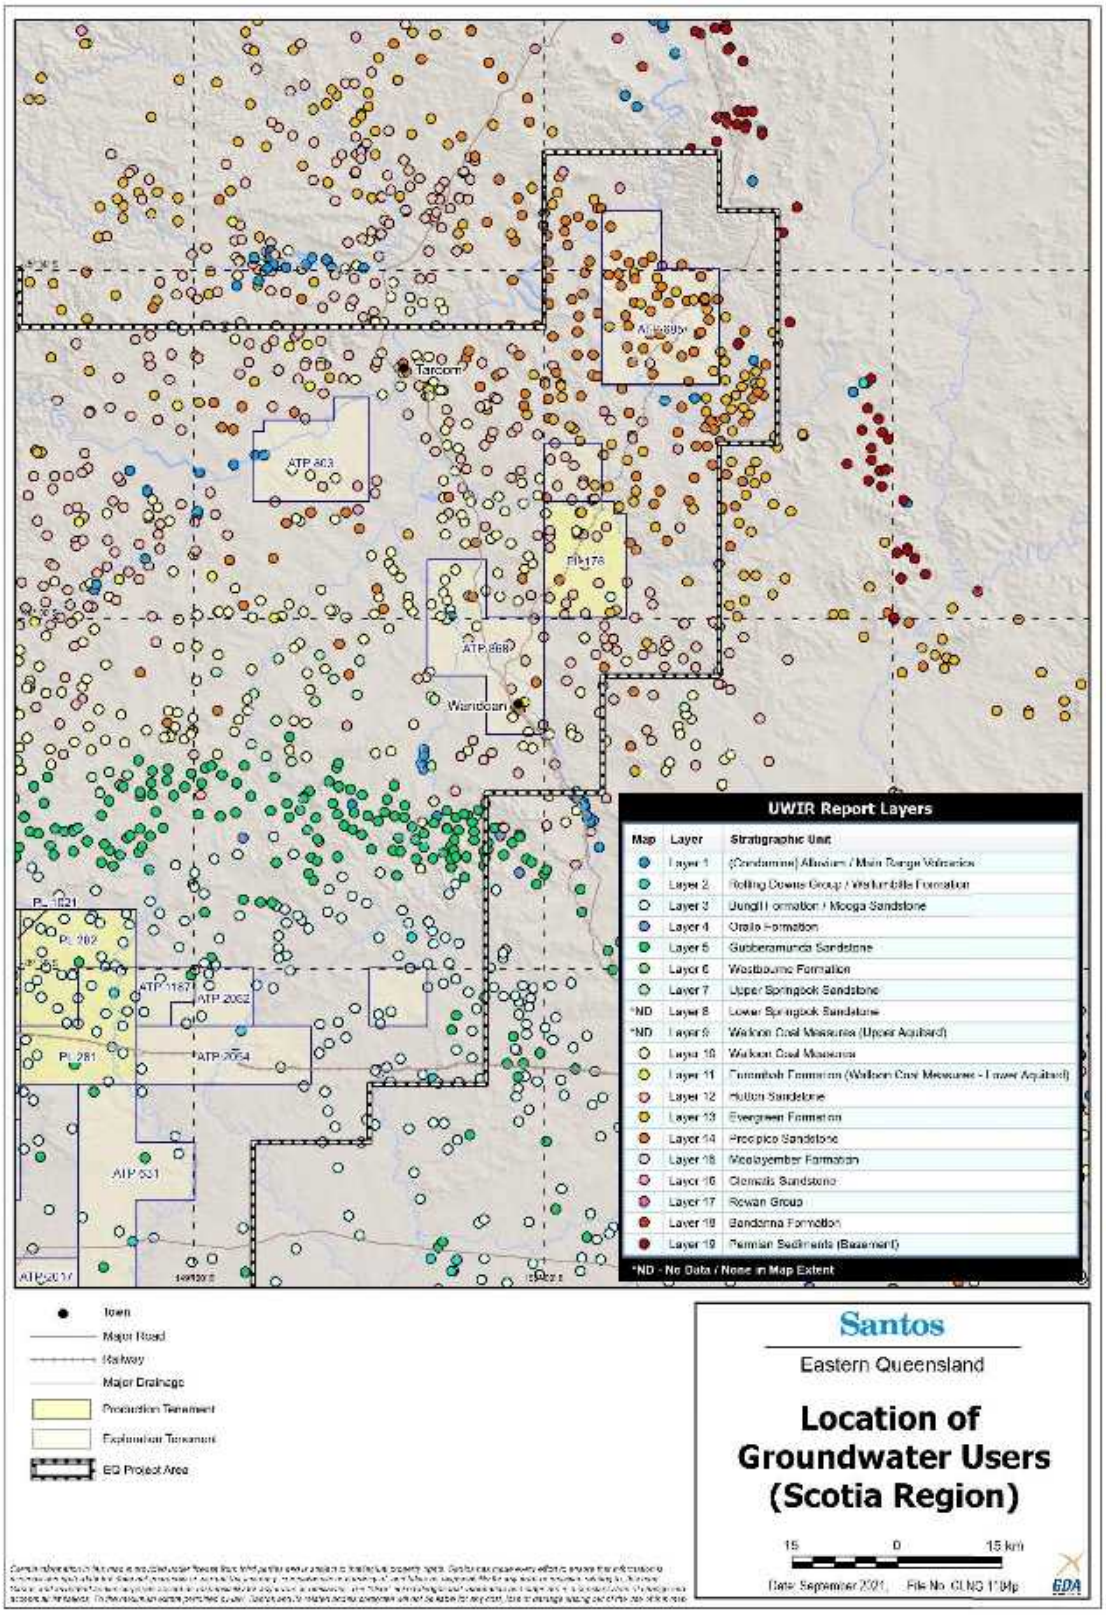

Figure 47. Location of Groundwater Users (Scotia Region)

3.6.2 Aquatic Ecosystems

The EVs associated with aquatic ecosystems comprise two inter-related aspects:

- The intrinsic value of aquatic ecosystems, habitat and wildlife in waterways and riparian areas – for example, biodiversity, ecological interactions, plants, animals, key species, (such as turtles or platypus) and their habitat, food and drinking water.
- Waterways which include perennial and intermittent surface waters, groundwaters, tidal and non-tidal waters, lakes, storages, reservoirs, dams, wetlands, swamps, marshes, lagoons, canals, natural and artificial channels and the bed and banks of waterways.

Whilst aquatic ecosystems are traditionally associated with surface water bodies rather than groundwater systems, any surface water body with a hydraulic connection to shallow groundwater would be potentially susceptible to impacts to shallow groundwater (either water quality degradation or lowering of the water table). This environmental value could be relevant to perennial creeks, rivers, and springs present within the Project area and is further defined below as GDE Sensitive Areas.

Table 13. Surface Water Environmental Value

Environmental Value	Comet River			Upper Dawson River					Lower Dawson River						Condamine-Balonne
	Main channel	Western tributaries	Eastern tributaries	Main channel (below Hutton Creek)	Western upland tributaries	Southern tributaries	Northern upland tributaries	Central tributaries	Northern upland tributaries	Main channel – unregulated reaches	Main channel – regulated reaches	Southern upland tributaries	Eastern Tributaries	Western tributaries	Dogwood Creek

3.6.2.1 Fairview Region

The waterways within the Fairview region are considered predominantly to consist of 'slightly to moderately disturbed ecosystems' and in accordance with the EPP (Water) are considered to be 'systems that have undergone some changes, with aquatic biological diversity affected to some degree but the natural communities are still largely intact and functioning' (EPA, 2005).

In the Fairview region, drainage from the Fairview and Springwater Plateaus, finds it way southward into Hutton Creek, while the northern half of the Fairview Plateau drains north into Baffle Creek and the Dawson River. In the downstream reaches of Hutton Creek, grazing, forestry and cropping are widespread. Water storages and weirs, located on the Dawson River are used for irrigation and recreational purposes supporting regional industry and urban communities.

A brief overview of the aquatic ecology, as evidenced from the field survey undertaken as part of the GLNG EIS (Santos, 2009) is provided below:

- Aquatic Flora: The diversity of aquatic macrophytes in the tributaries to the Upper Dawson is relatively low. The limited cover of macrophytes and the lack of submerged species is likely to be related to the largely ephemeral nature and/or turbid conditions of the waterways. The Upper Dawson River itself is largely perennial and is therefore likely to provide a more stable habitat for aquatic macrophytes. No rare or threatened species of aquatic flora have been recorded from the waterways in the FPA.
- Aquatic Macroinvertebrate Communities: Aquatic macroinvertebrate communities within the FPA were generally indicative of poor to moderate habitat and/or water quality. The larger waterways, such as the Upper Dawson, support more permanent water, and therefore offer a more stable habitat for a more abundant and diverse of macroinvertebrates.
- Fish Communities: Most of the fish species that were captured during the EIS survey within the FPA can tolerate a large range of water quality conditions. Spangles perch, glassfish, carp gudgeons, eastern rainbowfish and eel-tailed catfish are tolerant species that can live in water characterised by low dissolved oxygen (DO) levels, high electrical conductivity (EC) and relatively high turbidity. Although exact tolerances are not available for exotic carp, goldfish and mosquitofish, these fish are also known to have wide environmental tolerances.
- Turtle Communities: Krefft's river turtles and White-throated snapping turtles are likely to be relatively common in the larger permanent waterways of the Upper Dawson catchments. Saw shelled and Fitzroy River turtles may also be present in the faster flowing waterways of the Upper Dawson River. Eastern snake-necked turtles may be present in the ephemeral creeks of the Upper Dawson River, although their absence during the survey process (undertaken in the EIS) suggests that they are not likely to be common.

Within the Fairview region on the Upper Dawson River, there are around 30 artesian springs, which are located between Dawson's Bend and Yebna Crossing. The condition of the artesian springs varied considerably between the springs surveyed, with the state of each spring largely dependent on the presence of water, the ability of stock to gain access to the spring, and the presence and abundance of terrestrial weeds. The smaller, shallower springs provide little habitat for aquatic organisms, but usually supported some macrophytes. In contrast, the larger, more complex springs often supported abundant in-stream habitat (including larger fish and turtles) and macrophytes.

3.6.2.2 Roma Region

The Condamine-Balonne River catchments are considered predominantly to be of slightly to moderately disturbed ecosystems, as 'systems that have undergone some changes, with aquatic biological diversity affected to some degree but the natural communities are still largely intact and functioning' (EPA, 2005).

As the region is located in the upper catchment area of the MDB (predominantly the Condamine- Balonne River catchment, **Figure 6**), it is the local tributaries (extensive but largely ephemeral or intermittent meandering streams) of this drainage system that would be the receiving environment. The main streams that run through the Condamine-Balonne River catchment include Yuleba Creek, Wallumbilla Creek, Bungil Creek and the Balonne River. The four creeks discharge to the Balonne River, which in turn flows into the MDB. There are five creeks running through region, which drain south to the Balonne River, including Dargal Creek, Bungil Creek, Blyth Creek, Wallumbilla Creek and Yuleba Creek. . In the eastern part of the region, the main creeks Kangaroo, Yuleba and Cottage Creeks, with the Yuleba Creek being the main watercourse.

A brief overview of the aquatic ecology, as evidenced from the field survey undertaken as part of the EIS (Santos, 2009) is provided below:

- Aquatic Flora: The diversity of aquatic macrophytes is relatively low. The limited cover of macrophytes and the lack of submerged species is likely to be related to the largely ephemeral nature and/or turbid conditions of the waterways.
- Aquatic Macroinvertebrate Communities: Aquatic macroinvertebrate communities within the RSGPA were limited in number and diversity and generally indicative of poor to moderate habitat and/or water quality.
- Fish Communities: Most of the fish species that were captured during the EIS survey within the region can tolerate a large range of water quality conditions. Spangles perch, glassfish, carp gudgeons, eastern rainbowfish and eel-tailed catfish are tolerant species that can live in water characterised by low DO levels, high EC and relatively high turbidity. Although exact tolerances are not available for exotic carp, goldfish and mosquitofish, these fish are also known to have wide environmental tolerances.

3.6.2.3 Arcadia Valley Region

The Arcadia Valley region is part of the Fitzroy Basin (**Figure 8**). In the downstream reaches of Hutton Creek, grazing, forestry and cropping are widespread. Water storages and weirs, located on the Dawson River, are used for irrigation and recreational purposes supporting regional industry and urban communities.

There are no rare or threatened species of aquatic flora recorded from the waterways in the region. A brief overview of the aquatic ecology, as evidenced from the field survey undertaken as part of the EIS (Santos, 2009) is provided below:

- Aquatic Macroinvertebrate Communities: Aquatic macroinvertebrate communities within the Upper Dawson River were generally indicative of poor to moderate habitat and/or water quality. The larger waterways, such as the Upper Dawson, support more permanent water, and therefore offer a more stable habitat for a more abundant and diverse community of macroinvertebrates.
- Fish Communities: Most of the fish species that were captured during the EIS survey within the Dawson River can tolerate a large range of water quality conditions. Spangles perch, glassfish, carp gudgeons, eastern rainbowfish and eel-tailed catfish are tolerant species that can live in water characterised by low DO levels, high EC and relatively high turbidity. Although exact tolerances are not available for exotic carp, goldfish and mosquitofish, these fish are also known to have wide environmental tolerances.
- Turtle Communities: Krefft's river turtles and White-throated snapping turtles are likely to be relatively common in the larger permanent waterways of the Upper Dawson catchments. The Fitzroy Turtle is listed as 'Vulnerable' under the EPBC Act and is found in the drainage system of the Fitzroy River. Saw shelled and Fitzroy River turtles may also be present in the faster flowing waterways of the Upper Dawson River. Eastern snake-necked turtles may be present in the ephemeral creeks of the Upper Dawson River, although their absence during the survey process (undertaken for the EIS) suggests that they are not likely to be common.

3.6.2.4 Denison Region

The Denison tenures lie wholly within the Fitzroy River Basin. The northern and central sections form part of the catchment area of the Comet River, which is a major tributary of the Fitzroy River.

Several tributaries of the Comet River, as well as the Comet River itself, flow in a northerly direction and include the Brown River, Carnarvon Creek, Arcadia Creek, Meteor Creek and Clematis Creek. The tributaries of the Comet River are ephemeral and typically experience periods of no flow for over 50% of time.

The southern section of the Denison region lies within the upper catchment area of the Dawson River, which is also a major tributary of the Fitzroy River. Tributaries of the Dawson River that flow through the southern tenures include Baffle Creek, Hutton Creek and Injune Creek. These creeks rise in the Great Dividing Range which separates this river system from the catchment area of the Maranoa River, which is part of the Balonne-Condamine River Basin. These tributaries of the Dawson River tend to be deeply incised streams flowing through sandstone areas of the Great Dividing Range, and consequently have sustained base flows, unlike the tributaries of the Comet River catchment.

The environmental values for the watercourses within the Upper Dawson River catchment are not defined within the *Environmental Protection (Water) Policy 2009* (EPP (Water)). However, the Fitzroy River sub-basin Environmental Values and Water Quality Objectives (DEHP 2011) defines the environmental values which would apply to the Upper Dawson River.

The waterways are considered predominantly to consist of 'slightly to moderately disturbed ecosystems' and in accordance with the EPP (Water) are considered to be *'systems that have undergone some changes, with aquatic*

biological diversity affected to some degree but the natural communities are still largely intact and functioning' (URS, 2009).

3.6.2.5 Scotia Region

The Scotia region is located in the upper catchment area of the Dawson River which drains northwards and is a tributary of the Fitzroy River. The main surface water system in the region the Dawson River, Bungaban Creek and Cockatoo Creek. As above, these waterway are likely considered 'slightly to moderately disturbed ecosystems' and in accordance with the EPP (Water) are considered to be '*systems that have undergone some changes, with aquatic biological diversity affected to some degree but the natural communities are still largely intact and functioning*'.

3.6.3 Groundwater Dependent Ecosystems

Groundwater Dependent Ecosystems require access to groundwater permanently or intermittently to maintain ecological assemblages, processes and ecosystem services (Eamus et al., 2006). Three types of GDEs are broadly recognised (SKM, 2011):

- ecosystems dependent on the surface expression of groundwater: associated with wetlands, lakes, seeps, springs and river baseflow
- ecosystems dependent on the sub-surface presence of groundwater: associated with terrestrial vegetation accessing the water table below ground
- cave and aquifer ecosystems: located within the pore or void spaces of caves and aquifers.

With respect to the first two points above, the ecosystems supported by groundwater discharge vary considerably. Although it is important to understand the mechanism and source aquifer supporting a wetland/ecosystem, it is the receiving environment which will influence the way an ecosystem will respond to a change in the groundwater regime. For this reason, a wetland typology has been developed for spring ecosystems of the Surat and southern Bowen Basins which identifies five types of wetland ecosystems. The key attributes used to differentiate the types are their landscape setting, geomorphology, the nature of the groundwater flow system, the regolith and water regime.

The five wetland types are:

- Type 1: Permanent fresh-to-brackish, palustrine wetlands, dense vegetation coverage and mainly connected to artesian regional and local groundwater systems. These are typically found outside the Santos EQ Project Area but can occur where fault systems cause deeper groundwater to see to surface.
- Type 2: Semi-permanent brackish, palustrine wetlands with minor wetland soils and minor vegetation cover, mainly connected to regional groundwater systems. These are typically found in the Fairview, Scotia and Denison regions.
- Type 3: Permanent to semi-permanent riverine wetlands with minor wetland soils and moderate vegetation cover, sourced from local and regional groundwater systems and significantly influenced by surface water flows. These are typically found in the Arcadia Valley and Scotia and southern parts of the Roma regions.
- Type 4: Semi-permanent fresh riverine-to-palustrine wetlands with minor wetland soils and moderate vegetation cover, mainly connected to local groundwater systems, located within riverine environments with deep, sandy, alluvial deposits. These are typically found in the all the parts of the Santos EQ Project Area where local flow systems exist.
- Type 5: Wetlands located within riverine-to-palustrine environments with shallow-to-nil unconsolidated material. These wetlands can form in areas of where there is significant topographic variation, such as the recharge areas of the Great Artesian Basin.

An overview of each GDE type is shown on **Figure 48** with **Figure 49** to **Figure 53** detailing each type and where they are likely to occur within the Santos EQ Project Area. The location of these GDE is show on **Figure 54** to **Figure 56**.

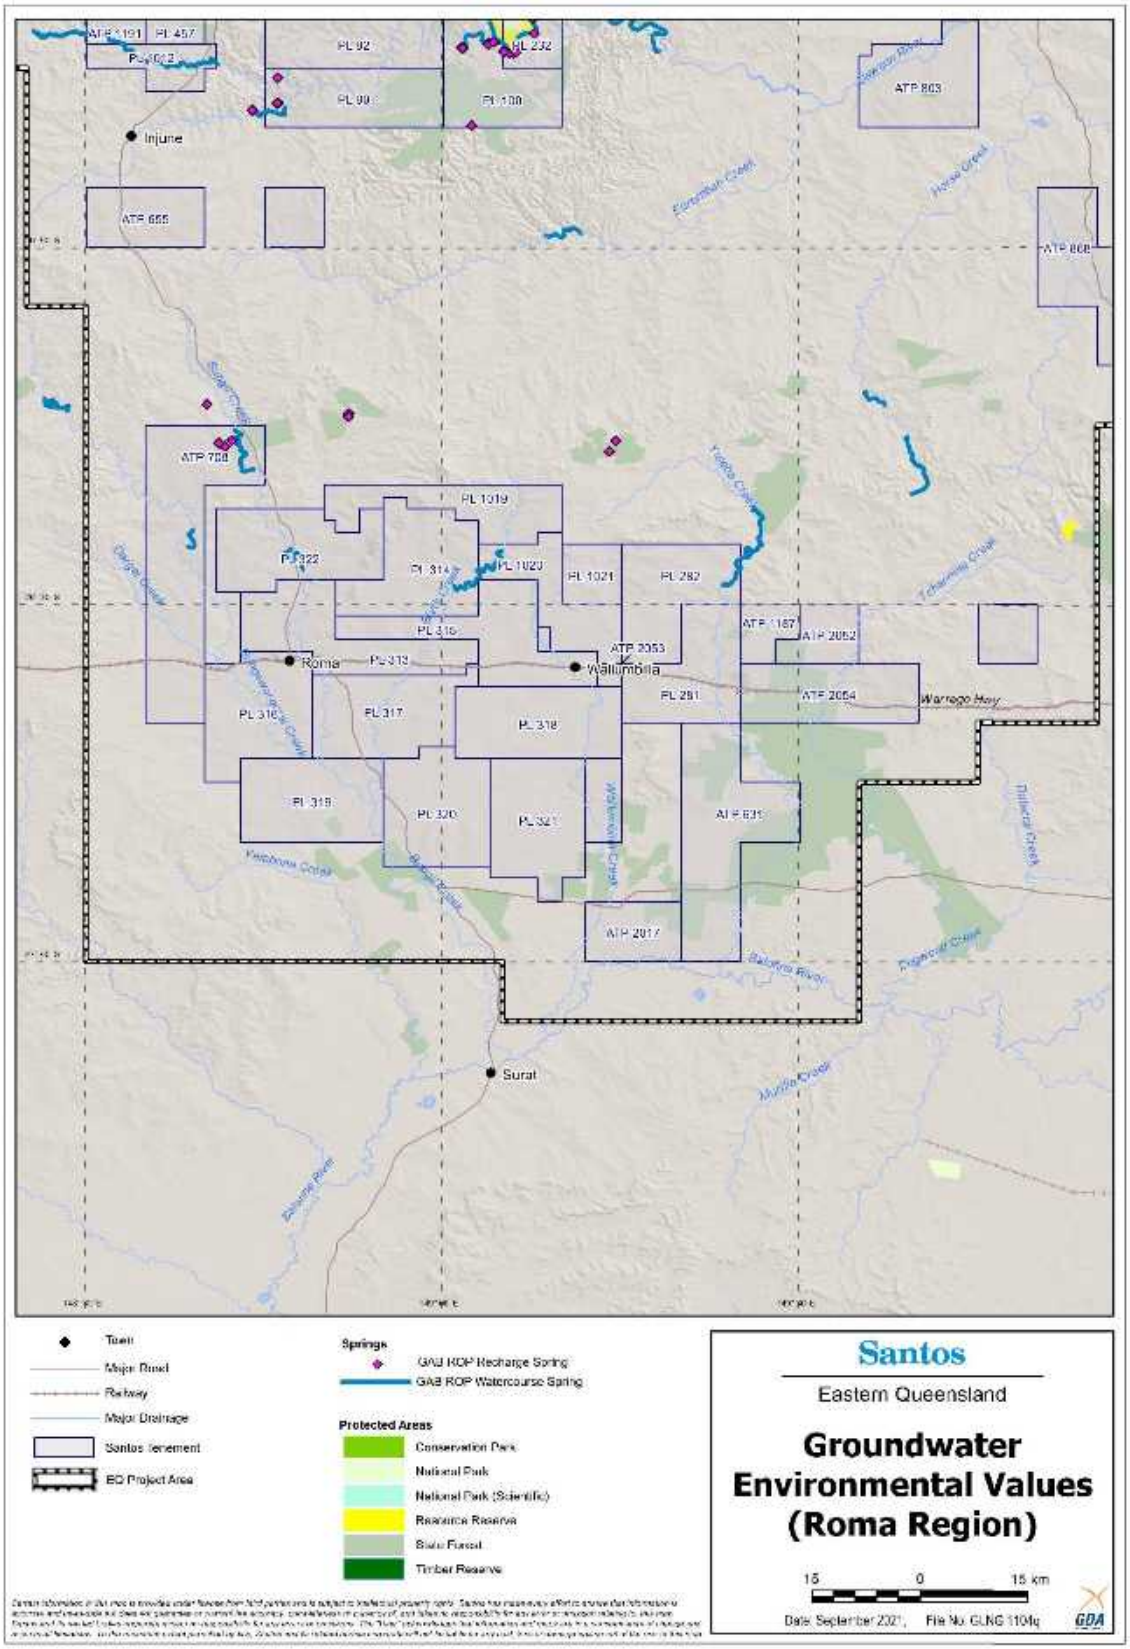

Figure 55. Environmental Values (Roma Region)

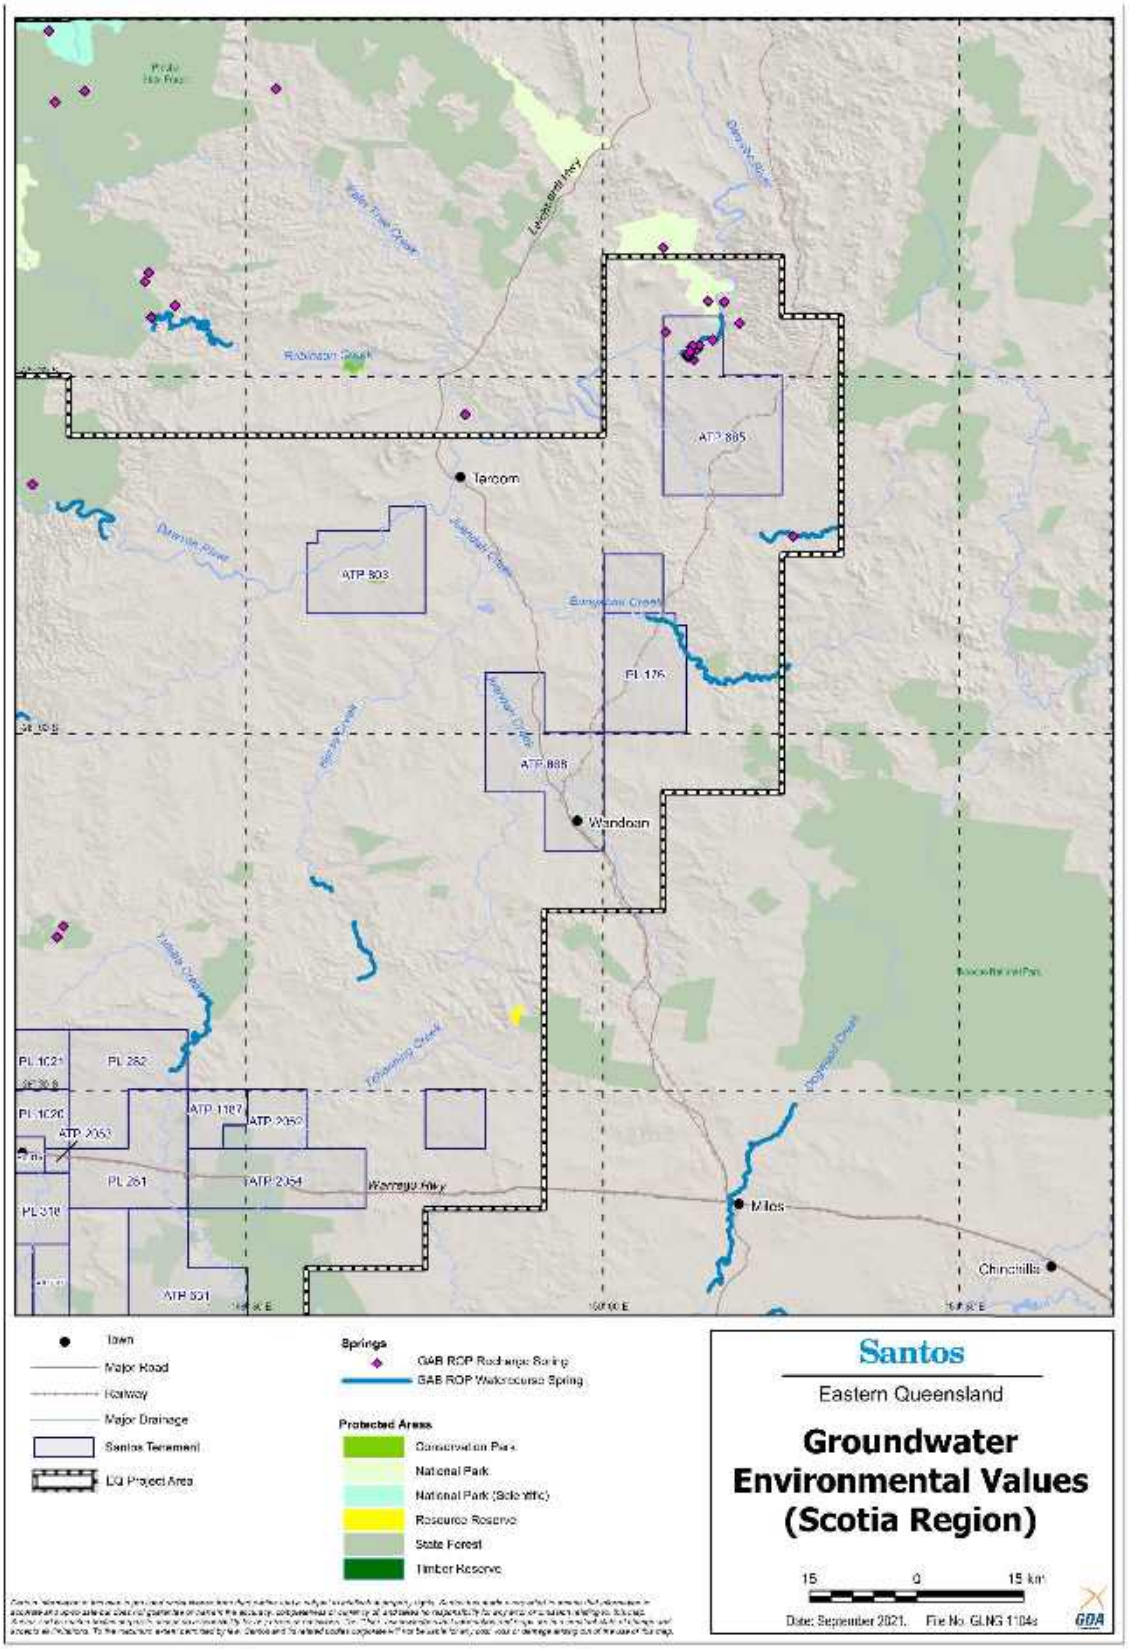

Figure 56. Environmental Values (Scotia Region)

3.7 Proximity of Overlying and Underlying Aquifers to Coal Sequences

The key aquifer units in the Santos EQ Project Area are considered to be the:

- Mooga Sandstone.
- Gubberamunda Sandstone.
- Hutton Sandstone.
- Precipice Sandstone.

The geological cross-sections provided in **Figure 18** to **Figure 20**, **Figure 21** to **Figure 26** and **Figure 30** to **Figure 35** illustrate the vertical thickness of stratigraphy, which separates the key GAB aquifers from the targeted coal measures. These thicknesses are estimated and summarised in **Table 14**.

Table 14. Stratigraphic Thickness Ranges Separating Coal Measures and Reservoirs from Aquifers

Development Area	Roma Region	Arcadia Valley Region	Fairview Region	Denison Region	Scotia Region
Mooga (GAB)	250 – 550 m	np	np	np	np
Gubberamunda (GAB)	65 – 200 m	np	np	np	np
Springbok (GAB)	0 m**	np	np	np	100 – 350 m
Hutton (GAB)	150 – 350 m	np	780 – 980 m	np, >800 m	>440
Precipice (GAB)	90 – 400 m	np	300 – 520 m	500 – 850 m	100 – 350 m
Clematis Sandstone (BB)	>550 m	200 – >750 m	220 – >760 m	350 – 450 m	np
Aldebaran Sandstone (BB)	>650 m*	>650 m*	>650 m*	>650 m*	np

np = not present
GAB = Great Artesian Basin (Surat Sub-basin, Jurassic-Cretaceous)
BB = Bowen Basin (Permian-Triassic)
** maximum (uncertain due to lack of information)*
*** generally a poor aquifer in the RSGPA but may be more viable in the eastern parts of the project area.*

3.8 Proximity of Aquifers with EVs and Potential Impacts on Surface Water

Across the Santos EQ project area, potable water supplies are primarily resourced from the following aquifers:

- Mooga Sandstone
- Gubberamunda Sandstone
- Hutton Sandstone
- Precipice Sandstone
- Clematis Sandstone
- Aldebaran Sandstone.

The proximity of these drinking water supply aquifers to the targeted coal seams are detailed in **Table 14**, described in detail in **Section 3.5** and spatially illustrated in **Figure 45** through **Figure 47.**

The Santos EQ Project Area is located in what is considered a portion of the recharge beds area for the GAB. The GAB recharge area is commonly defined as the area where the GAB sandstone aquifer formations subcrop or

outcrop on the eastern margins of the GAB. Several GAB recharge springs have been identified in the Project Area.

A reduction or loss of baseflow contribution from groundwater to rivers and creeks could potentially affect the aquatic ecology of the surface water ecosystems. For this to occur, inter-aquifer transfer associated with coal seam depressurisation would have to propagate through a thick stratigraphic sequence above the coal seams to affect the shallow 'water table' aquifers.

The Santos GLNG Project Coal Seam Water Monitoring and Management Plan – Stage 2 (S2 CWMMP) (April 2013), details groundwater modelling which indicates that the effects of inter-aquifer transfer are likely to be limited to the aquifers in close stratigraphic succession to the depressurised gas-bearing coal seams targeted by Santos EQ.

The shallow groundwater resources and surface water features are considered unlikely to be affected in Roma region.

In Fairview region, groundwater modelling has predicted impacts between 3 m (a base case scenario modelled) and 8 m (worst case scenario) within the Precipice Sandstone in the southwest corner of the FPA where the Bandanna Formation is in direct contact with the Precipice Sandstone (Rewan Formation absent). In the worst-case scenario, the predicted impact to the baseflow of the Dawson River is a decrease of 1.5% of current baseflow (UWIR, 2019).

3.9 Groundwater Extraction and Use

3.9.1 Surat CMA

There are approximately 22,500 water bores in the Surat CMA (UWIR, 2019). Of these, around 8,100 access the formations in the GAB, predominantly for stock and domestic (S&D), stock intensive, industrial and town water supply purposes. About 13,500 bores access the overlying alluvium (mainly the Condamine Alluvium) and tertiary basalts for irrigation and S&D purposes. The remaining bores access the underlying Bowen Basin.

The majority of non-CSG groundwater extraction is not metered, resulting in a high degree of uncertainty in relation to actual use. The approach initially developed for the UWIR 2016 for estimating unmetered groundwater is now further improved. Based on this refined approach and new data, current non-CSG groundwater extraction in the CMA is estimated to be around 164,000 ML/year – 20% less than previous estimates. Of this, about 25% is from the GAB formations.

CSG groundwater extraction has been relatively steady over the last three years at around 60,000 ML/year. This is likely due to a combination of declining water extraction from maturing fields and an increasing number of CSG wells in nearby areas. Extracted water is treated and primarily used for beneficial purposes or reinjected into aquifers. One reinjection scheme

3.9.2 Santos EQ Project Area

Within the Santos EQ Project Area, groundwater from the various aquifers is generally of good quality and is used for a range of activities. As previously presented, **Figure 45** to **Figure 47** show the locations of groundwater users across the Santos EQ Project Area, however some bores with non- active licenses, or bores which could not be related to GMAs (i.e., no coordinates provided), may not be presented. Of the bores above, illustrates the estimated proportional usage of groundwater in each GMA, based on information extracted from the NRM water-licensing database – Water Entitlements Registration Database (WERD).

Note that the data presented here may not account for all stock and domestic bores as those bores have not always been required to be registered in Queensland.

The primary use of water within the Surat, Surat North and Mimosa GMAs is for stock, the secondary use for domestic purposes and to a lesser extent for urban water supply, agriculture (including irrigation and intensive stock watering) and industrial purposes. suggests that the primary use of groundwater to north and north-west of the AVPA (Bowen Basin) is for irrigation, urban supply (namely town water supplies) and stock. Groundwater bores licensed for urban supply are concentrated around the town of Emerald and the irrigation bores are more spread through the region. Most of the irrigation bores are completed within the shallow alluvium deposits and a few in the Aldebaran Sandstone (Back Creek Group). The 2005 Australian Natural Resources Atlas (ANRA, 2005) confirms most bores in the Bowen Basin are being used for irrigation purposes.

Figure 58 illustrates the proportional number of licensed groundwater bores across the Project area completed within the aquifers of significant importance.

The primary aquifers targeted for groundwater extraction around Roma region are the Mooga Sandstone and Gubberamunda Sandstone. This is contrasted with the allocations around Fairview region with the largest allocations to the Hutton Sandstone and Precipice Sandstone. The primary uses of the bores in the Mooga and Gubberamunda Sandstones are domestic and stock supply whereas the primary use of the Hutton Sandstone and Precipice Sandstone bores are stock intensive and town supply, which generally require formal allocations and entitlements.

The primary aquifer targeted for groundwater extraction in Fairview region is the Hutton Sandstone, with the primary use for town water supply and domestic and stock use for the stratigraphy of the Bowen and Surat Basin). Only one percent of the licensed bores around Fairview region are completed in the alluvial and tertiary deposits within the region but significant allocations are provided from these deposits for irrigation use.

North of Fairview and within Arcadia Valley region, the primary target aquifer includes the Clematis Sandstone. Water is assigned for town water supply, domestic and stock use. Bores completed in alluvium, tertiary deposits and basalt are assigned large nominal allocations in this area and are used primarily for irrigation. As for bores in the Permian deposits of the Bowen Basin, the Aldebaran Sandstone, most bores have been licensed for town supply and irrigation.

In the Scotia region, the Precipice and Hutton Sandstone are primarily targeted however these aquifers become quite deep and uneconomical to access in the southern part of the Scotia region. In this location the lower yielding and poorer quality shallow systems are targeted for stock watering.

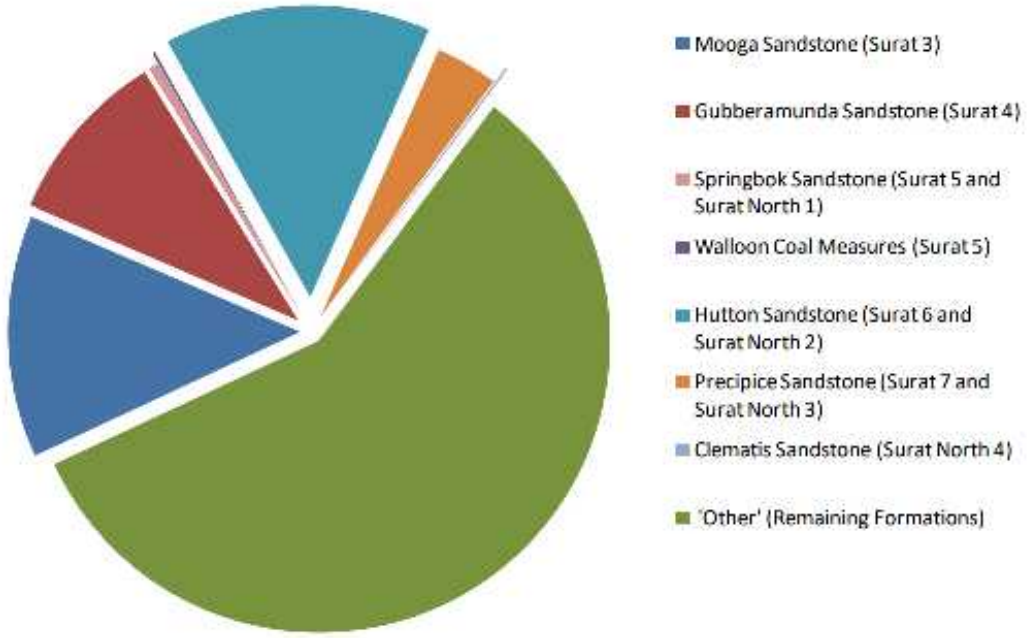

Figure 58. Distribution of Bores Completed in Aquifers of Significant Importance across the Santos EQ Project Area Currently Being Developed

4 Hydraulic Fracturing Process

The information provided in this section addresses the following EA approval requirements: conditions (a), (b), (m), (n), (o), (r), (t) and (z)(1).

4.1 Introduction

The description of the hydraulic fracturing process is covered under the following headings:

- Description of the coal seams and the gas they contain
- Purpose of the hydraulic fracturing process
- Description of the hydraulic fracturing process
- How is hydraulic fracturing carried out
- Infrastructure and equipment used
- Stages of hydraulic fracturing
- Assessment techniques for determining extent of stimulation activities
- Practices and procedures used to ensure fracture remains in target zone
- Program for wells to be fractured
- Frequency of hydraulic fracturing
- Distribution of wells fractured to date and to be fractured
- Location of landholders' active bores
- Chemical constituents in acid and hydraulic fracturing package.

Prior to considering the practice of hydraulic fracturing to enhance gas well production, two important matters require addressing in accordance with the requirements of the EA conditions, namely:

- Comparison to international best practice – are the procedures employed by Santos' contractors considered international best practice?
- Well mechanical integrity – are the gas production wells constructed by Santos EQ and their well contractors completed in a manner to ensure well integrity? What testing methods are employed by Santos to ensure that they are built in an appropriate manner such that they maintain their integrity under normal operational use?

These matters are discussed in the following sections.

4.2 Code of Practice and International Best Practice

The Queensland government has developed a *Code of Practice for the Construction and Abandonment of Petroleum Wells and Associated Bores in Queensland* (Version 2, 16 December 2019). The code covers all petroleum well types including exploration, appraisal, monitoring, injection, development and production wells. It also covers water bores, including water observation, water supply and water injection bores. The Code of Practice applies to the following well life cycle phases:

a) well planning and well design
b) well construction (up to the production wing valve of the well head/Christmas tree) including construction of new water bores by operators
c) well evaluation
d) well completion including hydraulic fracture stimulation activities
e) well production and operation
f) well integrity management
g) conversion of petroleum wells to water bores
h) well suspension
i) well abandonment

For all the stages the code of practice considers equipment and material selection, risk assessment (both safety and environment), industry practices, monitoring and reporting. This guidance has been developed using international best practices including the following key guidance and references:

- Queensland Government, Code of Practice for Constructing and Abandoning Coal Seam Gas Wells in Queensland. Version 1. November 2011.
- American Petroleum Institute (API) Recommended Practice 10B-2/International Standards Organisation (ISO) 10426-2, Recommended Practice for Testing Well Cements
- API Recommended Practice 10B-3/ISO 10426-3, Recommended Practice on Testing of Deepwater Well Cement Formulations.
- API Recommended Practice 10B-4/ISO 10426-4, Recommended Practice on Preparation and Testing of Foamed Cement Slurries at Atmospheric Pressure.
- API Recommended Practice 10B-5/ISO 10426-5, Recommended Practice on Determination of Shrinkage and Expansion of Well Cement Formulations at Atmospheric Pressure.
- API Recommended Practice 10B-6/ISO 10426-6, Recommended Practice on Determining the Static Gel Strength of Cement Formulations.
- API Specification 10D/ISO 10427-1, Specification for Bow-Spring Casing Centralizers.
- API Specification 10D-2/ISO 10427-2, Recommended Practice for Centralizer Placement and Stop Collar Testing.
- API Recommended Practice 10F/ISO 10427-3, Recommended Practice for Performance Testing of Cementing Float Equipment.
- API Technical Report 10TR1, Cement Sheath Evaluation.
- API Technical Report 10TR3, Temperatures for API Cement Operating Thickening Time Tests.
- API Technical Report 10TR4, Technical Report on Considerations Regarding Selection of Centralizers for Primary Cementing Operations.
- API Technical Report 10TR5, Technical Report on Methods for Testing of Solid and Rigid Centralizers.
- API Recommended Practice 13B-1/ISO 10414-1, Recommended Practice for Field Testing Water- Based Drilling Fluids.
- API Recommended Practice 13B-2/ISO 10414-2, Recommended Practice for Field Testing Oil- based Drilling Fluids.
- API Recommended Practice 53, Blowout Prevention Equipment Systems for Drilling Operations.
- API Recommended Practice 65, Cementing Shallow Water Flow Zones in Deep Water Wells.
- API Recommended Practice 90, Annular Casing Pressure Management for Offshore Wells.

