The primary aerobic biodegradability of MIT has been examined in a river sediment-water system by use of a ^{14}C-labelled model compound. During the 7-day experiment ^{14}C-labelled MIT was rapidly metabolized as only 12.6% of the initial MIT was present after 24 hours of incubation at 25 The calculated half-life for the parent compound was 9.1 hours (Reynolds, 1994a). MIT was metabolized to several unidentified metabolites. One of the major metabolites reached a level corresponding to 18.2% of the ^{14}C added after 24 hours of incubation. This metabolite decreased to 6.8% after 7 days which indicates further transformation. Other metabolites tended to increase during the 7-day experiment. At the end of the experiment metabolites that were bound in the sediment corresponded to 55%, whereas $^{14}CO_2$ attained 9% of the added ^{14}C. Most of the formed metabolites have shorter chromatographic retention times than MI which indicates that they are polar compounds. On the basis of the identification of metabolites from transformation of 4,5-dichloro-2-(n-octyl)-4-isothiazolin-3-one, it has been proposed that MI is transformed via N-methyl malonamic acid, N-methyl acetamide, and malonic acid (Madsen, 2000).

The primary biodegradability of CMIT has been examined with the same type of sediment and water as described for MIT. The ^{14}C-labelled CMIT was rapidly metabolized as only 30% of the initial CMI remained after 24 hours of incubation at 25 The calculated half-life for the intact CMIT was 17.3 hours (Reynolds, 1994b). At the end of the 7-day experiment, the sediment bound metabolites corresponded to 57.1% of the added ^{14}C, whereas 2.8% of the added ^{14}C was released as $^{14}CO_2$. Due to the structural similarities of MI and CMIT, it is suggested that the major metabolites for the transformation of CMIT are the same as described for MIT.

MIT was tested in an OECD 301B test modified for low concentrations of ^{14}C-labelled

compounds. The accumulated $^{14}CO_2$ attained 54.1%, 55.8%, and 47.6% in the respective concentrations (0.1, 0.03 and 0.01 mg/l) after 29 days. During the 10-day window, 37%, 30% and 30%, respectively, of the initial MIT was mineralized to $^{14}CO_2$ (Bashir, 1998a).

CMIT was tested in an OECD 301B modified for low concentrations of ^{14}C-labelled compounds. The accumulated $^{14}CO_2$ attained 38.8%, 55.3%, and 62% in the respective concentrations (0.3, 0.1, and 0.03 mg/l) after 29 days. During the 10- day window, 25%, 40%, and 48%, respectively, of the initial CMIT was mineralized to $^{14}CO_2$. The ultimate biodegradability of CMIT exceeded the 60%-pass level for ready biodegradability at the lowest test concentration of 0.03 mg/L, but the pass level was not reached within the 10-day window Bashir, 1998b).

From Dow Chemicals MSDS for ROCIMA GT:
Biodegradation (aquatic metabolism): 5-Chloro-2-methyl-4-isothiazolin-3-one (CMIT): t ½ anaerobic = 0.2 day, t ½ aerobic = 0.38 – 1.3 days; 2-Methyl-4-isothiazolin-3-one (MIT): t ½ aerobic = 0.38 – 1.4 days.

Bioaccumulation

The bioaccumulation of CMIT in bluegill sunfish *(Lepomis macrochirus)* resulted in BCF values of 102, 114, and 67 at nominal concentrations of 0.02, 0.12, and 0.8 mg/L (Erikson *et al*. 1995). These BCF values are based on total accumulated ^{14}C and include both the parent compound and metabolites. The BCF for MIT has been determined to 2.3 at a nominal concentration of 0.12 mg/L (Erikson *et al*. 1995).

Aquatic Toxicity

From Dow Chemicals MSDS for ROCIMA GT:
The 96-hour LC_{50} for Bluegill sunfish (*Lepomis macrochirus*) is 0.28 mg/L, and the 96-hour LC_{50} for Rainbow trout (*Oncorhynchus mykiss*) is 0.188 mg/L. The 48-hour EC_{50} for *Daphnia magna* is 0.126 mg/L. The 72-hour ErC_{50} for algae (*Selenastrum capricornutum*) is 0.027 mg/L.

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.188 mg/L), Daphnia (0.126 mg/L), and algae (0.027 mg/L). On the basis that the data consists of short-term results from three trophic levels,

an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.027 mg/L for Daphnia. The $PNEC_{aquatic}$ is 2.7×10^{-5} mg/L or 0.027 µg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.025 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.022 µg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.007 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.0043 µg/kg.

PBT Assessment

The half-lives of CMIT and MIT is a river water-sediment system were 17.3 hours and 9.1 hours, respectively. Thus, CMIT/MIT do not meet the criteria for persistence.

The experimental BCF for CMIT is 67-114 in bluefish sunfish, and the BCF for MIT was determined to be 2.3. Thus, CMIT/MIT do not meet the criteria for bioaccumulation.

No chronic toxicity data are available for CMIT/MIT; however, the acute $E(L)C_{50}$ values for algae are >0.01 but <0.1 mg/L. Thus, CMIT/MIT meet the screening criteria for toxicity.

The overall conclusion is that CMIT/MIT mixture is not PBT substances.

Environmental Assessment

C6-C10 Alcohol Ethoxylates

The alcohol ethoxylate (AE) family is defined for the HERA report purposes to be of the basic structure Cx-yAEn. The subscript following the 'C' indicates the range of carbon chain units. AEs with carbon unit range between C8 to C18 are most commonly used in household detergent products. Further, AEs contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by a subscript which indicates the average number of ethylene oxide units. In household products the average ethylene oxide chain length commonly ranges between 3 and 12 units.

Biodegradation

AE homologues with hydrocarbon chain lengths ranging from 8 to 18 and with from 2 to more than 20 ethylene oxide units are readily biodegradable.

As a class, AE undergo rapid primary and ultimate biodegradation under both laboratory and field conditions. The biodegradability of the different AE homologues used in HERA applications is relatively unaffected by the alkyl carbon chain length and the number of EO units.

Proposed half-lives in river water at 12^{o}C: 4 to 24 hours (based on experimental data).

AE are also anaerobically biodegradable.

Bioaccumulation

The AE homologues used for domestic cleaning applications are very likely to have a log Kow value greater than 3.

Environment Canada and Health Canada (2006) has established that the degree of bioaccumulation expected from AE is well below the Canadian bioconcentration criterion of 5000. The sixteen measured BCF values for 15 AE homologues showed the lack of a linear relationship between alkyl or ethoxylate chain length and BCF, with the highest measured BCF value being under 800. Environment Canada (2006) concluded that it is evident that the AE metabolism rates prevent any significant accumulation. The data indicated that there may be an optimal structural combination of ethoxylate and alkyl chain lengths, at or around C14EO7, where BCF is maximized, but even the measured BCF for this chemical is well below the criterion of 5000. Thus Environment Canada (2006) concluded that ethoxylated aliphatic alcohols are not bioaccumulative.

Aquatic Toxicity

Acute aquatic effects data are presented in the HERA report to only establish that the essentially linear and branched AE used in household detergents are not more toxic than the linear AE which have the same uses. The toxicity mechanism for AE is accepted to be non-polar narcosis, in which the AE homologues with longer hydrocarbon chains and higher log K_{ow} are more efficient at penetration of the cell membrane, and thus more toxic. However, the AE homologues must be sufficiently soluble in water to allow a toxic concentration to reach the target organism. For the long chain alcohols, generally the least soluble and the most toxic of the AE homologues, the long chain alcohol OECD-Screening Information Assessment Report (SIAR) (SIAR, 2006) shows that the toxicity is restricted by solubility considerations at hydrocarbon chain lengths of 15 and above. Although the addition of ethylene oxide groups makes the other AE homologues more soluble, solubility considerations may reduce the toxicity of several higher hydrocarbon chain length and lower EO chain length AE. The available acute toxicity data follows this generally accepted pattern, and also indicates that the linear, essentially linear and branches AE are of similar toxicity.

Toxicity to Terrestrial Organisms

Acute soil toxicity measurements for both plants and soil invertebrates are available from standard tests carried out on commercial AE mixtures, which contain differing distributions of AE homologues. The available data are reviewed in the HERA report.

A range of chronic soil tests has been carried out for two pure AE homologues, C12EO4 and C16EO4. The two AE homologues chosen for the chronic tests span the hydrocarbon chain length range of high tonnage AE, and have an EO chain length value at which the toxicity is expected to be in the high range for each hydrocarbon chain length. The chronic tests, to assess the survival and reproduction of earthworms (*Eisenia fetida fetida)*, springtails (*Folsomia candida*), and nematodes (*Caenorhabditas elegans*), were carried out using a natural sandy loam soil, with an organic carbon content of 1.3%, which could be assumed to be free of pesticide. If an application factor of 10 were applied to the lowest chronic NOEC value to determine a PNEC, a PNEC of 22 mg/kg would result for C12EO4 and a PNEC of 46 mg/kg would result for the C16EO4 AE homologue. Comparison of the acute test data with the equilibrium partition soil PNEC values show very similar values. Thus, the chronic soil toxicity results for C12EO4 and C16EO4 support the validity of the PNEC values determined by equilibrium partitioning.

Information showing the relatively small difference between acute and chronic toxicity for soil organisms means that available single homologue acute data also supports the PNEC calculated by equilibrium partitioning from aquatic monitoring data. In addition, available data for AE mixtures is consistent with the equilibrium partitioning PNEC values.

Determination of $PNEC_{aquatic}$

The chronic *Daphnia magna* QSAR developed by Boeije *et al.* (2006) can be used, with an appropriate application factor, to determine the PNEC for each AE homologue. Of the three trophic level QSARs discussed here, the chronic *Daphnia magna* QSAR is the most robust. The algal QSAR work by Wind and Belanger (2006) has shown that AE toxicity to algae, daphnia, and fish are of similar magnitude, while the chronic AE toxicity data given indicates that *Daphnia magna* are among the most sensitive invertebrates.

The PNEC values determined for each AE homologue using both the chronic *Daphnia magna* QSAR with an application factor of 10 given in Table 4.38 of the HERA report. For the *Daphnia magna* QSAR, the application factor of 10 is used as three chronic QSARs are available for AE homologues. The *Daphnia magna* QSAR has been chosen as it is the most robust of these three chronic QSARs, and has the most sensitive endpoint over much of the range of AE homologues.