The following guidance documents published by API specifically for hydraulic fracturing activities describe an overview of the international best practices and procedures. Information from these guidance documents is also referenced throughout this report:

- API, Guidance Document HF1 (HF1), Hydraulic Fracturing Operations – Well Construction and Integrity Guidelines, First Edition/October 2009.
- API HF1 highlights industry recommended practices for well construction and integrity for hydraulically fractured wells and provides guidance to ensure that shallow groundwater aquifers and the environment will be protected.
- API, Guidance Document HF3 (HF3), Practices for Mitigating Surface Impacts Associated with Hydraulic Fracturing, First Edition/January 2011.
- API HF3 identifies and describes the current practices used in the oil and gas industry to minimize surface environmental impacts—potential impacts on surface water, soils, wildlife and other surface ecosystems and nearby communities—associated with hydraulic fracturing operations.

Both Santos and the hydraulic fracturing contractors operating in Australia have adopted the requirements of the Code of Practice and international best practices (as described above) which are also discussed within the Code of Practice.

In addition, the State (through disclosures to the Department of Natural Resources Mines and Energy) and the Commonwealth require full disclosure of the chemicals used in hydraulic fracturing fluid systems. Including, the chemical products used, their chemical makeup and the mass ratios of all chemicals used in the hydraulic fracturing fluid system.

Additional advancements in technology and practices – for example, using company-researched licensed technologies for placement of specifically designed treatments into each perforated zone are evolving. These innovations have included synthetic proppants, perforation agents and sealing and bridging compounds.

4.2.1 Risk Assessment and Site Location

As documented in the Code of Practice, “operators must carry out a risk assessment to identify the risks that may occur during well or bore construction, operation and abandonment. Risks to be managed must include, as a minimum, site access and preparation, well integrity, groundwater protection and safety of personnel and the community.” The core strategies of avoidance, management and mitigation (in this order) are implemented to address potential risks with the core strategies for hydraulic fracturing being focused on avoidance and management.

A core component of risk management is associated with appropriate siting of the wells. As documented in the Code of Practice this process identifies through desk top evaluations potential or suitable sites within known constraints such as tenement boundaries, topographic constraints, geologic constraints to development and environmental restrictions. Supplemental work is conducted to inform the process including seismic surveys and ground truthing with a focus on ensuring the location is ideally suited to development and that key risk and/or environmental factors (faults that have the potential to propagate from the target sequence into overlying aquifers, poorly constructed historic bores etc.) are not present.

As part of this assessment (and consistent with the requires of the Code of Practice), Santos consults with relevant stakeholders, including landholders, to choose the final, most appropriate site. This process considers all other potential constraints (e.g., access routes, environmental constraints, cultural heritage and landowner constraints). Through the combination of desk top studies, supplemental assessments, ground truthing and stakeholder engagement Santos completes all assessments required by law including:

1. environmental checks (e.g., distance from specific flora and fauna communities)
2. cultural heritage inspections (particularly regarding indigenous cultural heritage)
3. topography restrictions and issues (avoiding water courses, ravines, steep cliff faces)
4. land use restrictions (including consultation with landholders)
5. safety offsets from landholder bores to ensure no impacts on water usage or water quality
6. Avoidance of areas where inter-aquifer connectivity may exist and or structures that may facilitate movement of hydraulic fracturing fluids into overlying aquifers
7. Stakeholder and landowner liaison requirements.

Once the site location has been determined (as described above), the primary concern is the management of safety and the environment impacts during the execution of work. For safety of both site personnel and landholders, the Code of Conduct recommends that well sites be sized and prepared appropriately and may also be fenced for safety and to provide a barrier to exclude livestock and large wildlife.

4.3 Well Mechanical Integrity

A critical component of maintaining a high degree of protection of the various aquifers within the Surat and Bowen Basin sequences is through the robustness and longevity of the well construction itself. The well is required to isolate the production fluids from the aquifer units during its working life and beyond, even after it has been formally abandoned by the mandated well abandonment processes (including pressure cementing). It is this robustness of construction that permits the well to maintain its integrity.

Throughout the entire process, stringent quality control and testing is undertaken to ensure the integrity of the casing and seals. These quality control procedures are implemented through the material selection and sourcing process and installation.

NOTE: The discussion of well integrity has been drawn from discussions and information provided by Santos EQ and supplemented by information directly sourced from American Petroleum Institute publication ‘Hydraulic Fracturing Operations – Well Construction and Integrity Guidelines’ (API Guidance Document HF1 First Edition, October 2009) and the Code of Practice. The reader is urged to consult this document for a detailed description of the well completion process.

Maintaining a gas production well's integrity is essential for the two following reasons:

- To isolate the internal conduit of the well, namely the well casing pipe, from the surface and subsurface environment. This is critical in protecting the environment, including the groundwater, and in enabling well drilling and production.
- To isolate and contain the well's produced fluid (i.e., the gas) to a production well casing pipe within the well.

Groundwater is protected from the contents of the gas well during drilling, hydraulic fracturing, and production operations by a combination of drilling muds used in the process, steel casing and cement sheaths, and other mechanical isolation devices installed as a part of the well construction process. Well design and construction seek to achieve this level of robustness in a much more thorough manner than is achieved by the impermeable rock formations that lie between the gas-bearing target formations and the groundwater which have effectively isolated the groundwater over millions of years. The construction of the well is done to prevent communication (the migration and/or transport of fluids between these subsurface layers).

The primary method used for protecting groundwater consists of drilling the well borehole and then cementing steel pipe into place using specialised cement types. The casing and cement are specifically selected to accommodate several factors including formation types, groundwater quality, gas characteristics and operational conditions.

As documented in the Code of Practice (pp 10), 'all wells must be designed and constructed to ensure the safe and environmentally sound production of fluids by:

a) well objectives being met
b) preventing any cross-flow contamination between hydrocarbon bearing formations and aquifers
c) ensuring that fluids are contained within the well and associated pipework and equipment without leakage. Failure of one barrier must not lead to an uncontrolled release of formation fluids (blowout). It is noted that CSG wells typically have a single barrier between surface and a hydrocarbon bearing zone for portions of its life due to its producing arrangement. Operators must have appropriate processes in place to address this.
d) ensuring zonal isolation between differently pressured permeable formations (e.g., aquifers and hydrocarbon bearing zones) is achieved
e) prevent/avoid the introduction of substances that may cause environmental harm
f) testing and acceptance requirements are satisfied
g) wells can be monitored and maintained to contain and control wellbore fluids, provide structural support and otherwise retain well integrity throughout all reasonably anticipated construction, testing, production, injection, intervention, workover, suspension and abandonment load conditions – as may occur during the specified design life of the well.
h) The completion needs to be designed to operate within the maximum expected pressures and load conditions until final abandonment.

In accordance with the requirements of the code the casing and cement of the wells is critical for protection of aquifers.

The coal seams and reservoirs containing gas produce into the well through perforations in the steel pipe and cement sheaths opposite the respective coal seams, with the produced gas being contained within the well pipe and the production all the way to the surface. The concrete annular seal between the casing and the formation. This containment is what is meant by the term 'well integrity'.

Regular monitoring takes place during drilling and production operations to ensure that these operations proceed within established parameters and in accordance with the well design, well plan, and permit requirements. This includes testing of the well integrity during well construction and over the life of the well as described in subsequent text.

4.3.1 Drilling and Well Completions

Drilling a typical oil or gas well consists of several cycles of drilling, running casing (steel pipe for well construction), and cementing the casing in place to ensure isolation. In each cycle, steel casing is installed in sequentially smaller sizes inside the previous installed casing string. The last cycle of the well construction is well completion, which can include perforating (creating holes in the steel pipe opposite the coal seam) and hydraulic fracturing or other stimulation techniques depending on the well type.

Drilling and completing an oil and/or gas well consists of several sequential activities. A list of these activities appears below. In sequential order, these activities are as follows:

- Preparing the well location (drill pad) and installing fluid handling equipment

- Setting up the drilling rig and associated equipment
- Drilling the borehole
- Logging the borehole (running geophysical survey instruments down the borehole) (if required)
- Running casing (steel pipe)
- Cementing the casing using grouting equipment to inject specialised cement mixes
- Removing the drilling rig and ancillary equipment
- Logging the casing to test for integrity (if required)
- Perforating the casing (depending on well completion type)
- Hydraulic fracturing or stimulating the well
- Installing artificial lift equipment (if necessary)
- Install surface production equipment
- Putting the well on production
- Monitoring well performance and integrity
- Rehabilitating those areas of the drilling pad that are no longer needed and removing equipment no longer used in the gas production operations.

It is the activities highlighted in italicised text that largely ensure the integrity of the well, and which are discussed in further explanatory text below.

4.3.2 Selection and Sourcing of Casing Material

To ensure long term casing integrity, Santos EQ has developed detailed specifications for all well casings and well completion materials. These specifications meet or exceed the specifications/recommendations contained within the Code of Practice. These materials have been specifically designed and selected for the proposed application and lifecycle of the well. Material specifications differ based on the depth of the well, formation pressures, anticipated gas pressures, geochemical considerations and the nature of proposed down-well infrastructure.

All materials are inspected by Santos EQ and the contractors prior to installation to ensure compliance with the Santos EQ specifications. A similar process of inspections and testing are utilised throughout the drilling and casing installation program. This testing and inspection is discussed in the sections below.

4.3.3 Logging the Borehole

Borehole and well logging can be carried out at various stages of the wells drilling and completion, including:

- Open borehole logging is used to obtain specific information of the properties for the rock formations drilled, gas-bearing coal seam properties and the nature of the borehole created. This is primarily used to assess the gas resource, the media properties, and to provide geological and hydrogeological information used to design the well and cementing requirements.
- Cased well logging can be used to obtain specific information of the properties of the rock, cement and/or casing integrity, depending on the logging tool used. These specific issues are discussed in further detail below.

Upon completion of the drilling of a borehole section, and before casing is installed and cementing operations begin, sensor instruments can be run into the open (uncased) drilled borehole on a data cable. Alternatively, logging tools or sensors may be included in the drilling bottom hole assembly so the well may be logged as it is being drilled. The information collected and the process used is typically referred to as ‘well logging’ or ‘geophysical borehole logging’, while the sensor is typically referred to as a ‘logging tool’. Typical geophysical logging methods that are run in a well are designed for the specific location, geology, resource and well design information types and include:

- Gamma Ray: a sensor that detects naturally occurring gamma radiation (it identifies clay mineral rich rock, due to the presence of radioactive potassium commonly found in the rock mass).

- Resistivity: a sensor, which measures the electrical resistance between probes on the logging tool in the wellbore. Resistivity logging is commonly for formation evaluation in oil- and gas-well drilling. Most rock materials are essentially insulators, while their enclosed fluids are conductors. Coal and hydrocarbon fluids are an exception, because they are almost infinitely resistive. In addition, when a formation is porous and contains salty water, the overall resistivity will be low (more conductive). High resistivity values may indicate a hydrocarbon bearing formation, and this includes coal.
- Spontaneous Potential (or Self Potential, Shale Potential log) (SP): The SP log is a voltmeter measurement of the voltage or electrical potential difference between the drilling mud in the borehole at a particular depth and a copper ground stake driven into the surface of the earth a short distance from the borehole. A salinity difference between the drilling mud and the formation water is detected, and the nature of the formation can be assessed based on the differences in conductivity measured. The resulting log curve reflects the permeability of the rocks and, indirectly, their lithology (e.g., shale versus sandstones).
- Density and the Neutron log: A device used to measure the bulk density of, and, by inference, the porosity of the formation. See also sonic log.
- Calliper: A physical measurement of the diameter of the wellbore. A calliper log run through a well borehole is used to calculate the borehole size, shape and volume of the hole.

Sonic Log: Sonic logs use a pinger and microphone arrangement to measure the velocity of sound in the formation from one end of the sonde to the other. For a given type of rock, acoustic velocity varies indirectly with porosity. If the velocity of sound through solid rock is taken as a measurement of zero per cent porosity, a slower velocity is an indication of a higher porosity that is usually filled with formation water with a slower sonic velocity. Both

- sonic and density-neutron logs give porosity as their primary information. Sonic logs read farther away from the borehole so they are more useful where sections of the borehole are caved. Because they read deeper, they also tend to average more formation than the density-neutron logs do. As such, they are complimentary in that they output and provide more definitive information as to the rock types at various depth locations in the borehole being logged.

Logging produces detailed information on all rock formations logged and the groundwater quality they might contain. Logging also determines the actual depth and thickness of the subsurface formations in the drilled hole.

Many other types of logging tools are available and may be run on a case specific basis.

After cementing the casing pipe in place, ‘cased-hole’ logs can be run inside the casing to validate the quality and integrity of the cement job. These logs can include the following:

- Gamma ray (described previously)
- Collar locator (a magnetic device that detects the casing collars)
- Cement bond log (CBL) and variable density log (VDL) that measures the presence of cement and the quality of the cement bond or seal between the casing and the formation.

The CBL-VDL is an acoustic device that can detect cemented or non-cemented casing. The CBL works by transmitting a sound or vibration signal, and then recording the amplitude of the arrival signal. Casing that has no cement surrounding it (i.e., free pipe) will have large amplitude acoustic signal because the energy remains in the pipe. While casing pipe that has a good cement sheath that fills the annular space between the casing and the formation will have a much smaller amplitude signal since the casing is ‘acoustically coupled’ with the cement and the formation which causes the acoustic energy to be absorbed.

Santos EQ contract experienced contractors to run the CBL – VDL and the results are evaluated to determine the integrity of the cement seal.

Santos EQ contractors most commonly use CBL-VDL cement evaluation tools, however other types of cement evaluation tools are available and, depending on the situation, are considered as a part of the cement evaluation program.

Cement logging and evaluation is completed in accordance with the Code of Practice. Logging is completed in each new field/geological area or for each significant change in design to demonstrate repetitive successful zonal isolation.

4.3.4 Well Completion Design

On the basis of the drill-chips and borehole core retrieved from the drilling of the well hole (when applicable), together with the information gained and analysed from the geophysical logging of the borehole, a well completion

design for the well is determined by the well engineering team; a typical design is illustrated in **Figure 59**. The basis of the site-specific design for the well construction emphasises barrier performance and zone isolation (including aquifer, low quality groundwater and unstable formation isolation), as well as gas production efficiency.

The well design and specifications include wellbore preparation, mud removal, casing pipe running and cement placement to provide barriers that prevent fluid migration and well leakage. The selection of the materials for cementing and casing, and the process of cement placement are important considerations in designing the well such that it ensures optimum performance of the barrier system to protect groundwater and isolate the hydrocarbon bearing zones. The well design process also includes contingency planning to mitigate and eliminate the risk failure due to unforeseen events.

The well design process also accommodates the analysis of those factors which determine the hydraulic fracturing outcomes. These include defining the optimal location and orientation of perforations such that the zone of hydraulic fracturing is contained entirely within the target formation. The latter involves the assessment of borehole core, porosity analysis, cleat orientation and density testing, bedding plane analysis, coal interbed content, and stress field analysis.

4.3.5 Casing Design and Completion

Drilling typically consists of several cycles of drilling, running casing and cementing the casing in place to ensure isolation. In each cycle, casing is installed in sequentially smaller sizes inside the previous installed casing string. These casing strings are typically installed in the order as follows: conductor casing (if required due to local ground conditions), surface casing and production casing. Specific considerations for each of these casing strings are presented below. It is important to note that the shallow portions of the well have multiple concentric strings of steel casing installed.

- If required due to local ground conditions, the conductor casing stabilises the soil zone from the drilling action of subsequent drilling phases (prevents the lose soils from caving into the borehole) and is cemented into place to ensure an appropriately robust seal (back up to ground level).
- The surface casing is typically installed to protect the shallow formations (weathered or unconsolidated rock layers) and to stabilise the well from the later drilling phases of deeper sections of the borehole.
- The surface casing is designed to achieve all regulatory requirements for isolating groundwater encountered in this hole section and also to contain pressures that might occur in the subsequent drilling process. This casing pipe is cemented into place to ensure an appropriately robust seal.
- After the production hole is drilled and logged, production casing pipe is lowered to the total depth of the borehole and cemented in place. The purpose of the production casing is to provide the final isolation between the gas-bearing coal seams and all other formations for containing and pumping the various fluids used to hydraulically fracture the coal seams from the surface into the producing formation without affecting the shallower layers penetrated by the well. It also houses the downhole production pumping equipment when the well becomes operational. During the operational phase, its most important function is internally containing the gas produced from the coal seams within the well.
- The production casing pipe is pressure cemented to achieve robust and effective isolation of the well from the various subsurface layers (aquifers and aquitards alike).

In accordance with the requirements of the Code of Practice, casing pressure tests are carried out at each stage to ensure integrity of the casing pipe for further drilling or operational conditions. These tests are conducted at pressures that will determine whether the casing integrity is adequate to meet the well design and construction objectives. The test pressure applied is greater than the maximum anticipated formation pressure that could occur at surface but does not exceed the burst pressure rating of the casing with the design safety factor applied.

4.3.6 Cementing

Cement types, additives and mixes are engineered products and are selected and designed to address site-specific conditions relevant to a particular well. Cement mixtures and installation techniques are employed to provide a robust seal that isolates the well from the

surrounding formations and protects the well materials from potentially aggressive groundwater or formation conditions. The selected cement types, additives and mixing fluid are specifically designed and laboratory tested in advance to ensure they meet the requirements of the well design and subsurface conditions at the well location. The cements are not typical building/construction cements, but are tailored cements designed for use in well construction. The type of equipment used for to place cement in the annulus in and around the casing are shown in

Figure **59**.

Placement of the cement is carried out in such a manner (and using appropriate centralising equipment) as to completely surround the casing pipe to achieve successful seal isolation and pipe integrity (

Figure **59**). That is, effective isolation of the well pipe from the various subsurface formations requires complete and even annular filling and tight cement interfaces with the formation and casing. Complete displacement of drilling fluid by cement (to eliminate ‘bubbles’ or voids) and good bonding of the cement interfaces between the

drilled hole and the casing immediately above the gas-bearing coal are important factors taken into account when designing and completing the well to ensure effective and long-lasting well and seal integrity.

The following well design, materials selection and cement procedures are typically implemented at Santos EQ well completion sites:

- The Santos EQ well design team prepares an appropriate well completion design based on a detailed assessment of borehole core, the regional geological model, reservoir analysis, and the history of nearby wells. Historical problems encountered in the area (lost returns, irregular hole erosion, poor hole cleaning, poor cement displacement, etc.) are considered during the design process.
- Computer simulation and completion planning is carried out to optimise cement placement procedures.
- Santos EQ drilling contractors are selected based on their repute, adherence to industry best practice methods and regulatory requirements. Importantly, as it effects cementing, they are required use established, effective drilling practices to achieve a uniform, stable well borehole with desired hole geometry. Additionally, they are required to satisfy Santos EQ health-safety-environmental (HSE) requirements regarding their personnel and equipment. They are required to ensure that their cementing equipment provides adequate mixing, blending and pumping of the cement in the field.
- Santos EQ drilling contractors are required to ensure that the drilling fluid selection is appropriate for the designed well and the geologic conditions likely to be encountered and present a low risk to the environment.
- Site drilling and cementing equipment are selected to adequately achieve the well design that will meet the well design objective and ensure effective isolation.
- Prior to cementing a section of well casing pipe in place, Santos EQ drilling contractors ensure that appropriate well borehole preparation, hole cleaning, and conditioning measured implemented to ensure the cementing works are effective.
- Santos EQ drilling contractors are required to employ casing pipe centralisers to help centre the casing pipe within the borehole and provide for good mud removal and cement placement, especially in critical areas, such as coal seam zones, and groundwater aquifers.
- Santos EQ drilling contractors are required to use appropriate cement testing procedures to ensure cement slurry quality and designs are adequate. These include implementation of appropriate cement slurry quality controls - with testing to measure the following parameters depending on site- specific geological and groundwater quality conditions:
  - Slurry density
  - Thickening time
  - Fluid loss control
  - Free fluid
  - Compressive strength development
  - Fluid compatibility (cement, mix fluid, mud)
  - Sedimentation control
  - Expansion or shrinkage characteristics of the set cement
  - Static gel strength development
  - Mechanical properties (Young’s Modulus, Poisson’s Ratio, elastic/compressibility characteristics, etc.)
- Cement design may include pumping two different slurry designs, using a ‘lead’ cement of lower density and a ‘tail’ cement of higher density and compressive strength. Typically, the tail cement is used to isolate critical intervals in the well.
- Adherence to appropriate setting times ensures that the cement seals are optimal prior to commencing further drilling, hydraulic fracturing and/or operational testing.

In accordance with the Code of Practice (Section 3.6.2) achievement of primary cementing objectives can be demonstrated by achieving a minimum of three of the verification methods below:

- Slurry mixed and placed in accordance with contractor approved cementation procedures and the cement job pressure charts show pressure rise during cement displacement in line with expectations.

- Shoe track volume not over displaced when displacing cement slurry.
- Downhole losses not greater than the excess pumped within the cement procedure, and calculated TOC using final circulating pressure (FCP) and measured fluid returns achieves the objective(s) identified within the cementation program.
- No significant losses or slumping post placement of cement.
- Casing successfully pressure tested.
- Completion of an appropriate cement integrity test such as a formation integrity test.
- Completion of an appropriate cement evaluation log.

4.3.7 Summary

These logging, well design, well completion and well cementing methods ensure that the risk of impact to the containing formations is negligible by ensuring the well completion quality and integrity is maintained. This is carried out to make certain that the aquifer layers intersected by the well do not become impacted by subsequent hydraulic fracturing activities or gas production activities through the operating life of the well concerned.

4.4 Description of the Hydraulic Fracturing Process

As discussed in Section 2, the coal layers or coal 'seams' which host the gas (methane) occur as a series of interbedded layers of coal (in the coals seams of the Walloon Coal Measure and

Blackwater Group/Bandanna Formation) and interburden layers comprising mudstones-siltstones- sandstone assemblages, themselves situated at depth within a much thicker sequence of highly variable sedimentary rock types, also comprising sandstones, siltstones, mudstones and shales (**Table 3**).

The gas is predominantly adsorbed to the surface matrix of the coal or stored as free gas in the natural fracture systems commonly found in coal. Under the natural confining pressure of a typical coal seam, the gas exists in a near liquid state.

The pore spaces within the coal rock mass are made up of fracture, joint plane and micro-fracture voids (the latter are referred to as 'cleats[1]'), as is illustrated in

[1] The vertical cleavage or fracture plane in coal seams. There are usually two cleat systems developed perpendicular to each other. The main set of joints along which coal breaks when mined. They provide the predominant pore space within the coal mass and can provide void space and a conduit plane for groundwater movement and storage.

Figure 60. They impart a generally low permeability characteristic to the coal material, which means that groundwater does not readily flow through the coal under natural conditions. Even under water well pumping conditions coal seams and petroleum reservoirs are seldom considered to be good aquifers.

The procedure for recovering the gas involves drilling a series of production wells into the targeted coal seams and then pumping out the groundwater contained within the coal layers. This process lowers the hydraulic pressure within coal seams, which in turn causes the release of the methane gas from the coal. Specifically, the reduction of pressure in the coal layers causes the methane to desorb from the coal matrix and form gaseous methane, which can be drawn off to the surface via the well.

Gas production is therefore closely linked to reservoir pressure reduction, achieved by groundwater extraction. The groundwater and gas extraction process is accomplished by operating a pump in the production well, typically set in the well casing at a location below the perforations at the coal seam and initiating groundwater extraction to lower the water level in the production well, and consequentially the piezometric head pressure in the coal seam layer.

Groundwater pumping continues until the gas flows freely. Often, no pumping is required once the gas begins to flow strongly as the velocity of the gas acts as a lifting mechanism for the groundwater and the pump may be removed. When the gas flow rate falls, and the groundwater can no longer be extracted by the gas lifting effect, a pump is again set back into the well to continue the groundwater extraction until the gas has been exhausted to an economic level.

Hydraulic fracturing is employed in the gas industry to improve the production efficiency of gas wells. This is achieved by increasing the overall permeability of the coal immediately adjacent to the wells and creating a more efficient pathway for the flow of groundwater and gas from the reservoir into the well bore.

Where necessary it is carried out as one of the last activities involved in the construction of a gas production well and prior to bringing the well into service. It is typically performed on newly installed production wells, that is, after the final (there are normally many) well casing pipe has been inserted and the bore annulus cemented, the casing pipe perforated opposite the target coal seams and the well opened to access the coal seam. Production wells may be subject to multiple fracturing events over their operational life.

A process referred to as ‘cavitation’ is also used to stimulate gas production wells. This method of well stimulation involves injecting air or nitrogen gas at high pressures into the coal seam causing it to fracture and break up. This method is not considered further here since no chemical additives are added to the compressed air used in the procedure.

4.4.1 Hydraulic Fracturing Design Process

As discussed in detail in **Section 4.2**, the borehole core retrieved from the drilling of the well hole, information gained and analysed from the geophysical logging of the borehole, geomechanical stress analyses and the analysed properties of the coal media are considered by Santos EQ's well engineering team to arrive at an appropriate well completion and hydraulic fracture design for the proposed well location.

The basis of the site-specific design for the well to be hydraulically fractured is to exploit the key coal characteristics and properties to optimise the fracture density, spread, orientation and containment. The restrictions considered include but are not limited to, the following key controlling features:

- The coal porosity
- Coal cleat orientation and density (from core and geophysical logs)
- Coal quality (brightness)
- Interbed (net coal) content, density, bedding and quantity
- Bedding plane configuration
- Bulk density, elastic properties and compressibility
- Coal seam thickness
- Thickness of 'seal' rock (aquitard layer) above the top of the uppermost coal seam and below the base of the lowermost coals seam
- Interburden thickness and rock strength
- Stress field analysis to determine the maximum principal stress direction and the minimum principal stress direction.

The well design process therefore accommodates detailed analysis of those parameters, which determine the hydraulic fracturing outcomes and containment within the coal seam concerned. These include defining the optimal location and orientation of perforations such that the zone of hydraulic fracturing is contained entirely within the target formation.

The importance of maximising the in-coal fracturing density and connectedness, whilst controlling the overall containment of the fracturing entirely within the coal seam itself is paramount in achieving a useful outcome. Any fracture, which moves outside of the coal seam, has the potential to connect to groundwater from a non-coal layer (say, an aquifer unit, e.g., The Springbok Sandstone). Such an outcome would result in an inefficient gas well since excessive groundwater would have to be extracted to achieve gas liberation. As such, the well would be costly to operate, inefficient and produce excessive water requiring costly treatment and handling. Hydraulic fracturing design is thus tightly controlled to avoid such occurrences.

Section 2.4.2 provides a discussion of the methodology employed by Santos EQ for the analysis of stress and rock strength in the development areas. It is generally undertaken in-house (geomechanics team). Borehole studies utilise image log data, wireline log data, rock strength testing and drilling experience to model the stress variation between geological rock units from surface to the target coal seams, namely, the Walloons and Bandanna Coals of the Surat and Bowens Basins sequences, respectively.

The tectonic contribution to the regional compressive stress field within continental Australia is reflected in the N-NNE orientated major horizontal stress field prevalent in the Surat and Bowen Basins. The minor horizontal stress will be approximately normal to this, viz. E-ESE. The horizontal in-situ stress can be relatively high and anisotropic and exceed the vertical stress due to gravity. These factors typically define the orientation and pressures employed in hydraulic fracturing in the Santos EQ Project Area.

Again as discussed in **Section 2.4.2**, at the local scale, this regional stress field (magnitude and orientation) will be affected by discontinuities in the rock mass such as faults, and close to the surface, by topography. The magnitude of horizontal stress will also be influenced by the geotechnical properties of the layered sedimentary rocks. The stiffer rock layers, such as sandstone with few discontinuities, will attract a higher stress magnitude compared to more jointed or fractured rock layers, such as coal, which will have a lower horizontal stress. Coal seams are fractured in nature with generally near vertical and horizontal cleats or joints, which can contain water and have a higher permeability compared with a less fractured sandstone layer.

Hydraulic fracturing is very carefully designed to create hydraulically induced fractures by applying highly controlled fluid pressures to the coal seam rock concerned. This induces new fractures in the rock for the fluid to migrate along as well as along existing fractures (cleats and joints). Typical hydraulic fracturing pressures are

designed to consider the overburden pressures amongst other factors. Fracturing may be of the order of 7 to 100 megapascals (1,000 to 15,000 pounds per square inch (psi)) depending on location and depth of the coal seam being fractured and its geotechnical properties. Thus, the induced fractures are likely to be near vertical in a vertical borehole and orientated parallel to the major horizontal in-situ stress direction and likely to truncate along a low shear strength plane such as the top of a coal seam.

Casing isolations are used to isolate the fracture pressures to the target coal seams and to limit the potential for fracturing of sequences above and below the target interval. In addition, extensive monitoring is conducted to assess the fracture propagation and ensure it is contained within the targeted interval. Further discussion of the fracture-monitoring program is provided in **Section 4.4.3**.

4.4.2 The Physical Process of Hydraulic Fracturing

Hydraulic fracturing uses specially designed fluids, primarily consisting of water and sand, mixed on the surface and then injected down into the well and then through the perforations into the coal seam. Typical wellhead and possible fracture stimulation downhole equipment are shown in

Figure 61.

As discussed above, the hydraulic fracturing process occurs under varying positive high hydraulic pressures in order to physically fracture the coal matrix. The hydraulic fracturing fluids are injected through perforations in the steel well casing pipe. The perforations are 10 to 20 mm diameter holes created in the steel casing pipe and surrounding cement seal using a projectile or a high-pressure water jet.

The hydraulic fracturing fluids are injected from the surface via the wellhead works on the surface with either a coil-tubing or bridge plugs, balls and baffles used to isolate the coal seam to be fractured. The coil tubing wellhead works and setup are shown in

Figure 61 and the bridge plug or ball and baffle isolation tools are shown in **Figure 62**.

Alternative methodologies, such as multi-zone hydraulic fracturing process [e.g., Just In Time Perforating (JITP© process)] are also used in select circumstances. This process simply uses a top packer and perforation balls to provide isolation below the targeted perforation. Identical to the coil-tubing and bridge plug and packer approaches, the JITP© hydraulic fracturing process is conducted from the bottom upwards. However, unlike the previous methodology, the process is more streamlined with perforation balls used to provide the required zone isolation in the previous perforated and hydraulically fractured intervals. The perforation balls are injected at each subsequent hydraulic fracturing injection cycle to clog the perforations of the previous intervals prior to perforation of the new interval and the commencement of fracturing in this interval.

The fracture or fractures (a network of fracture openings are typically generated along inherent planes of weakness, the cleat and bedding planes) created in this manner radiate outward into the coal matrix in the immediate vicinity of the well, with fracture radii potentially up to 200 m (**Figure 63**, **Figure 64**, and **Figure 65**). These fractures provide open and connected pathways for the groundwater and gas to more efficiently flow to the gas well than would otherwise be the case.

During the hydraulic fracturing process, the hydraulic fracturing contractor closely monitors down hole pressure and hydraulic fracturing fluid viscosity (if gel-based systems are being used). This allows the hydraulic fracturing contractor to optimise the performance of the hydraulic fracturing process, and rapidly identify unexpected pressure changes that could indicate a loss of well or confining layer integrity, and hence trigger a hold point for the hydraulic fracturing operation. Further discussion of the monitoring process is provided in the sections below.

Technically speaking, the zone of fractured coal material created in the coal seam around the gas well (as illustrated on **Figure 65**) provides highly conductive channels that more effectively drain the coal seam of its adsorbed gas (i.e., it increases the ‘effective radius’ of the well from the typical casing pipe radius of up to 200 mm diameter to potentially up to 200 m). In the absence of fracturing, as groundwater and gas flows towards a coal seam well, flow rates are reduced as the flow converges radially inwards towards the well screen due to the tortuousness of the pathways to the well. This flow throttling effect is minimised considerably by the fractured rock mass when compared to the un-fractured rock mass due to its improved permeability. These new fractures also allow the gas to travel much more freely from the natural fracture cleat system and in the surface matrix of the coal, where it is trapped, to the gas production well.

In the case of Santos EQ, most of the gas wells are vertically orientated and intersect the coal at a near right angle. Increasingly, Santos EQ is employing inclined wells (referred to as ‘deviated’ wells) and horizontal wells, which intersect the coal seam at an angle.

As discussed above, because of the existing stress field properties prevalent within the Santos EQ Project Area, together with the generally horizontal nature of the bedding layers of the coal seams and its brittle nature, the fractures created by the hydraulic fracturing process, are largely contained within the coal seam. The likelihood that the fracture extends into the overlying and underlying sedimentary rock layers is considered remote, with very limited probability of fractures intercepting heavily used aquifer systems. Overlying rock types include shales, siltstone, mudstones to sandstones, which are strongly horizontally bedded rock types.

It is noted that the aquitard formations that predominantly separate the coal from the developed aquifer formations typically behave elastically and would therefore respond to applied stresses through ductile deformation rather than brittle fracturing. They would therefore be expected to resist fracture propagation beyond the target coal seam and truncate along a low shear strength plane such as the top or bottom of a coal seam.

4.4.3 Operational Monitoring and Reporting of Hydraulic Fracturing

As described above, continuous monitoring of the casing pressure and fluid viscosity during the hydraulic fracturing process provides feedback to optimize performance. Any significant changes in pressure are closely monitored to immediately identify conditions that would indicate loss of well integrity or overburden layer integrity.

Pressures are closely monitored or calculated during the activities in two critical areas:

- Inside the casing delivering the fluids.
- Calculated bottom hole pressures based on wellhead pressure, fluid densities and casing diameter and depth to the target formation.

Where a coiled-tubing tool is used, the pressures can be monitored in three areas:

- Inside the open space above the tool within the casing.
- Inside the tubing delivering the fluids.
- Inside the gas wellhead at the surface, which is outside production casing and inside surface casing.

Casing (or tubing if coiled-tubing tools are used) pressure indicates the delivered pressure to the rock underground and is used to gauge job performance in breaking down the formation and delivering fluid and proppant into it. Where bridge plugs or ball and baffles are used for isolation, temperature surveys and negative pressure testing of the bridge plugs can be conducted to assess fluid communication across the plug or packer.

Where coiled-tubing tools are used, the casing pressure monitors any fluid communication from the treatment zone to the area above the top packer. The wellhead pressure indicates if any fluid or pressure has migrated behind casing to the surface.

The casing pressure helps assess the height of fracture propagation, as perforated zones will show an increase in pressure. The safe margin for interval spacing is the upper height limit of fracture growth, based on performance, volumetric assessment and fracture modelling. Typically, the fractures propagate horizontally with very little height propagation.

In addition to process pressures, the flow rate and total volumes of hydraulic fracturing fluids are monitored. Changes in the flow rate in conjunction with pressure changes are utilised along with modelled simulations to determine the performance and propagation of fractures.

Good process monitoring and quality control during the hydraulic fracture treatment are essential for carrying out a successful treatment and for protection of the groundwater. There are certain monitoring parameters that should be observed in virtually all hydraulic fracture treatments, and others that are employed from time to time based on site-specific needs.

Sophisticated software can be used to design hydraulic fracture treatments prior to their execution and during the treatment to monitor and control treatment progression and fracture geometry in real time. During the hydraulic fracture treatment, key parameters are continuously monitored, including surface injection pressure, slurry rate, proppant concentration, fluid rate, and proppant rate.

The data that are collected are used to refine computer models that are used to plan future hydraulic fracture treatments. In areas with significant experience in performing hydraulic fracture treatments, the data that are collected in a particular area on previous fracture treatments are a good indicator of what should happen during the treatment.

Following the hydraulic fracturing activities for the gas well location, a close-out report is prepared providing the details the real-time monitoring, assessments, injection volumes and quality control reporting.

4.4.4 Hydraulic Fracturing Process Description and Methodologies

The process of hydraulic fracturing involves a stepwise implementation of a series of tasks, including pre-hydraulic fracturing well improvement tasks, and fluid injection and extraction events using a combination of specialised equipment. These events are referred to in the following terminology:

- Well casing perforation acid injection – only occasionally employed to open the coal seam cleats where they are filled with natural calcite
- Pad volume injection – hydraulic fracturing fluid, which sometimes preceded by a water injection
- Slurry volume injection – hydraulic fracturing fluid mix plus sand

- Flush volume injection – hydraulic fracturing fluid
- Flow-back – extraction of injected fluids.

The hydraulic fracturing process tasks are undertaken as a series of sequential tasks carried out with pauses in-between event types.

The following sections describe the stimulation-site equipment, the sequence of injection/flow-back events and hydraulic fracturing fluid constituents required to carry out a hydraulic fracturing event.

4.4.5 Infrastructure and Equipment Used

A hydraulic fracturing setup typically consists of the following key pieces of equipment (see **Figure 66** and **Figure 67**):

- 'Clean Fluids' Pit or Turkey's nest or Frac Tanks– Water for hydraulic fracturing is either stored in a clean fluids pit (a lined excavation such as a turkey's nest) or in Fracc Tanks/Concept Tanks. The water used for hydraulic fracturing is usually untreated groundwater pumped from the coal seam/s or blended water from a water management facility. A biocide (bacteriacide) is added to this water to eliminate and settle out algal growth prior to the hydraulic fracturing process. The lined pond or tanks provide temporary storage of the water used in production of the hydraulic fracturing fluid mixes used during the various stages of hydraulic fracturing.
- Hydration Units – water from the pond is pumped into a blending device where it is mixed with a guar gum powder/solution. The blend is then sent to the hydration unit where guar gum hydrates (absorbs water) over a period of several minutes. This produces the 'guar slurry' which is the prime constituent of the hydraulic fracturing fluid (aside from water and sand).
- Sand Trailer Unit – which is a large sand trailer that holds the 'proppant' (fine graded quartz beach sand) and delivers it to the blender unit in a measured rate when it is required in the second stage of hydraulic fracturing.
- Blender Unit – mixes the hydraulic fracturing fluid ingredients 'on-the-fly' (OTF) and, later, the hydraulic fracturing fluid chemicals plus sand proppant.
- High Pressure Pumps – draw in the specific hydraulic fracturing fluid mixtures from the downhole blender unit and then pressurises this fluid mix prior to injecting it into the particular coal seam being fractured.
- Control or 'Data' Unit – is the central control room from which all the hydraulic fracturing equipment is electronically controlled (it is provided for the automated preparation of the hydraulic fracturing mixtures and injection pumps).
- 'Coil Tubing' Unit – remains sited over the well installation to provide the means of precisely injecting the hydraulic fracturing fluids. This comprises a crane or similar to support a coil of steel tubing, which is uncoiled and/or lowered down the well to facilitate the hydraulic fracturing. This equipment supports the packer system, which isolates the specific coal seam proposed for hydraulic fracturing).
- Wireline Unit - provides a means of running isolation plugs and perforating zones.
- Flowback Tanks – acts as a receiving pit for the initial flow-back of fluids leaving the well annulus during and immediately after the hydraulic fracturing process. It is typically put in place to provide a recirculation and sedimentation pit for the drilling fluids during the well borehole-drilling phase of the well construction and is reused during hydraulic fracturing. Once the initial flow back is removed, the production water (also referred to as Associated Water) is pumped from the well and directed to the frac tanks for re-use (in its untreated form) or treated in an on-site Water Treatment Plant (WTP) for beneficial reuse or directed to the conveyance network for management within the coal seam water scheme.

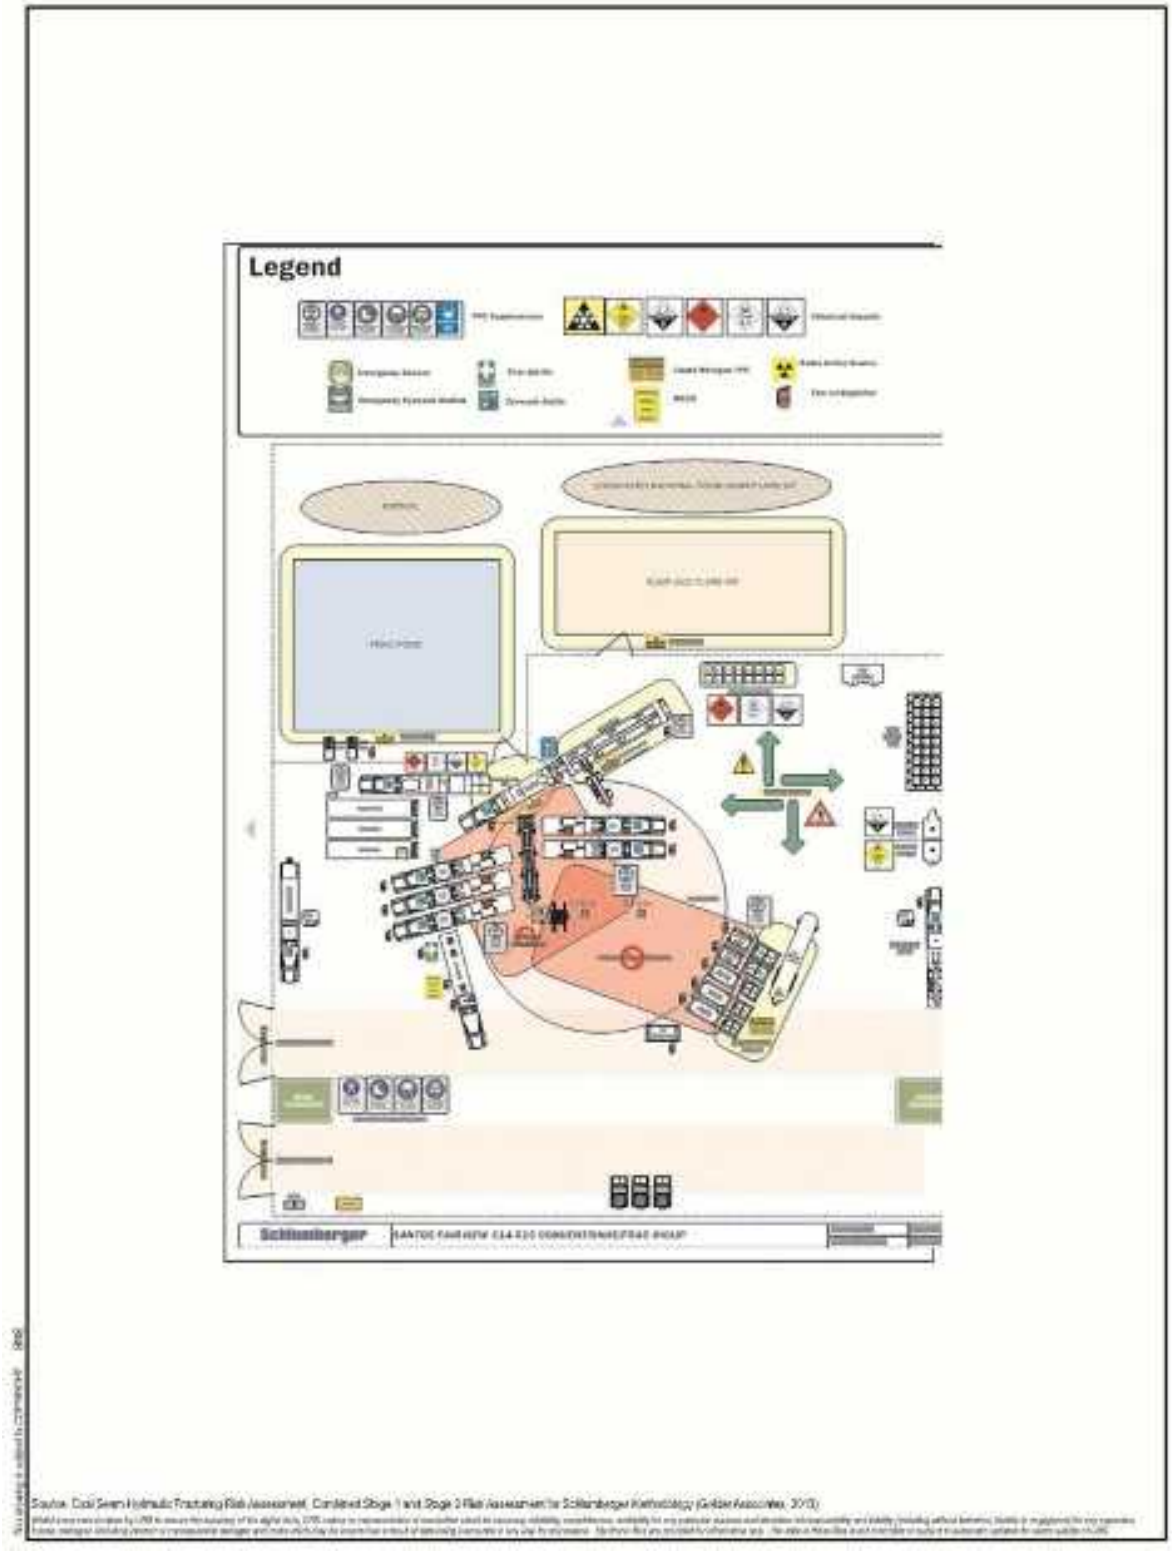

Figure 66. Diagrammatic Layout of a Typical Hydraulic Fracturing Operation on a Well Lease[2]

[2] Note: In CSG operations, frac ponds and flare pits have been largely replaced by frac tanks and flowback tanks, respectively.

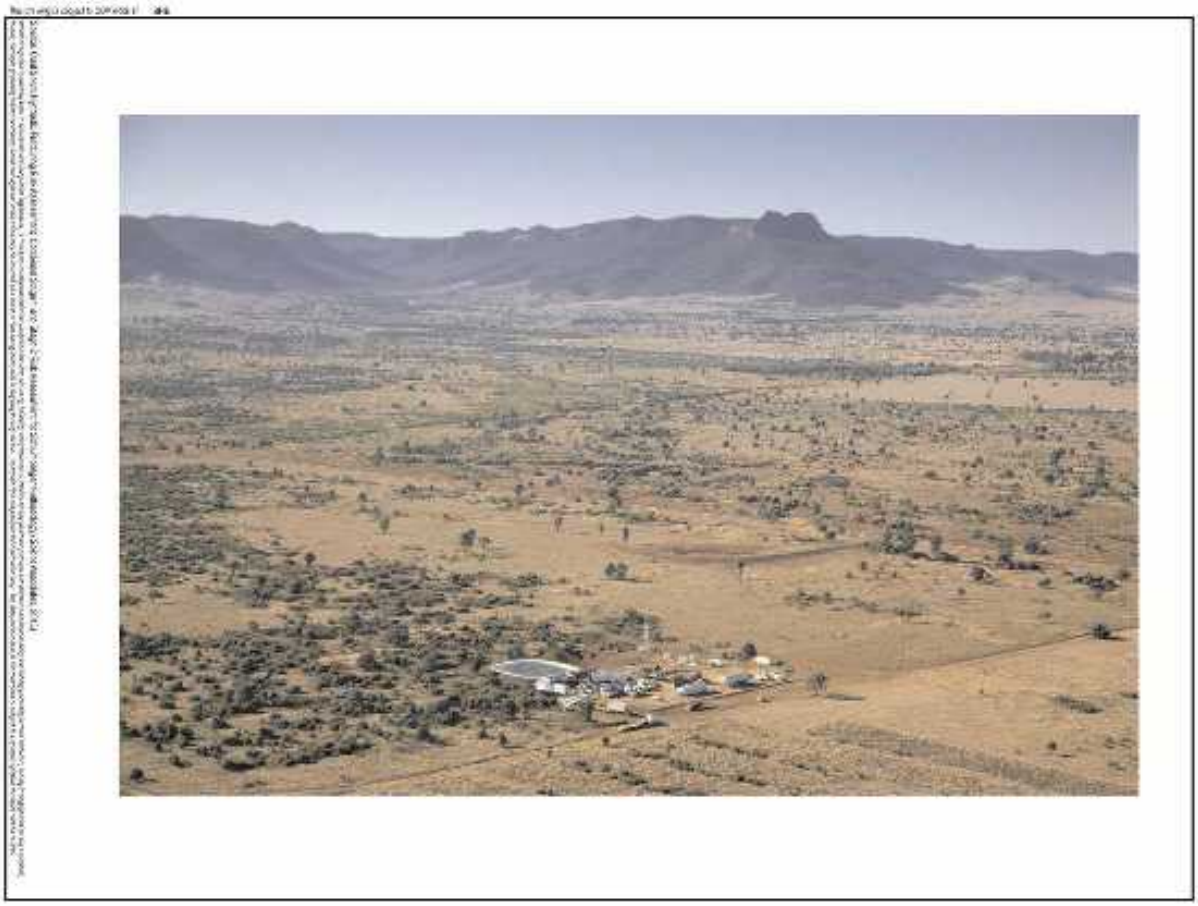

Figure 67. Photograph of a Typical Hydraulic Fracturing Setup Operation on a Well Lease

4.5 Stages of Hydraulic Fracturing

Hydraulic fracturing events are individually designed in detail as part of the well completions design process described in **Section 4.2.** The design input parameters are described in that section.

As part of the hydraulic fracturing process detailed fracture modelling is intermittently performed to refine field designs using computer modelling methods.

- Equipment requirements (depth, pressures and water requirements) and personnel
- Fracture fluid type/s and volumes required
- Likely fracture pressure profile (for real-time comparison with that monitored in the field during the fracturing event)
- Fluid pumping and staging
- Flowback design and prediction
- Logistics for materials procurement, handing, transport, site management, site mobilisation and demobilisation.

4.5.1 Well Perforation

Holes are created in the well casing pipe at locations, which align to the centre of the coal seams targeted for gas production; these are referred to as ‘perforations’. A section of the casing pipe approximately 1 m long is selected for perforation to allow the well to discretely access the coal seam. They are generally aligned slightly below the midpoint of the coal seam being fractured to accommodate the tendency for upward propagation of the fracture, in the direction of least stress.

The perforations are created by one of two methods. The first method used small explosive devices which blast a hole, approximately 10 mm in diameter, at a density of 6 shots per foot of well casing.

The second method used is referred to as 'water' or 'sand jetting' and involves blasting a jet of water or of fine sand and water mix at high pressure at the well pipe wall to abrade a hole in the pipe. Both methods penetrate the steel casing and the cement layer, and into the coal seam by up to a metre.

4.5.2 Acid Injection (if required)

If the coal seam cleats are found to be naturally filled with calcite mineral (calcium carbonate) then a dilute acid mix can be injected through the perforation holes into the coal seam to dissolve the calcite away prior to hydraulic fracturing. This is rarely performed. It is carried out after completion of the well casing and perforations, but prior to hydraulic fracturing. The selected coal seam can be pressurised with a 15% solution of hydrochloric acid (with preservatives).

It is noted that acid injection also results in some degree of aggressivity towards the cement in the bore annulus within the injection zone. However, given the relatively short duration of the acid injection the potential impact to the annular seal integrity is likely to be minor and localised to the immediate vicinity of the well perforations.

4.5.3 Pad Volume Injection

Pad volume injection is the initial hydraulic fluid mix being pumped down to the targeted coal seam stages. The pad volume is mixed on the surface prior to being injected down the casing, tubing or coiled tubing to the selected section of perforated well casing (adjacent to the coal seam being fractured) where coal fracturing is to occur.

The process of mixing additives is automated and is prepared dynamically (OTF) within specialised mixing equipment. The pad volume slurry comprises a mix of water (typically 99.5% by volume and usually comprises groundwater obtained from the coal seams) drawn from the frac tanks together with several preservatives and stabiliser chemicals. This system can comprise fluid systems as simple as water and weak organic acids through to complex gel-based systems. Gel based systems are typically preferred in settings where the coals are potentially more transmissive and/or fractured to minimise the amount of fluid loss and increase pressure of the formation and facilitate more widespread fracturing.

Where gel-based systems are used these typically comprise dehydrated cellulose or guar gum-based systems. Where a cellulose and guar gum is used, this is allowed to hydrate in a baffled tank, referred to as the Hydration Unit, for several minutes prior to adding further ingredients, which stabilise and thicken prior to being diluted with the water. The viscosity of the fluid at this point is typically 3 centipoise (cP), marginally greater than that of water.

Guar gum is a vegetable product, which is ground into a powder and used to create a viscous liquid for hydraulic fracturing(Economides and Martin, 2007).

Simultaneously, additives including cross-linker, stabiliser and thickener ingredients are added to the guar gum hydraulic fracturing slurries used by Santos EQ, including:

- Borate may then be added to cross-link the guar gum (depending on coal seam properties), raising the viscosity from 3 to 300 centipoise (a gel consistency)
- A biocide is added to knock out bacteria which could destroy the gel
- A buffering agent (e.g., potassium carbonate) is added to keep pH above 8.

At this point, the guar gum and associated ingredients comprise approximately 0.050% by volume of the pad volume slurry with the viscosity of the final hydraulic fracturing fluid being typically up to 300 cP, which is essentially a gel consistency (refer to

Figure 68).

The viscous hydraulic fracturing fluid is then injected down into the coal seam at a rate of approximately 10-17 bbl/min, and a pressure of up to 6500 psi for coiled tubing fracs, or at a rate of approximately 10-40 bbl/min and a pressure of up to 8500 psi for plug and perf fracs. The injection pressure is a function of the formation properties and well construction. The injection process continues until pressure drops or stabilises, indicating that the coal seam has 'cracked' or fractured under the pressure. This progressively drives the pad volume further out into the coal layer propagating the fractures to a maximum distance of up to 200 m. At this point, the injection of the pad volume ceases, and the injection of the slurry volume commences in a continuous and uninterrupted fashion.

4.5.4 Slurry Volume Injection

Immediately after the coal has been fractured and the pad volume injection ceases, hydraulic fracturing immediately proceeds to injection of the slurry volume. The slurry volume differs only in its content from the pad volume by the higher measured quantities of specifically graded quartz sands or manufactured ceramic grains, referred to as the 'proppant'. The process may start with fine graded proppant, progressing to coarser grades of proppant as the slurry volume injection stage progresses. Typical proppant grades used in Santos EQ wells can include: 100 Mesh, 40/70, 30/50 and 20/40 (shown in **Figure 69)**.

On completion of the hydraulic fracturing program, a known volume of slurry has been injected into the fractured coal and the fracture stimulation ceases.

Where gel-based systems have been used, breaker compounds are added at progressively increasing concentrations throughout the slurry volume injection. The breaker comprises an oxidizer or enzyme compound that breaks the chemical bond of the gel reducing the viscosity. Water based systems do not require the use of breakers and enzymes.

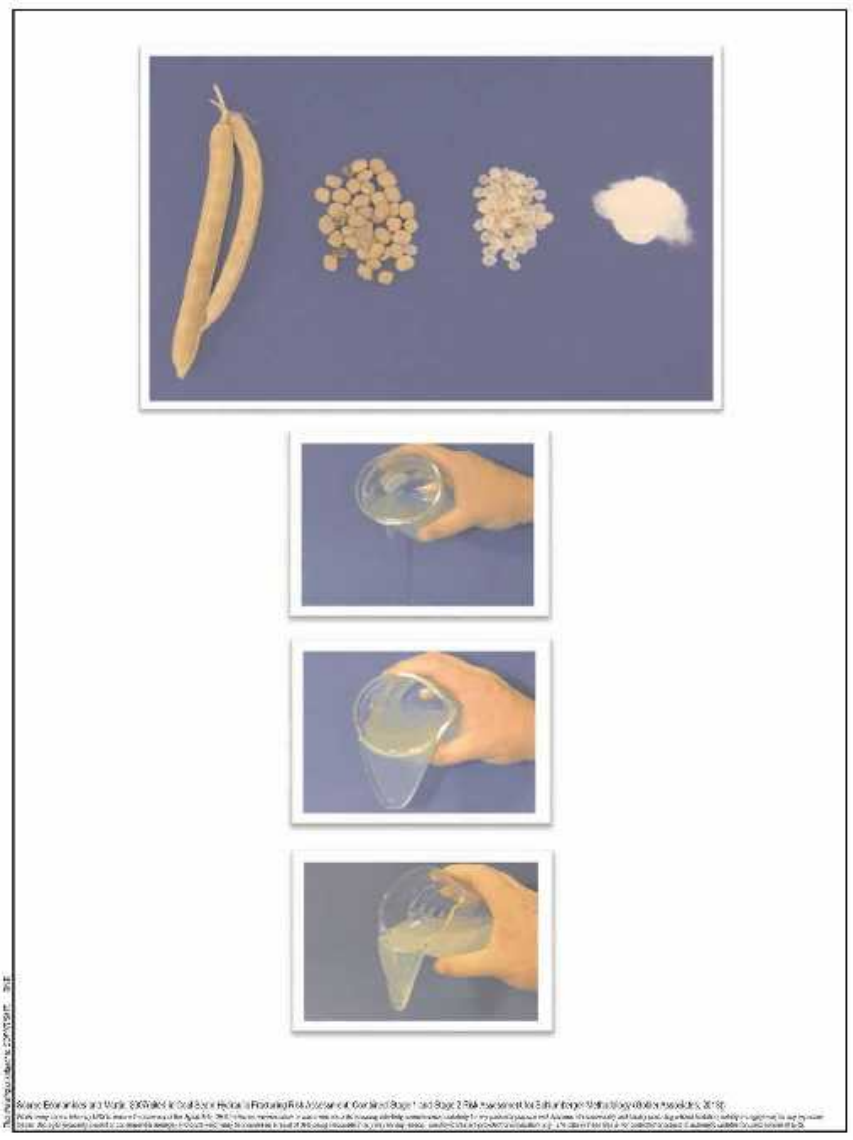

Figure 68. Guar Gum – Illustrating its Various Forms (Top) and Stages of Cross-Linking to Achieve 300 cP (Bottom)

The duration of the stimulation event and the slurry concentrations and volume are based on data from testing investigations on the coal seams (including drill stem tests and coal analysis data) and are tailored specifically to the coal seams and well characteristics as calculated using computer-based modelling.

The above procedure is carried out for each coal seam present in the target gas beds. In the case of Santos EQ's Project area, this equates to between three and twelve coal seams. Typically, up to 7,000 barrels (1,100 KL) of formation water carrying the hydraulic fracturing fluid is injected per well, with 600 to 1,400 barrels required per coal seam. Stimulation begins with the lowermost coal seam, working progressively upward through the various coal seams to be targeted. The well can be progressively perforated and fractured from the base of the well upwards. Composite plugs may be used to isolate the deeper sections after completion of the first fracture stage. This ensures that only the coal seam is pressurised during the hydraulic fracturing event for each seam.

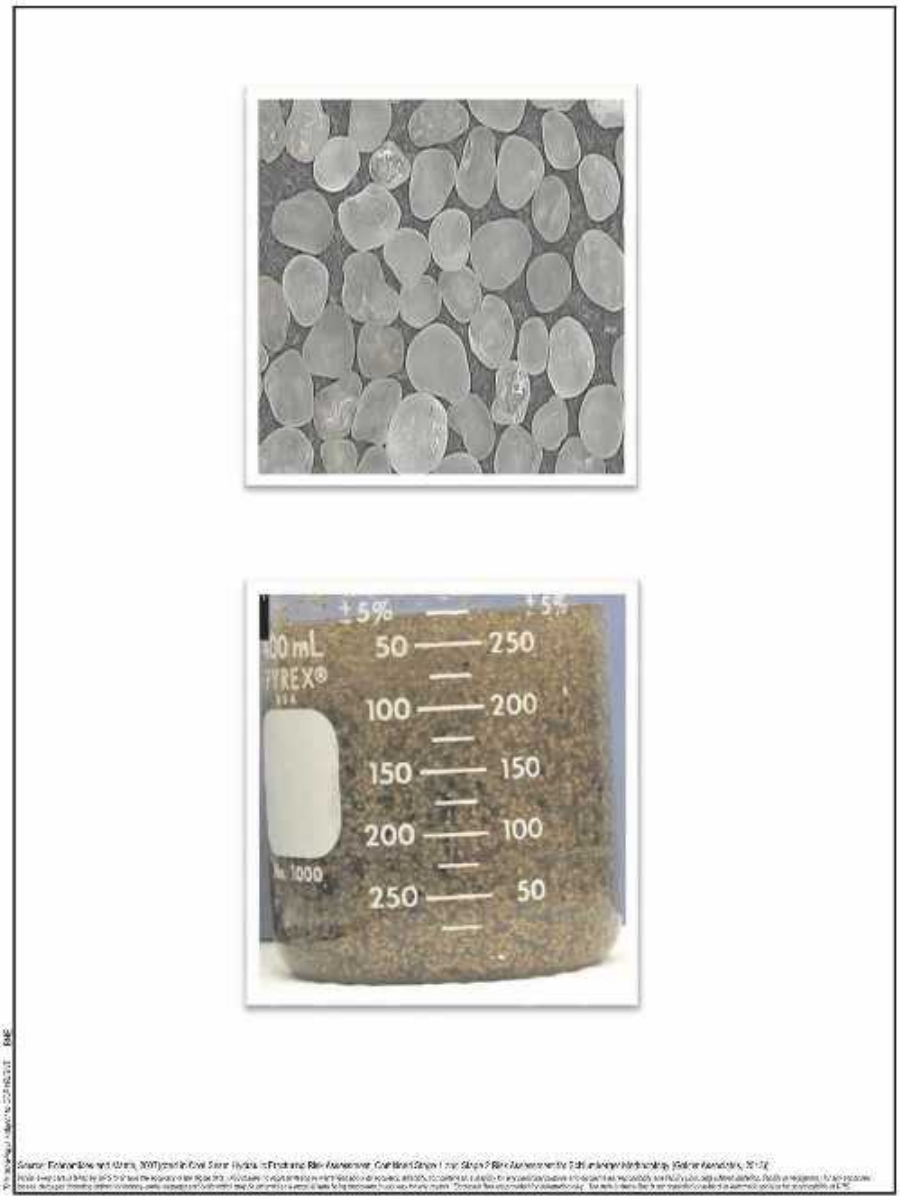

Figure 69. Typical 20-40 Grade Sand (Top) and Sand-guar Gum Fluid Mix (Bottom)

4.5.5 Flush Volume

Where required and between fracturing events a volume of hydraulic fracturing fluid, equivalent to the wellbore volume, or coiled tubing volume, down to the top of the perforations (20-100 barrels), is pumped to flush the slurry into the target formation. Since the coal seams are still pressurised following the final slurry volume injection, they are then allowed to depressurise. This allows residual fluids to flow to the surface under the residual pressure. These fluids are captured in the flowback tank and are recycled or disposed.

4.5.6 Initial Flowback and Well Completion

The initial flow back only occurs during removal of equipment and depressurisation of the well after hydraulic fracturing. Not all wells provide an initial flow back as insufficient pressure may exist for fluids to flow from the well. The flowback fluid is captured in tanks, the fluid consists of hydraulic fracturing fluid and potentially some solids (proppant, coal fines, etc.).

Hydraulic fracturing fluid not returned during initial flowback remains in the formation and is recovered during the production phase of the well. There is an indeterminate amount of hydraulic fracturing fluid lost in far reaching fractures that may never be recovered.

Once initial flowback is complete, typically a workover rig is used to drill out any plugs, clean out the wellbore and install the initial completion which typically consists of tubing, pump and rodstring.

4.5.7 Commissioning and Production

After the well has been completed with the required equipment, and gathering and surface equipment installed, the well is commissioned and put on production. Production pumping continues for the life of the well, with groundwater extraction over that period ranging from 2 ML to 25 ML. This flow is likely to flush all the available (mobile) components of the original hydraulic fracturing fluid, which may remain in the coal seam after flow-back.

The water produced during this phase is referred to as production or associated water and is not considered to be flowback. While low levels of chemicals associated with hydraulic fracturing may be detected in the water, the water quality reflects the general properties of CSG water. The pump will remain in the well in the long term for the purpose of pumping produced water. The associated water pumped from the well is of a quality suitable for management within the coal seam water management systems.

4.5.8 Timing of Hydraulic Fracturing Process

The hydraulic fracturing of a typical well of three to four seams takes two to four days to complete (noting that there are between 3 and 12 such coal seams in Santos EQ Project Area, this timeframe could extend up to 10 days).

The fracturing of each seam is carried out as a full sequence of each of the stages described above – the cycle being carried out to completion before moving to the next seam. Typically, seam fracturing is initiated with the lowermost seam planned for fracturing, moving progressively upward through the targeted seams.

The Well Completions Team then takes over to install the ‘completion’ equipment (pump, headworks and gas-water separator) and delivery pipelines (gas and coal seam water).

4.6 Program of Wells to be Fractured

Selected wells will be fractured prior to being brought into production, involving the various tasks described previously. Santos EQ has indicated that approximately 70% of wells will be fractured over the remainder of the field life in the Fairview, Denison, Scotia and Arcadia development areas and approximately 50% in the Roma development area. However, it is important to note that all wells have the potential to be hydraulically fractured at one or more point in time as operational requirements vary.

Once or twice during the life of the well, the wells may be subjected to additional hydraulic fracturing events, or the fractures may be ‘cleaned’ using nitrogen gas under high pressure. These processes are designed to open new pathways for gas and water to migrate to the well or flush out fine silts and clay particles which may contribute to clogging the fracture/s over time. Production wells in the Project area may require this re-fracturing.

According to information provided by Santos EQ, the average well spacing between gas wells is likely to range between 600 and 880 m.

Given the uncertainty in future hydraulic fracturing locations during field development planning, it has conservatively been assumed in this assessment that all gas well locations have the potential to be fractured; potential receptors for hydraulic fracturing operations (i.e., nearby water supply wells) have been assessed on this basis.

Santos implements the required notification and reporting requirements prior to the drilling of wells and the planning and execution of hydraulic fracturing activities. No hydraulic fracturing is conducted on a well without appropriate testing of the well, provision of well completion and testing records to the DNRME and the notification of proposed hydraulic fracturing (which includes the hydraulic fracturing design and proposed fluid systems). Further discussion is provided in the section below.

Based on the process of well drilling selection, no wells are established proximal to any structural faults or discontinuities that could lead to be vertical migration of fluids and gases into overlying aquifers, especially since the purpose of hydraulic fracturing is to facilitate gas recovery. Based on the Constraints Protocol (as described in **Section 1.3**) and stakeholder engagement, no wells are located within 500 m on potable bores and homesteads even where there is greater than 200 m vertical separation.

In accordance with the Code of Practice requirements, a risk evaluation is conducted for all wells and proposed hydraulic fracturing programs to ensure that areas where vertical migration into environmentally sensitive areas (eg. aquifers) could potentially occur and/or environmentally sensitive areas are avoided.

4.6.1 Regulatory Notification and Approval Process for Well Installation and Hydraulic Fracturing

As documented above, a Code of Practice and specific regulatory requirements for well completion and hydraulic fracturing are prescribed in Queensland. DNRME has rigorous requirements for notification and reporting which require the completion of numerous reports and the provision of completed registers. This process is designed to ensure that hydraulic fracturing is only conducted on appropriately constructed and tested wells which have been completed in approved areas of the Basin away from faults and other structural features that may impact on well performance and/or potential impacts to overlying aquifer systems.

The formal reporting process includes the development of prescribed assessments and reports that must be formally lodged online (http: geolodgement.drme.qld.gov.au). The specified reports include:

1. Prenotification of drilling and well installation activities
2. Prenotification of hydraulic fracturing activities (including landowner notifications)
3. Regulatory Notification of Completion of Hydraulic Fracturing – This comprises submission of DNRME Form PGGD-04 immediately on completion of the hydraulic fracturing activity.
4. Hydraulic Fracturing Activity Report – This report is filed online (typically within 90 days of completion the hydraulic fracturing event and includes the submission of:
    a. The Hydraulic Fracturing Vendors Hydraulic Fracturing Completion Report which documents:
        i. The well hydraulic stimulated, the stimulation method and chemicals
        ii. Pressure and flow monitoring data from the hydraulic fracturing event
        iii. Assessment and analysis of data to determine if the hydraulic fracturing activity was successful and if any matters of concern were identified during execution of the work.
5. Completion/Update of the DNRME submission template for each well including status and performance of:
    a. Tubing/Vasing
    b. Perforations
    c. Well Completion
    d. Additives/Chemicals Used
    e. Well Testing
    f. Well Treatments
    g. Water Analysis

4.7 Chemical Constituents in Hydraulic Fracturing Fluid Systems and Mass Balances

Several hydraulic fracturing vendors will potentially be undertaking hydraulic fracturing activities within the Santos EQ fields. These vendors all have multiple fluid systems with differing chemistries. The variability in fluid systems is primarily a function of the use of either water and gel-based systems and foam and non-foam versions. In addition, vendors use different biocides, breakers and enzymes in their gel-based systems.

The mass balance for these fluid systems including their respective Chemical Abstracts Service Registry Numbers (CASRN) is provided in the vendor specific Appendices (**Appendix C**). In addition, Toxicological Summaries are provided for the individual chemical compounds.

It should be noted that the information provided in the appendices will inevitably vary from, other published sources of hydraulic fracturing fluid compositions, as the specific hydraulic fracturing fluid mixtures are proprietary products of the hydraulic fracturing contractors and their product suppliers.

None of the fracturing fluid chemicals identified by the contractor contain benzene, toluene, ethylbenzene, xylenes (BTEX) or polycyclic aromatic hydrocarbons (PAHs). It is noted, however, that BTEX and PAHs occur naturally in coal, and it is possible that certain PAHs may naturally be present in the coal seam groundwater used in the hydraulic fracturing process. In terms of the reaction by products of these chemicals, none of the reaction by products is known to exhibit higher toxicity than the parent compounds. However, it is recognised that geochemical reactions in the formation are complex, and these will have to be assessed on a site-specific basis.

5 Risk Assessment Framework

The information provided in this section addresses the following EA approval requirements: conditions (q), (r) and (s).

5.1 Overview of Risk Assessment Process

A weight-of-evidence approach has been used by Santos EQ to evaluate the potential for human health and environmental (e.g., ecological) risks as a result of the hydraulic fracturing processes. In development of the risk assessment, the Site setting, landuse, hydrogeological conditions and beneficial uses of groundwater were considered.

The risk assessment involves a systematic assessment of the toxicity of the chemicals used in hydraulic fracturing and the potential for exposures to humans and ecological receptors. During this process, key constituents of potential concern are identified, and the effectiveness of exposure controls are considered. Through the process of evaluating potential exposure pathways, fate and transport modelling was also conducted to assess the mobility of chemicals within the coal seams. These components of work make up the qualitative component of the risk assessment.

The quantitative risk assessment utilised methodologies outlined in the National Water Quality Management Strategy (NWQMS), National Environment Protection (Site Assessment) Measure (NEPM) and enHealth methodologies. This risk assessment methodology evaluated the potential risks posed by the combined mixture of chemicals and where flowback data was available, the combined risks posed by hydraulic fracturing chemicals and naturally occurring geo-genic constituents.

Collectively the qualitative and quantitative assessment components make up the risk assessment methodology for the various fluid systems used in hydraulic fracturing. Details regarding the methodology of these components are discussed in the following sections with short salient summaries of their objectives as follows:

- **Section 6** – Qualitative Risk Assessment – a hazard assessment that includes a persistent bioaccumulative and toxic (PBT) substances assessment and defines which hydraulic fracturing fluids may potentially present a risk, based on the toxicity demonstrated in the PBT assessment, and the persistence and bioaccumulation that facilitates their potential for exposure by human and ecological receptors.
- **Section 7** – Exposure Assessment - involves the evaluation of the data available for the study, the details associated with the surrounding environment, the nature of the exposure identified and the potential mobility of the COPC to identify potential complete exposure pathways and receptors.
- **Section 8** – Quantitative Risk Assessment– includes the quantitative calculations for the exposure assessment and risk characterisation, and toxicity estimates for the hazard assessment, by incorporating exposure models to evaluate potential exposures to human and ecological receptors and estimated the potential risks to these receptors from the exposures.
- **Section 9** – Other Risks – assessment of risks from modifications of previously assessed fluid systems and proppants, as well as the assessment of potential risks not directly related to the COPCs in the fluid systems including noise, vibration, air quality, and radiological exposures.

The general findings from the risk assessments are provided in **Section 10**. The detailed assessment and results for individual hydraulic fracturing fluid systems are summarised in **Appendix C**. These summaries have been set up with headings based on the various assessment methodologies described above.

It should be noted that **Sections 6** and **7** make up the qualitative components of the risk assessment. The exposure assessment conducted as part of the qualitative assessment serves as the basis for the quantitative risk assessment, with assessment only completed on potential exposure pathways.

5.2 Tiered Framework Process

For chemicals used in stimulation activities since January 2020, a tiered assessment approach has been employed to streamline the risk assessment process. This process, hereafter referred to as the Chemical Risk Assessment Framework (CRAF), aligns with chemical assessment guidance provided by NICNAS and approach

used for industrial chemicals and aligns with Commonwealth Approval requirements. This allows for a defined and streamlined process to:

- Identify low hazard chemicals that can be addressed simply through a hazard assessment process;
- Identify higher hazard chemicals that should be assessed through completion of a quantitative risk assessment;
- Identify very high hazard chemicals that should be encouraged not to be used as part of the process;
- Identify very high hazard chemicals that cannot to be used as part of the process; and
- Incorporate the outcomes of the assessment into environmental mitigation and management controls.

This approach incorporates best practice risk assessment methodology to evaluate potential risks and effects of chemicals used during stimulation activities to environmental values and demonstrate that potential risks to environmental values have been eliminated or reduced as much as reasonably practicable. The methods used for qualitative risk assessment, toxicological assessment and the quantitative risk assessment align with the best practices referenced in the previous methodology with the only difference being that assessment is completed on a chemical-specific basis. On the basis that the potential risk in a fluid system is driven by higher Tier chemicals (Tier 3 and 4) this methodology is considered to effectively evaluate potential human health and ecological risks. Tier 5 chemicals will not be used.

This assessment process is designed to align with national guidance and other regulatory frameworks and assesses the full lifecycle of chemicals that are stored, handled, used and/or disposed of during or following hydraulic stimulation activities and in the treatment of produced formation water. Accidental release scenarios are not included.

The framework involves a two-step process:

- Step 1 – classification of chemicals (**Section 5.2.1**).
- Step 2 – assessment of chemicals (**Section 5.2.2**).

5.2.1 Classification of Chemicals

In accordance with the CRAF, chemicals are classified into five Tiers (Tier 1 through 5) based on the following criteria:

- Assessment of whether chemicals are identified on chemical databases used by NICNAS as indicators that these chemicals are of concern. These included:
  - European Union Substance of Very High Concern (EU SVHC).
  - US National Toxicology Program (US NTP) Report on Carcinogens or International Agency Research on Cancer (IARC) Monographs.
  - European Commission Endocrine Disruptors Strategy - list of Category 1 substances with endocrine disrupting capacity.
  - Chemical Substances Control Law of Japan (CSCL) Class I and II Specified Chemical.
  - Polymers identified as of low concern by NICNAS
- Completion of a formal PBT substances assessment (using environmental reference values contained within the categorisation guidelines) and the factors discussed in the meeting to develop the tiered framework.
- Evaluation of any other concerns associated with persistence in the environment (especially for inorganics) which is not captured in the PBT assessment but may be a consideration in the context of project activities (for example, irrigation of produced water).

The criteria to be used in the chemical category classification within this framework is provided as **Appendix D.1**.

A low-risk chemical is defined as a chemical that is not identified as a PBT chemical and is not listed as a chemical of concern on the following databases:

- EU SVHC.
- US NTP Report on Carcinogens or IARC Monographs.

- European Commission Endocrine Disruptors Strategy - list of Category 1 substances with endocrine disrupting capacity.
- CSCL Class I and II Specified Chemical.

A high-risk chemical is defined as a chemical that is identified as a PBT chemical, or a chemical which exhibits toxicity of potential concern, or is listed as a chemical of concern on the following chemical databases:

- EU SVHC.
- US NTP Report on Carcinogens or IARC Monographs.
- European Commission Endocrine Disruptors Strategy - list of Category 1 substances with endocrine disrupting capacity.
- CSCL Class I and II Specified Chemical.

For the purposes of the CRAF, chemicals categorised as Tier 1 or Tier 2 chemicals are designated as 'low risk' chemicals. Chemicals categorised as Tier 3, Tier 4 or Tier 5 chemicals are designated as 'high risk' chemicals. Tier 5 chemicals will not be used.

5.2.2 Assessment of Chemicals

Based on the category classification of the chemical (and its potential toxicity, persistence and bioaccumulation potential in the environment), different levels of assessment are conducted with the most robust assessment conducted on the highest classification (**Table 15**).

Table 15. Risk Assessment Requirements

Tier	Risk Category	Screening Assessment and Categorisation	Toxicological Profile)	Qualitative Risk Assessment)	Quantitative Risk Assessment	Site-Specific Assessment	Prohibited from Use on Project
1	Low Risk	X	X				
2		X	X	X			
3	High Risk	X	X	X	X		
4		X	X	X	X	X	
5		X					X

Consistent with the screening matrix in **Appendix D.1** and **Table 15**:

- Tier 1 chemicals, which are effectively low toxicity and therefore low hazard, would be subject to only the screening assessment.
- Tier 2 chemicals, in addition to the screening assessment, will be subjected to a qualitative risk assessment.
- Tier 3 and Tier 4 chemicals, in addition to the screening assessment and qualitative risk assessment, will be subject to a quantitative risk assessment with Tier 4 chemicals requiring an additional site-specific risk assessment.
- Site-specific risk assessment for Tier 4 chemicals will require site-specific per use approval by the Minister.
- Tier 5 chemicals will not be used.

Toxicological profiles (risk assessment dossiers) are developed for all chemicals. Depending on the category of the chemical being assessed (i.e., Tier 1, 2, 3 or 4), the toxicological profiles (dossiers) include chemical identification, physical and chemical properties, environmental fate properties, human health and environmental hazard assessments, derivation of non-cancer and cancer screening levels, a PBT assessment and regulatory status.

The qualitative and quantitative assessments are undertaken in accordance with best practice risk assessment methodologies including those contained within the international standards and Australian risk assessment guidance documents referenced in **Section 8**.

In the assessment of exposure pathways and risks, only authorised operational activities are considered (i.e., activities that are authorised in the respective EA and Commonwealth Approval). Where activities are specifically

precluded (e.g., release or disposal of wastes to surface or ground waters are explicitly not authorised), these are not considered in the risk assessment.

Further the qualitative risk assessment considers management plans developed as part of Commonwealth and State approvals, which have been developed to avoid, mitigate, manage and monitor potential impacts.

Based on the outcomes of the *National Assessment of the Chemicals used in Coal Seam Gas in Australia* (DoEE, 2016), hypothetical accidental releases associated with delivery truck rollovers, including into watercourses, represented the greatest potential risk to environmental values. Given the highly regulated nature of transportation of chemicals (at both a Commonwealth and State level), transport related scenarios and assessment will not be incorporated into the risk assessment process. However, the outcome of the assessment should be used to inform emergency response actions.

The chemical risk assessment qualitatively assesses the potential for one or more hazards associated with the chemicals used in hydraulic fracturing to impact environmental values. Further, the assessment of cumulative impacts to environmental values is evaluated for Tier 3 and Tier 4 chemicals only due to their potential persistence and/or potential to bioaccumulate.

Hydraulic stimulation fluid systems and chemicals evaluated in the tiered assessment approach for this report are tabulated in **Appendix D.2**. The table provides the chemical assessed, the associated fluid system and the classification tier determined. An example for a pre-2020 fluid system (Halliburton Hybor DFS-BGB) is also included for comparison. A detailed mass balance of the composition of the new (post-2020) fluid systems and associated CAS numbers are included in **Appendix D.3.** The findings of the screening assessment based on the tiered classification assessment is included in the Registry of Assessed Chemicals (discussed in **Section 5.2.3**).

5.2.3 Register of Assessed Chemicals

A Register of Assessed Chemicals is published and maintained on the Santos website (https://www.santos.com/about-us/corporate-governance/public-notices/) and full access will be provided to DES to review information contained within the register.

The Register of Assessed Chemicals will, for each published chemical, provide a summary of the outcomes of the screening assessment, including the Tier (and Risk Level) categorisation, the activities the chemical has been assessed for (i.e., hydraulic) and the assessed end use /fate of the chemical. The Register for Assessed Chemicals includes the following document control information, where required (typically by Commonwealth Approval):

- date of Register of Assessed Chemical publication;
- date of chemical assessment;
- date of independent chemical risk assessment expert review (Tier 1 and 2 chemicals only);
- date of notification to Commonwealth Environment Department (Tier 1 and 2 chemicals)/date of lodgement to Commonwealth Environment Department (Tier 3 and 4 chemicals);
- date of approval from Commonwealth Environment Minister; and
- date of chemical re-evaluation (only if chemical is still in use).

Supporting information (i.e., dossiers, qualitative and quantitative risk assessments) for each assessed chemical are made readily accessible via the Register of Assessed Chemicals.

5.2.4 Review Process

Where required by Commonwealth Approval conditions, the Tier 1, 2, 3 and 4 risk assessment information for chemicals still in use is to be re-evaluated and peer reviewed every five years by a chemical risk assessment expert. Peer review is only required for chemicals that are still in use.

Typically the 5-year review process will be provided with a statutory declaration provided by an independent suitably qualified person.

6 Qualitative Assessment Methodology

The information provided in this section addresses the following EA approval requirements: conditions (s) and (q).

The qualitative assessment methodology provides a hazard assessment of the hydraulic fracturing fluids used in the assessed fluid systems. The methodology includes a PBT substances assessment based on the Australia and EU Reach Criteria methodology.

The approach presented in the following paragraphs is an assessment of hazard, rather than environmental risk. Risk assessment of chemicals in the environment is based on a comparison between the levels to which an organism in a particular environmental compartment (e.g., water) is exposed, and a maximum level, which an organism can tolerate, based on a defined exposure scenario in an environmental compartment without significant adverse effect. The environmental hazard assessment presented herein, is not a risk assessment per se because it does not consider likely exposure concentrations for most of the hydraulic fracturing chemicals. However, it does define which hydraulic fracturing fluids may potentially present a risk, based on the toxicity demonstrated in the PBT assessment, and the persistence and bioaccumulation that facilitates their potential for exposure by human and ecological receptors.

6.1 PBT Assessment Using Australia DotE / EU REACH Criteria

PBT substances are substances that are persistent (P), bioaccumulative (B) and Toxic (T). A PBT assessment is conducted because of specific concerns for substances that can be shown to persist for long periods in the environment, to bioaccumulate in food chains, and can give rise to toxic effects after a longer time and over a greater distance than chemicals without these properties. These effects may be difficult to detect at an early stage because of long-term exposures at normally low concentration levels and long lifecycles of species at the top of the food chain.

The properties of PBT substances lead to an increased uncertainty in the estimation of risk to human health and the environment when applying quantitative risk assessment methodologies (ECHA, 2008). A ‘safe’ concentration in the environment cannot be established using the methods currently available with sufficient reliability for an acceptable risk to be determined in a quantitative way (ECHA, 2008). Therefore, separate PBT assessments are conducted in conjunction with the quantitative risk assessments. **Appendix B** provides the methodology used to develop the necessary PBT information to conduct the assessment.

Assessments for PBT substances are conducted according to the criteria developed by DotE (formerly DEWHA) (2009). The criteria are presented in **Table 16**.

Table 16. DotE Persistence, Bioaccumulative, and Toxic (PBT) Criteria

Criterion	PBT Criteria		
Persistence	For PBT purposes a chemical is considered persistent in a particular media if its half-life in the media exceeds the following: Half life ($T_{1/2}$) >2 months in water Half life ($T_{1/2}$) >6 months in soil Half life ($T_{1/2}$) >6 months in sediment Half life ($T_{1/2}$) >2 days in air		
Bioaccumulative	For PBT purposes a chemical is bioaccumulative if it has a BCF/BAF of >2000, or in its absence of any BCF/BAF measurement a log K_{ow} >4.2.		
Toxic	For PBT purposes, in respect of aquatic toxicity, a chemical may be toxic under the following circumstances (corresponding to criteria for GHS chronic category 1:		
	Non-rapidly degradable substances for which there are adequate chronic toxicity data available	Chronic NOEC or EC_x (for fish)	<0.1 mg/L and/or
		Chronic NOEC or EC_x (for crustacea)	<0.1 mg/L and/or

Criterion	PBT Criteria		
		Chronic NOEC or EC_x (for algae or other aquatic plants)	<0.1 mg/L
	Rapidly degradable substances for which adequate chronic toxicity data are available	Chronic NOEC or EC_x (for fish)	<0.01 mg/L and/or
		Chronic NOEC or EC_x (for crustacea)	<0.01 mg/L and/or
		Chronic NOEC or EC_x (for algae or other aquatic plants)	<0.01 mg/L
	Substances for which adequate chronic toxicity data are not available (if criteria for P and B are met)	96 h LC_{50} (for fish)	<1 mg/L and/or
		48 h EC_{50} (for crustacea)	<1 mg/L and/or
		72 or 96 ErC_{50} (for algae or other aquatic plants)	<1 mg/L
		And the substance is not rapidly degradable and/or the experimentally determined BCF is >500 (or, if absent, the log K_{ow} is >4.2	
	Toxicity to other (terrestrial) organisms	Should be considered on a case by cases basis, compared with the highly toxic classifications DotE has developed for ag/vet chemicals	
	Long term toxicity or evidence such as endocrine disruption effects	Should be considered on a case-by-case basis.	

Notes:
BAF = Bioaccumulation factor
BCF = Bioconcentration factor

For substances where the available data may not allow a definitive conclusion on the PBT properties, screening criteria developed by the EU for REACH (ECHA, 2008) are used as surrogate information to decide whether a substance may potentially fulfil the PBT criteria. A summary of these screening criteria is provided in **Table 17**.