The composition of C6-C10 alcohol ethoxylates are unknown. It is possible that it is a mixture of linear and branched alcohol ethoxylates with varying EO chain lengths. Therefore, a mean PNEC for this CASRN was calculated as follows: for each hydrocarbon chain length number, the PNEC value AE with EO units 1 to 20 were average together, providing a mean value that covers the range of PNECs for that hydrocarbon chain length number. Each of these mean PNECs were then averaged together to cover the hydrocarbon chain lengths included in this CASRN. It should be noted that the HERA document does not cover hydrocarbon numbers less that C8 and therefore PNEC values were not calculated for the C6 and C7 alcohol ethoxylates. Without knowing the hydrocarbon distribution in the supplier product, it is unclear how the limited data will influence the overall PNEC value for this substance.

$PNEC_{aquatic}$: Chronic Daphnia magna QSAR and an Application Factor of 10

	C8 + C9 (mg/L)	**C10 (mg/L)**
Mean	3.54	1.71
Range	0.171 – 11.9	0.118 – 6.23

$PNEC_{aquatic}$ (freshwater) = (3.54 + 1.71)/2 = 2.63 mg/L

Determination of $PNEC_{sediment}$

The equilibrium partitioning method is used to predict the sediment PNEC from the aquatic PNEC, if no sediment data are available. A probabilistic QSAR has been developed for aquatic species based on chronic data (see HERA report). This QSAR contains aquatic test data for species which live in sediment, such as *Chironomus tentans* and *Corbicula fluminea*, and others which live near or in the top sediment surface such as *Hyallela azteca*, *Dugesia gonocephala*, *Chlorella vulgaris* and *Navicula pelliculosa.*

Comparison of the chronic *Daphnia magna* data (which was used to derive the aquatic PNEC) with that for the sediment dwelling organisms shows that *Daphnia magna* is of similar sensitivity to the sediment dwelling organisms. As the deterministic chronic *Daphnia magna* QSAR is quite robust, and for the purposes of consistency, it was decided that the aquatic PNEC derived from the chronic *Daphnia magna* QSAR be used with the equilibrium partitioning method to determine the PNEC sediment for all the AE homologues. A mean PNEC for this CASRN was calculated similar to the approach for $PNEC_{aquatic}$.

The HERA report used the TGD (2003) approach to calculate the PNEC sediment using the equilibrium partitioning method according to PNECsed = (Ksusp-water / Rhosusp) * PNEC water *1000.

$PNEC_{sediment}$ values determined by the equilibrium partitioning method, based on the deterministic method using the chronic *Daphnia magna* QSAR

	C8 + C9 (mg/kg)	**C10 (mg/kg)**
Mean	232	254
Range	2.76 - 1140	3.11 - 1250

$PNEC_{sediment}$ = (232 + 254)/2 = 243 mg/kg

Determination of $PNEC_{soil}$

The equilibrium partitioning calculation for $PNEC_{soil}$ has was carried out using the $PNEC_{aquatic}$ values determined by using the deterministic *Daphnia magna* QSAR with an application factor of 10. The results of this calculation are shown in Table 4.47 of the HERA report for each AE homologue. A mean PNEC for this CASRN was calculated similar to the approach for $PNEC_{aquatic}$.

$PNEC_{soil}$ values determined by the equilibrium partitioning method, based on the deterministic method using the chronic *Daphnia magna* QSAR

	C8 + C9 (mg/kg)	**C10 (mg/kg)**
Mean	89	187
Range	1.03 - 440	2.14 - 1012

$PNEC_{soil}$ = (89 + 187)/2 = 138 mg/kg

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Diammonium peroxidisulfate
Ammonium persulfate
(CAS No. 7727-54-0)

Diammonium peroxisulfate or ammonium persulfate has been reviewed in the OECD-SIDS program (OECD, 2005a,b).

Environmental Fate

The inorganic persulfates are soluble in water (≥ 60 g/L) and their vapor pressures are negligible. Ammonium persulfate will be distributed into the water compartment in the ionic form of the ammonium cation and persulfate anion. Ammonium persulfate is expected to degrade in the environment mainly via hydrolysis, but metal catalyzed decomposition, and reactions with organic chemicals in the soil or water also are possible.

Persulfates are not expected to adsorb to soil due to its dissociation properties, instability (hydrolysis) and high water solubility. Persulfates should behave as free ions or decompose into sulfate ions. In soils, upon decomposition, the cation could form more stable sulfate or bisulfate salts.

Persulfates are not expected to bioaccumulate in the soil or in aqueous solution. They will decompose into inorganic sulfate or bisulfate.

Aquatic Toxicity

The 96-hour LC_{50} values for ammonium persulfate to fish are from 76 to 323 mg/L. The acute toxicity EC_{50} values for invertebrates are from 120 to 391 mg/L. The 72-hour EC_{50} values for ammonium persulfate to algae are 83.7 mg/L.

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (76 mg/L), Daphnia (120 mg/L), and algae (84 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 76 mg/L for fish. The $PNEC_{aquatic}$ is 0.076 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Diammonium peroxidisulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc do not readily apply to inorganics, such as diammonium peroxidisulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of diammonium peroxidisulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of diammonium peroxidisulfate is dominated by its water solubility. Sorption of diammonium peroxidisulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Kow and Koc parameters do not readily apply to inorganics, such as diammonium peroxidisulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, diammonium peroxidisulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

Environmental Assessment

Diatomaceous Earth
(CAS No. 61790-53-2)

Uncalcined diatomaceous earth (CAS No. 61790-53-2) typically contains around 1% crystalline silica. When diatomaceous earth is subjected to pressure or is processed ("calcined") at temperatures above 1000°C some of the amorphous silica is converted to crystalline silica in the form of cristobalite. Calcined diatomaceous earth can contain anywhere from 1% to 75% cristobalite.

Diatomaceous earth and crystalline silica are naturally occurring minerals that are insoluble in water.

The are persistent in the environment.

Diatomaceous earth and crystalline silica as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Diatomaceous earth and crystalline silica, quartz are not considered to be PBT substances.

Environmental Assessment

Ethylene Glycol Monobutyl Ether
2-Butoxylethanol
(CASRN 111-76-2)

Ethylene Glycol Monobutyl ether (EGBE) or 2-butoxyethanol has been reviewed in the OECD-SIDS program (OECD, 2005; 2006).

Environmental Transport

The results from a fugacity model (MacKay level I) show that EGBE would be expected to partition almost entirely to water (99.2%), with a small fraction to soil (0.55%).

Biodegradation

EGBE is readily biodegradable. Degradation was 88% after 20 days (APHA test). In an OECD 302B test, degradation was 100% after 5 days. Degradation was 95% after 28 days in an OECD 301E test.

Bioaccumulation

EPIWIN-generated log BCF = 0.5.

Aquatic Toxicity

The lowest concentrations for each trophic level in short-term studies were as follows: 7-day LC_{50} in *Poecilia reticulata* is 983 mg/L; the 72-hour EC_{50} in *Hydra attenuata* is 540 mg/L; and the 72-hour EC_{50} in *Pseudokirchneriella subcapitata* is 911 mg/L.

Chronic studies have been conducted on fish, invertebrates, and algae. In a 21-day fish (*Brachydanio rerio*) study, the NOEC was >100 mg/L. In a 21-day Daphnia study, the NOEC was 100 mg/L. The 72-hr NOEC for *Pseudokirchneriella subcapitata* was 286 mg/L.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (983 mg/L), invertebrates (540 mg/L), and algae (911 mg/L). Results from chronic studies are also available with NOECs for fish (>100 mg/L), Daphnia (100 mg/L), and algae (286 mg/L). On the basis of the long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 100 mg/L for Daphnia. The $PNEC_{aquatic}$ is 10 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE. Using a Koc of 2.823 and a $PNEC_{aquatic}$ of 10 mg/L, the $PNEC_{sediment}$ was calculated to be 6.7 mg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE. Using a Koc of 2.823 and a $PNEC_{aquatic}$ of 10 mg/L, the $PNEC_{soil}$ was calculated to be 0.3755 mg/kg.

PBT Assessment

EGBE is readily biodegradable and thus it does not meet the screening criteria for persistence.

The estimated BCF for EGBE is 3.16 based on QSAR modeling. Thus, EGBE does not meet the screening criteria for bioaccumulation.

The chronic toxicity values for fish, invertebrates and algae are $\geq$100 mg/L. Thus, EGBE does not meet the criteria for toxicity.

The overall conclusion is that EGBE is not a PBT substance.

Reference

OECD (2005). Screening Information Dataset (SIDS) Initial Assessment Report for Monoethylene Glycol Ethers Category (CAS No. 2807-30-9, 111-76-2, 112-07-2, 112-25-4), UNEP Publications.

OECD (2006). Screening Information Dataset (SIDS) Initial Assessment Profile (SIAP) for Ethylene Glycol Monobutyl Ether (CAS No. 111-76-2).

Environmental Assessment

Ethanol
(CAS No. 64-17-5)

Ethanol has been reviewed in the OECD-SIDS program (OECD, 2004a,b).

Environmental Transport

Fugacity-based modelling data show that ethanol released into the environment will become distributed mainly into air and water (OECD, 2004a,b).

Biodegradation

In aerobic conditions using adapted wastewater from domestic sewage, degradation was 74% after 5 days rising to 95% by day 15 and in similar conditions in synthetic seawater, ethanol was 45% degraded after 5 days rising to 75% by day 20 (Price, 1974).

Using a MITI protocol study, there was degradation of 89% after 14 days (>70% after 10 days, CERI, 2004) and (>90% within 10 days, Birch, 1991). Activated domestic sludges were capable of aerobically oxidizing ethanol, as measured by BOD, which was 37.3% of maximum after 1 day (Gerhold, 1966).

The rate of biodegradation in anaerobic conditions was calculated to be 17.9 ppm ethanol per day with a total methane recovery of 91% of the theoretical limit (Suflita, 1993). Biodegradation is the main method of removal of ethanol from water. Ethanol is stable to hydrolysis. Reaction with hydroxyl radicals in aquatic media will not likely be a significant process (Anbar, 1969).

Bioaccumulation

The bioconcentration factor (BCF) was estimated to be 3.16 L/kg using BCFBAF v. 3.01 (US EPA, 2011).