Table 17. EU REACH Persistence (P), Very Persistence (vP), Bioaccumulative (B), Very Bioaccumulative (vB) and Toxicity (T) Criteria

Type of Data	Criterion	Screening Assignment
Persistence		
Ready biodegradability test	Readily biodegradable	Not P and not vP
Enhanced ready biodegradability test	Readily biodegradable	Not P and not vP
Specified tests on inherent biodegradability		
Zahn-Wellens (OECD 302B)	>70% mineralization (dissolved oxygen carbon (DOC) removal) within 7 d; log phase no longer than 3 d; removal before degradation occurs below 15%; no pre-adapted inoculum	Not P
MITI II test (OECD 302C)	>70% mineralization (O_2 uptake) within 14 d; log phase no longer than 3 d; no pre-adapted inoculum	Not P
Biowin 2 (non-linear model prediction) and Biowin 3 (ultimate biodegradation time) or	Does not biodegrade fast (probability) and ultimate biodegradation timeframe prediction: >months (value <2.2) or	P

Type of Data	Criterion	Screening Assignment
Biowin 6 (MITI non-linear model prediction) and Biowin 3 (Ultimate biodegradation time)	Does not biodegrade fast (probability <0.5) and ultimate biodegradation timeframe prediction: >months (value <2.2)	P
Bioaccumulation		
Convincing evidence that a substance can biomagnify in the food chain (e.g., field data).	e.g., BMF >1	B or vB, definitive assignment possible
Octanol-water partition coefficient (experimentally derived or estimated by valid QSAR)	Log K_{ow} < 4.5	Not B and not vB
Toxicity		
Short-term toxicity aquatic toxicity (algae, daphnia, fish)	EC_{50} or LC_{50} <0.01 mg/L	T, criterion considered to be definitely fulfilled
Short-term toxicity aquatic toxicity (algae, daphnia, fish)	EC_{50} or LC_{50} <0.1 mg/L	T
Avian toxicity (subchronic or chronic toxicity or toxic for reproduction)	NOEC <30 mg/kilogram(kg) food	T

Note:
1 = Biowin is a biodegradable probability program that calculates the probability that an organic chemical will biodegrade rapidly (or slowly) under aerobic or anaerobic conditions, and only provides estimates of anaerobic biodegradation as either "biodegrades fast" or "does not biodegrade fast".
BMF = Biomagnification factor

6.2 Identification of COPCs from Combined Environmental (PBT) and Human Health Hazard Assessments

The hazard assessments from the environmental (PBT) provides criteria that evaluate substances that can be shown to persist for extended periods in the environment, bioaccumulate in food chains, and give rise to toxic effects after a longer time and over a greater distance than chemicals without these properties. This information is used in the overall identification of the COPCs.

A detailed discussion of the PBT process is provided in **Appendix B**, and the results of the assessments by fluid systems are included in **Appendix C**.

7 Exposure Assessment

The information provided in this section addresses the following EA approval requirements: conditions (j), (q), (r), (s), (v), (w), (y) and (aa).

The assessment of exposure involves the evaluation of the data available for the study, the details associated with the surrounding environment, the nature of the exposure identified and the potential mobility of the COPC.

For an exposure pathway to be complete there must be all the following:

- Source of COPC – how the chemical got into the environment and which environmental media are affected
- A transport media – how the chemical moves or migrates through the environment from one location to another, or from one environmental medium to another
- An exposure point – how organisms can come into contact with the chemicals (e.g., direct contact or via the food web)

- An exposure route – how the chemical could enter the organism (e.g., inhalation, ingestion or dermal contact).

If any one of these steps (source, transport media, exposure point or route) is not present, the exposure pathway is incomplete and further assessment of risks is not required. Thus, even if the COPC was a PBT, if there is no threshold concentration at the point of exposure, the potential risk to environmental and human receptors is considered acceptable and would not require mitigative measures.

7.1 Identification of Potential Exposure Pathways and Receptors

A detailed description of the EQ area environment is provided in **Section 2**. In general, the area is sparsely developed, and comprises rural communities and homesteads that are largely engaged in farming and livestock production.

The identification of exposure pathways and receptors has been split into those considered relevant for on-site (i.e., within the drill pad) and those relevant for off-site (i.e., anything beyond the drill pad boundary). A general description of the drill pad is provided in **Section 4**. Individual configurations of drill pads may change; however, the general layout is considered adequate for the identification of exposure pathways and receptors.

The environment surrounding the drill pad (i.e., off-site) may vary. To provide a conservative assessment, it has been assumed there is a homestead with a water supply bore located down gradient of the drill pad. It has also been assumed that a creek, livestock and native flora and fauna, are present in the surrounding environment. This hypothetical assumption was considered for the purposes of the exposure pathway assessment and may not actually occur in the vicinity of a hydraulically fractured well.

7.1.1 On-Site Exposure Pathways

A drill pad is a defined fenced area that contains all the equipment and infrastructure required to hydraulically fracture a well. While all drill pads are fenced, not all are secured with a locked gate. The entrance to some drill pads may have livestock grills rather than gates. A typical drill pad is described in **Section 4.4.5**. Of note for the exposure assessment are the turkey's nest, the blender unit and the mud pit.

As such, a drill pad is an occupational environment and accordingly it is unnecessary to consider any residential scenarios. Workers are typically housed in existing drill camps or camps specifically designed for hydraulic fracturing (frac camps). According to Santos EQ procedures (Hydraulic Fracture Stimulation Procedures, rev1 2005) '*The frac camp should not be located within one kilometre of operations*.' If a camp is located within 1 km, a risk assessment must be performed, and management approval obtained.

The environmental receptors on a drill pad are limited. Livestock and large native animals such as kangaroos are prevented from entering the pad by the fence. However, Santos EQ have indicated that cattle and kangaroos have been noted on drill pads on limited occasions when the fence has been removed for operational reasons (removal of site equipment).

Reptiles such as lizards and snakes are known to enter the pad and have the potential to be entrapped in the turkey's nest if no means of escape are provided. While no specific reports of birds in the drill pads have been noted, it is considered possible that birds may access the site.

As described in **Section 4**, the fracturing fluid is blended on site to the specific requirements of the fracture. The additives required for the fracture are brought onto site and stored in the blender unit and sand trailer, whilst the blending of the fluid is contained and completely automated. A typical fracturing operation is expected to be of limited duration (two to three days). As such, the chemicals are on site for a brief period of time. Any exposures associated with a spill of fracturing chemicals prior to injection is dealt with under appropriate occupational health and safety procedures and has not been considered further in this report.

The primary pathways for environmental and occupational exposures outside of spills are dermal, ingestion and inhalation of dust. Inhalation of volatile chemicals is of lesser concern as there are no indoor/enclosed environments with all activities conducted outside.

Typically, implemented measures to limit exposure include:

- Exposure by trespasses is limited through ensuring all drill pads are securely fenced. Signs are clearly displayed indicating water in the turkey's nest and mud pit is not potable and may contain contaminants.

- Exposure to livestock is limited through regular maintenance of fences.
- Exposures to sediments in the mud pit and turkeys' nest are limited by disposal or capping of sediments.

The main areas on site that are considered for occupational and environmental exposure are the turkey's nest and mud pit and these are discussed in more detail below.

7.1.1.1 Turkey's Nest

The turkey's nest is a lined (e.g., clay) storage area for the water used in fracturing. It can also be used to store the flowback water following temporary storage in the mud pit to allow sediment to settle. The turkeys nest typically has a 500 mm freeboard control requirement.

Occupational exposure to fracturing chemicals within the turkey's nest may occur from contact with the flowback water or from contact with sediments following drainage. Human exposure to the water in the turkey's nest during normal operation would be limited but may occur if the turkey's nest or liner becomes damaged and requires repair. Normal Occupational Health and Safety (OH&S) procedures are expected to limit workers exposure to flowback water under these scenarios. Human and/or ecological exposure may occur in the event of a flood where the freeboard is breached or if there is a breach of the walls.

The volume of sediment in the turkey's nest is expected to be small as the sediments are settled out of the fluid in the mud pit prior to storage in the turkey's nest. Alternatively, if the water has been sourced from offsite, there will not be any sediment in the turkey's nest.

Exposure to the sediment in the turkey's nest may occur if the turkey's nest is drained and the sediments dry out and contribute to wind borne dust. However, the small volume of dust from sediments is not likely to be of concern to human or ecological receptors and has not been considered further.

It is possible that trespassers may access the site if the pad is not fully secure, accidental and deliberate exposure to chemicals in the flowback water in the turkey's nest may occur. Ecological exposures to hydraulic fracturing chemicals within the turkey's nest may occur from contact with the flowback water or from contact with sediments following drainage. Ecological receptors may include stock animals, kangaroos and other native mammals, reptiles and birds.

7.1.1.2 Mud Pit

The mud pit is constructed during the well-drilling phase, to provide a recirculation and sedimentation pit for the drilling fluids. It is used during hydraulic fracturing as the first reservoir for flowback fluids once the first-flush fluids have been collected in tanks intended for off-site disposal. The fluid is held in the pit to allow the sediment to settle and until it meets the criteria for re-use or is sent for off-site disposal.

The occupational and ecological exposures to the chemicals in the mud pit are like those in the turkey's nest. Workers are expected to have limited contact with the flowback water during operational procedures.

Normal OH&S procedures are expected to limit worker exposure to flowback water in the event of a spill or if the mud pit becomes damaged and requires repair. Human and ecological exposure to the sediment may occur if the mud pit is drained and the sediments dry out and contribute to wind borne dust. The volume of sediments in the pit is considered to be small, unlikely to be of concern to either receptor group, and is not considered further in the exposure assessment.

Trespassers may access the site if the pad is not fully secure, and accidental or deliberate exposure to chemicals in the flowback water in the mud pit may occur. Ecological exposures to hydraulic fracturing chemicals within the mud pit may occur from contact with the flowback water or from contact with sediments following drainage. Ecological receptors may include stock animals, kangaroos and other native mammals, reptiles and birds.

7.1.2 Off-Site Potential Exposure Pathways

The off-site environment is considered anything outside the boundary of the drill pad. As discussed in **Section 1** and **Section 2,** the off-site environment is a sparsely developed with the predominant land use being the raising of livestock. For the purposes of developing a conservative worst-case scenario, of potential exposures, it has been assumed the environment surrounding a drill pad potentially could include:

- A homestead with a water supply bore. Adults and children living on the homestead and drinking water from the bore.

- A creek and associated ecosystems.
- Livestock with water provided by a water supply bore or the creek.
- Native flora and fauna.

The well pad sites where hydraulic fracturing will be conducted will be remote from water supply bores and not immediately adjacent to sensitive environments.

The possible exposure scenarios include receptors and exposure pathways considered relevant for off- site. The main possible sources identified are the hydraulic fracturing fluid, flowback water and gas. These are discussed in more detail below.

7.1.2.1 Exposure to Hydraulic Fracturing Fluid

Potential human and ecological exposures to fracturing fluid is unlikely but theoretically could occur due to casing failures or through fractures into surrounding aquifer. However, Santos EQ currently uses an extensive system of procedures to minimise the likelihood of the fracture (and then the fluid) leaving the target area and the loss of well integrity, as described in **Section 4**.

These systems include extensive testing programs, and operational and systems monitoring to ensure hydraulic fracturing activities are confined to the target units. If a loss of integrity is identified in a well immediate measures are employed to decommission the well or rectify the situation.

On this basis, there is an insignificant likelihood that exposure to fracturing fluids could occur due to the fluid escaping the target coal seam and contaminating overlying aquifers that are used for domestic or stock water supply or discharge into a creek. This conclusion is supported by a study completed by Osborn et al. (2011), which evaluated, aquifers overlying the Marcellus and Utica shale formations of north-eastern Pennsylvania and upstate New York. The study evaluated several issues associated with hydraulic fracturing including:

> 'Concerns for impacts to groundwater resources, from (i) fluid (water and gas) flow and discharge to shallow aquifers due to the high pressure of the injected fracturing fluids in the gas wells'.

The study evaluated groundwater from 68 private water wells, which ranged in depth from 36 to 190 m. The area of the study is undergoing an expansion of gas well drilling and hydraulic fracturing and is in an area with extensive fracture systems with several major faults and lineaments. The study found '*no evidence for contamination of the shallow wells near active drilling sites from deep brines and/or fracturing fluids*.'

A second source of possible human and ecological exposure to hydraulic fracturing fluids is the residual fluid in the coal seam. It is assumed that fluid may remain in the coal seam following fracturing. Exposure may occur if chemicals in the residual fluid migrate down gradient in the coal seam and into a natural spring or water supply bore in close vertical proximity to the coal seam. This pathway is evaluated through the fate and transport modelling provided below. However, migration of organic fracturing fluid chemicals in the coal seams is strongly attenuated by sorption to the carbon in the coal. In addition, the zone of hydraulic fracturing is less than 100 m, and all aquifers are identified within and beyond this zone in **Section 3.2.2**

7.1.2.2 Exposure to Sediments in the Turkey's Nest or Mud Pit

Potential off-site human and ecological exposure to the sediment from hydraulic fracturing could occur if the turkey's nest and/or mud pit is drained, and the sediments were left to dry out and contribute to wind borne dust.

The volume of sediments in the pit is considered to be small and unlikely to be of concern to either receptor group. Capping or disposal of the sediments (following drainage of the turkey's nest and mud pit) is conducted following the completion of drilling and removes the potential for off-site sediment exposure.

7.1.2.3 Exposure to flowback water

Potential off-site human and ecological exposure to chemicals in the flowback water could possibly occur under a range of conditions; however, the implementation of controls makes this the likelihood of this exposure minimal.

Exposure scenarios potentially could include:

- Releases of infiltration of flowback water into shallow aquifers that are used for domestic or stock water supply or which discharge to surface water.
- Direct releases to surface water.

However, for this exposure pathway to be complete there must be all of the following:

- A failure of the lining of the turkey's nest or mud pit.
- A high permeability unit beneath the drill pad that can transmit the flowback water to an underlying aquifer.
- A shallow aquifer located in the subsurface beneath the drill pad that either is used as water supply or discharges into a creek.

If any of the above conditions are not present, no exposure will occur. As previously noted, water supply bores are present in the shallow alluvium throughout the Santos EQ area. It is therefore considered possible that a high permeability unit and a shallow aquifer with a downgradient water supply bore may be present under the drill pad.

The concentrations of hydraulic fracturing chemicals in the flowback water are lower than those injected due to the capture of first flush, and the toxicity of those chemicals is expected to rapidly decrease due to the relatively rapid biodegradation, short biotransformation half-lives, and volatilisation of many of the chemicals. The concentrations of chemicals are also expected to be reduced along the flow path of the coal seam through degradation adsorption and dissolution. The likelihood of exposure to fracturing chemicals under this scenario in concentrations likely to be of concern is considered to be low.

7.1.3 Spills and Overflows from the Turkey's Nest of Mud Pit

Potential off-site human and ecological exposure to flowback water could possibly occur in the event of a spill or overflow from the turkey's nest or mud pit. However, the turkey's nests have been designed to exclude stormwater and will be operated with a 500 mm freeboard to limit the potential for overflow. On this basis, a release could only occur during a prolonged period of heavy rainfall. The probability of a spill or overflow event occurring is further reduced by minimising the duration that flowback fluids are stored in the pit or turkey's nest. In addition, the toxicity of the chemicals in the flowback fluid is likely to be rapidly reduce based on the dissociation of the inorganic chemicals, and the relatively rapid biodegradation, short biotransformation half-lives, and volatilisation of most organic chemicals. In the event of a release, human and ecological receptors could possibly be exposed however sampling of soil, groundwater and surface water (if relevant) in the affected area would be required to determine if unacceptable exposures had occurred.

7.1.4 Management Measures to Reduce Off-Site Exposure

Management measures that are implemented to reduce the potential for off-site exposure or assess the potential for exposure include:

- Lining of mud pits and turkey's nests to prevent seepage of flowback water into underlying aquifer.
- Capping or removal and disposal of the sediments immediately after drainage of the turkey's nest and mud pit.
- Fencing of well pads during drilling and hydraulic fracturing to preclude livestock and trespassers from the work area.
- Management of water levels in all dams prior to the onset of the wet season. This is consistent with the requirements contained within the each.
- Regular monitoring of water supply bores for fracturing fluid indicator parameters within 2 km of wells that are fractured. A stimulation impact monitoring plan has been developed to both identify potentially at-risk wells and undertake baseline and post hydraulic fracturing sampling.

7.2 Fate and Transport Assessment in Groundwater

Extraction bores represent a short circuit pathway for groundwater in the screened aquifer formations directly to the surface. Groundwater extraction through water supply bores represents a potential receiving environment. The types of environmental values potentially exposed to this groundwater may vary depending on the use of the bore, which can range from drinking water supply, irrigation, stock watering and industrial and commercial uses.

For this groundwater exposure pathway to be valid in the context of potential exposure to hydraulic fracturing fluids, a water supply well would need to be completed in close proximity (less than 100 m) to a gas production bore at which hydraulic fracturing had occurred, such that the capture zone of the well could conceivably include residual hydraulic fracturing fluid components from the coal seam. Realistically, this would require that the well be screened either within the coal seam itself, or in an aquifer formation immediately adjacent to the coal seams with the potential for inter-aquifer transfer to occur. Further, the well would need to be close enough to the area

affected by hydraulic fracturing fluids so that the chemical components did not have a chance to attenuate in the aquifer. It is noted that Santos EQ's procedures for selecting locations for gas production wells would preclude installation of a production well near an identified water supply bore. Further, there is no record of water supply wells screened within coal seams or near Santos EQ's petroleum lease areas. In many cases the salinity and presence of odoriferous compounds does not make the water conducive to potable uses.

To assess the fate and transports of hydraulic fracturing chemicals in the subsurface, Golder Associates (2010), as part of their hydraulic fracturing risk assessments, conducted fate and transport modelling. This modelling evaluated key constituents of interest within the fluid systems and provided the framework for assessing the potential mobility of all constituents used in hydraulic fracturing.

Based on the modelling and assessments described below, the selection of chemicals considered within the fate and transport modelling provides a broad range of physical properties which all assessment of varying physical properties on fate and transport.

In general, the model was not sensitive to the variability in physical properties of chemicals. The abundance of organic carbon within the coal seams and the generally low transmissivities (less than 10^5 m/s) preclude broad scale migration of constituents within the formation coals. Based on the broad range of physical properties assessed, the limited transport observed in the model and limited impact that physical properties have on transport distances, additional modelling for new fluid systems was not considered warranted.

Further details on the framework and general findings are provided below.

7.2.1 Subsurface Fate and Transport Considerations

The environmental mobility of COPC was considered for the scenario of fracturing fluid chemicals injected into coal seams. The approach to the assessment is described in the following sections.

7.2.2 Environmental Fate of Inorganic COPC

The inorganic chemicals with the highest hazards are either ionisable inorganic compounds (i.e., readily dissociate into simple salts) or have limited mobility in a coal seam environment due to their physical properties when hydrated (amorphous silica).

Given the fact that all of the inorganic COPC would either rapidly dissociate into simple ions or would have limited mobility based on physical properties when hydrated (i.e., form a gel consistency) it was considered unnecessary to attempt to model the migration of inorganic COPC within the coal seam. The likely result of the dissociation of inorganic compounds in fracturing fluid is a local change in the pH and total dissolved solids load in the immediate vicinity of the fracture zone. Given that the receiving coal seam groundwater is already brackish to saline, the incremental increase in dissolved salt load from dissociated inorganic COPC was considered to represent a low risk in an aquifer environment and did not warrant further assessment through modelling.

7.2.3 Fate and Transport Modelling of Organic COPC

A contaminant fate and transport model was developed to assess the potential for migration of organic COPC in groundwater based on the estimated concentrations in the hydraulic fracturing fluids. The objective of the modelling was to assess the migration potential of organic COPC of the residual hydraulic fracturing fluids remaining in the coal seam following the completion of the hydraulic fracturing process. Golder Associates (2011a) assessed the following organics for mobility in the environment through fate and transport modelling. These included:

Standard Schlumberger Fluid System

- Tetrasodium EDTA
- 5-chloro-2-methyl-4-isothiazolin-3-one
- 2-methyl-4-isothiazolin-3-one
- Vinylidene chloride.

Standard Halliburton Fluid System

- Fatty acid ester
- 1,2 benzisothiazolin -3-one
- Alkylated quaternary chloride

- Sweet orange oil
- Polyethlyene glycol oleate ester.

This selection of organic chemicals provides a broad range of physical properties with the biocides and fatty acids providing the highest potential mobility.

Acetic acid was not considered for fate and transport modelling. This simple organic acid is added to fracturing fluids for pH adjustment and is rapidly buffered in the system. Hence, similar to the inorganic COPC, it is likely to be rapidly consumed within the fracturing radius yielding simple by-products (ultimately carbon dioxide and water). Hence modelling the migration of acetic acid in an aquifer in unreacted form was considered to be unrealistically conservative and accordingly was not considered further from a fate and transport perspective.

7.2.4 Methodology

A one-dimensional fate and transport model, ConSim version 2.5 (Golder, 2010), was used to assess the potential extent of migration of organic COPC in groundwater. The software is based on a probabilistic methodology using a Monte Carlo simulation technique that allows for specification of a range of values for each input parameter rather than a single number. Each simulation comprises multiple iterations of the model run, with input parameters selected from within the range specified for each, to provide a range of modelling results, which reflect the uncertainty inherent in the input values. The modelling results are presented as charts of the statistical probability of a given chemical concentration reaching a specified distance from a gas well at specified time intervals.

The modelling results for chemical concentrations have been reported as both the 50% and 95% confidence limit values generated by the Monte Carlo simulator. The 50% value should be considered as a median, or most likely, value, while the 95% value is conservative (i.e., there is only a 5% chance that the 95% confidence limit value would be exceeded based on the range of model input parameters).

7.2.5 Input Parameters and Model Assumptions

A fate and transport model was developed to simulate the major physical, chemical and biological processes that would influence the transport of residual COPC in the coal seam following hydraulic fracturing. The model considered the scenario of a single gas well, to function as a proxy for evaluating potential exposure pathways for each gas production well that could potentially be subject to hydraulic fracturing. The details regarding parameter selection and model assumptions are summarised in the following sections and chemical information sheets are provided in **Appendix E**.

Table 18. Summary of ConSim Input Parameters

Parameters	Data Distribution	Distribution Parameters			Comment
		Minimum	Maximum	Likely Value	
Hydraulic parameters					
Hydraulic conductivity (m/s)	Log triangular	5 x10-10	1.2 x 10-5	1.0 x 10-6	Data from pumping test (Matrixplus, 2009)
Hydraulic gradient	Uniform	0.002	0.004	-	Estimated from Surat North
Effective porosity (fraction)	Uniform	0.02	0.11	-	Estimated 2% for coal seam and 11% for fractures, modelled as a range
Estimated plume length (m)	-	20	-	-	-

Parameters	Data Distribution	Distribution Parameters			Comment
		Minimum	Maximum	Likely Value	
Initial dispersivity (m)					
Longitudinal	Uniform	2.9	5.0	-	Calculated based on the estimated plume length of 20 m using equation Xu and Eckstein (1995), or estimated as 10% of the plume length
Transverse	Uniform	0.3	0.5	-	10% of the longitudinal dispersivity
Aquifer properties					
Dry bulk density (g/cm3)	Single	-	-	1.3	Published value for bituminous coal (Allen- King et al, 2002)
Organic carbon content (%)	Triangular	56	72	65	Published data for Walloon Subgroup (Scott et al., 2007)
Source concentrations (mg/L)					
Schlumberger fluid system – key constituents					
Tetrasodium EDTA	Triangular	4	12	8	Calculated from mass fraction information provided by the contractor
5-chloro-2-methyl-4-isothiazolin-3-one	Triangular	2	6	4	Calculated from mass fraction information provided by the contractor
2-methyl-4-isothiazolin-3-one	Triangular	0.5	1.5	1	Calculated from mass fraction information provided by the contractor
Vinylidene chloride	Triangular	9	27	18	Calculated from mass fraction information provided by the contractor
Halliburton fluid system – key constituents					
Fatty acid ester	Triangular	141	422	281	Calculated from mass fraction information provided by the contractor

Parameters	Data Distribution	Distribution Parameters			Comment
		Minimum	Maximum	Likely Value	
1,2-benzisothiazolin-3-one	Triangular	1	3	2	Calculated from mass fraction information provided by the contractor
Alkylated quaternary chloride	Triangular	1.35	3104	2069	Calculated from mass fraction information provided by the contractor
Sweet orange oil	Triangular	47	141	94	Calculated from mass fraction information provided by the contractor
Source dimensions					
Thickness (m)	Uniform	0.8	6.3	-	Thickness of coal seams in the study area (Matrixplus, 2009)
Area (m^2)	31,415	-	-	-	Assumes a radial fracture distribution around injection point approximately 200 m in diameter
Partitioning coefficient Koc (kg/L)					
Schlumberger fluid system					
Tetrasodium EDTA	Single		-	-	312.7
5-chloro-2-methyl-4-isothiazolin-3-one	Single	-	-	19.38	Estimated using episuite v.4.0, USEPA
2-methyl-4-isothiazolin-3-one	Single	-	-	12.08	Estimated using episuite v.4.0, USEPA
Vinylidene chloride	Single	-	-	64	Estimated using episuite v.4.0, USEPA
Halliburton fluid system					
Fatty acid ester	Single		-	-	2,423
1,2-benzisothiazolin-3-one	Single		-	-	34.5
Alkylated quaternary chloride	Single		-	-	8.2
Sweet orange oil	Single		-	-	1,119
Polyethylene glycol oleate ester	Single		-	-	3,321

7.2.5.1 Source Specification and Concentrations

The source was the residual hydraulic fracturing fluid components associated with a single gas well. It has been assumed that:

- Injection of the hydraulic fracturing fluids into coal seams creates a source zone with a typical maximum radius of 100 m around the injection well which penetrates the whole thickness of the coal seam. This is conservative in that typically only discrete, thin fractures are created, rather than full penetration of the coal seam.
- The source of dissolved chemicals was conservatively assumed to be infinite (no recovery or biodegradation) releasing constant dissolved chemical concentrations (no dilution) over the simulated period (up to 1,000 years).
- Natural groundwater flow conditions have been established immediately following the injection of hydraulic fracturing fluids, which would only apply to the limited duration between completion of the fracturing event and the gas well being brought into operation.

The estimated concentrations of the hydraulic fracturing fluid additives were calculated from mass balances provided for the various fluid systems. These mass balances for the Halliburton and Schlumberger fluid systems modelled are provided in **Appendix C**.

7.2.5.2 Aquifer Properties

It has been assumed for this modelling that the fractured coal seam can be represented as an equivalent porous medium. Aquifer property data was based on reported values in Matrixplus (2009) (see **Figure 70**) and URS (2011). Porosity data obtained from field measurements followed a polynomial distribution. Therefore, a uniform distribution ranging between 2% and 11% was estimated for this parameter. A log triangular distribution was assumed for hydraulic conductivity. A triangular data distribution is generally applied where, in addition to minimum and maximum values, it is possible to identify a value that is likely to occur; the use of a log triangular distribution prevents a bias towards the larger values. The range of hydraulic conductivity values varied between $5.0x10^{-10}$ m/s to $1.2x10^{-5}$ m/s with the most likely value corresponding to $1.0x10^{-6}$ m/s. The hydraulic gradient was estimated from previously reported groundwater elevation data (Golder, 2009) for the Surat 5 (Surat North1) GMU. The estimated hydraulic gradient ranged between 0.002 and0.004 across this GMU.

A coal seam bulk density of 1.3 grams per cubic centimetre (g/cm^3) was adopted from published data on volatile bituminous coals (Allen- King et al., 2002).

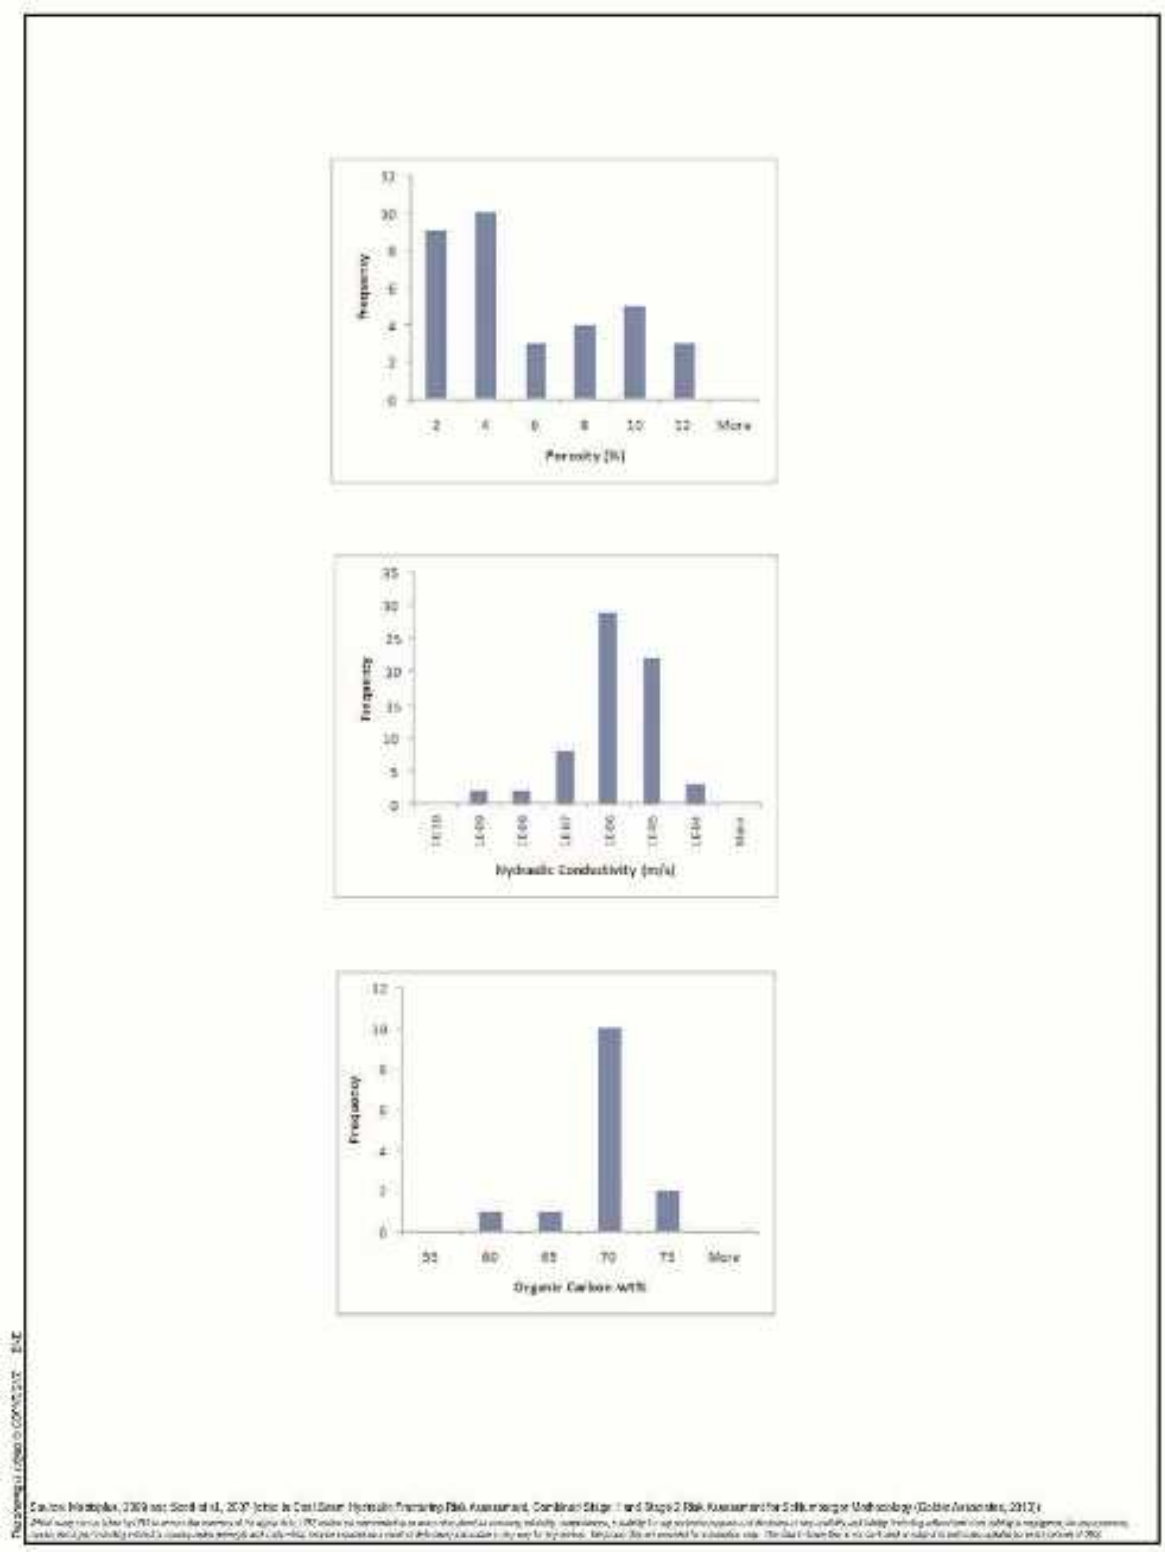

Figure 70. Histogram of Coal Seam Aquifer Porosity and Hydraulic Conductivity

Source: Matrixplus, 2009

7.2.6 Adsorption

7.2.6.1 Fraction of Organic Carbon

The organic carbon content of an aquifer is considered the principal factor contributing to the sorption of dissolved organic compounds in groundwater. Based on published studies by Scott et al. (2007) the middle Jurassic coals of the WCM in the Surat Basin are classified as highly volatile bituminous coals with high carbon content [50-70 weight percent (wt%)] and a moderate to high ash content (approx. 30 wt%). The distribution of organic carbon data was assumed to be triangular within the defined range from 56 wt% to 72 wt% and the most likely value corresponding to 67 wt% (Golder, 2011a).

7.2.6.2 Organic carbon partitioning coefficient (K_{oc})

The organic carbon partitioning coefficient (K_{oc}) is a measure of a chemical's affinity for adsorption to organic matter in soils, where higher values correspond to higher retention in organic matter. Only a single value was used for each of the COPC considered.

Uniform data distributions were assigned to the K_{oc} values for all modelled hydraulic fracturing fluid components.

7.2.7 Conservatism of Modelling Assumptions

A significant degree of conservatism was incorporated into the modelling assumptions to represent a worst-case scenario. The model is conservative in terms of the following assumptions:

- An infinite and constant source for each chemical (i.e., no degradation or depletion of chemical concentrations in the source over time).
- Dispersion and sorption were the only processes simulated (i.e., biodegradation was not considered).
- Natural groundwater flow conditions prevail at the site (i.e., no additional capture of residual hydraulic fracturing fluid due to groundwater extraction during gas production).

7.2.8 Results

The modelling provided unretarded travel times as a basis for comparison to the influence of the physical and chemical processes that retard the migration rate of hydraulic fracturing fluid chemicals relative to the groundwater flow velocity. The simulated unretarded travel times at different distances downgradient from the source are presented in **Table 19.** The simulated unretarded travel time to reach a monitoring point located 20 m down hydraulic gradient from the source ranged from 2 to 35,000 years, which reflects the large range of potential hydraulic conductivity values reported for the coal seams (i.e. five orders of magnitude). The minimum travel times can be considered as the most conservative in this case (i.e., fastest migration rate), while the 50th percentile values can be considered the median or most likely travel times to reach the various distances.

Table 19. Unretarded Travel Time (years)

Distance down hydraulic gradient from the source	Min	Max	50th percentile	95th percentile
5 m	0.5	22,000	45	3,245
20 m	2.0	35,000	85	5,530
50 m	3.0	61,750	155	10,760
100 m	5.0	107,700	280	19,900

7.2.9 Tetrasodium EDTA

The model results presented in **Table 20** below suggest that the mobility of tetrasodium EDTA is extremely low, with a maximum estimated concentration of $3x10^{-11}$ mg/L reaching 5 m beyond the fracturing radius after 1,000 years (i.e., undetectable by analytical laboratories).

Table 20. Predicted Tetrasodium EDTA Concentrations in Groundwater Down Hydraulic Gradient from Hydraulically Fractured Area (Dispersion and Sorption)

Distance from the source	Range of 50th, 95th percentile concentrations					
	Predicted concentrations at 20 years (mg/L)		Predicted concentrations at 100 years (mg/L)		Predicted concentrations at 1000 years (mg/L)

100 m	< LOR	< LOR	< LOR	< LOR	< LOR	< LOR

7.2.12 Vinylidene Chloride

The model results presented in **Table 23** below suggest that the mobility of vinylidene chloride is extremely low, with a maximum predicted concentration of 0.56 mg/L reaching 5 m beyond the fracturing radius after 1,000 years, and concentrations below the assumed reporting limit at 20 m beyond the fracturing radius after 1,000 years.

Table 23. Predicted Vinylidene Chloride Concentrations in Groundwater Down Hydraulic Gradient from Hydraulically Fractured Area (Dispersion and Sorption)

Distance from the source	Range of 50th, 95th percentile concentrations

100 m	< LOR	< LOR	< LOR;	< LOR	< LOR	< LOR

Note: Typical conservative LOR for organic chemicals was assumed to be 0.001 mg/L.

7.2.14 1,2-benzisothiazolin-3-one

The model results presented in **Table 25** below suggest that the mobility of 1,2-benzisothiazolin-3-one is extremely low, with a maximum predicted concentration of 0.39 mg/L reaching 5m beyond the fracturing radius after 1,000 years.

Table 25. Predicted 1,2-benzisothiazolin-3-one Concentrations in Groundwater Down Hydraulic Gradient from Hydraulically Fractured Area (Dispersion and Sorption)

Distance from the source	Range of 50th, 95th percentile concentrations					
	Predicted concentrations at 20 years (mg/L)		Predicted concentrations at 100 years (mg/L)		Predicted concentrations at 1000 years (mg/L)

50 m	< LOR	< LOR	< LOR	< LOR	< LOR	< LOR
100 m	< LOR	< LOR	< LOR	< LOR	< LOR	< LOR

7.2.15 Alkylated Quaternary Chloride

The model results presented in **Table 26** below suggest that the mobility of alkylated quaternary chloride is limited. Despite having the lowest Koc value of the COPC evaluated, the upper end concentration predicted to reach 20 m beyond the fracturing radius after 100 years is still less than one part per billion (i.e., below the standard laboratory limit of reporting (LOR) for most organic chemicals).

Table 26. Predicted Alkylated Quaternary Chloride Concentrations in Groundwater Down Hydraulic Gradient from Hydraulically Fractured Area (Dispersion and Sorption)

Distance from the source	Range of 50th, 95th percentile concentrations					
	Predicted concentrations at 20 years (mg/L)		Predicted concentrations at 100 years (mg/L)		Predicted concentrations at 1000 years (mg/L)

100 m	< LOR	< LOR	< LOR	< LOR	< LOR	< LOR

Note: Typical conservative LOR for organic chemicals was assumed to be 0.001 mg/L.

7.2.17 Polyethylene Glycol Oleate Ester

The model results presented in **Table 28** below suggest that the mobility of polyethylene glycol oleate ester is extremely low, with a maximum predicted concentration of $7x10^{-16}$ mg/L reaching 5 m beyond the fracturing radius after 1,000 years.

Table 28 . Predicted Polyethylene Glycol Oleate Ester Concentrations in Groundwater Down Hydraulic Gradient from Hydraulically Fractured Area (Dispersion and Sorption)

Distance from the source	Range of 50th, 95th percentile concentrations

100 m	< LOR	< LOR	< LOR	< LOR	< LOR	< LOR

7.2.18 Summary of Groundwater Fate and Transport Modelling

The modelling results suggest that organic COPC in the hydraulic fracturing fluid will be strongly attenuated within the coal seam, predominantly by adsorption. The extent of sorption of organic chemicals in aquifers depends on the content as well as nature of the organic carbon. The natural attenuation potential for organic chemicals within coal seam is significantly higher than that of natural soils due to the high content of organic carbon (50-70%).

Previous published studies have demonstrated that the presence of thermally altered carbonaceous materials such as coals, chars, and kerogen in soils, sediment and rocks has a significant influence on sorption even when present in small fractions (Allen-King et al., 2002). The model simulations suggested a strong attenuation capacity for all organic COPC considered. Sorption was predicted to significantly limit the transport of all constituents with the exception of the alkylated quaternary chloride. Even with the adoption of source concentrations one to three orders of magnitude above the estimated solubility limits for the chemicals no inherent transport was observed.

The exception was alkylated quaternary chloride, for which the upper end modelling predictions suggest migration of detectable concentrations to between 50 and 100 m beyond the fracturing radius after 1,000 years. It is reiterated, however, that the modelling excluded biodegradation as an attenuation process for the sake of conservatism, and assumed a constant mass in the source zone, both of which result in unrealistically conservative migration estimates over long timeframes. The dissolved plumes associated with each of the organic COPC would reach equilibrium with respect to the attenuation capacity.

Further, the assumption of the residual hydraulic fracturing fluids being subject to a natural groundwater flow field is also very conservative, as hydraulically fractured gas wells are typically brought into production within approximately one year after the hydraulic fracturing process and are typically operated for five to thirty years.

During gas production, groundwater is extracted from the gas well to depressurise the coal seam, which creates a significant inward hydraulic gradient that would likely act to prevent migration and capture and remove most of the residual hydraulic fracturing fluid mass over the operational lifespan of the gas production well.

In summary, the modelling results suggest that the strong sorption capacity of the coal seam aquifers will significantly limit the transport potential of the organic hydraulic fracturing fluid components. Migration of most of the organic COPC was predicted to be less than 5 m beyond the hydraulic fracturing radius of influence over 1,000-year simulation. On this basis, migration of constituents in groundwater to potential receptors is not considered a potentially complete exposure pathway.

7.3 Identification of Complete Exposure Pathways

The potential for exposures has been assessed qualitatively and through groundwater fate and transport modelling. These are summarised below separately for on-site and off-site receptors.

7.3.1 On-Site Exposure Pathways

The most likely potential exposures were evaluated for workers, trespassers, native fauna and stock animals. Based on information provided by Santos EQ, there does not appear to be complete exposure pathways identified for on-site workers under normal circumstances, provided the following conditions are met:

- Adequate OH&S procedures are adhered to that prevent direct contact with chemicals during spills and when handling flowback water or sediments.
- Sediments in the mud pit and turkey's nest are disposed of appropriately or capped immediately following drainage.

Exposure by trespassers is considered to be an unlikely occurrence. Exposure to sediments or flowback water is a complete exposure pathway (ingestion, dermal and inhalation) if trespassing occurs on unsecured sites. Exposure will be limited through ensuring all drill pads are securely fenced with signage clearly displayed to indicate that the water in the turkey's nest and mud pit is not potable and may contain contaminants.

Exposure pathways to the flowback water in the turkey's nest and mud pit for large native fauna (i.e., kangaroos) and stock animals can be considered incomplete on the basis of the fencing that Santos EQ will establish and maintain around the well pads, during operations and while back flow water is stored on-site. Exposure pathways (direct contact) for small native fauna (i.e., small mammals, snakes, lizards and birds) is considered complete for exposure to the flowback water in the turkey's nest and mud pit, with practical measures implemented by Santos EQ to minimize potential exposures.

7.3.2 Off-Site Exposure Pathways

Four possible sources were identified:

- Hydraulic fracturing fluids
- Sediments from mud pit or turkey's nest
- Flowback water
- Gas (methane).

Exposures were considered unlikely for all scenarios based on the engineering (liners/stormwater diversion) and operational controls that are being implemented by Santos EQ. In the unlikely event that an uncontrolled release was to occur, potential exposures could include direct contact and inhalation exposures for residents, stock animals, native flora and fauna and aquatic ecosystems. The probability of a release from a pond or turkeys nest occurring can be reduced through minimising the duration of flowback fluid storage. In addition, the concentrations of chemicals in flow back water are likely to be considerably less than in the injected fluid and the toxicity of the chemicals in the flowback fluid are likely to rapidly reduce through dissociation of organic chemicals and the relatively short biotransformation half-lives of the majority of the organic chemicals. Sampling would be required to characterise exposure should a release occur.

8 Quantitative Risk Assessment Methodology

The information provided in this section addresses the following EA approval requirements: conditions (q), (s), (x) and (aa).

The methodology used in the Qualitative Risk Assessment included quantitative calculations for the exposure assessment and risk characterisation, and toxicity estimates for the hazard assessment. This methodology taken to the quantitative assessment of human health and environmental risks is in accordance with guidelines/protocols provided by enHealth. These guidelines draw on, and are supplemented by, those provided by NWQMS and National Health and Medical Research Council (NHMRC), as well as international human health and environmental risk agency guidance such as the US Environmental Protection Agency (USEPA).

Information presented in the qualitative risk assessment was reviewed for applicability in the quantitative risk assessment, and was either incorporated into the quantitative risk assessment, or was replaced with an alternative methodology.

The risk assessment process in the quantitative risk assessment included a comprehensive assessment of both the theoretical and empirical concentrations of hydraulic fracturing fluids in the flow back water. A robust toxicity assessment was conducted that develops both human health and ecological toxicity criteria utilizing extensive toxicological databases, industry toxicological assessments not available to Golder (2011a) and less reliance on toxicological modelling methodologies. The quantitative risk assessment extends the qualitative risk assessment presented in **Section 6** by incorporating exposure models to evaluate potential exposures to human and ecological receptors and estimated the potential risks to these receptors from the exposures. Based on the risk characterisation, existing operational control activities are in place that will limit the potential risks.

8.1 Exposure Assessment

This section identifies the organisms or group of organisms (receptors) which may be exposed to the COPCs identified for the study and outlines the mechanisms (exposure pathways) by which these receptors may be exposed.

The assessment of exposure involves the evaluation of the data available for the study, the details associated with the surrounding environment, the nature of the exposure identified and the potential mobility of the COPC.

For an exposure pathway to be complete there must be all of the following:

- Source–COPC - how the chemical got into the environment and which environmental media are affected.
- A transport–media - how the chemical moves or migrates through the environment from one location to another, or from one environmental medium to another.
- An exposure–point - how organisms can come into contact with the chemicals (e.g., direct contact or via the food web).
- An exposure–route - how the chemical could enter the organism (e.g., inhalation, ingestion or dermal contact).

If any one of these steps (source, transport media, exposure point or route) is not present, the exposure pathway is incomplete and further assessment of risks is not required. Thus, even if the COPC was a PBT, if there is no threshold concentration at the point of exposure, the potential risk to environmental and human receptors is considered acceptable and would not require mitigative measures.

8.2 Identification of Exposure Pathways and Receptors

A detailed description of the EQ study area environmental values is provided in **Section 3**. In general, the area is sparsely developed, and comprises rural communities and homesteads that are largely engaged in farming and livestock production. The identification of exposure pathways and receptors has been split into those considered relevant for on-site (i.e., within the drill pad) and those relevant for off- site (i.e., anything beyond the drill pad boundary) as identified in **Section 7**. The general drill pad includes a cleared area with drilling mud pits, flare pits and turkey nests (water storage dams) constructed in designated areas. Individual configurations of drill pads may change; however, the general layout is considered adequate for the identification of exposure pathways and receptors.

Consistent with the assumptions made in the Qualitative Risk Assessment, the environment surrounding the drill pad (i.e., off-site) may vary. In order to provide a conservative assessment, it has been assumed there is a homestead with a water supply bore located down gradient of the drill pad. It has also been assumed that a creek, livestock and native flora and fauna, are present in the surrounding environment. This hypothetical assumption was considered for the purposes of the exposure pathway assessment and may not actually occur in the vicinity of a hydraulically fractured well. Onsite and off-site exposure pathways were presented previously in **Sections 7.1.1** and **7.1.2**.

8.3 Exposure Point Concentration – Theoretical and Empirical

Two datasets were evaluated in the quantitative risk assessment: a theoretical dataset and an empirical dataset. The theoretical dataset calculated exposure point concentrations (EPCs) based on theoretical calculations of exposure using the mass-balance data for each vendor's hydraulic fracturing fluid system. The EPCs for the empirical dataset are limited to the Schlumberger fluid system which has been widely used and has sufficient monitoring data from the SIMP.

8.4 Human Health Risk Assessment

The enHealth (2012) human health risk assessment (HHRA) process involves three components:

- Hazard assessment
- Exposure assessment
- Risk characterisation

The hazard assessment includes:

The hazard identification, which is the characterisation of the exposure data, and the statistical evaluation of the exposure data; and

The toxicity assessment, which defines the relationship between the potential extent of exposure and the toxicological effects of the exposure and is estimated for each COPC. For the HHRA, the COPC-specific toxicity criteria are presented (when available), including:

  - Cancer slope factors (CSFs) or unit risk factors (URFs) for carcinogens, genotoxics (where a non-threshold dose-response approach is appropriate).
  - Reference doses (RfDs) (or acceptable/tolerable daily intakes RfDs acceptable daily intakes (ADIs) or tolerable daily intakes (TDIs) or reference concentrations (RfCs) or tolerable concentrations (TCs).

In the exposure assessment, the potential human receptors are identified and their potential for exposure to COPCs is characterized. Potential exposure pathways are evaluated to determine which, if any, are potentially complete. Next, the EPCs of COPCs in the flow-back water exposure areas are calculated and are used in conjunction with exposure assumptions to determine systemic doses for the applicable potential receptors. Finally, the magnitude, frequency and duration of these potential exposures are integrated to calculate estimates of daily intakes over a specified exposure period.

Integration of the results of the toxicity assessment and the exposure assessment to derive quantitative estimates of human health risks is accomplished in the risk characterisation for COPC evaluated based on a threshold and/or non-threshold approach. Finally, the level of uncertainty relevant for the completion of the risk assessment is evaluated.

The approach taken to the quantitative assessment of human health risks is in accordance with guidelines/protocols provided by enHealth (2012). In addition to these guidelines, the following documents provided supplemental guidance for the quantitative HHRA:

- The NEPM [2013], (Schedule B(4) Guideline on Health Risk Assessment Methodology, Schedule B(6) Guideline on Risk Based Assessment of Groundwater Contamination, Schedule (7a) Guideline on Health-Based Investigation Levels, Schedule B (7b) Guideline on Exposure Scenarios and Exposure Settings and Schedule (5) Guideline on Ecological Risk Assessment).
- 'The Health Risk Assessment and Management of Contaminated Sites' (CSMS, 1991, 1993, 1996 and 1998 and enHealth, 2012).
- Australian Drinking Water Guidelines (ADWG) (2011) National Water Quality Management Strategy. ADWG, Section 6, Australian Government, National Health and Medical Research Council, Natural Resource Management Ministerial Council.
- USEPA, 2002. A Review of the Reference Dose and Reference Concentration Processes. External
- Peer Review Draft. USEPA, Washington, D.C. EPA/630/P-02/002A.
- Environmental Risk Assessment Guidance Manual for Industrial Chemicals, Australian Environmental Agency Pty, Ltd., Commonwealth of Australia, 2009.
- European Commission, Technical Guidance Document on Risk Assessment, 2003.

8.4.1 Hazard Assessment

The purpose of the hazard assessment is to summarize the environmental data and to address the toxicological assessment of the COPCs that will be further evaluated in the quantitative risk assessment process. The environmental media data used in the HHRA will be managed in an electronic database and compiled by constituent, medium and sample location, if applicable. All descriptive and statistical analyses of the data will be

performed using ProUCL Version 4.1 that was developed for the USEPA (2010). Both the theoretical and empirical sampling data will be included in the electronic database.

8.4.2 Toxicity Assessment

The toxicity assessment was conducted to determine the relationship between the dose of a COPC taken into the body and the probability that an adverse effect will result from that dose.

Quantitative estimates of the potency of COPCs include two sets of toxicity values, one for genotoxic carcinogens and one for other non-genotoxic carcinogens and non-carcinogenic effects. For the assessment of genotoxic carcinogenic effects, a non-threshold toxicological mechanism was assumed and there was no level of exposure that does not pose a probability that an adverse effect will result from that dose. For toxicity criteria for other, non-genotoxic carcinogens and non-carcinogenic effects, it was assumed that there is a threshold effects level, below which adverse health effects are not expected to occur.

The assessment of carcinogenic effects was conducted following the review of the available data utilising a weight-of-evidence approach in relation to genotoxicity. Genotoxic carcinogens were evaluated based on a non-threshold dose-response relationship, quantified using a URF for inhalation exposures and/or slope factor (SF) for oral and dermal exposures. The URF (expressed as 1/(µg/m^3)) or SFs (expressed as 1/(mg/kg/day)) evaluated were upper-bound estimates of the excess cancer risk due to continuous exposure to a COPC averaged throughout the course of a 70-year lifetime. The referenced bases of URF and SFs were data from lifetime animal bioassays, although human data are used when available.

Where carcinogenic effects were associated with a non-genotoxic mode of action (or where insufficient weight of evidence was available to support a genotoxic mode of action), these effects were characterized based on a threshold. Other non-carcinogenic effects, such as organ damage or reproductive effects, were evaluated based on a threshold. These threshold values were defined as RfC or TCs for inhalation exposures and RfDs or ADIs/TDIs for oral and dermal exposures. These threshold values may be available for different durations of exposure ranging from acute to chronic exposures), with the focus of the assessment presented in this report on chronic exposures. A chronic RfC/TC or RfD/ADI/TDI was defined as the concentration or intake that all members of the public may be exposed to every day for a lifetime with no adverse health effects.

The threshold value was commonly derived from a point of departure (POD), defined as the lowest concentration that is associated with no (or the lowest) observed adverse health effects (no observed adverse effect level [NOAEL] or lowest observed adverse effect level [LOAEL] or a benchmark dose), determined from experimental animal studies (most common) or human studies (less common). The POD was then divided by a safety/uncertainty factor to obtain the threshold toxicity value. Uncertainty factors were typically factors of 10 that account for interspecies variation and sensitive human populations. Additional factors of 10 were included in the uncertainty factor if the RfC is based on the lowest observed adverse effect level instead of the NOAEL, or an experiment that included a less-than- lifetime exposure.

The assessment of toxicity of the COPCs was used to develop initial screening criteria for human health exposure scenarios.

8.4.2.1 Toxicological database and literature review

The following toxicity-based screening guidance's were used to develop the necessary toxicity assessment information used in this quantitative risk assessment:

- Australian and New Zealand Environment Conservation Council (ANZECC) (2000) and Australian and New Zealand Guidelines for Fresh and Marine Water Quality (ANZG) (2018) guidelines for fresh and marine water quality.
- National Health and Medical Research Council and National Resource Management Ministries Council (NHMRC/NRMMC) 2011 ADWG for physical and chemical characteristics. World Health Organization (WHO) 2011 Guidelines for Drinking-water Quality (Fourth Edition).
- USEPA. 2009a. National Recommended Water Quality Criteria (2009) for protection of aquatic life and human health.

If no relevant guidelines exist, other applicable international guidelines have been used for the screening process (or risk screening values derived) to ensure that all chemicals are adequately considered.

The following is a list of resources that have potentially been queried:

- Chemical Risk Information Platform (CHRIP) [Japan] Information on Biodegradation and Bioconcentration of the Existing Chemical Substances Database (http://www.safe.nite.go.jp/english/db.html).
- European Chemicals Agency (ECHA) public database of Registration, Evaluation, Authorization and Restriction of Chemical Substances (REACH). Registered substances (ECHA CHEM) (http://apps.echa.europa.eu/registered/registered-sub.aspx).
- European Commission (EC) Joint Research Centre (JRC) Institute for Health and Consumer Protection - European Chemical Substances Information System (ESIS) (http://ecb.jrc.ec.europa.eu/esis).
- USEPA High Production Volume Information System (HPVIS) (http://www.epa.gov/chemrtk/hpvis/index.html).
- New Zealand Environmental Protection Authority - New Zealand Hazardous Substances and New Organisms (HSNO) Chemical Classification Information Database (CCID) (http://www.epa.govt.nz/search-databases/Pages/HSNO-CCID.aspx).
- WHO International Programme on Chemical Safety (IPCS) Chemical Safety Information from Intergovernmental Organizations (INCHEM) (http://www.inchem.org/).
- Japan CHEmicals Collaborative Knowledge database (J-CHECK) (http://www.safe.nite.go.jp/jcheck/english/top.action).
- Japan Existing Chemical Data Base (JECDB) (http://dra4.nihs.go.jp/mhlw_data/jsp/SearchPageENG.jsp).
- Australian NICNAS Priority Existing Chemical (PEC) Assessment Reports (http://www.nicnas.gov.au/Publications/CAR/PEC.asp).
- Organisation for Economic Cooperation and Development (OECD) High Production Volume (HPV) Existing Chemicals Database (http://webnet.oecd.org/hpv/ui/Default.aspx).
- OECD Screening Information Dataset (SIDS) Database OECD Existing Chemicals Screening Information Data Sets (SIDS) Database (in IUCLID software) (http://oecdsids.jrc.ec.europa.eu:80/i5browser/Welcome.do).
- OECD Initial Assessment Reports for HPV Chemicals including Screening Information Data Sets (SIDS) as maintained by United Nations Environment Programme (UNEP) Chemicals (http://www.chem.unep.ch/irptc/sids/OECDSIDS/sidspub.html).

In addition, a general Google search by product name and CASRN was conducted, which is a basic requirement for programs such as REACH.

8.4.2.2 Derivation of oral reference dose and drinking water guideline values

Existing oral RfDs and drinking water guideline values were used when applicable. Otherwise, information on mammalian toxicity was acquired primarily from reported data that had already been through a screening process such as the OECD SIDS program, the U.S. Cosmetics

Ingredient Review or the EU Scientific Committee on Consumer Safety (SCCS). The data from these programs were considered sufficiently reviewed as to not require further evaluation. Data reported as part of other equivalent peer reviewed risk assessment programs (e.g., HERA (www.heraproject.com/); USEPA HPV Chemical Challenge Program) were also considered in a similar fashion, although a certain level of expert judgment was required to evaluate the quality of these programs.

Toxicity information was also obtained via the ECHA CHEM database. This database provides electronic public access to information on chemical substances manufactured or imported in Europe. The information originates from the registration dossiers submitted by companies to ECHA in the framework of REACH Regulation.

Where data was not available from the above sources or the available data were considered insufficient for the determination of oral RfDs and drinking water guideline values, then toxicity information on MSDSs was used, as well as read-across from available experimental data on a structurally related substances and predicted values from quantitative structure-activity relationship (QSAR) models.

With exception to the USEPA integrated risk information system (IRIS) values, the most appropriate or reliable NOAEL or LOAEL, if a NOAEL was unavailable and the critical effect were identified.

8.4.2.3 Oral reference dose derivation

The oral RfD was calculated using the following equation:

$$Oral\ Reference\ Dose\ =\ NOAEL\ /\ UF_{Total}$$

Where:

- NOAEL = No-Observed-Adverse-Effect
- UF_{Total} = Total uncertainty factors

Note that for NOAELs, when dosing regimens were 5 days/week, the NOAEL was adjusted to 7 days/week by multiplying the NOAEL by 5/7.

Uncertainty factors of 10 were used to account for:

- Variation in sensitivity among members of the human population, i.e., interindividual variability
- The uncertainty in extrapolating animal data to humans, i.e., interspecies uncertainty
- The uncertainty in extrapolating data obtained in a study with less-than-lifetime exposures, i.e., extrapolating from subchronic to chronic exposure
- The uncertainty in extrapolating from a LOAEL rather than from a NOAEL (USEPA, 2002).

8.4.2.4 Determination of drinking water guideline values

The ADWG values were used when applicable (2011). The WHO, and then USEPA, were also consulted for any additional drinking water standards when there were no ADWGs values. For the theoretical approach, limited additional drinking water standards were found that were applicable to the hydraulic fracturing chemicals used in this quantitative risk assessment.

For those chemicals where there are no regulatory drinking water guidelines, and for which a threshold exists, the guideline value was derived from animal toxicity data using the following equation (ADWG, 2011):

$$Guidance\ values = animal\ dose\ *\ human\ weight * proportion\ of\ intake\ from\ water\ volume\ of\ water\ consumed\ *\ safety\ factor$$

Where:

- Animal dose = NOAEL (or LOAEL)
- Human weight = 70 kg
- Proportion of intake from water = 10%
- Volume of water consumed = 2 L/day

As indicated above, the overall toxicity assessment used in this quantitative risk assessment included a more comprehensive review of the available literature and existing regulatory databases than provided in Golder (2011a). **Appendix F** and **Appendix G** includes the detailed toxicological profiles and supporting documents for the hydraulic fracturing chemicals.

8.4.2.5 Exposure equations and models

The following equations were used for calculating the intake of COPCs:

Ingestion of water:

$$Intake\ (mg/kg-day)\ =\ (CW\ x\ IR\ X\ EF\ X\ ED)\ /\ (BW\ x\ AT)$$

Dermal contact with water:

$$Intake\ (mg/kg-day)\ =\ (CW\ x\ IR\ X\ EF\ X\ ED)\ /\ (BW\ x\ AT)$$

Where:

- CW = concentration in water (mg/l)
- ET = exposure time (hr/day or hours/hours)
- EF = exposure frequency (day/year)
- ED = exposure duration (years)
- CF = correction factor (1 x 10^{-3} l/cm^3)
- AT = averaging time (days)
- IR = ingestion rate (l/hr)
- BW = body weight (kg)
- SA = skin surface area available for contact (cm^2/d)
- DP = dermal permeability factor (Kp – cm/hr).

The exposure assumptions to be used in the equations above for the human trespasser receptor was developed based on default (e.g., enHealth) or site-specific exposure assumptions including information contained in the Golder (2011a) risk assessment and the literature, as well as professional judgment. The human trespasser receptor exposure pathway includes a small child to teenager that may come in contact with the above grade water exposure scenario for approximately 20 days/year for a 10-year period with potential incidental ingestion (of 50 mL water) and dermal contact (e.g., swimming where the whole body gets wet) for a half hour. This assumption is consistent with the typical exposure assumptions utilized by USEPA (2009) for recreational exposure. This assumption also recognises that the storage of flowback water at individual well pad sites will be only a temporary activity, with operational controls and activities at the well sites likely limiting the occurrence of trespasser entry and exposures.

It is noted that the selected exposure assumptions are considered conservative because the above grade water would only be available in the flowback storage ponds for a maximum period of six to nine months based on the expected operational activities.

8.4.3 Risk Characterisation

The purpose of the risk characterisation is to provide a conservative estimate of the potential risk resulting from exposure to COPCs identified in the affected theoretical and empirical flowback groundwater at the site. Included in this section is a quantitative estimate of potential carcinogenic and non-carcinogenic risks for each complete exposure pathway for the human trespasser receptor.

8.4.4 Risk Estimation

For this risk assessment, carcinogenic risks were estimated in the HHRA by summing the excess lifetime cancer risk over all the COPCs, and comparing the total risk to a target risk range of one in ten thousand (1 x 10^{-4}) to one in one million (1 x 10^{-6}).

Carcinogenic risk less than 1x10^{-6} is considered acceptable, risks between 1x10^{-6} and 1x10^{-4} require best practice reductions and risks greater than 1x10^{-4} are not acceptable, consistent with the approaches commonly applied within Australia.

It should be noted that specific Australian guidance relating to an acceptable cancer risk threshold is not available in enHealth (2012), but the interpretation of cancer risk values in Australia is generally consistent with USEPA policy that adopts a risk value of 1 x 10^{-6} as representative of minimal risk, and a risk value of 1 x 10^{-4} as an action level. That is, where risk estimates are less than 1 x 10^{-4}, action is generally considered not to be warranted, but where action is warranted remediation goals are commonly based on a target cancer risk of 1 x 10^{-6}. However, an acceptable risk level in relation to exposure to site contamination issues of 1 x 10^{-5} is consistent with the approach in NEPM and enHealth guidance documents.

For the assessment of threshold effects, the individual hazard quotients (HQs) were summed for an overall HI. If the HI is less than or equal to one, then no adverse health effects are likely associated with exposures. However, if the total HI is greater than one, adverse health effects may be likely without control management measures currently in place.

8.5 Ecological Risk Assessment

An Ecological Risk Assessment (ERA) was conducted as part of the quantitative risk assessment to evaluate the potential for adverse ecological effects to terrestrial and aquatic ecological receptors that may be exposed to residual levels of hydraulic fracturing fluids in surface water used in the development areas. The approach for the ERA component of the quantitative risk assessment presented in this report provides a methodology for the assessment of the risks posed by mixtures. The quantitative risk assessment approach for the characterisation of potential risks to aquatic receptors has been conducted in accordance with the former ANZECC 2000 and ANZG 2018 guidelines and includes screening the individual constituents in the hydraulic fracturing fluids against trigger values contained within this guideline, or where no ANZECC/ANZG trigger values are available, relevant international screening values or conservatively derived chemical specific trigger values (i.e. for the theoretical hydraulic fracturing chemical fluid constituents). To address the potential for additive effects from the mixture of constituents in the hydraulic fracturing fluids, a cumulative risk characterisation will be conducted that incorporates the same risk assessment methodology used for the human health and terrestrial risk characterisation, and provides a margin of safety to ensure that the total ecotoxicological effects from the potential exposure to the hydraulic fracturing fluids are included in the characterisation of risks, consistent with guidance available from ANZECC (2000) and ANZG (2018). The NEPC (2013) addresses the mixture of constituents and has adopted the hazard quotient approach for the Guideline for ERA. This approach also has been used in other risk assessment frameworks (e.g., USEPA, 1998).

The first step in the ERA approach is to conduct a screening level ERA. The screening level ERA will compare water quality criteria to EPCs. Intake modelling will used for Level II ERA to evaluate exposure of terrestrial receptors to the fracturing water and the EPCs for the exposure scenarios.

The subsequent step in the ERA process is for the characterisation of the potential risks to terrestrial (wildlife and domestic livestock) receptors will follow the enHealth methodology (2012). This methodology includes the identification of the hazards of the constituents in the flowback water, compilation of the toxicity criteria for each constituent, development of exposure models to estimate the daily intake of the constituents, and calculations of individual constituent hazard quotients (daily intake divided by the toxicity criteria) and a cumulative constituent HI for each potentially complete exposure pathway for each human or terrestrial receptor.

8.5.1 Problem Formulation

As described in the NEPC (2013), the problem formulation establishes the goals and focus of the assessment. In addition, the problem formulation defines the conceptual model for the site that describes the current conditions, affected environmental media, ecological effects, potential receptors, complete exposure pathways and assessment endpoints. The problem formulation builds on the problem formulation defined in the PBT/Hazard assessment process by focusing on the site conceptual model and the additional site-specific information collected in the SIMP.

8.5.1.1 Ecological Habitats

As described in in **Sections 2** and **3**, the study area includes both the operational areas of the project and the land areas that immediately surround the operational areas. The objective of the ERA is to assess the typical potential exposures that may occur at any of the operational areas. Therefore, the exposure assumptions for aquatic and terrestrial ecological receptors were based on a typical operational layout, and adjacent land use that includes primary agricultural land and a flowing surface water body.

For the purposes of this ERA, the study area is divided into the operational area and the off-site agricultural area. Such division is relevant to discussions of wildlife habitat characteristics (e.g., land use, habitat fragmentation and anthropogenic effects) associated with the study area.

The operational area has minimal wildlife habitat to support a functioning aquatic or terrestrial ecosystem including foraging and breeding habitat. Normal operational activities and infrastructure and gravel and compacted soil cover on the well pad sites and around infrastructure would significantly inhibit establishment of the requisite wildlife habitat. In addition, as was presented in the HHRA, there are operational controls, security and management practices that would limit the exposure of ecological receptors to the hydraulic fracturing chemicals and fluids. Regarding exposure of potential ecological receptors, these controls and practices include installation and maintenance of fences around the gas pads, and implementation of spill containment and prevention procedures to minimize releases. However, as noted above, there are occasional incursions of wildlife on the operational areas, and these will be evaluated in the ERA.

The off-site agricultural areas do present a terrestrial and aquatic habitat that would support a functioning ecosystem, and therefore, would support a viable ecosystem with foraging and breeding habitat. The clearing and

farming practices pursuant to the extensive agricultural land use has diminished the overall habitat quality, which would potentially exist in an unaltered natural ecosystem. Therefore, the adjacent ecosystem to be evaluated in the ERA will be based on a rural agricultural terrestrial habitat and associated rural agricultural streams.

8.5.1.2 Ecological receptors

Potential ecological receptors are those species that are resident within the study area boundaries, or species resident to adjacent habitats that could be potentially exposed due to their foraging or migratory behavioural characteristics. Extensive ecological surveys were conducted for the Santos EQ Project Area that identified flora and fauna that may inhabit the local and regional environments. Potential ecological receptors include domesticated livestock, agricultural and native plants, local and regional wildlife, and aquatic fish and invertebrates. However, as previously noted, the objective of this ERA is to evaluate the potential risks from a typical gas well field in the Santos EQ Project Area; therefore, the selection of ecological receptors for this ERA is based on understanding that the selected ecological receptors all have an equal opportunity to be exposed to residual hydraulic fracturing flowback water.

8.5.2 Selection of Ecological Values

In accordance with NEPC (2013), ecological values are the actual assessment values that are to be protected from adverse effects on ecological receptors. The criteria for selecting ecological values or assessment endpoints are that they should be ecologically relevant, susceptible to the known or potential stressors and relevant to management decision-making. The ecological values must then be operationally defined. Two elements are required to define an assessment endpoint (USEPA, 1998): identification of the specific-valued ecological entity and a characteristic about the entity that is important to protect.

The Santos EQ Project Area is currently divided into an operational area and an agricultural land use area. The offsite agricultural area would support a limited (based on agricultural disturbance activities) habitat ecosystem, including an associated area for foraging of the selected ecological receptors. The operational area would provide an open area where domesticated and native wildlife may potentially occasionally occur from inadvertent entry, but one that would not be readily preferred due to operational activities and the absence of foraging habitat. Assessment endpoints were selected that were appropriate for these two land use scenarios. Selecting endpoints that are typical of a larger, more ‘natural’ ecosystem (e.g., a mature forested area or natural grasslands) would not contribute to the decision-making for this area. The assessment endpoints, or ecological values, described below are relevant to management goals for the study area. These assessment endpoints are all sensitive to the residual hydraulic fracturing flowback water COPCs identified and have the requisite toxicological and life history databases to support their use as representatives of the study area ecosystem. The assessment endpoints represent ecological receptors for both aquatic and terrestrial trophic levels within the area ecosystem. The selected assessment endpoints and their ecological relevance are:

Survival and reproduction of beef cattle – beef cattle were selected as representative of a large, domesticated livestock species that are known to inhabit the study area and may occasionally enter areas where hydraulic fracturing flowback water is stored on the well pad.

Survival and reproduction of kangaroo – kangaroo were selected as representative of a large wildlife species that are known to inhabit the study area and may occasionally enter areas where hydraulic fracturing flowback water is stored on the well pad.

Survival and reproduction of dingo – dingo were selected as representative of a small wildlife species that are known to inhabit the study area and may occasionally enter areas where hydraulic fracturing flowback water is stored on the well pad.

Survival and reproduction of aquatic invertebrates and fish – aquatic invertebrates and fish were selected as representative of the aquatic ecosystems that are known to exist within the study area. Whilst considered minimal, there is the potential for a release of stored hydraulic fracturing flowback water to surface water ecosystems located near the gas well pads in the situation of an accidental release, such as from piping or the flowback storage pond, especially due to a failure of a containment system during a flood event.

8.5.3 Characterisation of Ecological Effects

To evaluate the assessment endpoints and ecological values, measures of effects (or measurement endpoints) are developed that represent the COPC exposure levels that are conservative thresholds for adverse ecological effects. An effects evaluation was not conducted on the potential ecological effects of landscape maintenance activities, such as mowing, vehicle travel or farming. Physical stressors unrelated to the COPCs in the hydraulic fracturing flowback water are not the focus of this ERA. To evaluate the potential for adverse ecological effects, toxicity reference values (TRVs) are selected as measurement endpoints for the ERA that will be used in the risk

analysis. The TRVs are based on COPC levels that imply no adverse effects or levels that represent the lowest concentration at which adverse effects may occur. The ERA used two types of TRVs. The first TRV is a concentration-based TRV to evaluate the concentration of the selected COPC in the surface water and direct exposure by the aquatic ecological receptor. The second TRV is a dose-based TRV to evaluate the intake dose of the selected COPC from exposure to surface water by ingestion.

The Toxicological Database and Literature Review includes the sources for ecotoxicological information used in the ERA. A hierarchy was used to compile the TRV information as follows:

- ANZECC (2000) and ANZG (2018) guidelines for fresh and marine water quality.
- Western Australia (WA) Department of Environment and Conservation. Assessment Levels for Soil, Sediment and Water. February 2010. Contaminated Site Management Series.
- Department of Environmental and Resource Management. Approval of Coal Seam Gas Water for Beneficial Use. Environmental Protection (Waste Management) Regulation 2000. Queensland Government. March 2010.
- International Guidance including USEPA, American Petroleum Institute and Oak Ridge National Laboratory/Risk Assessment Information System (ORNL/RAIS).

8.5.3.1 Concentration- based TRV

Where possible, existing water quality guidelines for protection of aquatic life were researched and compiled using the hierarch outlined above. If water quality guidelines are available, information on aquatic toxicity was acquired from reported values that had already been through a screening process such as the OECD-SIDS program or through a European Union (EU) existing substances risk assessment. The data from these programs were considered sufficiently reviewed as to not require further evaluation. Data reported as part of other equivalent peer reviewed risk assessment programs (e.g., HERA (www.heraproject.com/); USEPA HPVC Challenge Program) were also considered in a similar fashion, although a certain level of expert judgment was required to evaluate the quality of these programs.

Aquatic toxicity information was also obtained via the ECHA CHEM database. This database provides electronic public access to information on chemical substances manufactured or imported in Europe. The information originates from the registration dossiers submitted by companies to ECHA in the framework of REACH Regulation.

If no data were available from the above sources or the available data were considered insufficient for TRV determinations, then toxicity information on MSDSs were used, as well as read-across from available experimental data on a structurally related substances and predicted values from QSAR models.

Calculation of PNEC for freshwater

The determination of TRVs for freshwater will be conducted according to the predicted no-effects concentration (PNEC) guidance in the Environmental Risk Assessment Guidance Manual for Industrial Chemicals prepared by the Australian Environmental Agency (AEA, 2009).

The PNECs are determined by dividing the lowest toxicity value from a laboratory test by the relevant assessment factor. Results of long-term tests (expressed as the 10 percent effective concentration [EC_{10}] or no observable effects concentration [NOEC]) are preferred to those of short-term tests (50 percent effective concentration/lethal concentration [EC/LC_{50}]) because the results give a more realistic picture of effects on the organisms during their entire life cycle. In order to extrapolate from laboratory data to a multi-species ecosystem, the assessment factors reflect several uncertainties in the data including:

- Intra- and inter-species variations
- Intra- and inter-laboratory variation of toxicity data
- Short-term toxicity to long-term toxicity extrapolation
- Laboratory data to field impact extrapolation.

When only short-term toxicity data are available, an assessment factor of 1,000 was applied on the lowest EC/LC_{50} of the relevant available toxicity data, irrespective of whether the species tested is a standard test organism. This value was reduced to 100 if the following evidence was available:

- Availability of data from a wide variety of species including those considered to represent sensitive species
- Information from structurally similar compounds or QSAR, to suggest that the acute to chronic ratio is likely to be low

- Information to suggest that the chemical acts in a non-specific or narcotic manner, with little inter-species variation in toxicity
- Information to suggest that the release of the chemical is short-term or intermittent, and that the chemical would not be persistent in the environment.

When chronic toxicity data were available in addition to acute data, often an assessment factor from 10 to 100 was applied to the lowest NOEC, taking the following situation into account:

- If a chronic NOEC was available from one or two species representing one or two trophic levels (i.e., fish, *Daphnia* or algae), a factor of 100 or 50, respectively, was applied to the lowest NOEC. In this case, a PNEC value derived from chronic data should be compared to that derived from the lowest acute data. It is then the lowest value that is used in the assessment; and
- If chronic NOECs was available from three species representing three trophic levels (i.e., fish, Daphnia and algae), a factor of 10 was applied to the lowest NOEC. If there was convincing evidence that the most sensitive species for which acute toxicity data were available have been tested chronically, a factor of 10 may also be applied to the lowest NOEC from two species representing two trophic levels (i.e., fish and/or Daphnia and/or algae).

It should be noted that in the case of algae studies, which are actually multigenerational studies, it is generally accepted that a 72-hour (or longer) EC_{50} value may be considered as equivalent to a short- term result and that a 72-hour (or longer) EC_{10} or NOEC value can be considered as a long-term result.

It is preferable to use actual measured data in effects assessment and in estimation of PNECs. However, when limited or no data were available (e.g., data for only one test species) or when the measured data for a species were unacceptable, then estimation using QSARs was considered. With the exception of the $PNEC_{aquatic}$ value for nitrate (used for magnesium nitrate), the aquatic toxicity data sets for the chemicals were insufficient for using the species sensitivity distribution approach. In the case of nitrate, the ANZECC water quality guideline of 700 µg/L was used for the $PNEC_{aquatic}$; this value had been derived using the statistical distribution method.

8.5.3.2 Dosed-based TRV

The basic principles applied in human health toxicity assessments also apply to ecological toxicity assessments, however, carcinogenicity is rarely considered because of a lack of methodologies and the understanding of the modes of action of potential carcinogens on ecological receptors. For the ecological receptors, TRVs are developed based on adverse health effects. The sources of TRVs are from the published literature, or the application of dose-response equations incorporating the relationship of size of the selected receptor to the test species for the dose-response data.

For ecological receptors, the TRVs are calculated based on body weight (BW) scaling methodology that uses the NOAELs and LOAELs, which are daily dose levels normalized to the BW of the test animals (e.g., milligrams of chemical per kilogram BW/day). The use of toxicity data on an mg/kg/day basis allows the comparisons across toxicity tests and across test species with appropriate consideration for differences in body size. Studies have shown that numerous physiological functions such as metabolic rates, as well as responses to toxic chemicals, are a function of body size. Smaller animals have higher metabolic rates and usually are more resistant to toxic chemicals because of more rapid rates of detoxification. After a review of various dose-response models for wildlife, the allometric scaling method was developed using linear regression models of lethal dose versus body weight for a variety of chemicals to extrapolate toxicity between species (Sample and Arenal, 1999). To assess the sensitivity of the model, residuals from the allometric scaling were analysed using regression models. The patterns of sensitivity among mammalian species were relatively constant across chemical classes. The development of this new allometric scaling model improved the extrapolation of toxicity effects between species, thus providing a more accurate assessment of potential ecological risks when data are limited for the specific species being assessed. The allometric scaling method was used to estimate the population level effects on wildlife based on individual level of exposures (Sample et al., 1999).

For mammals, it has been shown that this allometric scaling relationship is best expressed in terms of BW raised to the ¾ power ($bw^{3/4}$). Therefore, the dose for the selected ecological receptor is a function of the BW of the test species divided by the BW of the selected ecological receptor to the ¾ power, and then is multiplied times the dose of the test species.

$$NOAEL_w = NOAEL_t \left(\frac{bw_t}{bw_w}\right)^{3/4}$$

The calculated TRVs for each of the mammalian ecological receptors evaluated in the ERA are presented in the species-specific ecological risk models. It is noted that the allometric scaling methodology was only used to calculate TRVs for terrestrial mammals. Aquatic receptors were evaluated using the $PNEC_{aquatic}$ values.

8.5.4 Characterisation of Exposure

As presented in the HHRA, the exposure scenarios for the ERA will be the same as the HHRA: theoretical exposure to the returning fracturing fluids used in the stimulation events.

8.5.4.1 Exposure Point Concentrations (EPCs)

EPCs for the exposure assessment were calculated using the results of theoretical fate and transport modelling calculations for each fluid system (**Appendix C**). The potentially affected flowback water that represents complete exposure pathways for the ecological receptors includes the surface water systems (e.g., flowback storage ponds and mud pits) that were used to estimate the EPCs for the human health receptors (**Appendix C**). Similar to the EPCs for the human health receptors, the EPCs for the ecological receptors assumed various mass percentages returned in the flowback water, which were diluted within 150% of the injected volume of return water. These EPCs were then adjusted based on biodegradation rates to calculate the theoretical EPCs for the four exposure time periods (0, 30, 150, and 300 days).

8.5.4.2 Exposure Equations

The estimate for dose-based or intake rates for the assessment endpoints for wildlife representing domestic livestock and native mammalian species used the following general equation:

$$TI = Cwater \; x \; IRwater \; x \; EF \; x \; ED \; / \; BW \; x \; ED \; x \; 365 \; days/year$$

Where:

- TI = Total intake of COPC (mg/kg/day)
- Cwater = Concentration of COPC in water (mg/l)
- IRwater = Ingestion rate (litres/day)
- EF = Exposure frequency (days/year)
- ED = Exposure duration (years)
- BW = Body weight (kg).

Water ingestion and BW were obtained from the following: livestock cattle from API (2004); kangaroo from Dawson (1995); and dingo from Fleming et al. (2001). The water ingestion rate (IR) for kangaroo assumed that although they may go extended periods without water (getting water from the grasses they eat); they would conservatively take advantage of the presence

of surface water to replenish themselves, up to three litres per event. Dingoes in general drink one litre of water a day in the summer and about half a litre a day in winter (Dawson, 1995), a rate of 0.75 litres per day was selected as an average.

Exposure frequency and duration were based on professional judgment that incorporated operational considerations for the frequency and duration of the potential for exposure to the gas site in the three scenarios, and a conservative estimate of potential for domestic livestock and mammalian wildlife to be exposed. The use of EF and duration replaced the use of a home range ratio that is commonly used in intake modelling equations for ecological receptors. This was because the exposure of the domestic livestock and mammalian wildlife was not considered habitat-driven (they would normally forage and breed in the operational areas), but similar to a 'trespasser' exposure scenario used in the HHRA. As noted previously, the excluded ecological receptors (e.g., soil microbes, soil invertebrates, terrestrial plants, and localized smaller mammals) would have exposure that is habitat-driven (they would be limited to the unexposed surrounding lands). The exposure assumptions also recognizes that the storage of flowback water at individual well pad sites will be only a temporary activity, with operational controls and activities at the well sites likely limiting the occurrence of livestock and wildlife entry and exposures. In addition, it is not reasonable to assume that they would be exposed to multiple gas well sites that are located miles apart. Therefore, the receptors were assumed to obtain drinking water from the flowback water only on occasions when they inadvertently entered on to the operational area of a unique modelled gas well site as follows:

- Livestock cattle – this receptor exposure pathway includes livestock cattle that may come in contact with the flowback storage pond water exposure scenarios for approximately 15 days/year for an 8-year period with the potential for incidental ingestion (watering).

- Kangaroo – this receptor exposure pathway includes kangaroos that may come in contact with the above grade water exposure scenarios for approximately 10 days/year for a 15-year period with the potential for incidental ingestion (watering).
- Dingo – this receptor exposure pathway includes dingos that may come in contact with the above grade water exposure scenarios for approximately 10 days/year for a 15-year period with the potential for incidental ingestion (watering).

8.5.5 Risk Characterisation

In accordance with NEPC (2013) and USEPA guidance (1997), the risk characterisation integrates the information obtained in the ecological effects and exposure phase and provides an estimate of risk to those ecological entities included in the assessment endpoints. After the risk estimates are calculated, they are placed in the context of the significance of any adverse effects and lines of evidence supporting their likelihood, and associated uncertainties are described.

8.5.5.1 Estimation of Risk

Risks are estimated by comparing the EPC (for aquatic receptors) to a concentration-based TRV and the estimated TI (for livestock and wildlife) to a dose-based TRV. This comparison provides a HQ, which represents a ratio of the exposure to the potential for toxicological adverse effects.

The HQ estimate for concentration-based risks for the assessment points for aquatic receptors used the following general equation:

$$HQ = EPC / TRV$$

Where:

- HQ = hazard quotient
- EPC = COPC exposure point concentration in surface water (mg/l)

$$TRV = concentrat\text{-}on - based\ TRV\ (mg/l)$$

The HQ for intake-based risks for assessment endpoints for domestic livestock and mammalian wildlife used the following general equation:

$$TRV = concentrat\text{-}on - based\ TRV\ (mg/l)$$

Where:

- HQ = hazard quotient
- TI = total intake of COPC (mg/kg-day)
- TRV = dose-based TRV (mg/kg/day)

The resulting hazard quotient (HQ) must be less than or equal to one (rounded to one significant figure) for risks to be considered acceptable. If the quotient is greater than one, the exposure potentially may cause an adverse ecological effect and the substance is retained for further evaluation in the baseline ERA to refine the calculation of potential risks to exposed ecological receptors. If the hazard quotient is less than one, there is adequate information to conclude that ecological risks are negligible for that substance and, therefore, no further evaluation in the baseline ERA process is warranted.

8.6 Uncertainty Analysis

The procedures and inputs used to assess potential human health and ecological risks in this, and similar quantitative human health and ecological risk assessments are subject to a wide variety of uncertainties. In general, there are five main sources of uncertainty and variability in risk assessments of well-characterised sites:

- Environmental chemistry
- Environmental parameter measurements
- Fate and transport modelling
- Toxicological data and dose-response extrapolations

- Updated risk assessment methodologies, exposure assumptions, and toxicological data
- Combinations of the above.

Discussion regarding potential uncertainty inherent in the quantitative risk assessment process will be presented for each fluid system evaluated in **Appendix C**.

9 Other Potential Risks

The information provided in this section addresses the following EA approval requirements: conditions (u), (z)(2) and (aa).

Other potential risks associated with hydraulic fracturing were evaluated in the Golder Associated Stage 1 and Stage 2 Hydraulic Fracturing Risk Assessments (2011a). Evolution of the hydraulic fracturing process has also resulted in changes to the hydraulic fracturing methodologies and the proppants utilised.

Due to modifications to hydraulic fracturing systems and proppants, supplemental risk assessments have been completed including:

- A quantitative risk assessment conducted by EHS Support (2013a) on the use of radiological tracers and perforation balls
- A supplemental qualitative risk assessment conducted by Golder Associates (2013b) on the use of LiteProp 125 as an alternative to sand in the hydraulic fracturing process
- A supplemental qualitative risk assessment conducted by Golder Associates (2011b) on the substitution of potassium chloride for sodium chloride as a stabiliser in the drilling and hydraulic fracturing process.

The potential additional risks posed by these systems which may be used in any of the hydraulic fracturing processes and fluid systems are described below and further information is provided in **Appendix H**. It is anticipated that additional substitutions of chemicals, proppants, tracers and additives will be trialled over time and used as tools in the process. These supplement assessments (many of which are not part of fluid systems) will be simply added to the information provided in **Appendix H**.

9.1 Noise and Vibration

The Golder Associates (2011a) assessment considered the potential risks associated with noise, vibration and air quality. Key text from both of these documents is provided in the sections below.