Aquatic Toxicity

The aquatic toxicity data in fish, invertebrates, and algae indicate a low order of acute toxicity with LC_{50}/EC_{50} values >1,000 mg/L (OECD, 2004a,b). The most sensitive species were algae, with a 96-hr EC_{50} for *Chlorella vulgaris* of 1,000 mg/L (El Jay, 1996).

Chronic toxicity studies in a variety of freshwater invertebrates show LC_{50} values of

>100 mg/L (Cowgill and Milazzo,1991). The lowest reported NOEC was 9.6 mg/L for *Cerodaphnia sp*.

A 5-day study using *Skeletonema costatum* gave a NOEC ranging from 3,240 to 5,400 mg/L based on cell count, with corresponding EC_{50} values of 10,943 - 11,619 mg/L. The authors commented that ethanol was used as a carbon source stimulating growth of the alga before inhibition began (Cowgill, 1989).

Toxicity to Terrestrial Plants

The 7-d NOEC values of higher (vascular) plants *Lemna gibba* and *L. minor* were 280 and 778 mg/L, respectively. The EC_{50} values for both plants were 4,432 mg/L (Cowgill, 1991).

Toxicity to Terrestrial Organisms

In the only study of the effect of ethanol on soil dwelling organisms found, the oligochaete worm *Eisenia foetida* showed a 48- hr LC_{50} of 0.1-1.0 mg/cm^2 loading on a filter paper test. The 'dosage', presented in terms of concentration in a given area of substrate is difficult to interpret but would have equated to the worms being exposed to a theoretical vapor concentration in the range 200-2000 mg/L (Roberts, 1984).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>1,000 mg/L), Daphnia (>1,000 mg/L), and algae (1,000 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 9.6 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported long-term NOEC of 9.6 mg/L for invertebrates. The $PNEC_{aquatic}$ is 0.96 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE (MCI method). Using a Koc of 1.0 and a $PNEC_{aquatic}$ of 0.96 mg/L, the $PNEC_{sediment}$ was calculated to be 0.61 mg/kg.

$PNEC_{soil}$: No relevant experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI method). Using a Koc of 1.0 and a $PNEC_{aquatic}$ of 0.96 mg/L, the $PNEC_{soil}$ was calculated to be 0.0128 mg/kg.

PBT Assessment

Ethanol is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on an experimental log Kow of -0.31 and a calculated BCF of 3.16, ethanol does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on ethanol show NOECs of >0.01 mg/L. Thus, ethanol does not meet the screening criteria for toxicity.

The overall conclusion is that ethanol is not a PBT substance.

Environmental Assessment

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyanopsis tetragonolobus*. Structurally, it is a galactomannan (a polysaccharide) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum ranges from 200,000 to 300,000 daltons (Glickman, 1969).

Biodegradation

No information was found. Guar gum, being a polysaccharide composed of galactomannan, would be expected to be readily biodegradable.

Bioaccumulation

Not expected to bioaccumulate as a polysaccharide composed of galactomannans.

Aquatic Toxicity

The 48-hour LC_{50} for *Daphnia magna* was reported to be 42 mg/L (Biesinger *et al.*, 1976).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. An acute LC_{50} value is available for the invertebrate Daphnia (42 mg/L). On the basis that the data consists of only one short-term result from one trophic level, an assessment factor of 1,000 has been applied to the reported effect concentration of 42 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.042 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition

method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

No biodegradation was found on guar gum. However, guar gum is a naturally occurring polysaccharide which would be expected to readily biodegrade. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons, and it is also water soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The acute aquatic toxicity of guar gum is >0.1 mg/L. Thus, guar gum is not expected to meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

Environmental Assessment

Hydrochloric acid
(CAS No. 7647-01-0)

Hydrochloric acid has been reviewed in the OECD-SIDS program (OECD, 202a,b).

Environmental Fate and Transport

Hydrochloric acid is readily dissociated in water into hydrated protons and chloride ions.

The increase in the concentration of hydrochloric acid in water decreases the pH in the aquatic ecosystem. Generally, the buffer capacity to maintain the pH in the aquatic ecosystem is important and the equilibrium between CO_2, HCO_3^- and CO_3^{2-} in the aquatic ecosystem is mainly responsible for the buffer capacity of receiving water.

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

According to UNEP (1995), the mean, the 10th-percentile and the 90th-percentile of bicarbonate concentrations for 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania were 106, 20 and 195 mg/L, respectively. The buffering capacity for neutralization of receiving water with bicarbonate concentrations of 20, 106 and 195 mg/L is calculated to be 2.19, 11.60 and 21.3 mg/L, respectively.

Aquatic Toxicity

Several studies on the acute toxicity to fish have been published. The lowest 96-hour LC_{50} was reported to be 4.92 mg/L for *Cyprinus carpio* at pH 4.3 which was conducted according to OECD 203 guidelines (MLIT, 1999). The 96-hour LC_{50} for *Oncorhynchus mykiss* was 7.45 mg/L at pH 4.12 for hard water and 10.3 mg/L at pH 3.98 for soft water (Graham and Wood, 1981). The 96-hour LC_{50} in *Lepomis macrochirus* is 55.1 to 30.9 mg/L at pH 3.25 - 3.5; the low pH caused a reduction in the oxygen carrying capacity of hemoglobin and excessive secretion of mucus from the gills which in turn interfered with gas exchange (Ellgaard and Glimore, 1984).

Generally, the results of toxicity tests with acid or base depend on the buffer capacity of the test medium. Dechlorinated tap water was used as a test medium in the three tests described above. A 96-hour LC_{50} of 30.9 to 24.6 at pH 3.5-3.6 was obtained for *Lepomis macrochirus* using artificial water prepared from distilled water and analytical or reagent grade chemicals (Cairns and Scheier, 1959); other reported values are a 96-hour LC_{50} of 282 mg/L for *Gambusia affinis* (Wallen *et al.*, 1957) and a 16-hour LC_{100} value of 0.492 mg/L at pH 5.3 for the pike perch fry (*Lucioperca lucioperca*) conducted with pond water

(pH 6.0-8.2) are reported (Stangenberg, 1975). A 24-hr LC_{50} value of 60-80 mg/L for *Semotitus astromaculatus* with river water (pH 8.3) has also been reported. No long-term or chronic toxicity data on fish were located (Gillette *et al.*, 1952).

The 48-hour EC_{50} for *Daphnia magna* is 0.492 mg/L at pH 5.3 based on immobilization (MLIT, 1999). No long-term or chronic toxicity data on invertebrates have been reported. The 72-hour EC_{50} to *Selenastrum capriornutum* is 0.78 mg/L (pH 5.1) for biomass; 0.492 mg/L (pH 5.3) for growth rate; and the 72-hr-NOEC is 0.097 mg/L (pH 6.0) for biomass and growth rate (MLIT, 1999).

The hazard of hydrochloric acid for the environment is caused by the proton (pH effect). For this reason the effect of hydrochloric acid on the organisms depends on the buffer capacity of the aquatic ecosystem. Also, the variation in acute toxicity for aquatic organisms can be explained to a significant extent by the variation in buffer capacity of the test medium. For example, LC_{50} values of acute fish toxicity tests varied from 4.92 to 282 mg/L.

It is not considered useful to calculate a PNEC for hydrochloric acid because factors such as the buffer capacity, the natural pH, and the fluctuation of the pH are very specific for a certain ecosystem.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECS

$PNEC_{aquatic}$: Based on the information above, a $PNEC_{aquatic}$ was not derived for hydrochloric acid.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Kow and Koc parameters do not readily apply to inorganics, such as hydrochloric acid. Thus;, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of hydrochloric acid to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Sorption of hydrochloric acid should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as hydrochloric acid. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, hydrochloric acid is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Hydrochloric acid is an organic salt that dissociates completely to hydrogen and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and chloride ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Hydrogen and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, hydrochloric acid is not expected to bioaccumulate.

No chronic toxicity data exist on hydrochloric acid; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, hydrochloric acid does not meet the screening criteria for toxicity.

The overall conclusion is that hydrochloric acid is not a PBT substance.

Environmental Assessment

2-Propanol or Isopropanol
(CAS No. 67-63-0)

2-Propanol or isopropanol has been reviewed in the OECD-SIDS program (OECD, 1997a,b).

Environmental Fate and Transport

Based on calculated results from a Level I fugacity model, isopropanol is expected to partition primarily to the aquatic compartment (77.7%) with the remainder to the air (22.3%) (OECD, 1977a,b).

Biodegradation

Aerobic biodegradation of isopropanol has been shown to occur rapidly under non-acclimated conditions, based on a result of 49% biodegradation from a 5-day BOD test (Bridie *et al.*, 1979). Additional biodegradation data developed using standardized test methods show that isopropanol is readily biodegradable in both freshwater and saltwater media (72 to 78% biodegradation in 20 days) (Price *et al.*, 1974).

Bioaccumulation

Bioconcentration of isopropanol in aquatic organisms is not expected to occur based on a measured log n-octanol/water partition coefficient (log Kow) of 0.05, a calculated bioconcentration factor of 1 for a freshwater fish, and the unlikelihood of constant, long-term exposures (OECD 1977a,b).

Aquatic Toxicity

The 96-hour LC_{50} in *Pimephales promelas* is 9,640 mg/L (Veith *et al.*, 1983). The 24-hour EC_{50} in *Daphnia magna* is >10,000 mg/L (Brinkmann and Kuehn, 1977). Chronic aquatic toxicity has also been shown to be of low concern, based on 16- and 21-day NOEC values of 141 and 30 mg/L, respectively, for the freshwater invertebrate *Daphnia magna* (Hermens *et al.*, 1985); OECD, 1977a,b). Toxicity of isopropanol to plants is expected to be low, based on a 7-day toxicity threshold value of 1,800 mg/L for a freshwater algae (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Plants

Toxicity of isopropanol to plants is expected to be low, based on an EC_{50} value of 2,100 mg/L from a lettuce seed germination test (Reynolds, 1977).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (9,640 mg/L) and invertebrates (>10,000 mg/L). Results from chronic studies are available for invertebrates (16- and 21-day NOECs for Daphnia are 141 and 30 mg/L, respectively). On the basis that the data consists of a chronic study on one trophic level, an assessment factor of 100 has been applied to the lowest reported NOEC of 30 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.3 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE. Using a Koc of 1.53 and a $PNEC_{aquatic}$ of 0.3 mg/L, the $PNEC_{sediment}$ was calculated to be 0.19 mg/kg.

$PNEC_{soil}$: Insufficient experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE. Using a Koc of 1.53 and a $PNEC_{aquatic}$ of 0.3 mg/L, the $PNEC_{soil}$ was calculated to be 0.0061 mg/kg.

PBT Assessment

Isopropanol is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of 0.05 and a calculated BCF of 1, isopropanol does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on isopropanol show NOECs of >0.01 mg/L. Thus, isopropanol does not meet the screening criteria for toxicity.

The overall conclusion is that isopropanol is not a PBT substance.

Environmental Assessment

Magnesium chloride
(CAS No. 7786-30-3)

Environmental Fate

Magnesium chloride dissociates completely in water to the Mg^{++} cation and the chloride anion (Cl^-).

Aquatic Toxicity

The 96-hour LC_{50} of magnesium chloride to *Pimephales promelas* is 541 mg of Mg/L (or 2,119.3 mg of $MgCl_2$/L).

The 48-hour LC_{50} for *Daphnia magna* is 140 mg Mg/L (or 548.4 mg of $MgCl_2$/L). In another study, the 48-hour LC_{50} to *Daphnia magna* and *Ceriodaphnia dubia* were 339 mg of Mg/L and 225 mg of Mg/L, respectively (or 1328 and 881.4 mg of $MgCl_2$/L, respectively).

The 72-hour EC_{50} of magnesium chloride for algae *Scenedesmus subspicatus* is >100 mg/L and the NOEC is 100 mg/L.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (2,119 mg/L as $MgCl_2$), Daphnia (548 mg/L as $MgCl_2$), and algae (100 mg/L $MgCl_2$). Even though a NOEC was obtained from the algae study, there were no chronic studies conducted on fish or Daphnia. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 0.1 mg/L. The $PNEC_{aquatic}$ is 0.1 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium chloride is dominated by its water solubility.

Sorption of magnesium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium chloride. Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium chloride is an organic salt that dissociates completely to magnesium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and chloride ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, magnesium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, maganesium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium chloride is not a PBT substance.

Environmental Assessment

Magnesium nitrate (CAS No. 10377-60-3)

Environmental Fate

Magnesium nitrate dissociates completely in water to Mg^{++} and the nitrate anion (NO_3^-).

Determination of PNECs

$PNEC_{aquatic}$: The ANZECC water quality guideline (2000) uses acute and chronic laboratory toxicity data for the derivation of "trigger values" for nitrate. The guideline summary for freshwaters is: *"A freshwater moderate reliability trigger value for nitrate toxicity as NO_3 (nitrate) of 700 µg/L was calculated using the statistical distribution method 95% protection and the default ACR."*

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium nitrate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium nitrate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium nitrate is dominated by its water solubility. Sorption of magnesium nitrate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium nitrate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium nitrate is an organic salt that dissociates completely to magnesium and nitrate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and nitrate ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium ions are essential to all living organisms and its intracellular and extracellular concentrations are actively regulated. Nitrates are ions that are very soluble in aqueous solutions. Thus, magnesium nitrate is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium nitrate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, maganesium nitrate does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium nitrate is not a PBT substance.

Environmental Assessment

Polyethylene Glycol
(CAS No. 25322-68-3)

Polyethylene glycols (PEGs) are water-soluble linear polymers formed by the addition reaction of ethylene oxide to an ethylene glycol equivalent. The general formula for polyethylene glycol is: $H-(OCH_2CH_2)_n-OH$ where "n" is the average number of repeating oxyethylene groups. PEGs are available in average molecular weights ranging from 200 to 8000.

No information on the aquatic toxicity and environmental fate and transport could be located for the PEGs. There are, however, data available on tetraEG and pentaEG, both being major constituents of the low molecular weight PEG 200. PEG 200 is a mixture consisting of ethylene glycols with an average molecular weight of approximately 200; there is an average of 4 oxyethylene units, but the range is from 2 to 8 oxyethylene units. The approximate composition of PEG 200 is as follows: 3% diethylene glycol (DEG), 17% triethylene glycol (TEG), 29% tetraEG, 25% pentaEG, 16% hexaEG, 8% heptaEG, and 2% octaEG (Bailey and Koleske, 1966).

Environmental Fate and Transport

PEG is a water-soluble polymer with molecular weights ranging from 200 to 8,000. PEG 200 consists of approximately 29% tetraEG and 25% pentaEG. A Mackay III fugacity model predicts that tetraEG and pentaEG will essentially distribute to water (45.3%) to soil (54.6%) (OECD, 2004).

Biodegradation

Both tetraEG and pentaEG are inherently biodegradable. For tetraEG, there was 22% degradation after 20 days in a BOD test and 40% degradation after 28 days in an OECD 301D test (Waggy *et al.*, 1994). For pentaEG, there was 34% degradation after 20 days in a BOD test (OECD, 2004).

Bioaccumulation

The log K_{ow} values for the PEG polymers were not found. Log K_{ow} and BCF values were estimated for tetraEG and pentaEG, the major constituents of the low molecular weight PEG 200. The log K_{ow} values for tetraEG and pentaEG were estimated to be -2.0 and -2.3, respectively, using EPISUITE v.4.11. The BCF values were estimated to be 3.16 for both tetraEG and pentaEG.

Aquatic Toxicity

No aquatic toxicity data were found on the PEG polymers. However, data are available on tetraEG and pentaEG.

For tetraEG, the acute 96-hour LC_{50} to fathead minnows (*Pimephales promelas*) is >10,000 mg/L (OECD, 2004), and the acute 48-hour LC_{50} to *Daphnia magna* is 7,746 mg/L (OECD, 2004).

For pentaEG, the acute 96-hour LC_{50} to fathead minnows (*Pimephales promelas*) is >50,000 mg/L (OECD, 2004); the acute 48-hour LC_{50} to *Daphnia magna* is >20,000 mg/L (OECD, 2004); and the 72-hour EC_{50} to algae *Pseudokirchneriella subcapitata* is >100 mg/L; the NOEC is 100 mg/L (OECD, 2004).

A 7-day LC_{50} for triethylene glycol in guppies was reported to be 63,000 mg/L (Könemann, 1981).

Toxicity to Terrestrial Organisms

No data were located on either PEG 200 or on the higher ethylene glycols, such as tetraEG and pentaEG.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels for PEG 200 constituents tetraEG and pentaEG. Acute $E(L)C_{50}$ values are available for fish (>10,000 mg/L), Daphnia (7,746 mg/L), and algae (>100 mg/L). Chronic toxicity data on pentaEG are available for algae (NOEC = 100 mg/L); and a chronic fish toxicity study has been conducted on triethylene glycol (NOEC = 63,000 mg/L), which is also found in PEG 200 but at lower concentrations than either tetraEG or pentaEG. On the basis that the data consists of short-term results from three trophic levels and long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported short-term EC_{50} of 100 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 2.0 mg/L.

PBT Assessment

No biodegradation data could be found on the PEG polymers. PEG is a water-soluble polymer, with molecular weights ranging from 200 to 8,000. The high molecular weight PEGs would be expected to meet the screening criteria for persistence. TetraEG and pentaEG are major constituents of the low molecular weight PEG 200. Biowin 2 predicts that both tetraEG and pentaEG will not biodegrade fast and Biowin 3 predicts the ultimate biodegradation timeframe is in weeks. Thus, the low molecular weight PEGs do not meet the screening criteria for persistence.

No information on log K_{ow} or BCF could be found on the PEG polymers. The molecular weights of PEGs range from 200 to 8,000. The high molecular weight PEGs would not be expected to bioaccumulate due to limitations in bioavailability because of the size of the polymer. TetraEG and pentaEG are major constituents of the low molecular weight PEG 200. The log K_{ow} values for tetraEG and penta were estimated to be -2.0 and -2.3, respectively; the BCF values were estimated to be 3.16 for both tetraEG and pentaEG. Thus, the low molecular weight PEGs are also not expected to meet the criteria for bioaccumulation.

No aquatic toxicity data could be located for the PEG polymers. The molecular weights of PEGs range from 200 to 8,000. The high molecular PEGs are not expected to meet the screening criteria of toxicity because the molecular size would limit bioavailability. TetraEG and pentaEG are major constituents of the low molecular weight PEG 200. There are no chronic aquatic toxicity on tetraEG or pentaEG; however, the acute aquatic toxicity is >0.1 mg/L. Thus, the low molecular weight PEGs are also not expected to meet the screening criteria for toxicity.

The overall conclusion is that the polyethylene glycol polymers are not PBT substances.

Environmental Assessment

Benzenesulfonic acid, 4-ethyenyl-, sodium salt, homopolymer (CAS No. 25704-18-1)

Acetic acid ethenyl ester, polymer with ethanol (CAS No. 25213-24-5)

Vinylidene chloride/methacrylate copolymer (CAS No. 25038-72-6)

Polyvinyl acetate, partially hydrolyzed (CAS No. 30443-60-5) THIS IS NOT THE CORRECT CASRN

All of these substances are polymers. Aquatic toxicity data was located for only for acetic acid, ethenyl ester, polymer with ethanol (CAS No. 25213-24-5) on a supplier's MSDS. However, all of the polymers listed above are expected to exhibit similar environmental fate and aquatic toxicity (Boethling and Nabholz, 1997).

Biodegradation

Generally, polymers are considered to be essentially non-biodegradable.

Bioaccumulation

Polymers are not generally absorbed through biological membranes to bioaccumulate in tissues.

Aquatic Toxicity

These polymers are not very insoluble in water and are expected to be essentially non-toxic to aquatic organisms.

The MSDS for DuPont's product ELVANOL 60-30, a polyvinyl alcohol with CAS No. 25213-24-5 (>93%) reported that concentrations of "ELVANOL" up to 10,000 mg of liter of water showed no mortality or other effect when tested on bluegill sunfish.

Determination of PNECs

$PNEC_{aquatic}$: Not determined.

PBT Assessment

These polymers are not expected to biodegrade and thus meets the criteria for persistence.

Polymers are not generally absorbed through biological membranes to bioaccumulate in tissues. Thus, these polymers do not meet the criteria for bioaccumulation.

The acute aquatic toxicity to fish (LC_{50} of >10,000 mg/L) for CASRN 25213-24-5 indicates that these polymers do not meet the criteria for toxicity.

Thus, these polymers are not considered to be PBT substances.