The activities associated with hydraulic fracturing have the potential to generate noise or vibration that could potentially impact nearby receptors. Whilst the proposed activities will take place on a continuous basis, they will be undertaken sequentially for short periods of time at different sites over a wide area. As a result, individual sensitive receivers are only likely to be exposed to the effects of nose from these activities for a few weeks at a time. Such short-term noise and vibration effects can be considered to equate to construction works and may be evaluated and controlled accordingly.

In February 2012, the Queensland DEHP, formerly DERM, published the guideline Prescribing Noise Conditions for Environmental Authorities for Petroleum and Gas Activities (Noise Assessment Guideline) to supplement the application of EPP Noise in the administration of an EA for petroleum and gas activity projects.

This guideline applies to the Santos EQ Project Area as it specifies ‘best practice’ noise limits which are considered to protect the acoustic values of a noise receptor in rural or isolated areas and achieve acoustic quality objectives set out in the EPP Noise, whilst considering cumulative impacts and background creep.

The best practice noise emission limits are reproduced in **Table 29**. These best practice noise limits are applicable to noise emissions from both construction and operation, the duration and work hours of the activity determining the applicable noise limit for the activity.

Table 29. Best Practice Noise Limits

Time Period	Parameter	Noise Limit (dBA)[1]		
		Short-term[2]	Medium-term[3]	Long-term[4]
7:00 am – 6:00 pm	LAeq, adj, 15mins	45	43	40

Time Period	Parameter	Noise Limit (dBA)[1]		
		Short-term[2]	Medium-term[3]	Long-term[4]
6:00 pm – 10:00 pm	LAeq, adj, 15mins	40	38	35
10:00 pm – 6:00 am	LAeq, adj, 15mins	28	28	28
	Max LpA, 15 mins	55	55	55
6:00 am – 7:00 am	LAeq, adj, 15mins	40	38	35

[1] *Based on the deemed background noise levels.*
[2] *A short-term noise event is defined as a noise exposure lasting for no greater than eight (8) hours and does not reoccur for at least seven (7) days.*
[3] *A medium-term noise event is defined as a noise exposure lasting for no greater than five (5) days and does not reoccur for at least four (4) weeks.*
[4] *A long-term noise event is defined as a noise exposure lasting for greater than five (5) days, even when there are respite periods when noise is inaudible within those five (5) days. Almost all construction and operational scenarios will fall within this long-term noise event specification*

The Queensland Government's Environmental Protection Agency's Ecoaccess Guideline – Noise and vibration from blasting identifies a vibration performance human comfort criteria for blasting of 5 mm/s for nine out of ten blasts and a maximum limit of 10 mm/ s for any blast. Australian Standard AS 2670.1-1990 provides for generally higher standards for human comfort for continuous or extended transient periods. In the absence of an Australian Standard, the vibration criteria of BS 7385: Part 2:1993 and/or DIN 4150-Part 3:1999 are generally applied to protect building structures. These provide for similar standards of 5 mm/s for continuous vibration and 10 mm/s for transient vibration, except for heritage/vulnerable buildings where lower limits apply.

9.2 Qualitative Noise Assessment

Information regarding the main sources of noise associated with a typical hydraulic fracturing process was provided by Santos EQ and the individual source terms for each source (sound power levels – SWLs) have been calculated from this data to be:

- Annulus – 1 off – SWL 90.3 dB(A)
- Frac Van – 1 off – SWL 98.8 dB(A)
- Power Pack – 1 off – SWL 106.7 dB(A)
- High pressure pump – 4 off – SWL 104.7-107.6 dB(A) – average SWL 106.1 dB(A)
- Low pressure pump – 1 off – 99.5 dB(A)
- Downhole Blender – 1 off – SWL 105.4 dB(A)
- Sand trailer —1 off - SWL 100.2 dB(A)
- Pregel – 1 off – SWL 104.6 dB(A)
- LGC – 1 off – SWL 97.9 dB(A).

Adding all noise sources together provides a conservative estimate of the total noise emissions from the process plant of SWL 115 dB(A), assuming that all noise sources are operational at full load at the same time. On this basis under neutral meteorological conditions, assuming minimal ground attenuation and no topographic screening, noise levels in the region of 50 dB LAeq 1- hour could be expected at a distance of 500 m from the worksite, falling to about 45 dB LAeq 1- hour at 1 km, 40 dB LAeq 1- hour at 2 km and about 35 dB LAeq 1- hour at 4 km.

However, on the basis of the distance calculations for the 85 dB exclusion zone (where hearing protection is needed) in the information provided, it would appear that the quoted values are sound pressure levels (SPL) at an unspecified distance from the source and if this is the case the actual SWLs may well be up to 10 dB(A) higher, which could extend the separation distances required to achieve the identified noise levels by an order of magnitude.

The estimated noise levels over distance are based conservatively on the simultaneous operation of all noise sources, lower levels would be generated if some or all of the identified equipment were to be operated sequentially or intermittently. It should be noted that Hydraulic Fracturing operations are generally conducted during the day and as such the potential impacts from these short-term activities will be lower. Where potential impacts on sensitive receptors may occur a number of mitigation methods will be employed to dampen noise emissions and minimise nuisance to receptors.

9.3 Qualitative Vibration Assessment

The effects of ground vibration on receivers will depend upon the source strength, separation distance and the nature of the transmission pathway.

Typically, significant vibration effects are only likely within, at most, a few 100s of metres of the source and any potential adverse effects are, therefore, unlikely to extend as far as those arising from noise emissions.

SLR has undertaken vibration measurements adjacent to two Santos EQ employed drill rigs (Santos pers. comm). At both locations, the measured vibration levels (PPV) during air drilling operations were below 0.1 mm/s at the drill lease boundary. Based on the nature of hydraulic fracturing activities which have many similarities with drilling no vibration impacts are anticipated.

9.4 Air Quality

An assessment of potential air quality impacts was completed by Golder Associates (2011a) as part of the Stage 1 and Stage 2 Hydraulic Fracturing Risk Assessments. The basis and key findings from these assessments are described below.

9.4.1 Airborne Contaminants

Exposure to airborne contaminants has been evaluated through a review of chemicals considered volatile. In general, most chemicals used in hydraulic fracturing exhibit low volatility.

The volatility of individual chemicals within a water mixture can be assessed based on the Henry's law constant (KH). According to NEPC (2013) chemicals can be considered highly volatile if the KH value is >2.5 x 10-3, moderately volatile for a KH value between 2.5 x 10-7 and 2.5 x 10-3 and not volatile if KH value is < 2.5 x 10-7. The KH values included in the chemical information sheets indicate that most chemicals used exhibit low solubility. A number of chemicals do exhibit high or moderate volatility these include some of the organic acids, alcohols (e.g., ethanol) terpenoids and terpene alcohols, food-based oils and biocides.

In general, the use of these agents is at low concentrations and the environment on and off-site is predominantly outdoors and not enclosed areas, and as such, inhalation is considered to represent a minor exposure pathway. In addition, there are control measures to manage any potential risks to workers.

9.4.2 9.4.2 Dust Suppression

Certain chemicals within the fracturing fluid additives, for example crystalline silica, represent a potential human health risk related to inhalation of dust generated during storage, transport or handling of the product. This is principally an occupational health hazard that is controlled through existing operational management procedures relating to the handling and storage of the additives. Information provided by the service contractor indicates that a health and safety management system exists that specifically addresses hazards related to materials storage and handling. In addition, Golder understands that the hydraulic fracturing additives are blended into the fluid mixture in enclosed vessels, and therefore the inhalation risk related to dust particulates is considered to be low on the basis of the engineering controls in place.

9.5 Alternative Proppants and Hydraulic Fracturing Agents

As noted above, modifications to the hydraulic methodologies over time have result in the inclusion of alternative proppants, and agents in the hydraulic fracturing process. These agents while introduced into the well are not reactive chemicals and technically are not part of the fluid system, which must be assessed. Rather they act as either inert substances designed to fill induced fractures (proppants), provide mechanical isolation of intervals or act as a stabiliser in the fluid system.

The potential risks associated with these agents are only assessed through the PBT framework to determine whether they have any hazardous properties and demonstrate that they are inert and non- reactive.

The PBT assessments conducted on these agents (which are provided in **Appendix H**) demonstrate that these substances are inert and not considered PBT substances. The size and inert nature of agents such as the perforation balls and proppants and their insolubility in water prevent their uptake by aquatic or terrestrial organisms.

9.6 Radiological Exposures

The potential for radiological exposures associated with the use of radiological tracers during the hydraulic fracturing process was evaluated in a risk assessment completed by EHS Support (2013a). The risk assessment involved an assessment of the chemical and physical properties of the ProTechnics tracer beads, a literature review and review of quantitative risk assessment conducted by the supplier.

The ProTechnics zero wash beads are utilised in the hydraulic fracturing process to allow for tracing of vertical and lateral distribution of proppants in the formation. The tracer beads are manufactured using a process that binds the radioisotope to the carrier particle and prevents washout. The ceramic beads are not biodegradable and are persistent in the formation, the radioactive tracers used are short lived with half-lives of less than 90 days. No chemical exposures to organisms are anticipated based on the absence of reactivity of these compounds; however, radiological exposures may potentially exist and were evaluated further.

Exposure to radionucleides can increase the risk for human cancer because of their high-energy gamma radiation. Gamma radiation is high-energy electromagnetic radiation emitted by certain radionucleides when their nuclei transition from a higher to a lower energy value.

A quantitative radiological risk assessment was completed on the transportation, use and management (refer **Appendix H**). The assessment demonstrated that there are no adverse impacts from the use of radiological tracers with the resulting dosages similar to the magnitude of sources that people are exposed to in everyday life. On this basis, the existing exposure controls implemented by Santos EQ for hydraulic fracturing activities and management of flowback water are considered sufficient for management of potential impacts on human health and the environment.

9.7 Cumulative Underground Impacts

Cumulative underground impacts are not anticipated as part of the project based on the controls described above. Fracturing will be confined to the target formation and vertical fracturing into overlying aquifer units will not occur.

The only cumulative impacts associated with the development activities are associated with extraction of water from the coal sequences (after completion of the hydraulic fracturing activities) and depressurization of overlying aquifer systems. These cumulative impacts have been assessed separately and a groundwater monitoring and management plan developed which includes make good provisions for potentially affected bores which may see reductions in water levels and associated yield.

10 Risk Assessment Findings

As described in Section 5, a weight of evidence approach has been used to the risks associated with hydraulic fracturing. A combination of assessment methodologies and models has been used to assess the fate and transport of chemicals and their associated risks. The results for risk assessments completed on the individual hydraulic fracturing fluid systems is provided in **Appendix C**, with the summary of results mirroring the various steps in the assessment process.

The toxicity of the chemicals used in the hydraulic fracturing process has been assessed for PBT, terrestrial toxicity and human health toxicity. The qualitative risk assessment methodology in some cases has used a semi-quantitative ranking of the hazards. Through this assessment methodology it has been determined that the chemicals used in hydraulic fracturing fluid systems can be generally characterised as non-hazardous with no chemicals identified with no high hazard chemicals identified in the semi-quantitative assessments. Overall, the health concerns from these chemicals are limited with the primary concerns identified associated with potential risks to aquatic receptors.

Consistent with the NWQMS, the quantitative risk assessment evaluated the toxicity of the individual substances and characterised the cumulative risks of the total fluid to human receptors and ecological terrestrial and aquatic

receptors. The methodology incorporated an assessment of potential exposures to human and ecological receptors, with the following identified as the only potentially complete exposure pathways:

- Incidental ingestion and dermal contact by trespassers at well pads
- Livestock and native fauna exposure to flowback water (ingestion only) at the well pads
- Potential releases of water to aquatic environments.

Based on groundwater fate and transport modelling, no potentially complete exposure pathways were identified for groundwater.

EPCs were developed for each of the hydraulic fracturing fluid systems using a combination of theoretical calculations and the results of flowback sampling. It should be noted that theoretical calculations have been completed for each fluid system. However, sampling of the flowback from all fluid systems has not been conducted, with a number of fluid systems still to be used in the fields.

No carcinogenic compounds are used in any of the hydraulic fracturing fluid systems used by Santos EQ. The chemicals used in the hydraulic fracturing process do not contain BTEX or PAHs as additives, which are recognised carcinogens.

For the assessment of non-carcinogenic human health and ecological terrestrial and aquatic risks, the risks posed by the mixture were calculated. For the assessment of carcinogenic or threshold effects levels to human receptors, the actual uptake of COPCs by ingestion and dermal contact were compared to acceptable risk-based intakes to calculate an individual HQ and then summed for all constituents into a HI. Similarly, potential ecological risks were estimated by comparing the EPC (for aquatic and terrestrial receptors) to reference values to provide a HQ, which was cumulated for a HI of the mixture.

Consistent with risk assessment methodologies, if the HI is less than or equal to 1, then no adverse health effects are likely associated with exposures. However, if the total HI is greater than 1, adverse health effects may be likely, but the evaluation requires further evaluation to define the risk characterisation process.

On the basis of the risk evaluations, the exposure pathways were generally less than 1 for human health and terrestrial receptors. In a number of cases, only at high theoretical concentrations were potential unacceptable risks observed. However, sampling of flow-back from hydraulic fracturing completed to date has indicated that the concentrations observed in flowback are considerably lower than the theoretical concentrations and the theoretical assumptions are highly conservative and not representative of long-term EPCs.

The quantitative risk assessment identified potential impacts if releases of flow-back water were to occur to aquatic environments. The magnitude of the impacts on receiving water (surface water) would be determined by the magnitude of the release, the mixing and dilution within the receiving water, and the physical properties and conditions within the receiving water. Potential impacts occurred for all exposure biodegradation periods for both theoretical and empirical data sets.

Considering the findings of the hazard and exposure assessment and the controls implemented by Santos EQ, the overall risk to human health and environment associated with the chemicals involved in hydraulic fracturing is low and acceptable. These operational controls include:

- Compliance with all EA requirements on siting of well bores including the lateral and vertical separation of hydraulically fractured wells relative to landholder bores. EA requirements have been incorporated within Santos's constraints planning protocol which is used for siting of all wells.
- Continued conformance with the Code of Practice for well siting, well installation, testing and hydraulic fracturing of wells.
- Application of DNRME assessment, notification and reporting requirements to ensure that wells are appropriately installed, tested and hydraulically fractured. This is combined with Santos EQ operational procedures to ensure well integrity and design of fracture to stay within the target seam, which are included in all reports submitted to DNRME.
- OH&S procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals
- Lining of mud pits and turkey's nests to prevent seepage of flowback water into underlying aquifers

- Disposal or capping of sediments contained within drained mud pits and turkey nests, to prevent exposure to contaminates in windborne dust
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna
- Santos EQ operational procedures to ensure well integrity and design of fracture to stay within the target seam

The adequacy and appropriateness of these exposure controls will be routinely evaluated by Santos EQ and modifications and revisions made, where necessary. This will be further supported by regular monitoring of water supply bores and surface water for hydraulic fracturing chemicals and routine audits and inspections to ensure that these operational and exposure controls are effectively implemented and maintained.

In addition to the potential hazards associated with the use of chemicals in hydraulic fracturing, an assessment of the potential impacts of noise and vibration from the process and the use of alternative proppants and radiological tracers was completed. No unacceptable risks to receptors were identified from noise and vibration during the hydraulic fracturing process. The additional risks were identified from the use of alternative proppants, with these proppants providing the benefit of reducing potential inhalation (siliceous) risks to workers. The use of radiological tracers, at the design concentrations and in accordance with manufacturer specifications provided no unacceptable risks. Risk Assessment summaries for the alternative proppants and radiological tracers are provided in **Appendix H**.

In addition, a tiered assessment approach (CRAF) was presented to streamline the risk assessment process. This assessment process is designed to align with state and national guidance and other regulatory frameworks and assesses the full lifecycle of chemicals that are stored, handled, used and/or disposed of during or following hydraulic stimulation activities and in the treatment of produced formation water. By using the CRAF, potential risks to environmental values associated with stimulation activities will be demonstrated to be eliminated or reduced as much as reasonably practicable.

Forty-eight (48) hydraulic fracturing chemicals were assessed as part of this tiered assessment approach:

- 38 chemicals were assessed as Tier 1 chemicals
- Seven (7) chemicals were assessed as Tier 2 chemicals
- Three (3) chemicals were assessed as Tier 3 chemicals
- No chemicals were assessed as Tier 4 or 5 chemicals

The chemical risk assessments completed for each chemical indicated no negligible risks and effects of chemicals used during hydraulic fracturing to environmental values when appropriate management and mitigation controls were in place. Should assessments of additional chemicals indicate additional management control, the associated management plans will be updated accordingly.

It is the intent of Santos EQ that this new methodology will be the process moving forward to assess new chemicals. As described in **Section 5.2.3**, the Register of Assessed Chemicals will, for each published chemical, provide a summary of the outcomes of the screening assessment, including the Tier (and Risk Level) categorisation, the activities the chemical has been assessed for (i.e., hydraulic) and the assessed end use /fate of the chemical. Supporting information (i.e., dossiers, qualitative and quantitative risk assessments) for each assessed chemical are also readily accessible via the published register. The dossiers that are published in the Register of Assessed Chemicals are considered the most up to date.

Based on this assessment of risk, stimulation impact monitoring will be conducted in accordance with the requirements specified in the EA. Monitoring of water quality in landholder bores should include the minimum parameter lists and standard reporting limits, with the exception of PAHs where ultra-low reporting limits are required to support comparison to relevant regulatory criteria. Based on the limited risks identified in the study (based on management and administrative controls) a reduced suite of analytes associated with operational requirements is recommended to address primarily operational requirements for water management and provide indicator/tracer compounds for technical assessments.

APPENDIX A SUMMARY OF HYDRAULIC FRACTURING CHEMICALS

Santos

Schlumberger Guar Based Systems	
Chemical Name	**CAS No.**
Tetrasodium ethylenediaminetetraacetate (EDTA)	64-02-8
Carbohydrate polymer (guar gum)	9000-30-0
Hydrochloric acid	7647-01-0
Polypropylene Glycol	25322-69-4
Postassium Chloride	7447-40-7
Sodium Hydroxide	1310-73-2
Sodium Hypochlorite	7681-52-9
Nitrogen, liquid form	7727-37-9
Crystalline silica (cristobalite)	14464-46-1
Crystalline silica (quartz)	14808-60-7
Magnesium silicate hydrate (talc)	14807-96-6
Vinylidene Chloride/methylacrylate	25038-72-6
Non crystalline silica (amorphous silica surrogate)	7631-86-9
Diammonium peroxidisulphate (ammonium persulphate)	7727-54-0
Magnesium Chloride	7786-30-3
Diatomaceous Earth, calcined	91053-39-3
Alcohols C6-C10 ethoxylated (surrogate C6 - C12)	68439-45-2
Alkylaryl Sulfonate	25155-30-0
Timethylammonium chloride	8030-78-2
trimethyl-3-[{1-oxooctadecyl)amino]propylammonium methyl sulphate	19277-88-4
Propane 1,2 diol	57-55-6
Ammonium C6-C10 alcohol ethoxysulfate	68187-17-7
Carbonic acid, sodium salt	533-96-0

Assessment provided in Appendix C1

Santos

Halliburton Water and Guar Based Systems (Original DeltaFoam 140 Formulation)	
Chemical Name	**CAS No.**
Acetic Acid	64-19-7
Calcium chloride	10043-52-4
Coffee Extract	68916-18-7
Ethanol	67-17-5
Guar Gum	9000-30-0
Monoethanolamine borate	26038-87-9
Sodium chloride	7647-14-5
Sodium hydroxide	1310-73-2
Sodium sulfate	7757-82-6
Tetrakis (hydroxymethyl) phosphonium sulphate (THPS)	55566-30-8
Alkylated quaternary chloride (surrogate tetramethylammonium chloride)	75-57-0
Coco dimethylaminopropyl betaine	61789-40-0
Sodium sulfite	7757-83-7
Silica gel	112926-00-8
Crystalline silica	14808-60-7
Terpenes and terpenoids, sweet orange oil	68647-72-3
Terpene hydrocarbons by products™	68956-56-9
1,2 Benzisothiazolin -3-one	2634-33-5
Non-ionic surfactant mix™	-*
Surfactant mix™	-*
Fatty acid ester™	-*
Ethoxylated fatty acid ester™	-*
Enzyme™	-*
Sodium thiosulfate	7772-98-7
Bentonite	121888-68-4

** The CAS numbers for fatty acid ester, ethoxylated fatty acid ester, non-ionic surfactant mix, surfactant mix, terpene hydrocarbon by products and enzyme have not been included in this table due to commercial confidentiality.*

Assessment provided in Appendix C2

Santos

Halliburton CleanStimAUs System	
Chemical Name	**CAS No.**
Hemicellulase enzyme™	9012-54-8
Carbohydrate (Lactose)	63-42-3
Potassium chloride	7447-40-7
Polysaccharide (Sodium carboxymethyl cellulose)	9004-32-4
Fatty acid ester™ (Sorbitan, monododecanoate, poly(oxy-1,2-diethanediyl))	9005-64-5
Sulfuric acid	7664-93-9
Sodium lauryl sulfate	75-57-0
Tri tetradecyl phosphonium chloride (TTPC)	81741-28-8
Cyrstalline silica, quartz	14808-60-7
Talc	14807-96-6
Saccharide (Maltodextrin)	9050-36-6
Inorganic salt (Aluminium sulfate)	10043-01-3
Food coating (Shellac, ammonium salt)	68308-35-8

Assessment provided in Appendix C3

ClearFrac	
Chemical Name	**CAS No.**
Cholinium chloride	67-48-1
Hydrochloric acid	7647-01-0
Propan-2-ol	67-63-0
Sodium chloride	7647-14-5
Acetic acid ethenyl ester, polymer with ethenol	25213-24-5
Cristobalite	14464-46-1
Cyrstalline silica	14808-60-7
Magnesium nitrate	13077-60-3
Magnesium silicate hydrate (talc)	14807-96-6
Vinylidene chloride/methalacrylate copolymer	25038-72-6
Magnesium chloride	7786-30-3
Diatomaceous earth, calcined	91053-39-3
2-methyl-2h-isothiazol-3-one	2682-20-4
5-chloro-2-methyl-2h-isothiazolol-3-one	26172-55-4
Erucic amidopropyl dimethyl betaine	149879-98-1
Benzenesulfonic acid, 4-ethenyl-, sodium salt, homopolymer	25704-18-1
Sodium chloroacetate	3926-62-3
Polyvinyl acetate, partially hydrolyzed	304443-60-5

Assessment provided in Appendix C4

Santos

Halliburton Alternative System (Delta 140 Formulation)	
Chemical Name	**CAS No.**
Acetic Acid	64-19-7
Hemicellulase enzyme	9012-54-8
Choline chloride	67-48-1
Ethylene glycol	107-21-1
Guar Gum	9000-30-0
Hydrochloric acid	7647-01-0
Monoethanolamine borate	26038-87-9
Sodium hydroxide	1310-73-2
Tetrakis (hydroxymethyl) phosphonium sulphate (THPS)	55566-30-8
Coco dimethylaminopropyl betaine	61789-40-0
Crystalline silica and Cyrstalline silica, quartz	14808-60-7
Coffee beans (green coffee bean extract; chlorogenic acid)	327-97-9
Coffee beans (caffeine)	58-08-2
Alcohols, C6-C-12, ethoxylated propoxylated	68937-66-6
Alcohols, C10-C16, ethoxylated propoxylated	69227-22-1
Maltodextrin	9050-36-6
Polyethylene glycol	25322-68-3

Assessment provided in Appendix C5

Schlumberger YF120 Flex with J318 System	
Chemical Name	**CAS No.**
Cholinium chloride	67-48-1
Glycerol	56-81-5
Guar gum	9000-30-0
Hydrochloric acid	7647-01-0
Potassium hydroxide	1310-58-3
2,2`,2"-nitrilotriethanol	102-71-6
Cristobalite	14464-46-1
Crystalline silica	14808-60-7
Magnesium nitrate	10377-60-3
Potassium borate	1332-77-0
Magnesium silicate hydrate (talc)	14807-96-6
Vinylidene chloride/methylacrylate copolymer	25038-72-6
Non-crystalline silica	7631-86-9
Diammonium peroxidisulphate	7727-54-0
Magnesium chloride	7786-30-3
Diatomaceous earth, calcined	91053-39-3
2-methyl-2h-isothiazol-3-one	2682-20-4
5-chloro-2-methyl-2h-isothiazolol-3-one	26172-55-4

Assessment provided in Appendix C6

Schlumberger Sapphire LF System	
Chemical Name	**CAS No.**
2-hydroxy-N,N,N-trimethylethanaminium chloride (Choline chloride)	67-48-1
Sodium carboxymethylcellulose	9004-32-4
2,2`,2"-nitrilotriethanol	102-71-6
Cristobalite	14464-46-1
Crystalline silica	14808-60-7
Magnesium nitrate	10377-60-3
Magnesium silicate hydrate (talc)	14807-96-6
Vinylidene chloride/methylacrylate copolymer	25038-72-6
Diammonium peroxidisulphate	7727-54-0
Magnesium chloride	7786-30-3
Diatomaceous earth, calcined	91053-39-3
2-methyl-2h-isothiazol-3-one	2682-20-4
5-chloro-2-methyl-2h-isothiazolol-3-one	26172-55-4

Assessment provided in Appendix C7

Halliburton Hydraulic Fracturing Fluid System - Well RM 08-14-3	
Chemical Name	**CAS No.**
Acetic acid	64-19-2
Hemicellulase enzyme	9012-54-8
Diethanolamine	111-42-2
Ethylene glycol	107-21-1
Lactose	63-42-3
Monoethanolamine borate	26038-87-9
Sodium carbonate	497-19-8
Sodium hydroxide	1310-73-2
Tributyl tetradecyl phosphonium chloride	81741-28-8
Hydroxypropyl guar	39421-75-5
Triethanolamine	107-71-6
Ulexite	1319-33-1
Crystalline Silica	14808-60-7
Silica dioxide	7631-86-9
Disodium octaborate tetrahydrate	12280-03-4

Assessment provided in Appendix C8

Fluorescein Dye Hydraulic Fracturing Fluid System	
Chemical Name	**CAS No.**
Potassium chloride	7447-40-7
Tributyl tetradecyl phosphonium chloride	81741-28-8
Sodium fluorescein	518-47-8

Assessment provided in Appendix C9

Santos

Condor Energy Hydraulic Fracturing Fluid System	
Chemical Name	**CAS No.**
2-Mercaptoethyl Alcohol	60-24-2
Polyacrylamide	25085-02-3
Acetic Acid	64-19-7
N-Benzyl-Alkylpyridinium Chloride	68909-18-2
Hemicellulase	9025-56-3
Choline Chloride	67-48-1
Ethylene Glycol	107-21-1
Polyoxyethylene-polyoxypropylene Block Copolymer	9003-11-6
Glutaraldehyde	111-30-8
Glycerol	56-81-5
Guar Gum	9000-30-0
Distillates, Hydrotreated Light	64742-47-8
HydroChloric Acid	7647-01-0
Isopropanol	67-63-0
Methanol	67-56-1
Potassium Chloride	7447-40-7
Potassium Hydroxide	1310-58-3
Sodium bisulfite	7631-90-5
Sodium Hydroxide	1310-73-2
Sodium polyacrylate	9003-04-7
Sodium erythorbate	6381-77-7
Diethylene Glycol	111-46-6
Cinnamaldehyde	104-55-2
Formic Acid	64-18-6
Ammonium Persulphate	7727-54-0
Alcohols, C9-11, ethoxylated	68439-46-3
Ethoxylated C11 Alcohol	34398-01-1
Ammonium Sulphate	7783-20-2
2-Propenoic acid, homopolymer, ammonium salt	9003-03-6
Potassium persulfate	7727-21-1
2-Ethoxy-naphthalene	93-18-5
Inorganic Salt	584-08-7
Sodium Tetraborate	1330-43-4
1,6-Hexanediol	629-11-8
Amylase, Alpha	9000-90-2
Sodium Benzoate	532-32-1
Pottasium Sorbate	24634-61-5
Polyoxyethylene nonylphenol ether	9016-45-9
Quaternary ammonium compounds, bis(hydrogenated tallow alkyl)dimethyl, salts with bentonite	68953-58-2
Water in Additive	7732-18-5
Tar Bases, Quinoline Derivatives, Benzyl Chloride-Quat	72480-70-7

Chemical Name	CAS No.
Castor Oil	61791-12-6
Pine Oil	8002-09-3

Assessment provided in Appendix C10

Santos

Halliburton Hybor and Delta Hyraulic Fracturing Fluid Systems (Hybor DFS-BCG-H)	
Chemical Name	**CAS No.**
Acetic acid	64-19-7
Alcohols, C12-15, ethoxylated	68131-39-5
Amides, tall-oil fatty, N,N-bis(hydroxyethyl)	68155-20-4
Butyl alcohol	71-36-3
Choline Chloride	67-48-1
Citric acid	77-92-9
Coffee Extract	68916-18-7
Diethanolamine	111-42-2
Ethanol	64-17-5
Ethylene glycol	107-21-1
Fatty acids, tall-oil, ethoxylated	61791-00-2
Glutaraldehyde	111-30-8
Hydrotreated light petroleum distillate	64742-47-8
Hydrochloric acid	7647-01-0
Methanol	67-56-1
Sodium bisulfite	7631-90-5
Sodium carbonate	497-19-8
Sodium Chloride	7647-14-5
Sodium hydroxide	1310-73-2
Sodium persulfate	7775-27-1
Sodium polyacrylate	9003-04-7
Sodium Sulfate	7757-82-6
Tributyl tetradecyl phosphonium chloride	81741-28-8
Hydroxylpropyl guar	39421-75-5
Triethanol amine	102-71-6
Silica dioxide	112926-00-8
Chlorous acid, sodium salt	7758-19-2

APPENDIX B SUPPLEMENTAL INFORMATION FOR HAZARD ASSESSMENT APPROACH

B.1 Supporting Documentation

The environmental hazard assessment approach is consistent with national and international guidance for assessment of potential for PBT[1] in the risk assessment, classification, and regulation of chemicals. Physical and chemical properties that affect the fate and behaviour of chemicals in the environment, degradation rates, partition coefficients, and aquatic ecotoxicological data are used in assessment of environmental mobility and PBT potential.

The Australian National Framework for Chemicals Environmental Management (NChEM) guidance manuals were consulted in preparation of the environmental hazard assessment approach, namely:

- EPHC (2009a). Environmental Risk Assessment Guidance Manual for Industrial Chemicals; and
- EPHC (2009b). Environmental Risk Assessment Guidance Manual for Agricultural and Veterinary Chemicals.

These guidance manuals present the data requirements and methodology for assessment for environmental hazard and risk assessment of industrial and agriculture and veterinary chemicals, consistent with international best practice. NChEM guidance is prepared by the National Environment Protection and Heritage Council (EPHC) for the Minister for the Commonwealth Department of the Environment (DotE) (formerly Department of the Environment, Water, Heritage and the Arts [DEWHA]).

DEWHA undertakes environmental risk assessments of industrial chemicals for the National Industrial Chemicals Notification and Assessment Scheme (NICNAS) and of agricultural and veterinary chemicals for the Australian Pesticides and Veterinary Medicines Authority (APVMA).

The methodology used to develop the necessary PBT information to conduct the assessment is discussed herein.

B.1.1 Persistence

Persistence refers to whether, and how fast, a chemical degrades in the environment over time. Chemicals degrade in the environment in a variety of ways, and biotic (microbial) and abiotic transformation pathways should be considered. Abiotic pathways include degradation by hydrolysis, photolytic degradation and by reaction with atmospheric hydroxyl radicals.

The Stockholm Convention provides scientifically based criteria for identifying persistent organic pollutants (POP)[2]. The criteria for persistence in Annex D of the Stockholm Convention are expressed as single-media criteria, as follows:

- evidence that the half-life of the chemical in water is greater than two months, or that its half-life in soil is greater than six months, or that its half-life in sediment is greater than six months; or

[1] PBT substances are substances that are persistent (P), bioaccumulative (B) and Toxic (T).
[2] For further information on the Stockholm Convention see:
http://www.environment.gov.au/protection/chemicals-management/pops and
http://chm.pops.int/default.aspx.

- evidence that the chemical is otherwise sufficiently persistent to justify its consideration within the scope of the Convention.

Considerations under the second criteria may include, for example, where the chemical has a half-life greater than six months in anaerobic conditions but less than six months under aerobic conditions (DEWHA, 2009).

Australian threshold criteria for persistence are based on half-life data. Standard OECD guideline tests for half-life in various media are preferred where available. However, qualitative results from biodegradation studies may be used to perform persistence categorisation (DoEE, 2017).

B.1.2 Bioaccumulation

Assessment of bioaccumulation potential are evaluated for organic chemicals only. Bioaccumulation is not assessed for inorganic chemicals in accordance with guidance in Environment Canada (2003).

Bioaccumulation is discussed in terms of the bioconcentration factor (BCF) or the bioaccumulation factor (BAF) depending on the type of data available, and the predominant route of uptake. The BCF is defined as the ratio of the concentration of the chemical in an organism relative to the concentration in the surrounding medium, and only takes into account uptake from the medium in which the organism lives. For aquatic organisms, uptake from water is considered to be the predominant route of uptake unless the chemical is very hydrophobic, in which case, uptake from food becomes important. BAF measurements take dietary uptake into consideration in addition to uptake from the medium. BCF measurements are generally appropriate for chemicals with a log octanol / water partition coefficient (Kow) of less than 6. For highly lipophilic chemicals with with a log Kow of greater than 6, a BAF measurement is more appropriate than a BCF (DEWHA, 2009).

Several standard test guidelines are available for determining the BCF or BAF of a chemical, but the OECD 305 test guideline for bioaccumulation in fish is normally used. In the absence of measured BCF or BAF data, the log Kow may be used as a surrogate (DEWHA, 2009).

A discussion of secondary exposure through the aquatic food chain may also be appropriate. The biomagnification factor (BMF) describes the relative concentration of the chemical in a predatory animal compared with the concentration in its prey. A BMF of greater than 1 indicates that chemical has the potential to biomagnify in the food chain. Such a chemical is also classified as bioaccumulative. The BMF may be estimated from either the measured BCF or the measured log Kow using criteria set out by DEWHA (2009).

B.1.3 Toxicity

To assess the toxic (T) potential of the chemicals, readily available acute (i.e., predominantly L(E)C_{50}[3]) and chronic (i.e., no observed effect concentration [NOEC], lowest observed effect concentration [LOEC], maximum acceptable tolerable concentration [MATC] and EC_{50}) data for aquatic organisms are obtained from the following sources in order of priority:

- USEPA (2011) ECOTOXicology Database Version 4.0
- Australasian Journal of Ecotoxicology.

Where ecotoxicological data were not available for the chemicals of interest or a suitable surrogate, data were modelled using EPISUITE™ ECOSAR™ software. ECOSAR™ (stands

[3] Lethal (or effect) concentration that kills (or effects) 50% of the test population

for Ecological Structure Activity Relationships) estimates the toxicity of chemicals to fish, aquatic invertebrates and algae in water.

Toxic effect predictions are made using a set of quantitative structure-activity relationships (QSARs) models. QSARs predict the aquatic toxicity of untested chemicals based on their structural similarity to chemicals for which aquatic toxicity data are available. The toxicity data used to build the QSARs come from a database of publicly available and confidential data submitted to the US EPA New Chemicals Program. The QSARs used in ECOSAR™ correlate a compound's physicochemical properties and its aquatic toxicity within specific chemical classes, and applies rules for selecting the appropriate chemical class for the compound.

ECOSAR™ generates acute (short-term) toxicity and, when available, chronic (long-term or delayed) toxicity.

The trophic level groupings considered for aquatic organisms are plant, invertebrate and fish. As freshwater aquatic organisms are considered the receptor of concern for the hydraulic fracturing chemicals, freshwater ecotoxicological data are used in the assessment of toxic potential.

The downloaded data from USEPA ECOTOX database are screened. The following endpoints are selected: mortality (acute), growth (chronic) and reproduction (chronic) for plants, invertebrates and fish. Additional screening include the following: studies shorter than 24 hours are not considered; chronic mortality exposures are not considered; and $L(E)C_x$ endpoints other than $L(E)C_{50}$ are not considered, (e.g. EC_0, EC_{100}, EC_{10}, EC_{20})

Where modelled data were generated using EPISUITE™ ECOSAR™ software the chronic data do not specify the endpoint (i.e., it is not known if the endpoint is NOEC or LOEC/MATC, or EC_{50}.) The chronic data are assumed to be LOEC/MATC or EC_{50} endpoints which results in a higher (more conservative) hazard classification.

B.2 Exclusions and Limitations

The environmental hazard assessment is a relative assessment and not a comprehensive evaluation of environmental hazards. Below are the exclusion and limitations:

- The approaches consulted for assessment of PBT in devising the environmental hazard assessment approach are predominantly focussed on the assessment of organic chemicals. There is limited guidance for PBT assessment of inorganic chemicals;
- The environmental hazard assessment approach is subject to professional judgment and the evaluator's subjectivity in designating the parameter ranges for each parameter assessed;
- The environmental hazard assessment does not consider, inter alia:
  - Breakdown or reactive products of the chemicals that may pose more or less of an environmental hazard than the parent compound;
  - The quality, adequacy or accuracy of the available information sourced, noting that only sources considered to be reputable were used;
  - Endocrine disruption effects that are not assessed by standard ecotoxicological tests;
  - The combined effects of these chemicals when present in mixture.
- The data collated in the Chemical Information Sheets are treated the same regardless of whether the data are measured experimental values or estimated / calculated values;
- The test endpoint description in the (secondary) sources consulted are relied upon although it should be noted that true chronic and acute NOEC, LOEC, or L(E)C_{50} are dependent on a variety of factors such as test duration, species tested, stage in the life-cycle, etc. which can only be verified by review of the primary literature;
- It is noted in relation to the aquatic ecotoxicological data that the species *Daphnia magna* are a sensitive species, frequently displaying sensitivity to chemicals orders of magnitude greater than other invertebrate species;
- Sources of Australian aquatic ecotoxicological data are consulted but the information is very limited. Furthermore, many species reported in the Australian literature are not necessarily indigenous species;
- The environmental hazard assessment approach devised for this study will not adequately assess chemicals which are:
  - Hydrophilic i.e., are highly soluble and have low K_{ow}. Where aquatic ecotoxicological data are limited for these types of chemicals, toxicity may be underestimated because there is potential for these chemicals to be highly toxic;
  - Poorly biodegradable, have low acute toxicity, but are bioaccumulative (based on the BCF or K_{ow}). These chemicals may exert chronic toxicity.
- Use of surrogate toxicity data for hydraulic fracturing chemicals, which are best described as mixtures, may further bias the hazard assessment towards assessment of T potential. Where a highly toxic chemical is present in only small quantities the effect on the overall hazard assessment is greater compared to a chemical with lower toxicity.

Santos

APPENDIX C ASSESSED HYDRAULIC FRACTURING FLUID SYSTEMS

Santos

Appendix C1
Schlumberger Methodology – Guar Based Systems

C1.0 Introduction

As presented in **Section 5.0** of the Hydraulic Fracturing Risk Assessment, a weight-of-evidence approach was used by Santos to evaluate the potential for human health and environmental (e.g., ecological) risks as a result of the hydraulic fracturing processes.

Golder Associates (Golder), on behalf of Santos, completed a qualitative risk assessment (Golder, 2013c) that evaluated the nature of the geology in the areas undergoing stimulation, the potential for impacts on water resources, the process and chemicals used.

A Quantitative Risk Assessment (QRA), completed by EHS Support, LLC (EHS Support), supplemented the qualitative risk assessment (EHS Support, 2012). The QRA was conducted to meet Conditions 49e and 49f of the 2 October 2011 approval under the Environmental Protection and Biodiversity Conservation Act 1999 (EPBC 2008/4059) and the EA conditions to assess the toxicity of the mixtures.

Key reports and studies previously submitted for these fluid systems comprise:

- Golder Associates. (2013c). Coal Seam Hydraulic Fracturing Risk Assessment - Combined Stage 1 and Stage 2 Risk Assessment for Schlumberger Methodology. Revision 1. 14 March 2013.
- EHS Support (2012). Gladstone Liquefied Natural Gas (GLNG) Project. Coal Seam Gas Hydraulic Fracturing Quantitative Risk Assessment for Schlumberger Chemistry. EHS Support Report. 16 October 16, 2012.

The results and conclusions of the qualitative risk assessment components and the QRA are summarised below. Refer to the text of this report for detailed discussions on methodologies employed for each component; specific tables referred to in this summary are included for review with this document. Table numbers specific to the original reports were retained for consistency between documents.

Santos

C2.0 Qualitative Risk Assessment and Evaluation

C2.1 Chemicals Evaluated

Three 'fluid systems' were assessed, each having a foamed and non-foamed version, for a total of six hydraulic fracturing fluid mixtures. Chemical constituents identified in each hydraulic fracturing fluid system were evaluated in the hydraulic fracturing risk assessments. The list of individual chemicals present within the three fluid systems is presented in Table 1 below. A mass balance of the chemicals within each of the hydraulic fracturing fluid systems is provided as **Appendix C1-1** (Table D-3; Golder, 2013c). Information regarding the chemical and physical properties of the individual chemicals listed below can be found in **Appendix E**.

It is noted, while none of the fracturing fluid chemicals identified contain benzene, toluene, ethylbenzene, xylenes (BTEX) or polycyclic aromatic hydrocarbons (PAHs), that PAHs occur naturally in coal and it is possible that certain PAHs may naturally be present in the coal seam groundwater used in the hydraulic fracturing process.

Table 1

Chemical	Cas Number
Carbohydrate polymer (guar gum)	9000-30-0
Polypropylene Glycol	25322-69-4
Alcohols C6-C10 ethoxylated (surrogate C6 - C12)	68439-45-2
Vinylidene Chloride/methylacrylate	25038-72-6
Tetrasodium ethylenediaminetetraacetate (EDTA)	64-02-8
Alkylaryl Sulfonate	25155-30-0
Timethylammonium chloride	8030-78-2
Nitrogen, liquid form	7727-37-9
trimethyl-3-[{1-oxooctadecyl)amino]propylammonium methyl sulphate	19277-88-4
Propane 1,2 diol	57-55-6
Magnesium Chloride	7786-30-3
Diatomaceous Earth, calcined	91053-39-3
Crystalline silica (cristobalite)	14464-46-1
Crystalline silica (quartz)	14808-60-7
Diammonium peroxidisulphate (ammonium persulphate)	7727-54-0
Ammonium C6-C10 alcohol ethoxysulfate	68187-17-7
Carbonic acid, sodium salt	533-96-0
Hydrochloric acid	7647-01-0
Magnesium silicate hydrate (talc)	14807-96-6
Sodium Hydroxide	1310-73-2
Non crystalline silica (amorphous silica surrogate)	7631-86-9
Postassium Chloride	7447-40-7
Sodium Hypochlorite	7681-52-9

C2.2 Risk Assessment Framework and Findings

As discussed in **Section 5.0** of the systematic weight of evidence approach was utilised to complete the risk assessment for the Schlumberger Fluid Systems. The work has involved the following evaluations:

Qualitative Assessment Methodologies

- Environmental Hazard Assessment
- Exposure Assessment including Fate and Transport Assessment in Groundwater
- Mass Balance of the fluid systems
- Groundwater Fate and Transport Modelling.

Quantitative Risk Assessment Methodologies

- Quantitative Human Health Risk Assessment
- Quantitative Ecological Risk Assessment for Terrestrial and Aquatic Receptors.