Environmental Assessment

Sodium carbonate
(CAS No. 497-19-8)

Sodium carbonate has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Sodium carbonate is a strong alkaline compound with a pH of 11.6 for a 0.1M aqueous solution (The Merck Index, 1983; Johnson and Swanson, 1987). The pKa of CO_3^{2-} is 10.33, which means that at a pH of 10.33 both carbonate and bicarbonate are present in equal amounts.

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium carbonate will be found predominantly in the aquatic environment. In water, sodium carbonate dissociates into sodium (Na^+) and carbonate (CO_3^{2-}) and both ions will not adsorb on particulate matter or surfaces and will not accumulate in living tissues. Addition of potassium carbonate to water will result in an increase in alkalinity and a tendency to raise the pH value. The carbonate ions will react with water, resulting in the formation of bicarbonate (HCO_3^-) and hydroxide (OH^-), until an equilibrium is established.

Background concentration of carbonate
If carbonate (CO_3^{2-}) is dissolved in water a re-equilibration takes place according to the following equations:

$HCO_3^- \rightleftharpoons CO_3^{2-} + H^+$ pKa=10.33
$CO_2 + H_2O \rightleftharpoons HCO_3^- + H^+$ pKa = 6.35

Only a small fraction of the dissolved CO_2 is present as H_2CO_3, the major part is present as CO_2. The amount of CO_2 in water is in equilibrium with the partial pressure of CO_2 in the atmosphere. The CO_2/ HCO_3^-/ CO_3^{2-} equilibria are the major buffer of the pH of freshwater and seawater throughout the world.

Based on the above equations, CO_2 is the predominant species at a pH smaller than 6.35, while HCO_3^- is the predominant species at a pH in the range of 6.35-10.33 and CO_3^{2-} is the predominant species at a pH higher than 10.33.

The natural concentration of CO_2/ HCO_3^-/ CO_3^{2-} in freshwater is influenced by geochemical and biological processes. Many minerals are deposited as salts of the carbonate ion and for this reason the dissolution of these minerals is a continuous source of carbonate in freshwater. Carbon dioxide is produced in aquatic ecosystems from microbial decay of organic matter. On the other hand plants utilize dissolved carbon dioxide for the synthesis of biomass (photosynthesis). Because many factors influence the

natural concentration of CO_2/ HCO_3^-/ CO_3^{2-} in freshwater, significant variations of the concentrations do occur.

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th – percentile, mean and 90th-percentile were 20, 106 and 195 mg/L, respectively.

Aquatic Toxicity

The acute 96-hour LC_{50} to three sizes of Bluegill sunfish (*Lepomis macrochirus*) exposed to sodium carbonate is 300 mg/L for all sizes. The acute 96-hour LC_{50} to mosquitofish (*Gambusia affinis*) is 740 mg/L. The acute 48-hour EC_{50} value to the invertebrate *Ceriodaphnia* cf. *dubia* is from 200 to 227 mg/L.

Toxicity to Terrestrial Organisms

Toxicity tests which determined the effect of sodium carbonate on terrestrial organisms are not available. The results of the tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil. Furthermore, carbonates are natural components of soil minerals.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (300 mg/L) and *Ceriodaphnia* (200 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 200 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.2 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium carbonate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium carbonate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium carbonate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium carbonate is dominated by its water solubility. Sorption of sodium carbonate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not

readily apply to inorganics, such as sodium carbonate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium carbonate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

Environmental Assessment

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium hydroxide (NaOH) will be found predominantly in the aquatic environment. NaOH is present in the environment as sodium (Na^+) and hydroxyl (OH^-) ions, which implies that it will not adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Measured concentrations in aquatic ecosystems
The concentration of hydroxyl ions in the environment has been determined very extensively via pH measurements. The pH is a very important parameter of aquatic ecosystems and it is a standard parameter of water quality monitoring programs. The most important freshwater aquatic ecosystems of the world revealed average annual pH values between 6.5 and 8.3 but lower and higher values have been measured in other aquatic ecosystems (UNEP, 1995). In aquatic ecosystems with dissolved organic acids a pH of less than 4.0 has been measured, while in waters with a high chlorophyll content the bicarbonate assimilation can result in pH values of higher than 9.0 at midday (UNEP, 1995). The pH of an aquatic ecosystem is mainly determined by geochemical, hydrological and/or biological processes.

Also sodium has been measured extensively in aquatic ecosystems. For example UNEP (1995) reported the concentration for a total number of 75 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th –percentile, mean and 90th-percentile were 1.5, 28 and 68 mg/l, respectively.

NaOH addition and buffer capacity
An addition of NaOH to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th– percentile, mean and 90th-percentile were 20, 106 and 195 mg/l, respectively.

Aquatic Toxicity

At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realized that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralized and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity *e.g.*, NH_3 is more toxic than NH_4^+.

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L . At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L. The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia* cf. *dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

No data are available on the effects of NaOH on algae.

Toxicity to Terrestrial Organisms

Toxicity tests, which determined the effects of NaOH on terrestrial organisms, are not available. Significant exposure of the terrestrial environment is not expected and for this reason there is no need to perform toxicity test with terrestrial organisms. The results of terrestrial toxicity tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil.

Determination of PNECs

In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available and the results of the tests are more or less consistent. Altogether they give a sufficient indication about acute toxicity levels of sodium hydroxide.

Furthermore acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterized by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.

Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,

- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and

- The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for NaOH there is a need to assess the environmental effect of an NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

$PNEC_{aquatic}$: Based on the information above, a PNEC was not derived for sodium hydroxide.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium hydroxide dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium hydroxide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium hydroxide to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium hydroxide is dominated by its water solubility.

Sorption of sodium hydroxide should probably be regarded as a reversible situation, i.e., the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium hydroxide Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium hydroxide is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium hydroxide is an organic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

References

OECD (2002b). Screening Information Dataset (SIDS) Initial Assessment Report for Sodium hydroxide (CAS No. 1310-73-2), UNEP Publications.

Environmental Assessment

Talc
(CAS No. 61789-40-0)

Talc is a mineral composed of hydrated magnesium silicate with the chemical formula $Mg_3Si4O_{10}(OH)_2$ or $H_2Mg_3(SiO_3)_4$. Talc is not soluble in water.

Biodegradation

As a mineral, talc does not biodegrade.

Aquatic Toxicity

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to aquatic organisms.

Toxicity to Sediment Organisms

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to sediment organisms.

Toxicity to Terrestrial Organisms

No data were found.

Determination of PNECs

PNEC values for talc cannot be calculated.

PBT Assessment

Talc is an inorganic mineral that is insoluble in water. Talc is not expected to be bioavailable to aquatic organisms; thus, it is does not meet the criteria for bioaccumulation or toxicity. Talc does not biodegrade in the environment. It is a naturally-occurring mineral and is persistent in the environment. However, for the purposes of this PBT assessment, it does not meet the criteria for persistence.

Environmental Assessment

Tetramethylammonium chloride
(CAS No. 75-57-0)

Environmental Fate

No measured data could be located on tetramethylammonium chloride.

The following information was obtained from EPISUITE v. 4.11 for this assessment (U.S. EPA, 2012). The water solubility was calculated to be 1 x 10^6 mg/L at 25^{o}C, and the octanol-water partition coefficient (log K_{ow}) was estimated to be -4.1817. A Mackay Level III model predicts that tetramethylammonim chloride will distribute 68.4% to soil, 31.6% to water, and 0.07% to sediment. Tetramethylammonium chloride is expected to biodegrade fast based on the Biowin 2 model and with an ultimate biodegradation timeframe of weeks based on the Biowin 3 model.

Bioaccumulation

No measured data could be located on tetramethylammonium chloride. The BCF was calculated to be 3.162, indicating a low bioaccumulation potential.

Aquatic Toxicity

A 96-hour LC_{50} for tetramethylammonium chloride xxxxxin fathead minnows has been reported to be 462 mg/L (ECOTOX).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. The acute 96-hour LC_{50} value for fish is 462 mg/L. Using an assessment factor of 1,000, the $PNEC_{aquatic}$ is 0.5 mg/L.

References

Environmental Assessment

Tetrasodium ethylenediaminetetraacetate
(CAS No. 64-02-8)

An EU Risk Assessment Report was completed for tetrasodium ethylenediaminetetra-acetate (2004).

Environmental Transport

As no value for the vapor pressure is known, a Henry's law constant cannot be calculated from vapor pressure and water solubility. Because of the ionic properties of ethylenediaminetetraacetate (EDTA) and its metal complexes, it has to be assumed that volatilization from aqueous solution will not occur. Due to the ionic structure under environmental relevant pH conditions, no adsorption onto the organic fraction of soils or sediments is expected. In a laboratory test, the mobility of EDTA in soil was tested. A solution of H_4EDTA was eluted through cores of two various surface soils. H_4EDTA was found to be very slightly adsorbed and moved quite readily through both soils.

Based on the physico-chemical properties of H_4EDTA, a calculation with the fugacity model Mackay level I predicts that the hydrosphere is the preferred environmental compartment (99.999%).

Biodegradation

"EDTA is not readily biodegradable. The results of different tests on inherent biodegradability are unequal. The available, not well documented tests show for instance biodegradation rates from 0 and 37% under application of pre-adapted inoculum after 14 days. In a Modified Zahn-Wellens Test (OECD 302 B) a biodegradation of < 20% could be found after 28 days with non-adapted sludge."

"Recent data suggest that under alkaline conditions EDTA can be degraded. Environmental samples from a river, a ditch and a lake were examined in the Closed Bottle test for their potential to degrade CaNa2EDTA in a concentration of 8.0 mg/l at pH 6.5 and 8.0 over a period of few weeks. The results show for all environmental samples that at pH 6.5 no or little biodegradation (2-12%) occurs within the first 28 days. After 49 days a biodegradation between 60 and 83% was obtained. At pH 8, rates of 53, 62 and 72% were obtained after 28 days and 75-89% after 35 days."

"Results obtained at pH of 8 could be relevant because the pH value of lake and river water ranges from 7.7 to 8.5. However, in surface waters, EDTA is preferably complexed with heavy metal ions. Regarding the degradation tests cited above, no biological degradation is expected. Ca-EDTA can only occur in the environment where strong point

sources release this species into a river with a low flow. Therefore, in the present exposure assessment EDTA is regarded as not biodegradable in surface waters, and a biodegradation rate constant of 0 d-1 is used."

Bioaccumulation

"Bishop and Maki (1980) studied bioaccumulation of EDTA on the fish *Lepomis macrochirus*, using the kinetic and the plateau method. Under actual requirements only the results of the plateau method can be used. After 28 days, the EDTA level in the fish, as determined by the plateau method, was of the same order of magnitude as the level in the ambient water. Depending on the used concentration BCF of 1.8±1.1 (0.08mg/l EDTA) and 1.1±0.95 (0.76 mg/l EDTA) could be obtained. From this data it can be concluded that no bioaccumulation takes place."

Aquatic Toxicity

"Most of the acute tests performed with fish and daphnids revealed LC/EC_{50} values well above 100 mg/L, indicating for complexed and non complexed EDTA no need for classification as dangerous for the environment. Exceptions are two fish tests using H_4EDTA, where the tests were performed in very soft (LC_{50} = 41 mg/L) or soft water (LC_{50} = 59.8 mg/L). In the test media a surplus of uncomplexed EDTA was present which is not expected in the environment, therefore this tests are not relevant for the assessment."

"Tests on acute toxicity with *Daphnia magna* resulted in 24-hr EC_{50} values of 480 and 790 mg/L."

"Algae tests performed in standard media resulted in effect values below 1 mg/L. The effect is probably caused by nutrient deficiency. This indirect effect is an artifact and not used in the effects assessment. Further experiments with increased nutrient metal concentrations reveal that the direct toxicity on algae is above 310 mg/L. Indirect effects like nutrient deficiency and eutrophication could only qualitatively be assessed; they are unlikely to occur in the environment although it cannot absolutely be excluded."

Determination of $PNEC_{aquatic}$

"According to the results from different ecotoxicological studies discussed above, the toxicological profile of EDTA is based on disturbances of metal metabolism. For the interpretation of toxicity tests, the complex formation properties of EDTA have to be taken into account."

"Beside Ca and Mg, test media contain a certain amount of heavy metal ions being necessary as trace nutrients. The complex forming constants of heavy metal complexes

are by several orders of magnitude higher than of Ca/Mg-complexes, thus after addition of the test substance EDTA (as acid or Na-salt) the concentration of uncomplexed trace metals decreases drastically. The degree of Ca/Mg complexation is dependent on the amount of added EDTA. Uncomplexed EDTA is only present when it is present in overstoichiometric concentrations."

"The choice of the complex species being relevant for effect testing should consider their different ecotoxicological properties. A mixture of metal complexes is always released or is being formed in surface waters. Effect tests should be conducted with a complex for which metal toxicity can be excluded. We propose to use the Ca-complex as test substance for all release scenarios. Effects from complexes with a higher toxicity are caused by the dissociated metal ions and should be covered by the risk assessment of the respective metals."

"Short-term tests on fish reveal that EDTA and Na-EDTA are more toxic in an uncomplexed form. This can only occur if they are available in over-stoichiometric amounts to the chelants. Under these conditions the complexing agents can cause nutrient deficiency by reducing the essential concentration of different ions. The higher the water hardness the higher was the concentration of EDTA necessary to cause a toxic effect expressed as mortality: 96-hr LC_{50} values for H_4EDTA between 41 mg/L and 1590 mg/L were found. The lowest acute toxicity recorded with H_4EDTA for the fish *Lepomis macrochirus* in very soft water with LC_{50} of 41 mg/L should not be used because it is probably influenced by pH effects. In the test result obtained with Na-EDTA and a water hardness of 103 mg/L $CaCO_3$ (96-hr LC_{50} =374 mg/L) pH effects of the acid are completely suspended. However, uncomplexed EDTA was applied in a stoichiometric excess which is in contrast to environmental conditions. Using $CaNa_2$EDTA as test substance, a LC_{50} of 1,827 mg/L was obtained being in a concentration range where unspecific effects are expected. The results of the test with *Pimephales promelas* (96-hour LC_{50} = 59.8 mg/L, obtained in water hardness of 40-48 mg/l $CaCO_3$ are doubtful, as the effects might have been caused by a low pH value. All tests on acute fish toxicity are of limited relevance for the PNEC derivation."

"In an early-life stage test on the zebrafish *Danio rerio*, the NOEC was determined to > 26.8 mg/L H_4EDTA based on analytically determined concentrations. CaNa2EDTA was used as test substance. This test is considered to be the most relevant fish test for the PNEC derivation."

"For daphnids no investigation on the influence of water hardness or possible reduced nutrient conditions are available. The available acute tests are carried out by in hard water (160 mg/l CaO). It is known, that calcium deficiency inhibited the development of fresh water crawfish. 24-hr EC_{50} values of 480 to 790 mg/L for *Daphnia magna* were found. In a long-term test a 21-day NOEC of 22 mg/lLfor reproduction could be obtained. In the latter test a surplus of Ca was present, thus mainly Ca-EDTA was formed in the medium being the active test substance."

“The apparent effects of complexing agents to algal growth are related to essential trace metal bioavailability. Trace metal levels tend to be more important in algae tests than in short-term tests on fish or daphnia, the main reason is the rapid increase of biomass during the test. It was demonstrated that not the absolute EDTA concentration, but rather the ratio of the EDTA concentration to the metal cations is crucial to algae growth. With sufficient trace metal amounts, H_4EDTA concentrations up to 310 mg/L caused no effects. Similar results are obtained when Fe(III)EDTA is used as test substance, due to its slow metal exchange kinetics overchelation of the nutrient metal ions is avoided. Therefore direct effects caused by the intrinsic toxicity of EDTA are not expected in surface waters, where in nearly every case a stoichiometric surplus of metal ions is present.”

“A standard growth inhibition test on *Scenedesmus subspicatus* resulted in an EC10 of 0.37 mg/L H_4EDTA. The effect is probably caused by nutrient deficiency, as essential metal ions like Cu, Zn and Co are largely complexed leading to drastically reduced concentrations. In a test with *Pseudokirchnerella subcapitata* (formerly *Selenastrum capricornutum*) with Fe(III)EDTA as an active test substance following OECD TG 201, ECb50 and ECr50 higher than 100 mg/L were found. The NOEC based on nominal concentrations was determined to 79.4 mg/L and to 48.4 mg/L when based on mean measured concentration.”

“Therefore, this inhibition of algae growth is an artifact which is caused by the drastic increase of biomass during the test. Indirect effects cannot be quantified from the laboratory tests, thus only theoretical considerations can be made. In German and Dutch rivers, heavy metal concentrations in the range of 10-20 µmol/L (predominantly Fe and Mn) are detected. In the environment heavy metals are generally present in over-stoichiometric amounts, thus those effects are not expected in low concentrations like in the tests. Nutrient deficiency in surface waters can only occur when essential metal ions are overchelated by high EDTA amounts. On the other hand, plant growth is influenced by many limiting parameters; probably the presence of macronutrients like phosphate or nitrate is of greater importance. Therefore, it is unlikely that nutrient deficiency occurs in the environment, although it cannot be excluded absolutely.”

“In addition to the discussed adverse effects, like growth inhibition, mortality and immobilization of EDTA the growth stimulating effects like eutrophication occurs. Standard media for algae tests contain EDTA (OECD 201: 100 µg/L) to prevent precipitation of nutrient metals as hydroxide. For two different river waters a significant increase in phytoplankton production was observed after addition of 30 to 300 µg/L EDTA. The observed increase in growth varied with algae species, preloading of the water with trace elements and other complexing agents e.g. humic acids from 22 to 50%. Thus, the higher availability of trace elements through the complexing agent EDTA depends on the preloading of the water and can significantly stimulate the processes of eutrophication. If trace elements like Fe, Co, Mn, and Zn are sufficiently available in a soluble form, the algae growth will be increased after addition of EDTA only insignificantly. This aspect of effects cannot be assessed quantitatively with the available methods.”

"The effects assessment of EDTA is based on long-term tests, which are available for fish, daphnids and algae. The most sensitive endpoint could be found for *Daphnia magna* with a NOEC of 22 mg/L H_4EDTA. According to TGD an assessment factor of 10 has to be used."

The $PNEC_{aquatic}$ is 2.2 mg/L.

Determination of $PNEC_{sediment}$

"There are no test results available with sediment dwelling organisms. A determination of the PNEC sediment is not possible. Based on the properties no adsorption of EDTA onto the sediment has to be expected, thus the assessment of this compartment will be covered by the aquatic assessment."

Determination of $PNEC_{soil}$

"There are only test results available which investigate the decrease of heavy metal toxicity caused by EDTA. It is not possible to derive a PNEC with this data. Therefore, the assessment can be based on the pore water concentration only."

APPENDIX G.2 HALLIBURTON WATER AND GUAR BASED SYSTEMS

Environmental Assessment

Acetic Acid
(CAS No. 64-19-7)

Acetic acid and its salts undergo dissociation in aqueous media into the acetate anion ($H_3C_2O_2^-$) and the respective cations (H^+, NH_4^+, Ca^{2+}, Mg^{2+}, Mn^{2+}, K^+, Na^+). The toxicity of each compound is driven by acetate, with the cations playing a minor role. The pH is 2.5 at 50 g/L and 20°C; and the pK_a is 4.76 at 20°C.

Environmental Transport

Level I fugacity modeling predicts that about 73% of any acetic acid released to the environment would partition to water, with the remainder partitioning into the air (U.S. HPVIS database).

Biodegradation

Acetic acid and its salts readily dissociate into their respective cations and the acetate anion; the anion acetate is readily biodegraded. In aerobic conditions using adapted wastewater from domestic sewage, degradation was 96% after 20 days (Price *et al.*, 1974). It was also shown to be readily biodegradable under anaerobic conditions using activated sludge (99% after 7 days) (Kameya *et al.*, 1995).

Aquatic Toxicity

The 96-hour LC_{50} in bluegill sunfish is 75 mg/L (Price *et al.*, 1974), and the 96-hour LC_{50} in mosquito fish is 251 mg/L (Wallen *et al.*, 1957). The 96-hour LC_{50} of 60% acetic acid in *Oncorhynchus mykiss* is 108 mg/L (64.8 mg acetic acid/L) (unpublished data, ECHA). In a chronic study with *Oncorhynchus mykiss*, the 21-day LC_{50} and NOEC for 60% acetic acid were 87 mg/L and 57.2 mg/L, respectively (unpublished data, ECHA). The 21-day LC_{50} and NOEC for 100% acetic acid were 52.2 mg/L and 34.3 mg/L, respectively (unpublished data, ECHA).