C2.3 Environmental Hazard Assessment

The environmental hazard assessment approach outlined in **Section 6.1** was undertaken to rank the hydraulic fracturing chemicals based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT).

A combination of data sets were used in the PBT assessment including chemical information sheets (**Appendix E** and **Appendix G**), the Hazardous Substance Database, and modelled data from USEPA (2009) EPISUITE modelling software, when data not available from other sources.

Of the 34 chemicals listed above, three were not considered for PBT ranking. Crystalline silica (quartz, 14808-60-7) and crystalline silica (cristobalite, 14464-64-1) relate to the sand used as the proppant and are therefore not considered to represent an environmental hazard. Similarly, amorphous silica is an inert element, also ubiquitous in the environment, and was therefore not considered further in the PBT ranking.

C2.4 Exposure Assessment

As discussed in **Section 7.0**, the exposure assessment identified receptors potentially exposed to COPCs identified for the study and outlines the exposure pathways by which the receptors may come in to contact with the COPCs.

C2.4.1 Onsite Exposures

Of the pathways evaluated, the onsite assessment indicated that the majority of exposures were unlikely or incomplete; given the application of operational controls by Santos. These operational controls include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals
- Disposal or capping of sediments contained within drained mud pits and turkey nests, to prevent exposure to contaminates in windborne dust

- Fencing of drill pads to prevent trespassers and installation of signs to indicate that the water in the turkey's nest and mud pit is not potable and may contain contaminants
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna
- Mud pits and turkey's nests lined with clay or similar material to prevent seepage of flowback water into underlying aquifer.

Details regarding onsite exposure scenarios, receptors, and pathways evaluated are provided in Table 50 (Golder, 2013c) attached to this Appendix.

The following on-site pathways were determined to be potentially complete and were evaluated:

- Exposure to COPCs in mud pit and turkeys nest sediments:
  - Workers and trespassers via direct contact (ingestion and dermal contact).
- Exposure to COPCs in flowback water in turkey's nest and mud pit:
  - Workers while working with turkey's nest inlet/liner or drainage of turkey's nest or mud pit via direct contact
  - Trespassers after entry (accidental or deliberate) to turkey's nest or mud pit via direct contact
  - Native terrestrial fauna after entry (accidental or deliberate) to turkey's nest or mud pit via ingestion
  - Stock animals after entry (accidental or deliberate) to turkey's nest or mud pit via ingestion.
- Exposure to COPCs in flowback water released to environment (spill, leak, mud pit, turkey nest delivery system failure or overflow):
  - Workers, terrestrial fauna, terrestrial flora via ingestion, dermal contact and inhalation.

One potentially complete exposure pathway was identified, which is direct contact to the flowback water in the turkey's nest and mud pit for small native fauna (i.e., lizards and birds). All reasonable measures will be conducted to discourage entry of small native fauna into the well pad area during hydraulic fracturing operations.

C2.4.2 Offsite Exposure Pathways

Of the pathways evaluated, the following off-site pathways were determined to be potentially complete and were evaluated:

- Exposure to COPCs in flowback water released to environment (spill, leak, mud pit, turkey nest delivery system failure or overflow):
  - Residents, terrestrial fauna, terrestrial flora via ingestion, dermal contact and inhalation.

Details regarding offsite exposure scenarios, receptors, and pathways evaluated are provided in Table 51 (Golder, 2013c) attached to this Appendix.

Potential off site exposure pathways were evaluated for residents, stock animals, native flora and fauna and aquatic ecosystems. Four possible sources were identified, hydraulic fracturing fluids, sediments from mud pit or turkey's nest, flowback water and coal seam gas (methane). The exposure assessment concluded that with the implementation of operational controls including use of liners in turkey nests, well integrity testing, operational monitoring and capping and/or removal of sludge all off-site exposures are considered unlikely and incomplete.

C2.5 Mass Balance of Fluid System

A quantitative mass balance calculation was undertaken to identify the amount of each chemical additive of the hydraulic fracturing fluid in the following fluid systems:

- Waterfrac / Slickwater
- WF130 Linear Gel
- WF130 Linear Base Gel for Foam Fluid
- YF125LG Crosslinked Gel.

The results of the mass balance calculations are presented in the referenced Table D-3 (Golder, 2013c) which is included in **Appendix C1-1**.

C2.6 Fate and Transport Modelling

For the sake of conservatism, the fate and transport of the highest ranked and most mobile organic chemicals was further assessed. This included the following chemicals evaluated in this fluid system:

- Tetrasodium EDTA
- Vinylidene chloride.

Details on the fate and transport modelling methodology and results are provided in **Section 7.2** of the report. The modelling demonstrated that there is limited potential for chemicals to migrate within the coal seams.

Santos

C3.0 Quantitative Risk Assessment

In accordance with the methodologies presented in **Section 8.0**, a QRA was conducted on both theoretical and empirical datasets for those chemicals identified in the Combined Stage 1 and 2 Risk Assessments (EHS Support, 2012). The QRA approach evaluates the toxicity of the individual substances and characterises the cumulative risks of the total effluent toxicity and ecotoxicity.

Generally, this methodology includes the identification of the hazards posed by constituents in the flowback water, compilation of the toxicity criteria for each constituent, development of exposure models to estimate the daily intake of the constituents, and calculations of individual constituent hazard quotients (daily intake divided by the toxicity criteria) and a cumulative constituent hazard index (HI) for each potentially complete exposure pathway for each human or terrestrial receptor.

Potential complete exposure pathways to the storage of flowback from hydraulically stimulated wells and potential risks to humans, terrestrial and aquatic receptors from the potential storage and accidental releases are evaluated in the QRA.

No further assessment of groundwater was determined to be necessary due to lack of potentially complete exposure pathways. Detailed operational procedures have been provided that are designed to contain the hydraulic fracturing fluids within the coal sequences, and no connection exists between groundwater in the coal seams and surface-water or springs (and therefore MNES). Further, the potential risks to workers involved with the hydraulic fracturing process were not considered as detailed Health and Safety (H&S) procedures are employed to manage exposures. The QRA considered the following specific exposure pathways:

1. Exposure of trespassers to flowback water contained within flowback storage ponds
2. Exposure of terrestrial receptors (e.g., livestock and wildlife) to flowback water contained within the flowback storage ponds
3. Exposure of aquatic receptors to flowback water in the situation of an accidental release, such as from piping or a release from the flowback storage pond. These potential releases could include a failure of containment systems, overtopping of the dam or in an extreme situation (considered highly unlikely) structural failure of the dam itself.

C3.1 Exposure Assessment

The purpose of the exposure assessment in the QRA was to predict the magnitude and frequency of potential human exposure to each COPC following the methodologies presented in **Section 8.1**. A conceptual site model (CSM) was developed which describes the potential receptors and exposure scenarios for the flowback water used in this exposure assessment. The potential exposures to receptors were evaluated based on the potential for a complete exposure pathway.

As discussed in **Section 8.3**, exposure point concentrations (EPCs) were derived for both the theoretical assessment and the empirical assessment. The EPCs for the theoretical assessment were calculated by estimating the mass and discharge flow of the COPCs from the flowback water monitoring data were used (**Appendix C1-2,** Table C-1**;** EHS Support, 2012). Operational data were utilized to assess the fate and transport of the constituents in the flowback storage ponds. Refer to Appendix C of the EHS Support QRA (**Appendix C1-2**, Tables C-2 through C-4) for the empirical data used in the QRA (EHS Support, 2012). The tables are included in this summary.

C3.2 Human Health QRA

A human health hazard assessment was conducted according to the methodologies presented in **Section 8.4**. The purpose of the hazard assessment process was to summarize the environmental data, and to address the toxicological assessment of the COPCs that will be evaluated further in the risk assessment process.

Exposure assumptions for the human trespasser scenario were developed based on default or site-specific assumptions (**Section 8.4**). This receptor exposure pathway includes a small child to teenager that may come in contact with the above grade water exposure scenario for approximately 20 days/year for a 10-year period with potential incidental ingestion (of 50 millilitre [mL] water) and dermal contact (e.g., swimming where the whole body gets wet) for ½ hour (Table 4; EHS Support, 2012, attached).

Calculation of intake of COPCs was performed using the equations presented below:

Ingestion of water:

$$Intake\ (mg/kg-day)\ =\ (CW\ x\ IR\ X\ EF\ X\ ED)\ /\ (BW\ x\ AT)$$

Dermal contact with water:

$$Absorbed\ dose\ (mg/kg-day)\ =\ (CW\ x\ SA\ x\ DP\ x\ ET\ x\ EF\ x\ ED\ x\ CF)\ /\ (BW\ x\ AT)$$

Where:

CW = concentration in water (mg/l)
ET = exposure time (hr/day or hours/hours)
EF = exposure frequency (day/year)
ED = exposure duration (years)
CF = correction factor (1 x 10-3 l/cm3)
AT = averaging time (days)
IR = ingestion rate (l/hr)
BW = body weight (kg)
SA = skin surface area available for contact (cm2/d)
DP = dermal permeability factor (Kp – cm/hr)

C3.3 Toxicity Assessment

A toxicity assessment was conducted to determine the relationship between the dose of a COPC taken into the body, and the probability that an adverse effect will result from that dose. Quantitative estimates of the potency of COPCs include two sets of toxicity values, one for genotoxic carcinogens and one for other non-genotoxic carcinogens and non-carcinogenic effects. As discussed in **Section 8.4,** detailed toxicological profiles were developed for the chemicals. The toxicological profiles are included as **Appendix F**.

The assessment of toxicity of the COPCs was used to develop initial screening criteria for human health exposure scenarios as discussed in **Section 8.4**. Refer to Tables 1, 2, and 3 of the QRA for details regarding the toxicity assessment of the COPCs (EHS Support, 2012).

C3.4 Risk Estimation

Risk estimation was performed in accordance with the methodologies outlined in **Section 8.4**. The total target risk range for carcinogens was 1 x 10^{-4} to 1 x 10^{-6}; the target hazard index (HI) for non-threshold effects is less than or equal to 1.0.

C3.4.1 Theoretical

No carcinogenic compounds are present in the stimulation fluids injected into the subsurface and as a result, only non-carcinogenic risks were calculated. The exposure scenarios include the specific fracturing fluids event from Table D-3 (Golder, 2013c), or the maximum of the fracturing fluids events, for the 20 and 80 percent (%) mass recovery from the fracturing fluid well flowback (**Appendix C1-1**). The modelled risks from injected chemicals in the flowback water were acceptable, with the trespasser for the maximum exposure to COPCs at the 80 % recovery indicating a potential risk below the HI of 1.0 (Tables 5 and 6; EHS Support, 2012, attached).

C3.4.2 Empirical

Two data sets, flowback storage ponds and untreated flowback, were used to characterize potential risks for the trespasser to COPCs. Trespasser exposure to water in flowback storage ponds did not have an unacceptable HI at either the mean or maximum concentrations; there were no carcinogens present (Tables 7 and 8; EHS Support, 2012).

While the mean scenario for the trespasser exposed to COPCs in pumped flowback did not have unacceptable levels of risk, the risk calculated using maximum concentrations did result in an unacceptable risk with an HI equal to 2.3 and an excess cancer lifetime risk of 5.1×10^{-7}.

C3.5 Ecological Risk Assessment

As discussed in **Section 8.5**, a screening level ecological risk assessment (ERA) was conducted to evaluate the potential for adverse ecological effects to terrestrial and aquatic ecological receptors that may be exposed to residual levels of hydraulic fracturing fluids in surface water used in the coal seam gas (CSG) fields.

Terrestrial receptors evaluated in the ERA include domesticated livestock, large mammalian wildlife and small mammalian wildlife. Beef cattle were used to evaluate domesticated livestock, kangaroos evaluated for large mammalian wildlife and dingos for small mammalian wildlife. Aquatic receptors evaluated included invertebrates and fishes.

Ecological effects were characterised following the methodologies outlined in **Section 8.5.3** (Table 9; EHS Support, 2012). Exposure scenarios were the same for ecological receptors as human receptors; EPCs were estimated in accordance with the methodology presented in **Section 8.5.4** (**Appendix C1-2**). Environmental fate information is provided in Table 10 (EHS Support, 2012).

Risks were characterised in accordance with the methodologies discussed in **Section 8.5.5**. The resulting ecological hazard quotient must be less than or equal to 1.0 for risks to be considered acceptable.

C3.5.1 Estimation of Risks

C3.5.1.1 Theoretical

Appendix C1-3 presents the calculated HI for flowback water (Appendix E, EHS Support, 2012). The HI calculated for flowback water for aquatic risk was elevated above the acceptable level for the majority of COPCs evaluated. Where large discharges of flowback water occur to surface water and/or flux dilution within the surface-water was insufficient, potential impacts on aquatic receptors could occur. As noted in the toxicity assessment section above, the lack

of a robust aquatic toxicological database resulted in aquatic screening values for the theoretical exposure scenario COPCs to be conservatively very low.

The modelled risks from injected chemicals in the flowback water were all acceptable for each of the ecological receptors modelled, with maximum HI ranging from 0.0034 (kangaroo) to 0.051 (cattle) (Tables 14 through 19; EHS Support, 2012, attached).

3.5.1.2 Empirical

Appendix C1-3 presents the calculated HI for flowback water (Appendix E, EHS Support, 2012). Aquatic life TRVs exceeded for the pump flowback water included toluene, xylene, C10-C36 Fraction (sum), aluminium, barium, boron, cadmium, chromium, copper, iron, lithium, manganese, molybdenum, nickel, strontium, tin, and zinc.

The modelled risks from the empirical exposure scenarios were all acceptable for each of the ecological receptors modelled, with the exception of the livestock cattle for the maximum exposure to COPCs in the flowback storage ponds and pump flowback, the HIs of 1.1 and 1.2, respectively, slightly exceeded the acceptable HI of 1.0 (Tables 20 through 25; EHS Support, 2012, attached). However, it is noted that this included a very conservative long-term exposure as compared to the typical duration that the flowback storage ponds surface water would be available for exposure.

Santos

C4.0 Summary of QRA findings

The QRA was completed as discussed in **Section 8.0**, using two (2) independent assessments to develop a weight-of-evidence approach for potential human health and ecological risks. The first assessment was conducted using highly conservative theoretical calculations based on the chemicals utilized by Schlumberger in hydraulic fracturing. This assessment assumed that a range of theoretical percentages of injected chemicals would be present in the flowback water. The second assessment utilized empirical data collected as part of the Stimulation Impact Monitoring Program from hydraulic stimulation events conducted by Schlumberger.

Consistent with the risk assessment and groundwater fate and transport modelling conducted by Golder, no potentially complete exposure pathways were identified for groundwater. Potential exposures are limited to the aboveground storage and handling of flowback water as part of the CSG Water Management Plan (WMP). Management of CSG water involves the temporary storage of flowback water in flowback storage ponds.

On the basis of the risk calculations, the potential risks associated with the flowback water are generally limited. Potential risks to trespassers could occur with repeated exposures to flowback water. However, the cumulative risks are only slightly above the non-carcinogenic threshold discussed above where management and operational controls can be implemented to control potential exposures. There were no carcinogenic risks identified.

Limited to no risks to cattle and native mammals were identified in the risk assessment using the most conservative theoretical calculations (80 % chemical mass in the flowback water). Based on contractor experience and the empirical data collected as part of the SIMP, concentrations of constituents detected in flowback water are orders of magnitude lower than theoretical concentrations and no potential risks exist for livestock or native mammals.

Similarly, potential impacts could occur if releases of flowback water were to occur to aquatic environments. Based on the use of liners and operational controls that limit the potential for turkey's nest and dam overflows, the potential for these risks are also considered limited.

A combination of management and operational controls are being implemented to eliminate and control the potential for exposures. These include:

- Worker training and hazard identification
- Use of appropriate personal protective equipment (gloves etc.)
- Flowback storage pond fencing to prevent entry of livestock and minimize trespassing.
- Installation of clay dam liners and routine dam inspections to prevent releases from flowback storage ponds
- Routine operational and security patrols to prevent trespassing.

.

Santos

C5.0 Conclusions

A weight-of-evidence evaluation of potential risks as described in **Section 5.0** was performed for the Schlumberger guar gum fluid system. Based on the qualitative and quantitative risk characterisations, the overall risk to human health and the environment is low. Existing operational control activities employed by Santos are in place that will limit the potential risks to human health and the environment. These measures include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments;
- Environmental authority conditions that preclude the construction of well pads within 100 m of a watercourse of water body.
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals;
- Disposal or capping of sediments contained within drained mud pits and turkey nests , to prevent exposure to contaminates in windborne dust;
- Fencing of drill pads to prevent trespassers and installation of signs to indicate that the water in the turkeys nest and mud pit is not potable and may contain contaminants;
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna;
- Santos operational procedures to ensure well integrity and design of fracture to stay within the target seam; and
- Mud pits and turkeys nests with clay liners, or similar material, to prevent seepage of flowback water into underlying aquifers.

Regular monitoring of water supply bores and surface water for a representative suite of chemicals within 2 kilometre of wells that are fractured is required to confirm the conclusion of incomplete exposure pathways and low risk.

No additional risks, other than those previously discussed, were identified with the chemicals or systems employed by Schlumberger in hydraulic fracturing. Evaluation of other potential risks associated with hydraulic fracturing (i.e., noise and vibration) was conducted. Refer to **Section 9.0** for methodology specifics and results of this evaluation.

Table 10 Environmental Fate Information

C6-C10 Alcohol Ethoxylates	Readily biodegradable and also anaerobically biodegradable. Proposed half-lives in river water at 12^{o}C: 4 to 24 hours (based on experimental data). BCF (see HERA report)
C6-C12 Alcohol Ethoxysulfate	AES are readily biodegradable under aerobic conditions; they are expected to be easily biodegradable under anaerobic conditions. Degradation rate in surface water: 0.48 d^{-1} (measured)
Guar gum	Expected to be readily biodegradable as a polysaccharide; not expected to bioaccumulate. [No data]
Vinylene chloride / methylacrylate polymer	Biologically inert. Persistent in the environment.
Polypropylene glycol	Readily biodegradable. 65% degradation after 20 days (OECD 301F). Bioconcentration potential is low (BCF less than 100 or log Pow less than 3).
Tetrasodium ethylenediamine tetraacetate	Not biodegraded. Biodegradation rate constant: 0 d^{-1}. Unlikely to bioaccumulate.

Golder Tables

Table 50: On site exposure assessment summary

Source	Exposure Scenario	Receptors	Exposure Pathways	Likelihood of exposure scenario	Comments
Mud pit and turkeys nest sediments	Entry to pit or excavation/stockpiling of pit sediments	Workers, trespassers	Ingestion, dermal	Unlikely	OH&S procedures limit workers exposure to sediment.
	Pit dries and pit sediments become windblown dusts	Workers, trespassers	Inhalation of dusts	Possible	Pathway is limited by disposal or capping of sediments contained in the mud pit and turkeys nest at the end of operations
	Pit dries and pit sediments become windblown dusts, contaminating surrounding soil	Native terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, uptake	Unlikely	Volume of pit sediments considered insufficient to cause significant contamination of drill pad.
	Entry to pit or exposure to excavated pit sediments	Native terrestrial fauna (mammals, reptiles, birds)	Ingestion	Unlikely	Mud pit and turkeys nest does not contain food or habitat for terrestrial species.
Flow back water in Turkey nest and mud pit	Working with turkey nest inlet/liner, or drainage of turkey nest or mud pit	Workers	Ingestion, dermal	Possible	OH&S procedures limit workers exposure to flow back water.
	Entry (accidental or deliberate) to Turkeys nest or mud pit	Trespassers	Ingestion, dermal	Possible	Trespassers entry is limited via fencing and signage around drill pad areas. Trespassers can be entirely precluded from areas.
	Entry (accidental or deliberate) to Turkeys nest or mud pit	Native terrestrial fauna (mammals, reptiles, birds)	Ingestion	Observed	Native fauna has been observed in and around the turkey nests, despite areas being fenced.
	Entry (accidental or deliberate) to Turkeys nest or mud pit	Stock animals	Ingestion	Observed	Maintained fences and grids with routine maintenance can be effective at precluding livestock however, some stock animals have been observed in well pad areas.
Hydraulic fracturing Chemicals	Spill, leak of well delivery system failure during surface handling. Supply or disposal vehicle accident on-site	Workers, terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, dermal	Unlikely	OH&S and spill containment, procedures adequately address this exposure.
Flow back water	Spill, leak, mud pit, turkey nest delivery system failure or overflow	Workers, terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, dermal, inhal	Possible	

Table 51: Off site exposure assessment summary

Source	Exposure Scenario	Receptors	Exposure Pathways	Likelihood of exposure scenario	Comment/Management/control measures
Hydraulic fracturing fluids	Fracture fluid escapes into aquifer via a well casing failure, or a fault/fracture/unconformity in seam/strata, and fluids enter aquifer used downgradient for domestic water supply	Residents: adults and children	Ingestion, dermal, inhalation	Unlikely	Exposure scenario unlikely however; dependant on Santos operational procedures i.e. well integrity testing and design of fracture to stay with the target seam. No recorded instances in peer-reviewed literature of fracturing chemicals in downgradient water supplies (Osborn et al 2011).
	Fracture fluid escapes into aquifer via a well casing failure, or a fault/fracture/unconformity in seam/strata, and fluids enter aquifer used downgradient for stock water supply	Stock animals	Ingestion	Unlikely	
	Fracture fluid escapes into aquifer via a well casing failure, or a fault/fracture/unconformity in seam/strata, and fluids enter aquifer that discharges to surface water	Aquatic ecosystems	Direct exposure	Unlikely	
	Residual fracturing fluid in the coal seam migrates down gradient and enters a spring or water supply bore	Residents, aquatic ecosystems, stock animals	Ingestion, dermal, inhalation	Unlikely	Fate and transport modelling used to estimate the likely extent of migration of residual fluids in coal seam (section 7.4)
Turkeys nest or mud pit sediments	Nest/Pit dries and sediments become windblown dusts, contaminating surrounding soil	Native terrestrial flora and fauna, stock, Residents adults and children	Direct exposure/ inhalation of dusts	Unlikely	Volume of pit sediments considered insufficient to result in concentrations of concern in the surrounding land.
Flow back water	Seepage of chemicals from mud pit or turkeys nest to a shallow aquifer used downgradient for domestic water supply	Residents: adults and children	Ingestion, dermal, inhalation	Unlikely	Considered unlikely that the concentrations of chemicals would be of a concern however regular maintenance of liners required to remove exposure pathway. Monitoring of down gradient bores also recommended to confirm no exposure.
	Seepage of chemicals from mud pit or turkeys nest to a shallow aquifer used downgradient for stock water supply	Stock animals	Ingestion	Unlikely	
	Seepage of chemicals from mud pit or turkeys nest to a shallow aquifer that discharges to surface water	Aquatic ecosystems	Direct exposure	Unlikely	
	Spill, leak, turkey nest overflow	Residents, terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, dermal, inhalation	Possible	Possible overflows during prolonged periods of high rainfall (>500 mm of rainfall required) based on freeboard control requirements. Likelihood of occurrence can be reduced through minimising duration of storage in pit and turkeys nest, and toxicity of fluid is likely to decrease rapidly due to short biotransformation half-lives of most chemicals.

Santos

Appendix C2
Halliburton Water and Guar Based Systems
(Original DeltaFoam 140 Formulation)

C1.0 Introduction

As presented in **Section 5.0** of the Hydraulic Fracturing Risk Assessment), a weight-of-evidence approach was used by Santos to evaluate the potential for human health and environmental (e.g., ecological) risks as a result of the hydraulic fracturing processes and the Halliburton water and guar-based fluid system (DeltaFoam 140 formulation).

Golder Associates (Golder), on behalf of Santos, completed a qualitative risk assessment (Golder, 2013d) that evaluated the nature of the geology in the areas undergoing stimulation, the potential for impacts on water resources, the process and chemicals used.

A Quantitative Risk Assessment (QRA), completed by EHS Support, LLC (EHS Support), supplemented the qualitative risk assessment (EHS Support, 2013b). The QRA was conducted to meet Conditions 49e and 49f of the 2 October 2011 approval under the Environmental Protection and Biodiversity Conservation Act 1999 (EPBC 2008/4059) and the EA conditions to assess the toxicity of the mixtures.

Key reports and studies previously submitted for these fluid systems comprise:

- Golder Associates. (2013d). Coal Seam Hydraulic Fracturing Risk Assessment. Combined Stage 1 and Stage 2 Risk Assessment for Halliburton. Revision 1. 3 May 2013.
- EHS Support. (2013b). Coal Seam Gas Hydraulic Fracturing Quantitative Risk Assessment Report for Halliburton Delta 140 Chemistry Report. 4 August 2013.

The QRA evaluated both the original DeltaFoam 140 and Delta 140 formulations; refer to Appendix C5 for discussion of the results of the QRA for the alternative fluid system (Delta 140).

The results and conclusions of the qualitative risk assessment components and the QRA are summarised below. Refer to the text of this report for detailed discussions on methodologies employed for each component; specific tables referred to in this summary are included for review with this document. Table numbers specific to the original reports were retained for consistency between documents.

C2.0 Qualitative Risk Assessment and Evaluation

C2.1 Chemicals Evaluated

Three 'fluid systems' were assessed, each having a foamed and non-foamed version, for a total of six hydraulic fracturing fluid mixtures. Chemical constituents identified in each hydraulic fracturing fluid system were evaluated in the hydraulic fracturing risk assessments. The list of individual chemicals is presented in Table 1. A mass balance of the chemicals within each of the hydraulic fracturing fluid systems is provided as **Appendix C2-1** (Table D-3; Golder, 2013d). The additive coffee extract was later added as a potential supplement to all fluid mixtures on an 'as-needed' basis to be used at an in-fluid concentration of 0.4 mg/L.

Information regarding the chemical and physical properties of the individual chemicals listed below can be found on the Safety Data Sheets in **Appendix E**.

It is noted, while none of the fracturing fluid chemicals identified contain benzene, toluene, ethylbenzene, xylenes (BTEX) or polycyclic aromatic hydrocarbons (PAHs), that PAHs occur naturally in coal and it is possible that certain PAHs may naturally be present in the coal seam groundwater used in the hydraulic fracturing process.

Table 1. Hydraulic fracturing chemicals

Chemical	Cas Number
Guar Gum	9000-30-0
Acetic Acid	64-19-7
Alkylated quaternary chloride (surrogate tetramethylammonium chloride)	75-57-0
Ethanol	67-17-5
Terpenes and terpenoids, sweet orange oil	68647-72-3
1,2 Benzisothiazolin -3-one	2634-33-5
Non-ionic surfactant mix™	-*
Surfactant mix™	-*
Coco dimethylaminopropyl betaine	61789-40-0
Fatty acid ester™	-*
Ethoxylated fatty acid ester™	-*
Tetrakis (hydroxymethyl) phosphonium sulphate (THPS)	55566-30-8
Enzyme™	-*

Calcium chloride	10043-52-4
Silica gel	112926-00-8
Sodium sulfate	7757-82-6
Sodium sulfite	7757-83-7
Crystalline silica	14808-60-7

Chemical	Cas Number
Monoethanolamine borate	26038-87-9
Coffee Extract	68916-18-7

* The CAS numbers for fatty acid ester, ethoxylated fatty acid ester, non-ionic surfactant mix, surfactant mix, terpene hydrocarbon by products and enzyme have not been included in this table due to commercial confidentiality.

C2.2 Risk Assessment Framework and Findings

As discussed in **Section 5.0** of the systematic weight of evidence approach was utilised to complete the risk assessment for the Schlumberger Fluid Systems. The work has involved the following evaluations:

Qualitative Assessment Methodologies

- Environmental Hazard Assessment
- Exposure Assessment including Fate and Transport Assessment in Groundwater
- Mass Balance of the fluid systems
- Groundwater Fate and Transport Modelling.

Quantitative Risk Assessment Methodologies

- Quantitative Human Health Risk Assessment
- Quantitative Ecological Risk Assessment for Terrestrial and Aquatic Receptors.

C2.3 Environmental Hazard Assessment

The environmental hazard assessment approach outlined in **Section 6.1** was undertaken to rank the hydraulic fracturing chemicals based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT).

A combination of data sets were used in the PBT assessment including chemical information sheets (**Appendix E** and **Appendix G**), the Hazardous Substance Database, and modelled data from USEPA (2009) EPISUITE modelling software, when data not available from other sources.

Of the 24 chemicals listed above, three were not considered for PBT ranking. Physico-chemical and/or toxicological data were not available, and surrogates could not be identified for silica gel (surrogate amorphous silica, 112926-00-8), crystalline silica (14808-60-7), and terpene hydrocarbon by products in a non-specified formulation (CAS number withheld for proprietary reasons). Crystalline silica (14808-60-7) relate to the sand used as the proppant, and therefore is not considered to represent an environmental hazard.

C2.4 Exposure Assessment

As discussed in **Section 7.0**, the exposure assessment identified receptors potentially exposed to COPCs identified for the study and outlines the exposure pathways by which the receptors may come in to contact with the COPCs.

C2.4.1 Onsite Exposures

Of the pathways evaluated, the onsite assessment indicated that the majority of exposures were unlikely or incomplete; given the application of operational controls by Santos. These operational controls include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals
- Disposal or capping of sediments contained within drained mud pits and turkey nests, to prevent exposure to contaminates in windborne dust
- Fencing of drill pads to prevent trespassers and installation of signs to indicate that the water in the turkey's nest and mud pit is not potable and may contain contaminants
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna
- Mud pits and turkey's nests lined with clay or similar material to prevent seepage of flowback water into underlying aquifer.

Details regarding onsite exposure scenarios, receptors, pathways evaluated are provided in Table 50 (Golder, 2013d) attached to this Appendix.

The following on-site pathways were determined to be potentially complete and were evaluated:

- Exposure to COPCs in mud pit and turkey's nest sediments:
  - Workers and trespassers via direct contact (inhalation of dusts).
- Exposure to COPCs in flowback water in turkey's nest and mud pit:
  - Workers while working with turkey's nest inlet/liner or drainage of turkey's nest or mud pit via direct contact
  - Trespassers after entry (accidental or deliberate) to turkey's nest or mud pit via direct contact
  - Native terrestrial fauna after entry (accidental or deliberate) to turkey's nest or mud pit via ingestion
  - Stock animals after entry (accidental or deliberate) to turkey's nest or mud pit via ingestion.
- Exposure to COPCs in flowback water released to environment (spill, leak, mud pit, turkey nest delivery system failure or overflow):
  - Workers, terrestrial fauna, terrestrial flora via ingestion, dermal contact and inhalation.

C2.4.2 Offsite Exposure Pathways

Potential off site exposure pathways were evaluated for residents, stock animals, native flora and fauna and aquatic ecosystems. Four possible sources were identified, hydraulic fracturing fluids, sediments from mud pit or turkey's nest, flowback water and coal seam gas (methane). The exposure assessment concluded that with the implementation of operational controls including use of clay liners in turkey nests, well integrity testing, operational monitoring and capping and/or removal of sludge all off-site exposures are considered unlikely and incomplete.

Of the pathways evaluated, the following off-site pathways were determined to be potentially complete and were evaluated:

- Exposure to COPCs in flowback water released to environment (spill, leak, mud pit, turkey nest delivery system failure or overflow):
  - Residents, terrestrial fauna, terrestrial flora via ingestion, dermal contact and inhalation.

Details regarding offsite exposure scenarios, receptors, pathways evaluated are provided in Table 51 (Golder, 2013d attached to this Appendix).

C2.5 Mass Balance of Fluid System

A quantitative mass balance calculation was undertaken to identify the amount of each chemical additive of the hydraulic fracturing fluid in the following fluid systems:

- Delta 140
- DeltaFoam 140
- Linear Gel
- Linear Gel Foamed
- Water
- Water Foamed.

The results of the mass balance calculations are presented in the referenced Table D-3 (Golder, 2013d) that is included in **Appendix C2-1**.

C2.6 Fate and Transport Modelling

For the sake of conservatism, the following chemicals were further assessed for mobility in the environment through fate and transport modelling:

- Fatty acid ester
- 1,2 Benzisothiazolin -3-one
- Alkylated quaternary chloride
- Sweet orange oil
- Surfactant mix.

Details on the fate and transport modelling methodology and results are provided in **Section 7.2** of the report. The modelling demonstrated that there is limited potential for chemicals to migrate within the coal seams.

C3.0 Quantitative Risk Assessment

In accordance with the methodologies presented in **Section 8.0**, a QRA was conducted on both theoretical and empirical datasets for those chemicals identified in the Combined Stage 1 and 2 Risk Assessments (EHS Support, 2013b). The QRA approach evaluates the toxicity of the individual substances and characterises the cumulative risks of the total effluent toxicity and ecotoxicity.

Generally, this methodology includes the identification of the hazards posed by constituents in the flowback water, compilation of the toxicity criteria for each constituent, development of exposure models to estimate the daily intake of the constituents, and calculations of individual constituent hazard quotients (daily intake divided by the toxicity criteria) and a cumulative constituent hazard index (HI) for each potentially complete exposure pathway for each human or terrestrial receptor.

Potential complete exposure pathways to the storage of flowback from hydraulically stimulated wells and potential risks to humans, terrestrial and aquatic receptors from the potential storage and accidental releases are evaluated in the QRA.

No further assessment of groundwater was determined to be necessary due to lack of potentially complete exposure pathways. Detailed operational procedures have been provided that are designed to contain the hydraulic fracturing fluids within the coal sequences, and no connection exists between groundwater in the coal seams and surface-water or springs (and therefore MNES). Further, the potential risks to workers involved with the hydraulic fracturing process were not considered as detailed Health and Safety (H&S) procedures are employed to manage exposures. The QRA considered the following specific exposure pathways:

1. Exposure of trespassers to flowback water contained within flowback storage ponds
2. Exposure of terrestrial receptors (e.g., livestock and wildlife) to flowback water contained within the flowback storage ponds
3. Exposure of aquatic receptors to flowback water in the situation of an accidental release, such as from piping or a release from the flowback storage pond. These potential releases could include a failure of containment systems, overtopping of the dam or in an extreme situation (considered highly unlikely) structural failure of the dam itself.

C3.1 Exposure Assessment

The purpose of the exposure assessment in the QRA was to predict the magnitude and frequency of potential human exposure to each COPC following the methodologies presented in **Section 8.1**. A conceptual site model (CSM) was developed which describes the potential receptors and exposure scenarios for the flowback water used in this exposure assessment. The potential exposures to receptors were evaluated based on the potential for a complete exposure pathway.

As discussed in **Section 8.3**, exposure point concentrations (EPCs) were derived for the theoretical assessment; empirical data were not available for evaluation. The EPCs for the theoretical assessment were calculated by estimating the mass and discharge flow of the COPCs from the flowback water monitoring data in **Appendix C2-2** (Appendix C, Table C-1; EHS Support, 2013b).

C3.2 Human Health QRA

A human health hazard assessment was conducted according to the methodologies presented in **Section 8.4**. The purpose of the hazard assessment process was to summarize the environmental data, and to address the toxicological assessment of the COPCs that will be evaluated further in the risk assessment process.

Exposure assumptions for the human trespasser scenario were developed based on default or site-specific assumptions (**Section 8.4**). This receptor exposure pathway includes a small child to teenager that may come in contact with the above grade water exposure scenario for approximately 20 days/year for a 10-year period with potential incidental ingestion (of 50 millitre [mL] water) and dermal contact (e.g., swimming where the whole body gets wet) for ½ hour (Table 3; EHS Support, 2013b).

Calculation of intake of COPCs was performed using the equations presented below:

Ingestion of water:

Intake (mg/kg-day) = (CW x IR X EF X ED) / (BW x AT)

Dermal contact with water:

Absorbed dose (mg/kg-day) = (CW x SA x DP x ET x EF x ED x CF) / (BW x AT)

Where:

CW = concentration in water (mg/l)
ET = exposure time (hr/day or hours/hours)
EF = exposure frequency (day/year)
ED = exposure duration (years)
CF = correction factor (1 x 10^{-3} l/cm^3)
AT = averaging time (days)
IR = ingestion rate (l/hr)
BW = body weight (kg)
SA = skin surface area available for contact (cm^2/d)
DP = dermal permeability factor (Kp – cm/hr)

C3.3 Toxicity Assessment

A toxicity assessment was conducted to determine the relationship between the dose of a COPC taken into the body, and the probability that an adverse effect will result from that dose. Quantitative estimates of the potency of COPCs include two sets of toxicity values, one for genotoxic carcinogens and one for other non-genotoxic carcinogens and non-carcinogenic effects. As discussed in **Section 8.4,** detailed toxicological profiles were developed for the chemicals. The toxicological profiles are included as **Appendix F**.

The assessment of toxicity of the COPCs was used to develop initial screening criteria for human health exposure scenarios as discussed in **Section 8.4**. Refer to Tables 1 and 2 of the QRA for details regarding the toxicity assessment of the COPCs (EHS Support, 2013b).

C3.4 Risk Estimation

Risk estimation was performed in accordance with the methodologies outlined in **Section 8.4**. The total target risk range for carcinogens was 1 x 10^{-4} to 1 x 10^{-6}; the target hazard index (HI) for non-threshold effects is less than or equal to 1.0.

No carcinogenic compounds are present in the stimulation fluids injected into the subsurface and as a result, only non-carcinogenic risks were calculated. The exposure scenarios include the specific fracturing fluids event from Golder (2013d) Table D-3, for the 20 and 80 percent (%) mass recovery from the fracturing fluid well flowback (**Appendix C2-1**). The modelled risks from injected chemicals in the flowback water at 20 % mass recovery were acceptable; the modelled risks to the trespasser for the maximum exposure to COPCs at the 80 % recovery predicted a HI of 2.5 (Tables 4 and 5; EHS Support, 2013b, attached). The primary risk drivers for this scenario were coco dimethylaminopropyl

betaine, alkylated quaternary chloride and tetrakis (hydroxylmethyl) phosphonium sulfate (THPS) via incidental ingestion, and alkylated quaternary chloride and terpenes via dermal contact.

Based on field observations, the risk assessment conducted on 80 per cent mass recovery in the flowback water diverted to the flowback storage ponds, is highly conservative. These conditions are not observed in the fields as the combination of biodegradation and sorption in the subsurface and biodegradation, complexation and settling of suspended solids in the flowback storage ponds results in lower concentrations. Based on stimulation flowback monitoring conducted by Santos and the QRA completed for the Schlumberger Fluid Systems (EHS Support, 2013b), 20 % of the total mass of constituents injected is assumed to be recovered in the flowback water. On this basis and using the theoretical concentrations, no adverse effects are predicted on trespassers.

C3.5 Ecological Risk Assessment

As discussed in **Section 8.5**, a screening level ecological risk assessment (ERA) was conducted to evaluate the potential for adverse ecological effects to terrestrial and aquatic ecological receptors that may be exposed to residual levels of hydraulic fracturing fluids in surface water used in the coal seam gas (CSG) fields.

Terrestrial receptors evaluated in the ERA include domesticated livestock, large mammalian wildlife and small mammalian wildlife. Beef cattle were used to evaluate domesticated livestock, kangaroos evaluated for large mammalian wildlife, and dingos for small mammalian wildlife. Aquatic receptors evaluated included invertebrates and fishes.

Ecological effects were characterised following the methodologies outlined in **Section 8.5.3** (Table 8; EHS Support, 2013b). Exposure scenarios were the same for ecological receptors as human receptors; EPCs were estimated in accordance with the methodology presented in **Section 8.5.4** (**Appendix C2-3**; Table A-1; EHS Support, 2013b). Environmental fate information is provided in Table 9 (EHS Support, 2013b).

Risks were characterised in accordance with the methodologies discussed in **Section 8.5.5**. The resulting ecological hazard quotient must be less than or equal to 1.0 for risks to be considered acceptable.

C3.5.1 Estimation of Risk

The HI calculated for flowback water for aquatic risk were elevated above the acceptable level for the majority of COPCs evaluated (**Appendix C2-2**, Table C-3; EHS Support, 2013b). Where large discharges of flowback water occur to surface water and/or flux dilution within the surface-water was insufficient, potential impacts on aquatic receptors could occur. As noted in the toxicity assessment section above, the lack of a robust aquatic toxicological database resulted in aquatic screening values for the theoretical exposure scenario COPCs to be conservatively very low.

The modelled risks from injected chemicals in the flowback water were all acceptable for each of the ecological receptors modelled, except livestock cattle for the maximum exposure to COPCs at the 80% recovery indicating a HI equal to 1.9 (Tables 13 and 14, 17 and 18, 21 and 22; EHS Support, 2013b, attached). Primary risk drivers were coco dimethylaminopropyl betaine, alkylated quaternary chloride and THPS via incidental ingestion; dermal contact was not evaluated for terrestrial ecological receptors. As discussed in the HHRA, 80 % recovery conditions are not observed in the fields. A recovery of 20 % is more realistic based on stimulation flow back monitoring conducted by Santos (EHS Support, 2013b).

C4.0 Summary of QRA Findings

The QRA was completed as discussed in **Section 8.0**. An assessment was conducted using highly conservative theoretical calculations based on the chemicals utilized by Halliburton in hydraulic fracturing. This assessment assumed that a range of theoretical percentages of injected chemicals would be present in the flow back water.

Consistent with the risk assessment and groundwater fate and transport modelling conducted by Golder, no potentially complete exposure pathways were identified for groundwater. Potential exposures are limited to the aboveground storage and handling of flowback water as part of the CSG Water Management Plan (WMP). Management of CSG water involves the temporary storage of flowback water in flowback storage ponds.

On the basis of the quantitative risk calculations, the potential risks associated with the flowback water are generally limited. Potential risks to trespassers could occur with repeated exposures to flowback water. However, the cumulative risks are only slightly above the non-carcinogenic threshold discussed above where management and operational controls can be implemented to control potential exposures. There were no carcinogenic risks identified.

Limited to no risks to cattle and native mammals were identified in the risk assessment; and only in the most conservative theoretical calculations (80 % chemical mass in the flowback water) were potentially unacceptable risks identified. Based on contractor experience and stimulation flowback monitoring, 20 % of the total mass constituents injected is assumed to be recovered in flowback water. Additionally, environmental fate information indicated primary risk drivers are readily biodegradable. Therefore, no potential risks exist for livestock or native mammals.

Similarly, potential impacts could occur if releases of flowback water were to occur to aquatic environments. Based on the use of clay liners and operational controls that limit the potential for turkey nest and dam overflows, the potential for these risks are also considered limited.

A combination of management and operational controls are being implemented to eliminate and control the potential for exposures. These include:

- Worker training and hazard identification
- Use of appropriate personal protective equipment (gloves etc.)
- Flowback storage pond fencing to prevent entry of livestock and minimize trespassing.
- Installation of clay dam liners and routine dam inspections to prevent releases from flowback storage ponds
- Routine operational and security patrols to prevent trespassing.

C5.0 Conclusions

A weight-of-evidence evaluation of potential risks as described in **Section 5.0** was performed for the Schlumberger ClearFRAC XT fluid system. Based on the qualitative and comparison to the Schlumberger water and guar based quantitative risk characterisations, the overall risk to human health and the environment is low. Existing operational control activities employed by Santos are in place that will limit the potential risks to human health and the environment. These measures include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments;
- Environmental authority conditions that preclude the construction of well pads within 100 metres of a watercourse of water body;
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals;
- Disposal or capping of sediments contained within drained mud pits and turkey's nests , to prevent exposure to contaminates in windborne dust;
- Fencing of drill pads to prevent trespassers and installation of signs to indicate that the water in the turkey's nest and mud pit is not potable and may contain contaminants;
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna;
- Santos operational procedures to ensure well integrity and design of fracture to stay within the target seam; and
- Mud pits and turkey's nests with clay liners, or similar material, to prevent seepage of flowback water into underlying aquifers.