The 24-hour EC_{50} to Daphnia was reported to be 95 mg/L (un-neutralized) and 6,000 mg/L (neutralized to pH 8.0) (Bringmann and Kuehn, 1982). One other study showed the 48-hour EC_{50} to be 65 mg/L (Janssen *et al.*, 1993). In a chronic Daphnia study, the 21-day NOEC for reproduction was reported to be 22.7 mg/L for 100% acetic acid (unpublished data, ECHA). In another chronic Daphnia study, the 21-day NOEC for reproduction was 31.4 mg/L for 100% acetic acid (unpublished data, ECHA).

In an algae growth inhibition study, the reported nominal ErC_{50} to *Desmodesmus subspicatus* was 810.9 mg/L for 60% acetic acid (unpublished data, ECHA). The

reported nominal ErC_{50} was 486.5 mg/L for 100% acetic acid (unpublished data, ECHA). The toxicity threshold to algae after 8 days in a growth inhibition test was reported to be 4,000 mg/L (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (65 mg/L) and Daphnia (65 mg/L), and algae (487 mg/L). Long-term results are also available for fish (NOEC = 34 mg/L) and Daphnia (NOEC = 23 mg/L). On the basis that the data consists of short-term results from three trophic levels and two chronic study for fish and another chronic study for Daphnia, an assessment factor of 50 has been applied to the lowest NOEC of 23 mg/L for Daphnia. The $PNEC_{aquatic}$ was calculated to be 0.5 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Thus, the determination of the $PNEC_{sediment}$ is not possible. Based on its properties, no adsorption of acetic acid to sediment is to be expected and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Thus, the determination of the $PNEC_{soil}$ is not possible. Based on its properties, no adsorption of acetic acid to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

The acetate ion of acetic acid is readily biodegradable and thus it does not meet the screening criteria for persistence.

The log Kow for acetic acid is reported to be -0.17 (Verschueren, 1966). Acetate is also found in the body and is metabolized as part of the body's biochemical pathways. Thus,

acetic acid (specifically, the acetate ion) does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity data on acetic acid are >0.01 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

Environmental Assessment

Alkylated Quaternary chloride

Environmental Fate

No measured data could be located on alkylated quaternary chloride.

The following information was obtained from EPISUITE v. 4.11 for this assessment (U.S. EPA, 2012). The water solubility was calculated to be 1 x 10^6 mg/L at 25°C, and the octanol-water partition coefficient (log K_{ow}) was estimated to be -4.1817. A Mackay Level III model predicts that alkylated quaternary chloride will distribute 68.4% to soil, 31.6% to water, and 0.07% to sediment. Alkylated quaternary chloride is expected to biodegrade fast based on the Biowin 2 model and with an ultimate biodegradation timeframe of weeks based on the Biowin 3 model.

Bioaccumulation

No measured data could be located on alkylated quaternary chloride. The BCF was calculated to be 3.162, indicating a low bioaccumulation potential.

Aquatic Toxicity

A 96-hour LC_{50} for alkylated quaternary chloride in fathead minnows has been reported to be 462 mg/L (ECOTOX).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. The acute 96-hour LC_{50} value for fish is 462 mg/L. Using an assessment factor of 1,000, the $PNEC_{aquatic}$ is 0.5 mg/L.

Environmental Assessment

Amorphous/Non-crystalline Silica
(CAS No. 7631-86-9[1])

Silica Gel
(CAS No. 112926-00-8)

Amorphous Silica and silica gel have been reviewed in the OECD-SIDS program (OECD, 2004a,b).

The CAS No. 7631-86-9 is the general CAS registry number for silicon dioxide which includes all forms of silicas (*e.g.*, also crystalline and natural forms). Only the silica sub-classes, the synthetic amorphous silicas, are subject of this assessment.

Synthetic amorphous silica and silicates are in powder form which have a low water solubility, based on the sum of soluble SiO_2 and cations (water-soluble fraction): ≤70 mg/l (SAS), approx. 70 – 80 mg/l (NAS), and approx. 260 mg/l (CS) at 20 °C.

Environmental Fate and Transport

Silicon oxides are the most abundant compounds in the earth's crust mass. Synthetic amorphous silica and silicates are released into the environment are expected to be distributed mainly into soils and sediments, weakly into water and probably not at all in the air due to their physico-chemical properties, particularly low water solubility and very low vapor pressure.

Synthetic amorphous silica and silicates released into the environment are expected to combine indistinguishably with the soil or sediment due to their similarity with inorganic soil/sediment matter and will be subjected to natural processes under environmental conditions (cation exchange, dissolution, sedimentation).

Biodegradation is not applicable to these inorganic substances. The bioavailable form of synthetic amorphous silica and silicates is the dissolved form which exists exclusively as monosilicic [$Si(OH)_4$] acid under environmental pH. In analogy to the general chemical reaction of weak acids and salts of weak acids with water, the water-soluble fraction of silica acts as a weak acid and, therefore, will tend to lower the pH value, while that of a silicate acts as a base tending to bind protons and, thus, raise the pH value by forming hydroxyl ions. But pH shifts which are measurable at high loadings under laboratory conditions are not expected to occur from the anthropogenic deposition in the aquatic environment of synthetic amorphous silicas due to low aquatic releases and sufficient natural buffer capacities. Finally, these materials are supposed to combine indistinguishably with the soil layer or sediment due to their chemical similarity with inorganic soil matter.

Dissolved silica can be actively assimilated by some marine and terrestrial organisms as normal natural processes mainly related to structural function.

Aquatic Toxicity

Studies on fish, Daphnia and algae using excess loadings of SAS or NAS showed no acute toxicity, although physical effects on Daphnia were observed in tests using unfiltered test medium. Test results, based on loading rates, are as follows: 96-hour LL_0 *(Brachydanio rerio)* is 10,000 mg/L for SAS and NAS; 24-hour EL_{50} *(Daphnia magna)* >10,000 mg/L for SAS; 72-hour NOEL *(Scenedesmus subspicatus)* is 10,000 mg/L for NAS.

There are no chronic aquatic toxicity data, but due to the known inherent physico-chemical properties, absence of acute toxic effects as well as the ubiquitous presence of silica/silicates in the environment, there is no evidence of harmful long-term effects arising from exposure to synthetic amorphous silica/silicates.

Toxicity to Terrestrial Organisms

No data are available.

PBT Assessment

Noncrystalline silica (silica gel) is silicon dioxide, an inorganic compound which is ubiquitous in the environment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

A log Kow is not applicable to noncrystalline silica. Noncrystalline silica (silica gel), as a stable crystalline solid, is expected to have negligible uptake through the gill or gut of aquatic organisms. Thus, noncrystalline silica (silica gel) is not expected to bioaccumulate.

No chronic toxicity data exist on noncrystalline silica or silica gel; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, noncrystalline silica (silica gel) does not meet the screening criteria for toxicity.

The overall conclusion is that noncrystalline silica (silica gel) is not a PBT substance.

Environmental Assessment

1,2-Benzothiazolin-3-one
(CAS 2634-33-5)

Environmental Transport

1,2-Benzisothiazolin-3-one is hydrolytically stable (half-life > 30 days), but breaks down fairly quickly in aerobic soils (half-life < 24 hours in sandy loam soil). 1,2-Benzisothiazolin-3-one shows moderate to strong binding to soils, with adsorption K_d values estimated to be between 1.24 and 9.56. If used outdoors, 1,2- benzisothiazolin-3-one may possibly move with soil during rainfall events and potentially reach surface waters. However, it breaks down aerobically on the surface soils. Since it has a moderate binding potential to soils, it is not likely to migrate into the ground and there is low potential for ground water contamination.

Bioaccumulation

With a K_{ow} value of 20 at 25ºC., 1,2-benzisothiazolin-3-one is unlikely to bioaccumulate in aquatic organisms.

Aquatic Toxicity

U.S. EPA RED: The acute LC_{50}s to rainbow trout are 1.3 mg/L and 1.6 mg/L. The acute LC_{50} to Sheepshead minnow is 12.2 mg/L. The acute LC_{50}s to Daphnia are 1.5 mg/L and 3.3 mg/L. The acute 72-hour EC_{50} to green algae is 0.15 mg/L.

Rohm & Haas MSDS for Koralone™ B-120: The acute 96-hour LC_{50} to rainbow trout is 1.9 mg/L, and the acute 96-hour LC_{50} to sheepshead minnow is 19 mg/L. The acute 48-hour EC_{50} to *Daphnia* is 3.7 mg/L. The acute 96-hoour EC_{50} to alga *Pseudokirschneriella subcapita* is 0.38 mg/L, and the acute 96-hour EC_{50} to *Skeletonema costatum* is 0.4 mg/L.

ISP MSDS for Nuosept® 498 Preservative: The acute EC_{50}s to algae are 0.084 and 0.15 mg/L.

Toxicity to Sediment Organisms

No data were located.

Toxicity to Soil Organisms

No data were located.

Toxicity to Terrestial Organisms

The acute oral LD_{50} to Bobwhite quail (*Colinus virginianus*) was reported to be 453 mg/kg. The subacute dietary LD_{50} to Bobwhite quail (*Colinus virginianus*) was reported to be >5,620 mg/kg.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (1.3 mg/L), Daphnia (1.5 mg/L), and algae (0.084 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.084 mg/L for algae. The $PNEC_{aquatic}$ is 8.4×10^{-5} mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE (MCI Method). Using a Koc of 34.48 and a $PNEC_{aquatic}$ of 0.084 µg/L, the $PNEC_{sediment}$ was calculated to be 0.096 µg/kg.

$PNEC_{soil}$: No adequate experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI Method). Using a Koc of 34.48 and a $PNEC_{aquatic}$ of 0.084 µg/L, the $PNEC_{soil}$ was calculated to be 0.039 µg/kg.

PBT Assessment

1,2-Benzisothiazolin-3-one is hydrolytically stable (half-life > 30 days), but breaks down fairly quickly in aerobic soils (half-life < 24 hours in sandy loam soil). The results of BIOWIN v4.10 for 1,2-benzothiazolin-3-one are as follows: biodegrade fast (Biowin2); ultimate biodegradation timeframe is weeks (Biowin3); and does not biodegrade fast (Biowin 6). Thus, 1,2-benzothiazolin-3-one does not meet the screening criteria for persistence.

The log Kow for 1,2-benzothiazolin-3-one is 1.3 and thus does not meet the screening criteria for bioaccumulation.