Regular monitoring of water supply bores and surface water for a representative suite of chemicals within 2 kilometre of wells that are fractured is required to confirm the conclusion of incomplete exposure pathways and low risk.

No additional risks, other than those previously discussed, were identified with the chemicals or systems employed by Schlumberger in hydraulic fracturing. Evaluation of other potential risks associated with hydraulic fracturing (i.e., noise and vibration) was conducted. Refer to **Section 9.0** for methodology specifics and results of this evaluation.

Golder Associates Tables

Table 50: On site exposure assessment summary

Source	Exposure Scenario	Receptors	Exposure Pathways	Likelihood of exposure scenario	Comments
Mud pit and turkeys nest sediments	Entry to pit or excavation/stockpiling of pit sediments	Workers, trespassers	Ingestion, dermal	Unlikely	OH&S procedures limit workers exposure to sediment.
	Pit dries and pit sediments become windblown dusts	Workers, trespassers	Inhalation of dusts	Possible	Pathway is limited by disposal or capping of sediments contained in the mud pit and turkeys nest at the end of operations
	Pit dries and pit sediments become windblown dusts, contaminating surrounding soil	Native terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, uptake	Unlikely	Volume of pit sediments considered insufficient to cause significant contamination of drill pad.
	Entry to pit or exposure to excavated pit sediments	Native terrestrial fauna (mammals, reptiles, birds)	Ingestion	Unlikely	Mud pit and turkeys nest does not contain food or habitat for terrestrial species.
Flow back water in Turkey nest and mud pit	Working with turkey nest inlet/liner, or drainage of turkey nest or mud pit	Workers	Ingestion, dermal	Possible	OH&S procedures limit workers exposure to flow back water.
	Entry (accidental or deliberate) to Turkeys nest or mud pit	Trespassers	Ingestion, dermal	Possible	Trespassers entry is limited via fencing and signage around drill pad areas. Trespassers can be entirely precluded from areas.
	Entry (accidental or deliberate) to Turkeys nest or mud pit	Native terrestrial fauna (mammals, reptiles, birds)	Ingestion	Observed	Native fauna has been observed in and around the turkey nests, despite areas being fenced.
	Entry (accidental or deliberate) to Turkeys nest or mud pit	Stock animals	Ingestion	Observed	Maintained fences and grids with routine maintenance can be effective at precluding livestock however, some stock animals have been observed in well pad areas.
Hydraulic fracturing Chemicals	Spill, leak of well delivery system failure during surface handling. Supply or disposal vehicle accident on site	Workers, terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, dermal	Unlikely	OH&S and spill containment, procedures adequately address this exposure.
Flow back water	Spill, leak, mud pit, turkey nest delivery system failure or overflow	Workers, terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, dermal, inhal	Possible	

Table 51: Off site exposure assessment summary

Source	Exposure Scenario	Receptors	Exposure Pathways	Likelihood of exposure scenario	Comment/Management/control measures
Hydraulic fracturing fluids	Fracture fluid escapes into aquifer via a well casing failure, or a fault/fracture/unconformity in seam/strata, and fluids enter aquifer used downgradient for domestic water supply	Residents: adults and children	Ingestion, dermal, inhalation	Unlikely	Exposure scenario unlikely however; dependant on Santos operational procedures i.e. well integrity testing and design of fracture to stay with the target seam. No recorded instances in peer-reviewed literature of fracturing chemicals in downgradient water supplies (Osborn et al 2011).
	Fracture fluid escapes into aquifer via a well casing failure, or a fault/fracture/unconformity in seam/strata, and fluids enter aquifer used downgradient for stock water supply	Stock animals	Ingestion	Unlikely	
	Fracture fluid escapes into aquifer via a well casing failure, or a fault/fracture/unconformity in seam/strata, and fluids enter aquifer that discharges to surface water	Aquatic ecosystems	Direct exposure	Unlikely	

Table 51: Off site exposure assessment summary

Source	Exposure Scenario	Receptors	Exposure Pathways	Likelihood of exposure scenario	Comment/Management/control measures
	Residual fracturing fluid in the coal seam migrates down gradient and enters a spring or water supply bore	Residents, aquatic ecosystems, stock animals	Ingestion, dermal, inhalation	Unlikely	Fate and transport modelling used to estimate the likely extent of migration of residual fluids in coal seam (section 7.4)
Turkeys nest or mud pit sediments	Nest/Pit dries and sediments become windblown dusts, contaminating surrounding soil	Native terrestrial flora and fauna, stock, Residents adults and children	Direct exposure/ inhalation of dusts	Unlikely	Volume of pit sediments considered insufficient to result in concentrations of concern in the surrounding land.
Flow back water	Seepage of chemicals from mud pit or turkeys nest to a shallow aquifer used downgradient for domestic water supply	Residents: adults and children	Ingestion, dermal, inhalation	Unlikely	Considered unlikely that the concentrations of chemicals would be of a concern however regular maintenance of liners required to remove exposure pathway. Monitoring of down gradient bores also recommended to confirm no exposure.
	Seepage of chemicals from mud pit or turkeys nest to a shallow aquifer used downgradient for stock water supply	Stock animals	Ingestion	Unlikely	
	Seepage of chemicals from mud pit or turkeys nest to a shallow aquifer that discharges to surface water	Aquatic ecosystems	Direct exposure	Unlikely	

Table 51: Off site exposure assessment summary

Source	Exposure Scenario	Receptors	Exposure Pathways	Likelihood of exposure scenario	Comment/Management/control measures
	Spill, leak, turkey nest overflow	Residents, terrestrial fauna (mammals, reptiles, birds), terrestrial flora	Ingestion, dermal, inhalation	Possible	Possible overflows during prolonged periods of high rainfall (>500 mm of rainfall required) based on freeboard control requirements. Likelihood of occurrence can be reduced through minimising duration of storage in pit and turkeys nest, and toxicity of fluid is likely to decrease rapidly due to short biotransformation half-lives of most chemicals.

[a]See HERA Report on Alcohol Ethoxylates.

[b]Interim Canadian Water Quality Guideline for the Protection of Aquatic Life for Didecyldimethyl ammonium chloride (DDAC).

[c]PNEC is the water solubility limit because the calculated acute toxicity values are estimated to be higher than the water solubility limit.

PEG = polyethylene glycol

PNEC = predicted no effects concentration

µg/L = microgram per litre

mg/L = milligrams per litre

NOEC = no observed effect concentration

QSAR = quantitative strucuture activity relationship

WAF = water-accommodated fraction

Table 9 Environmental Fate Information

DeltaFoam 140	
Acetic acid	Dissociates to H^+ and $CH_3CO_2^-$ in aqueous media. Acetate anion is readily biodegradable under aerobic and anaerobic conditions. Biodegradation: 74% (BOD) after 14 days (MITI-I, OECD 301C); 99% after 7 days under anaerobic conditions.
Alkylated Quaternary chloride	Surrogate: Didecyldimethylammonium chloride (DDAC), a cationic surfactant. DDAC adsorbs strongly and rapidly to sediments, clay materials, and other negatively charged surfaces. In unacclimated river water, half-lifes of AQCs range from <1 to several days. Half-life of the 12 carbon alkyl chain reported as 2.1 d. Rate of degradation - with $^-$ alkyl chain. BCF (experimental) = 81 (whole body fish tissues).
C6-C10 Alcohol Ethoxylates	Readily biodegradable and also anaerobically biodegradable. Proposed half-lives in river water at 12°C: 4 to 24 hours (based on experimental data). BCF (see HERA report)
Benzothiazolin-3-one	Hydrolytically stable ($T_{1/2}$ >30 d); breaks down fairly quickly in aerobic soil ($T_{1/2}$ <24 hr in sandy loam). Moderate to strong binding to soils.
Cocoamidopropyl betaine	Readily biodegradable; easily biodegradable under anaerobic conditions. BCF between 3 and 71. Biodegradation: 86 – 100 % after 28 days (OECD 301A/B/D/E), 90 – 93 % after 35 days (OECD 301B) and 100 % after 20 days (Directive 84/449/EEC, C.5).
Ethanol	Readily biodegradable; unlikely to bioaccumulate; and is not persistent in the environment. Biodegradation: 74% after 5 days. Calculated log BCF = 0.5.
Ethoxylated fatty acid	Expected to be biodegradable, but not readily biodegradable based on ethoxylated castor oil. OECD 302B: 90-100% after 21 days.
PEG Oleate ester	Expected to be biodegradable, but not readily biodegradable based on ethoxylated castor oil. OECD 02B: 90-100% after 21 days.
Guar gum	Expected to be readily biodegradable as a polysaccharide; not expected to bioaccumulate. [No data]
Enzyme X	Readily biodegradable; unlikely to bioaccumulate. 84-92% DOC removal after 28 days (OECD 301E); 78% BOD/COD after 28 days (OECD 301C)
Monoethanolamine borate	Readily biodegradable. MEA Polyborate(1:1): 73% after 28 days (OECD 301B). MEA Polyborate (1:3): 75% after 28 days (OECD 301B). Does not adsorb to soil.
Terpene hydrocarbons	Readily biodegradable. Biodegradation of limonene: 41-98% degradation by BOD in 14 days (OECD 301C). Biodegradation of terpinolene: 80% biodegradation after 28 and 31 days (OECD 302C); 62.1% after 28 days (OECD 301B).
Tetrakis(hydroxymethyl) phosphonium sulfate	Rapidly biodegrades under aerobic and anaerobic conditions. Binds poorly to environmental particulates
Delta 140	
Acetic acid	Dissociates to H^+ and acetate ($CH_3CO_2^-$) in aqueous media. Acetate anion is readily biodegradable under aerobic and anaerobic conditions. Biodegradation: 96% after 20 days under aerobic conditions; 99% after 7 days under anaerobic conditions.
Alcohols, C6-C12, ethoxylated propoxylated	Read-across to C6-C12 alcohol ethoxylates. Readily biodegradable and also anaerobically biodegradable. Proposed half-lives in river water at 12°C: 4 to 24 hours (based on experimental data).
Alcohols, C10-C16 ethoxylated, propoxylated	Read-across to C10-C16 ethoxylates. Readily biodegradable and also anaerobically biodegradable. Proposed half-lives in river water at 12°C: 4 to 24 hours (based on experimental data).
Choline chloride	Readily biodegradable (93% within 14 days in a MITI-I test. In another MITI-I test, biodegradation was ≥60%.
Crystalline silica	Naturally occurring mineral that is insoluble in water. It is persistent in the environment.
Ethylene glycol	Readily biodegradable under both aerobic and anaerobic conditions. There was 97% degradation after 20 days in a BOD test, and 96% degradation after 28 days in an OECD 301D test.
Guar gum	Expected to be readily biodegradable, as it ia a naturally occurring polysaccharide.
Hemicellulase	Readily biodegradable. 84-92% DOC removal after 28 days (OECD 301E); 78% BOD/COD after 28 days (OECD 301C)
Maltodextrin	Expected to biodegrade, as it is a naturally occurring polysaccharide.
Monoethanolamine borate	Readily biodegradable. MEA Polyborate(1:1): 73% after 28 days (OECD 301B). MEA Polyborate (1:3): 75% after 28 days (OECD 301B).
Polyethylene glycol	Read-across to tetra- and penta- ethylene glycol, major constituents of low-molecular weight polyethylene glycol. Inherently biodegradable. TetraEG: 22% degradation after 20 days (BOD test); 40% degradation after 28 days (OECD 301D). PentaEF: 3% degradation after 20 days (BOD test).

Table 9 Environmental Fate Information

Sodium hydroxide	Disociates to Na^+ and OH^- in aqueous media.
Tetrakis(hydroxymethyl) phosphonium sulfate	Inherently biodegradable. >20% degradation within 28 days (OECD 302B).

Santos

Appendix C3
Halliburton CleanStimAUs System

C1.0 Introduction

As presented in **Section 5.0** of the Hydraulic Fracturing Risk Assessment , a weight-of-evidence approach was used by Santos Ltd. (Santos) to evaluate the potential for human health and environmental (e.g., ecological) risks as a result of the hydraulic fracturing processes and the Halliburton CleanStimAUS fluid system.

Golder Associates Pty Ltd. (Golder), on behalf of Santos, completed a human health and ecological toxicity assessment (Golder, 2013e) that evaluated the nature of the geology in the areas undergoing stimulation, the potential for impacts on water resources, the process and chemicals used.

A Quantitative Risk Assessment (QRA), completed by EHS Support, LLC (EHS Support), supplemented the qualitative risk assessment (EHS Support, 2013a). The QRA was conducted to meet Conditions 49e and 49f of the 2 October 2011 approval under the Environmental Protection and Biodiversity Conservation Act 1999 (EPBC 2008/4059) and the Environmental Amendment (EA) conditions to assess the toxicity of the mixtures.

Key reports and studies previously submitted for these fluid systems comprise:

- Golder Associates (2013e). Coal Seam Hydraulic Fracturing Risk Assessment. Human Health and Ecological Risk Assessment - CleanStim-AU. Golder Associates Report. 1 July 2013..
- EHS Support. (2013a). Gladstone Liquefied Natural Gas (GLNG) Project. Coal Seam Gas Hydraulic Fracturing Quantified Risk Assessment for Halliburton CleanStim AUS Chemistry. 16 July 2013.. .

The results and conclusions of the qualitative risk assessment components and the QRA are summarised below. Refer to the text of this report for detailed discussions on methodologies employed for each component; specific tables referred to in this summary are included for review with this document. Table numbers specific to the original reports were retained for consistency between documents.

C2.0 Qualitative Risk Assessment and Evaluation

C2.1 Chemicals Evaluated

Chemical constituents identified in the CleanStimAUS fracturing fluid system were evaluated in the hydraulic fracturing risk assessments. The list of individual chemicals is presented in **Table 1**. A mass balance of the chemicals within each of the hydraulic fracturing fluid systems was provided in Table C-1 (Golder, 2013e).

Information regarding the chemical and physical properties of the individual chemicals listed below can be found on the Safety Data Sheets in **Appendix E**.

It is noted, while none of the fracturing fluid chemicals identified contain benzene, toluene, ethylbenzene, xylenes (BTEX) or polycyclic aromatic hydrocarbons (PAHs), that PAHs occur naturally in coal and it is possible that certain PAHs may naturally be present in the coal seam groundwater used in the hydraulic fracturing process.

Table 1: Hydraulic fracturing chemicals

Chemical	CAS Number
Carbohydrate	-*
Food coating	64-19-7
Sodium lauryl sulfate	75-57-0
Fatty acid ester™	-*
Hemicellulase enzyme™	9012-54-8
Saccharide	-*
Polysaccharide	-*
Tri tetradecyl phosphonium chloride (TTPC)	81741-28-8
Inorganic salt	-*
Potassium chloride	7447-40-7
Sulfuric acid	7664-93-9
Talc	14807-96-6
Cyrstalline silica, quartz	14808-60-7

* The CAS numbers have not been included in this table due to commercial confidentiality.

C2.2 Risk Assessment Framework and Findings

As discussed in **Section 5.0** of the systematic weight of evidence approach was utilised to complete the risk assessment for the Halliburton fluid systems. The work has involved the following evaluations:

Qualitative Assessment Methodologies

- Environmental Hazard Assessment
- Exposure Assessment
- Mass Balance of the fluid systems.

As noted in **Section 7.2**, fate and transport of previously modelled fluid systems was not sensitive to the variability in physical properties of chemicals. Due to the broad range of physical properties assessed, the limited transport observed in the model and limited impact that physical properties has

on transport distances, fate and transport of the chemicals present in this fluid system was not considered warranted.

Quantitative Risk Assessment Methodologies

- Quantitative Human Health Risk Assessment
- Quantitative Ecological Risk Assessment for Terrestrial and Aquatic Receptors.

C2.3 Environmental Hazard Assessment

The environmental hazard assessment approach outlined in **Section 6.2** was undertaken to rank the hydraulic fracturing chemicals based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT).

A combination of data sets were used in the PBT assessment including chemical information sheets (**Appendix E** and **Appendix G**) were compiled for each chemical from published guidelines, the Hazardous Substance Database, and modelled data from United States Environmental Protection Agency (USEPA) (2009) EPISUITE modelling software, when data not available from other sources.

Of the 13 chemicals listed above, three were not considered for PBT ranking. Physico-chemical and/or toxicological data were not available, and surrogates could not be identified for saccharide, talc, polysaccharide, and tri tetradecyl phosphonium chloride (TTPC) (81741-28-8)[1]. Crystalline silica (14808-60-7) relate to the sand used as the proppant, and therefore is not considered to represent an environmental hazard.

C2.4 Exposure Assessment

As discussed in **Section 7.0**, the exposure assessment identified receptors potentially exposed to COPCs identified for the study and outlines the exposure pathways by which the receptors may come in to contact with the COPCs. A detailed exposure assessment was not conducted in the qualitative risk assessment; however, hazards from potential exposures were determined to be primarily occupational concerns with some limited environmental matters (Golder, 2013e).

C2.5 Mass Balance of Fluid System

A quantitative mass balance calculation was undertaken to identify the amount of each chemical additive of the hydraulic fracturing fluid system. The results of the mass balance calculations are presented in the referenced Table C-1 (Golder, 2013e).

C2.6 Fate and Transport Modelling

As noted in previously, fate and transport of previously modelled fluid systems was not sensitive to the variability in physical properties of chemicals. Due to the broad range of physical properties assessed, the limited transport observed in the model and limited impact that physical properties has on transport distances, fate and transport of the chemicals present in this fluid system was not considered warranted. Additionally, the modelling demonstrated that there is limited potential for chemicals to migrate within the coal seams.

[1] TTPC assessed in subsequent fluid systems. Refer to Appendix C8, Appendix C9 and C11 for PBT assessments of TTPC.

C3.0 Quantitative Risk Assessment

In accordance with the methodologies presented in **Section 8.0**, a QRA was conducted on theoretical datasets for those chemicals identified in the human health and ecological toxicity evaluation (EHS Support, 2013a). The QRA approach evaluates the toxicity of the individual substances and characterises the cumulative risks of the total effluent toxicity and ecotoxicity.

Generally, this methodology includes the identification of the hazards posed by constituents in the flowback water, compilation of the toxicity criteria for each constituent, development of exposure models to estimate the daily intake of the constituents, and calculations of individual constituent hazard quotients (daily intake divided by the toxicity criteria) and a cumulative constituent hazard index (HI) for each potentially complete exposure pathway for each human or terrestrial receptor.

Potential complete exposure pathways to the storage of flowback from hydraulically stimulated wells and potential risks to humans, terrestrial and aquatic receptors from the potential storage and accidental releases are evaluated in the QRA.

No further assessment of groundwater was determined to be necessary due to lack of potentially complete exposure pathways. Detailed operational procedures have been provided that are designed to contain the hydraulic fracturing fluids within the coal sequences, and no connection exists between groundwater in the coal seams and surface-water or springs (and therefore Matters of National Environmental Significance [MNES]). Further, the potential risks to workers involved with the hydraulic fracturing process were not considered as detailed Health and Safety (H&S) procedures are employed to manage exposures. The QRA considered the following specific exposure pathways:

1. Exposure of trespassers to flowback water contained within flowback storage ponds.
2. Exposure of terrestrial receptors (e.g., livestock, wildlife) to flowback water contained within the flowback storage ponds.
3. Exposure of aquatic receptors to flowback water in the situation of an accidental release, such as from piping or a release from the flowback storage pond. These potential releases could include a failure of containment systems, overtopping of the dam or in an extreme situation (considered highly unlikely) structural failure of the dam itself.

C3.1 Exposure Assessment

The purpose of the exposure assessment in the QRA was to predict the magnitude and frequency of potential human exposure to each COPC following the methodologies presented in **Section 8.1**. A conceptual site model (CSM) was developed which describes the potential receptors and exposure scenarios for the flowback water used in this exposure assessment. The potential exposures to receptors were evaluated based on the potential for a complete exposure pathway.

As discussed in **Section 8.3**, exposure point concentrations (EPCs) were derived for the theoretical assessment; empirical data were not available for evaluation. The EPCs for the theoretical assessment were calculated by estimating the mass and discharge flow of the COPCs from the flowback water monitoring data were used **Appendix C3-1** (Appendix A, Table A-1; EHS Support, 2013a).

C3.2 Human Health QRA

A human health hazard assessment was conducted according to the methodologies presented in **Section 8.4**. The purpose of the hazard assessment process was to summarise the environmental data, and to address the toxicological assessment of the COPCs that will be evaluated further in the risk assessment process.

Exposure assumptions for the human trespasser scenario were developed based on default or site-specific assumptions (**Section 8.4**). This receptor exposure pathway includes a small child to teenager that may come in contact with the above grade water exposure scenario for approximately 20 days/year for a 10-year period with potential incidental ingestion (of 50 millilitre [mL] water) and dermal contact (e.g., swimming where the whole body gets wet) for half an hour (Table 4; EHS Support, 2013a).

Calculation of intake of COPCs was performed using the equations presented below:

Ingestion of water:

$$Intake\ (mg/kg-day)\ =\ (CW\ x\ IR\ X\ EF\ X\ ED)\ /\ (BW\ x\ AT)$$

Dermal contact with water:

$$Absorbed\ dose\ (mg/kg-day)\ =\ (CW\ x\ SA\ x\ DP\ x\ ET\ x\ EF\ x\ ED\ x\ CF)\ /\ (BW\ x\ AT)$$

Where:

CW = concentration in water (mg/l)
ET = exposure time (hr/day or hours/hours)
EF = exposure frequency (day/year)
ED = exposure duration (years)
CF = correction factor (1 x 10-3 l/cm3)
AT = averaging time (days)
IR = ingestion rate (l/hr)
BW = body weight (kg)
SA = skin surface area available for contact (cm2/d)
DP = dermal permeability factor (Kp – cm/hr)

C3.3 Toxicity Assessment

A toxicity assessment was conducted to determine the relationship between the dose of a COPC taken into the body, and the probability that an adverse effect will result from that dose. Quantitative estimates of the potency of COPCs include two sets of toxicity values, one for genotoxic carcinogens and one for other non-genotoxic carcinogens and non-carcinogenic effects. As discussed in **Section 8.4,** detailed toxicological profiles were developed for the chemicals. The toxicological profiles are included as **Appendix F**.

The assessment of toxicity of the COPCs was used to develop initial screening criteria for human health exposure scenarios as discussed in **Section 8.4**. Refer to Tables 1 and 2 of the EHS Support QRA for details regarding the toxicity assessment of the COPCs (EHS Support, 2013a, attached).

C3.4 Risk Estimation

Risk estimation was performed in accordance with the methodologies outlined in **Section 8.4**. The total target risk range for carcinogens was 1 x 10^{-4} to 1 x 10^{-6}; the target HI for non-threshold effects is less than or equal to 1.0.

No carcinogenic compounds are present in the stimulation fluids injected into the subsurface and as a result, only non-carcinogenic risks were calculated. The exposure scenarios include 20 percent mass recovery from the fracturing fluid well flowback from 0 to 150 days from injection of fluid. The modelled risks from injected chemicals in the flowback water in both scenarios were acceptable (Tables 5 and 6; EHS Support, 2013a, attached).

C3.5 Ecological Risk Assessment

As discussed in **Section 8.5**, a screening level ecological risk assessment (ERA) was conducted to evaluate the potential for adverse ecological effects to terrestrial and aquatic ecological receptors that may be exposed to residual levels of hydraulic fracturing fluids in surface water used in the coal seam gas (CSG) fields.

Terrestrial receptors evaluated in the ERA include domesticated livestock, large mammalian wildlife and small mammalian wildlife. Beef cattle were used to evaluate domesticated livestock, kangaroos evaluated for large mammalian wildlife, and dingos for small mammalian wildlife. Aquatic receptors evaluated included invertebrates and fishes.

Ecological effects were characterised following the methodologies outlined in **Section 8.5.3** (Table 7; EHS Support, 2013a, attached). Exposure scenarios were the same for ecological receptors as human receptors; EPCs were estimated in accordance with the methodology presented in **Section 8.5.4** (**Appendix C3-1**; Table A-1; EHS Support, 2013a). Environmental fate information is provided in Table 3 (EHS Support, 2013a).

Risks were characterised in accordance with the methodologies discussed in **Section 8.5.5**. The resulting ecological hazard quotient must be less than or equal to 1.0 for risks to be considered acceptable.

C3.5.1 Estimation of Risk

The HI calculated for flowback water for aquatic risk were elevated above the acceptable level for the majority of COPCs evaluated (**Appendix C3-2**, Table C-2; EHS Support, 2013a). Where large discharges of flowback water occur to surface water and/or flux dilution within the surface-water was insufficient, potential impacts on aquatic receptors could occur. As noted in the toxicity assessment section, the lack of a robust aquatic toxicological database resulted in aquatic screening values for the theoretical exposure scenario COPCs to be conservatively very low.

The modelled risks from injected chemicals in the flowback water were all acceptable for each of the ecological receptors modelled (Tables 11 through 16; EHS Support, 2013a, attached). Therefore, there were no estimated potential risks to domesticated wildlife or mammalian wildlife that are either present on operational areas infrequently or in the vicinity of the well pads.

C4.0 Summary of QRA Findings

The QRA was completed as discussed in **Section 8.0**. An assessment was conducted using highly conservative theoretical calculations based on the chemicals utilised by Halliburton in hydraulic fracturing. This assessment assumed that a range of theoretical percentages of injected chemicals would be present in the flowback water.

Consistent with the risk assessment and groundwater fate and transport modelling conducted by Golder, no potentially complete exposure pathways were identified for groundwater. Potential exposures are limited to the aboveground storage and handling of flowback water as part of the CSG Water Management Plan (WMP). Management of CSG water involves the temporary storage of flowback water in flowback storage ponds.

On the basis of the quantitative risk calculations, no elevated potential risks were identified for the trespasser scenarios. No potential risks exist for livestock or native mammals. Potential impacts could occur if releases of flowback water were to occur to aquatic environments. Based on the use of clay liners and operational controls that limit the potential for turkey nest and dam overflows, the potential for these risks are also considered limited.

A combination of management and operational controls are being implemented to eliminate and control the potential for exposures. These include:

- Worker training and hazard identification
- Use of appropriate personal protective equipment (gloves, etc.)
- Flowback storage pond fencing to prevent entry of livestock and minimise trespassing
- Installation of clay dam liners and routine dam inspections to prevent releases from flowback storage ponds
- Routine operational and security patrols to prevent trespassing.

C5.0 Conclusions

A weight-of-evidence evaluation of potential risks as described in **Section 5.0** was performed for the Halliburton CleanStimAUS. Based on the qualitative and quantitative risk characterisations, the overall risk to human health and the environment is low. Existing operational control activities employed by Santos are in place that will limit the potential risks to human health and the environment. These measures include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments;
- Environmental authority conditions that preclude the construction of well pads within 100 metres of a watercourse of water body;
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals;
- Disposal or capping of sediments contained within drained mud pits and turkey nests, to prevent exposure to contaminates in windborne dust;
- Fencing of drill pads to prevent trespassers and installation of signs to indicate that the water in the turkey's nest and mud pit is not potable and may contain contaminants;
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna;
- Santos operational procedures to ensure well integrity and design of fracture to stay within the target seam; and
- Mud pits and turkey's nests with clay liners, or similar material, to prevent seepage of flowback water into underlying aquifers.

Regular monitoring of water supply bores and surface water for a representative suite of chemicals within 2 kilometre of wells that are fractured is required to confirm the conclusion of incomplete exposure pathways and low risk.

No additional risks, other than those previously discussed, were identified with the chemicals or systems employed by Halliburton in hydraulic fracturing. Evaluation of other potential risks associated with hydraulic fracturing (i.e., noise and vibration) was conducted. Refer to **Section 9.0** for methodology specifics and results of this evaluation

a CEPA Priority Substance List Assessment Report (2010)

b Saccharide is a oligosaccharide composed of D-glucose sugars (molecular weights ranging from 550-3000). There are no data; however, it is not expected to be toxic to aquatic organisms due to molecular weight considerations and that D-glucose is a sugar found in the body and is an energy source.

c Food coating is a biopolymer and is insoluble in water. It is not expected to be bioavailable and therefore not hazardous to aquatic organisms.

d Talc is an inert mineral and is insoluble in water. It is not expected to be harmful to aquatic organisms.

Santos

Appendix C4
Schlumberger Clearfrac XT Fluid System

C1.0 Introduction

As presented in **Section 5.0** of the Hydraulic Fracturing Risk Assessment (RA Compendium), a weight-of-evidence approach was used by Santos to evaluate the potential for human health and environmental (e.g., ecological) risks as a result of the hydraulic fracturing processes and the Schlumberger ClearFRAC XT fluid system.

EHS Support, LLC (EHS Support) conducted a persistence, bioaccumulation, and toxicity (PBT) assessment and compared ClearFRAC XT fluid system to the Schlumberger water and guar-based system discussed in **Appendix C1** (EHS Support, 2013c). The assessment was conducted to meet Conditions 49e and 49f of the 2 October 2011 approval under the Environmental Protection and Biodiversity Conservation Act 1999 (EPBC 2008/4059) and the Environmental Amendment (EA) conditions to assess the toxicity of the mixtures.

Key reports and studies previously submitted for these fluid systems comprise:

- EHS Support. (2013c). ClearFRAC PBT Assessment and Comparison to Primary Hydraulic Fracturing Fluid. Memorandum. 27 June 2013.

The results and conclusions of the fluid system evaluation are summarised below. Refer to the text of this report for detailed discussions on methodologies employed for each component; specific tables referred to in this summary are included for review with this document. Table numbers specific to the original reports were retained for consistency between documents.

. .

C2.0 Qualitative Risk Assessment and Evaluation

C2.1 Chemicals Evaluated

Chemical constituents identified in the ClearFRAC XT fracturing fluid system were evaluated in the hydraulic fracturing risk assessments. The list of individual chemicals is presented in **Table 1**. A mass balance of the chemicals within each of the hydraulic fracturing fluid systems is provided as **Appendix C4-1** (Attachment 1; EHS Support, 2013c).

It is noted, while none of the fracturing fluid chemicals identified contain benzene, toluene, ethylbenzene, xylenes (BTEX), or polycyclic aromatic hydrocarbons (PAHs), that PAHs occur naturally in coal, and it is possible that certain PAHs will naturally be present in the coal seam groundwater used in the hydraulic fracturing process.

Table 1: Hydraulic fracturing chemicals

Chemical	CAS Number
Water (including mix water supplied by client)	-
Cyrstalline silica	14808-60-7
Erucic amidopropyl dimethyl betaine	149879-98-1
Propan-2-ol	67-63-0
Cholinium chloride	67-48-1
Sodium chloride	7647-14-5
Benzenesulfonic acid, 4-ethenyl-, sodium salt, homopolymer	25704-18-1
Hydrochloric acid	7647-01-1
Vinylidene chloride/methalacrylate copolymer	25038-72-6
Sodium chloroacetate	3926-62-3
Acetic acid ethenyl ester, polymer with ethenol	25213-24-5
Diatomaceous earth, calcined	91053-39-3
Polyvinyl acetate, partially hydrolyzed	304443-60-5
Magnesium silicate hydrate (talc)	14807-96-6
Magnesium nitrate	13077-60-3
5-chloro-2-methyl-2h-isothiazolol-3-one	26172-55-4
Magnesium chloride	7786-30-3
2-methyl-2h-isothiazol-3-one	2682-20-4
Cristobalite	14464-46-1

C2.2 Risk Assessment Framework and Findings

As discussed in **Section 5.0** of the systematic weight of evidence approach was utilised to complete the risk assessment for the Schlumberger ClearFRAC XT Fluid System. The work has involved the following evaluations:

Qualitative Assessment Methodologies

- PBT Assessment

- Exposure Assessment
- Mass Balance of the fluid system.

As noted in **Section 7.2**, fate and transport of previously modelled fluid systems was not sensitive to the variability in physical properties of chemicals. Due to the broad range of physical properties assessed, the limited transport observed in the model and limited impact that physical properties has on transport distances, fate and transport of the chemicals present in this fluid system was not considered warranted.

Quantitative Risk Assessment Methodologies

A quantitative risk assessment (QRA) was conducted for the original Schlumberger fluid system (**Appendix C1**) to estimate potential risks from exposures to the fluid system as discussed in Section **8.0**. The constituents of the ClearFRAC XT fluid system were compared to those present in the original fluid system to determine if toxicological information or projected chemical concentrations would result in a greater risk to human health or the environment than those in the Schlumberger water and guar-based system.

C2.3 PBT Assessment

The PBT approach outlined in **Section 6.1** was undertaken to rank the hydraulic fracturing chemicals based on persistence (P), bioaccumulation (B) and toxic (T) potential. As a result of this assessment, no chemical constituents identified in the ClearFRAC XT fluid system was classified as a PBT chemical and is therefore not considered to be inherently hazardous (Table 1; EHS Support, 2013c)

C2.4 Toxicity Assessment

As discussed in **Section 8.0**, detailed human health and environmental toxicological profiles and supporting documents were developed for the chemicals within the ClearFRAC XT system (**Appendices F and G**; Attachment 2, EHS Support, 2013c). Physical, chemical, and toxicoloigical data on the ClearFRAC XT constituents were collected in accordance with the methodology outlined in **Section 6.0** and the Schlumberger water and guar-based fluid system (**Appendix C1**).

C2.5 Summary of Qualitative PBT and Human Toxicity Assessment

In accordance with the methodology outlined in **Section 6.1**, the chemicals identified in the Schlumberger ClearFRAC XT fluid system were assessed for their potential persistence, bioaccumulation, and toxicity in the PBT assessment. None of the chemicals was considered to be inherently hazardous.

C2.6 Exposure Assessment

As discussed in **Section 7.0**, the exposure assessment identified receptors potentially exposed to chemicals of potential concern (COPC) identified for the study and outlines the exposure pathways by which the receptors may come in to contact with the COPCs. A detailed exposure assessment was not conducted in the qualitative risk assessment; however, hazards from potential exposures were determined to be consistent with exposures identified in the Schlumberger water and guar-based fluid system (**Appendix C1**): primarily occupational concerns with some limited environmental matters.

C2.7 Mass Balance of Fluid System

A quantitative mass balance calculation was undertaken to identify the amount of each chemical additive of the hydraulic fracturing fluid system. Specific details regarding the methodology of the calculation are presented in **Section 4.7** of this report. The results of the mass balance calculations are presented in the referenced Attachment 1 (EHS Support, 2013c) which is included in **Appendix C3-1**.

C2.8 Fate and Transport Modelling

As noted in previously, fate and transport of previously modelled fluid systems was not sensitive to the variability in physical properties of chemicals. Due to the broad range of physical properties assessed, the limited transport observed in the model and limited impact that physical properties has on transport distances, fate and transport of the chemicals present in this fluid system was not considered warranted. Additionally, the modelling demonstrated that there is limited potential for chemicals to migrate within the coal seams.

C3.0 Quantitative Risk Assessment

In accordance with the methodologies presented in **Section 8.0**, a QRA was conducted on theoretical and empirical datasets for those chemicals identified in the human health and ecological toxicity evaluation for the Schlumberger water and guar-based system (**Appendix C1**; EHS Support, 2013c). A QRA specific to ClearFRAC XT fluid system chemicals was not conducted; however, the chemicals were compared to the original Schlumberger fluid system components to identify relative risks in the ClearFRAC XT fluid system (Table 2; EHS Support, 2013c). The QRA approach evaluates the toxicity of the individual substances and characterises the cumulative risks of the total effluent toxicity and ecotoxicity.

Generally, this methodology includes the identification of the hazards posed by constituents in the flowback water, compilation of the toxicity criteria for each constituent, development of exposure models to estimate the daily intake of the constituents, and calculations of individual constituent hazard quotients (daily intake divided by the toxicity criteria) and a cumulative constituent hazard index (HI) for each potentially complete exposure pathway for each human or terrestrial receptor.

Potential complete exposure pathways to the storage of flowback from hydraulically stimulated wells and potential risks to humans, terrestrial and aquatic receptors from the potential storage and accidental releases are evaluated in the QRA.

No further assessment of groundwater was determined to be necessary due to lack of potentially complete exposure pathways. Detailed operational procedures have been provided that are designed to contain the hydraulic fracturing fluids within the coal sequences, and no connection exists between groundwater in the coal seams and surface-water or springs (and therefore Matters of National Environmental Significance [MNES]). Further, the potential risks to workers involved with the hydraulic fracturing process were not considered as detailed Health and Safety (H&S) procedures are employed to manage exposures. Similar to the original formulation, the following are considered specific exposure pathways:

1. Exposure of trespassers to flowback water contained within flowback storage ponds
2. Exposure of terrestrial receptors (e.g., livestock and wildlife) to flowback water contained within the flowback storage ponds
3. Exposure of aquatic receptors to flowback water in the situation of an accidental release, such as from piping or a release from the flowback storage pond. These potential releases could include a failure of containment systems, overtopping of the dam or in an extreme situation (considered highly unlikely) structural failure of the dam itself.

C3.1 Exposure Assessment

The purpose of the exposure assessment in the QRA was to predict the magnitude and frequency of potential human exposure to each COPC following the methodologies presented in **Section 8.1**. A conceptual site model (CSM) was developed which describes the potential receptors and exposure scenarios for the flowback water used in this exposure assessment. The potential exposures to receptors were evaluated based on the potential for a complete exposure pathway.

As discussed in **Section 8.3**, exposure point concentrations (EPCs) were derived for the theoretical assessment for ClearFRAC XT fluid system and compared to the theoretical EPCs developed for the Schlumberger water and guar-based system (Table 3; EHS Support, 2013c). In general, there were

fewer constituents in the ClearFRAC XT system, including fewer solvents. In addition, the estimated concentrations were less for chemicals present in both systems.

C3.2 Human Health QRA

A detailed human health hazard assessment was not conducted on the ClearFRAC XT chemicals. The QRA conducted on the previous Schlumberger fluid system (refer to **Appendix C1**) identified potential risks to human health that would be expected to be similar to or greater than the potential risks from ClearFRAC XT due to the toxicological properties previously discussed and the estimated EPCs (**Appendix C4-1**).

C3.3 Toxicity Assessment

A toxicity assessment was conducted to determine the relationship between the dose of a COPC taken into the body, and the probability that an adverse effect will result from that dose. Quantitative estimates of the potency of COPCs include two sets of toxicity values, one for genotoxic carcinogens and one for other non-genotoxic carcinogens and non-carcinogenic effects. As discussed in **Section 8.4,** detailed toxicological profiles were developed for the chemicals. The toxicological profiles are included as **Appendix F**.

The assessment of toxicity of the COPCs was used to develop initial screening criteria for human health exposure scenarios as discussed in **Section 8.4**. Refer to Table 2 for details regarding the toxicity assessment of the ClearFRAC XT chemicals (EHS Support, 2013c).

C3.4 Risk Estimation

A specific estimate of risk was not conducted for exposure to the ClearFRAC XT chemicals as the potential risks to human health and the environment presented in the Schlumberger water and guar-based system were expected to be similar or greater than the potential risks from the ClearFRAC XT chemicals (EHS Support, 2013c). Refer to **Appendix C1** for risk estimation on potential exposures to the water and guar-based system.

C3.5 Ecological Risk Assessment

Similar to the human health assessment, a detailed ecological risk assessment (ERA) was not conducted specifically for the ClearFRAC XT chemicals. Rather, an environmental health toxicological review was conducted, theoretical chemical concentrations in flowback water were estimated, and results were compared to the QRA conducted on the Schlumberger water and guar-based system (**Appendix C1**), which follows the approach outlined in **Section 8.5**.

C4.0 Summary of QRA Findings

The detailed QRA was not completed for the ClearFRAC XT chemicals as discussed in **Section C3.0**. However, a detailed QRA was conducted on the original Schlumberger fluid system (**Appendix C1**) in accordance with the methodology outlined in **Section 8.0**. As the ClearFRAC XT fluid system was developed by Schlumberger as a more environmentally fluid system than their original formulation, the composition is similar with substitutions for less hazardous chemicals.

Consistent with the risk assessment and groundwater fate and transport modelling conducted by Golder Associates Pty Ltd. (Golder), no potentially complete exposure pathways were identified for groundwater. Potential exposures are limited to the aboveground storage and handling of flowback water as part of the CSG Water Management Plan (WMP). Management of CSG water involves the temporary storage of flowback water in flowback storage ponds.

The ClearFRAC XT replacement chemicals were found to exhibit lower toxicity than those in the original formulation. Estimated concentrations in the pre-injection fluid system were found to be less than those in the original formulation. In addition, fewer constituents are present in the ClearFRAC XT fluid system than the water and guar-based system. On this basis, the potential risks from exposure to chemicals in ClearFRAC XT were expected to be less than or equal to those estimated for the water and guar-based system discussed in **Appendix C1**.

A combination of management and operational controls are being implemented to eliminate and control the potential for exposures. These include:

- Worker training and hazard identification
- Use of appropriate personal protective equipment (gloves, etc.)
- Flowback storage pond fencing to prevent entry of livestock and minimise trespassing.
- Installation of clay dam liners and routine dam inspections to prevent releases from flowback storage ponds
- Routine operational and security patrols to prevent trespassing.

C5.0 Conclusions

A weight-of-evidence evaluation of potential risks as described in **Section 5.0** was performed for the Schlumberger ClearFRAC XT fluid system. Based on the qualitative and comparison to the Schlumberger water and guar based quantitative risk characterisations, the overall risk to human health and the environment is low. Existing operational control activities employed by Santos are in place that will limit the potential risks to human health and the environment. These measures include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments;
- Environmental authority conditions that preclude the construction of well pads within 100 metres of a watercourse of water body;
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals;
- Disposal or capping of sediments contained within drained mud pits and turkey's nests , to prevent exposure to contaminates in windborne dust;
- Fencing of drill pads to prevent trespassers and installation of signs to indicate that the water in the turkey's nest and mud pit is not potable and may contain contaminants;
- Installation and maintenance of fences around the well pad to prevent access to the drill pad by livestock and large native fauna;
- Santos operational procedures to ensure well integrity and design of fracture to stay within the target seam; and
- Mud pits and turkey's nests with clay liners, or similar material, to prevent seepage of flowback water into underlying aquifers.

Regular monitoring of water supply bores and surface water for a representative suite of chemicals within 2 kilometre of wells that are fractured is required to confirm the conclusion of incomplete exposure pathways and low risk.

No additional risks, other than those previously discussed, were identified with the chemicals or systems employed by Schlumberger in hydraulic fracturing. Evaluation of other potential risks associated with hydraulic fracturing (i.e., noise and vibration) was conducted. Refer to **Section 9.0** for methodology specifics and results of this evaluation.

Tables

Table 1. PBT Assessment of the ClearFRAC XT Fluid System

Substance	P/vP criteria fulfilled?	B/vB criteria fulfilled?	T criteria fulfilled?	Overall Conclusion
Crystalline silica	Yes (naturally-occurring inorganic mineral)	No (water insoluble mineral; not bioavailable)	No (water insoluble mineral; not bioavailable)	Not PBT
Erucic amidopropyl dimethyl betaine	No (screening data available)	No (screening data available)	Yes (estimated)	Not PBT (based on screening and measured data)