No chronic toxicity data exist on 1,2-benzothiazolin-3-one; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, 1,2-benzothiazolin-3-one does not meet the screening criteria for toxicity.

The overall conclusion is that 1,2-benzothiazolin-3-one is not a PBT substance.

Environmental Assessment

C10-C12 Alcohol Ethoxylates
(CAS No. 67254-71-1)

Alcohol ethoxylates (AE) are a class of non-ionic surfactants that have the basic structure $C_{x-y}AE_n$. The subscript (x-y) following the 'C' indicates the range of carbon chain units. AEs with carbon unit range between C8 to C18 are most commonly used in household detergent products. The hydrocarbon chain can be either linear or branched. AEs also contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by the subscript (n) which indicates the average number of ethylene oxide units. In household products the average ethylene oxide chain length commonly ranges between 3 and 12 units.

The toxicity profile of C10-C12 alcohol ethoxylates has been developed from a risk assessment report on alcohol ethoxylates ranging from C8 to C18 prepared by the household cleaning product and chemical industry (HERA, 2009).

Biodegradation

AE homologues with hydrocarbon chain lengths ranging from 8 to 18 and with 2 to >20 ethylene oxide units are readily biodegradable.

As a class, AE undergo rapid primary and ultimate biodegradation under both laboratory and field conditions. The biodegradability of the different AE homologues used in HERA applications is relatively unaffected by the alkyl carbon chain length and the number of EO units.

Proposed half-lives in river water at 12^{o}C: 4 to 24 hours (based on experimental data).

AE are also anaerobically biodegradable.

Bioaccumulation

The AE homologues used for domestic cleaning applications are very likely to have a log Kow value greater than 3.

The Danish EPA report on surfactants (Danish EPA, 2001) found that bioaccumulation of alkyl ethoxylates in aquatic organisms had been determined only for fish. The majority of the limited data were based on studies with 14C-labelled compounds that do not allow the distinction between the parent compound and metabolites, or material incorporated into the cells during growth. Because alcohol ethoxylates are metabolized in aquatic organisms (Danish EPA, 2001), the bioconcentration factor for the parent compound may

well be overestimated in experiments in which 14C-labelled model surfactants are used. Tolls *et al.* (2000a,b) combined 14C-techniques and chemical analysis to determine the amount of AE actually present as the parent molecule in the fish. This showed that the parent AE (e.g. C13 EO8) was rapidly eliminated by transformation into metabolites, which were eliminated at a slower rate. The Danish EPA concluded that the data indicate that the more hydrophobic AE (e.g. C13 EO4, C14 EO4, and C16 EO8) have a moderate bioaccumulation potential (Danish EPA 2001). They also note that in the study by Tolls (1998) the BCF values ranged from < 5 to 387.5, whereas the uptake rates (*k*1) varied from 330 to 1660 (l x kg x d-1) and the elimination rates (*k*2) varied from 3.3 to 59 (d-1). The time to steady state and the BCF for AE increase with decreasing length of the ethoxylate chain (e.g., t95 for C13 EO8 = 2.4 h and BCF = 30-55, and t95 for C13 EO4 = 17.1 h and BCF = 233) (Danish EPA 2001).

Tolls *et al.* (2000a,b) concluded that the high values of the elimination rate constants suggest that fathead minnows efficiently biotransform AE, thereby preventing AE from attaining high concentrations in fish. They note that estimates of the bioconcentration potential of AE mixtures in influents and effluents of several wastewater treatment plants were similar to each other, implying that the bioconcentration potential was not significantly altered by the processes involved in wastewater treatment. These estimates of the bioconcentration potential were conservative and ranged around 140 L/kg.

Environment Canada and Health Canada (2006) has established that the degree of bioaccumulation expected from AE is well below the Canadian bioconcentration criterion of 5000. The sixteen measured BCF values for 15 AE homologues showed the lack of a linear relationship between alkyl or ethoxylate chain length and BCF, with the highest measured BCF value being under 800. Environment Canada (2006) concluded that it is evident that the AE metabolism rates prevent any significant accumulation. The data indicated that there may be an optimal structural combination of ethoxylate and alkyl chain lengths, at or around C14EO7, where BCF is maximized, but even the measured BCF for this chemical is well below the criterion of 5000. Thus Environment Canada (2006) concluded that ethoxylated aliphatic alcohols are not bioaccumulative.

Aquatic Toxicity

Acute aquatic effects data is presented in the HERA report only to establish that the essentially linear and branched AE used in household detergents are not more toxic than the linear AE which have the same uses. The toxicity mechanism for AE is accepted to be non-polar narcosis, in which the AE homologues with longer hydrocarbon chains and higher log K_{ow} are more efficient at penetration of the cell membrane, and thus more toxic. However, the AE homologues must be sufficiently soluble in water to allow a toxic concentration to reach the target organism. For the long chain alcohols, generally the least soluble and the most toxic of the AE homologues, the long chain alcohol OECD-Screening Information Assessment Report (SIAR) (SIAR, 2006) shows that the toxicity is restricted by solubility considerations at hydrocarbon chain lengths of 15 and above. Although the addition of ethylene oxide groups makes the other AE homologues more

soluble, solubility considerations may reduce the toxicity of several higher hydrocarbon chain length and lower EO chain length AE. The available acute toxicity data follows this generally accepted pattern, and also indicates that the linear, essentially linear and branches AE are of similar toxicity.

Toxicity to Terrestrial Organisms

Acute soil toxicity measurements for both plants and soil invertebrates are available from standard tests carried out on commercial AE mixtures, which contain differing distributions of AE homologues. The available data are reviewed in the HERA report.

A range of chronic soil tests has been carried out for two pure AE homologues, C12EO4 and C16EO4. The two AE homologues chosen for the chronic tests span the hydrocarbon chain length range of high tonnage AE, and have an EO chain length value at which the toxicity is expected to be in the high range for each hydrocarbon chain length. The chronic tests, to assess the survival and reproduction of earthworms (*Eisenia fetida fetida)*, springtails (*Folsomia candida*), and nematodes (*Caenorhabditas elegans*), were carried out using a natural sandy loam soil, with an organic carbon content of 1.3%, which could be assumed to be free of pesticide. If an application factor of 10 were applied to the lowest chronic NOEC value to determine a PNEC, a PNEC of 22 mg/kg would result for C12EO4 and a PNEC of 46 mg/kg would result for the C16EO4 AE homologue. Comparison of the acute test data with the equilibrium partition soil PNEC values show very similar values. Thus, the chronic soil toxicity results for C12EO4 and C16EO4 support the validity of the PNEC values determined by equilibrium partitioning.

Information showing the relatively small difference between acute and chronic toxicity for soil organisms means that available single homologue acute data also supports the PNEC calculated by equilibrium partitioning from aquatic monitoring data. In addition, available data for AE mixtures is consistent with the equilibrium partitioning PNEC values.

Determination of $PNEC_{aquatic}$

The chronic *Daphnia magna* QSAR developed by Boeije *et al.* (2006) can be used, with an appropriate application factor, to determine the PNEC for each AE homologue. Of the three trophic level QSARs discussed here, the chronic *Daphnia magna* QSAR is the most robust. The algal QSAR work by Wind and Belanger (2006) has shown that AE toxicity to algae, daphnia, and fish are of similar magnitude, while the chronic AE toxicity data given indicates that *Daphnia magna* are among the most sensitive invertebrates.

The PNEC values determined for each AE homologue using both the chronic *Daphnia magna* QSAR with an application factor of 10 given in Table 4.38 of the HERA report. For the *Daphnia magna* QSAR, the application factor of 10 is used as three chronic QSARs are available for AE homologues. The *Daphnia magna* QSAR has been chosen as it is the most robust of these three chronic QSARs, and has the most sensitive endpoint

over much of the range of AE homologues.

The composition of C10-C12 alcohol ethoxylates (CAS No. 67254-71-1) is unknown. It is possible that it is a mixture of linear and branched alcohol ethoxylates with varying EO chain lengths. Therefore, a mean PNEC for this CASRN was calculated as follows: for each hydrocarbon number, the PNEC value AE for EO units 1 to 20 were average together, providing a mean value that covers the range of PNECs calculated for that hydrocarbon number. Each of these mean PNECs were then averaged together to cover all of the hydrocarbon chain lengths included in this CASRN, *i.e.* C10 to C12.

$PNEC_{aquatic}$: Chronic Daphnia magna QSAR and an Application Factor of 10

	C10 (mg/L)	**C11 (mg/L)**	**C12 (mg/L)**
Mean	1.71	0.979	0.513
Range	0.118 – 6.23	0.0652 – 3.26	0.0358 – 1.7

$PNEC_{aquatic}$ (freshwater) = (1.71 + 0.979 + 0.513)/3 = 1.07 mg/L

Determination of $PNEC_{sediment}$

The equilibrium partitioning method is used to predict the sediment PNEC from the aquatic PNEC, if no sediment data are available. A probabilistic QSAR has been developed for aquatic species based on chronic data (see HERA report). This QSAR contains aquatic test data for species which live in sediment, such as *Chironomus tentans* and *Corbicula fluminea,* and others which live near or in the top sediment surface such as *Hyallela azteca, Dugesia gonocephala, Chlorella vulgaris* and *Navicula pelliculosa.* Comparison of the chronic *Daphnia magna* data (which was used to derive the aquatic PNEC) with that for the sediment dwelling organisms shows that *Daphnia magna* is of similar sensitivity to the sediment dwelling organisms. As the deterministic chronic *Daphnia magna* QSAR is quite robust, and for the purposes of consistency, it was decided that the aquatic PNEC derived from the chronic *Daphnia magna* QSAR be used with the equilibrium partitioning method to determine the PNEC sediment for all the AE homologues. A mean PNEC for this CASRN was calculated similar to the approach for $PNEC_{aquatic}$.

In order to account for uptake *via* sediment ingestion, an additional application factor of 10 will be applied to the PNEC for any chemicals with a log Kow value >5. This affect the following AEs: C12EO1-3.

The HERA report used the TGD (2003) approach to calculate the PNEC sediment using the equilibrium partitioning method according to PNECsed = (Ksusp-water / Rhosusp) * PNEC water *1000.

$PNEC_{sediment}$ values determined by the equilibrium partitioning method, based on the deterministic method using the chronic *Daphnia magna* QSAR (Log Kow ≤5)

	C10 (mg/kg)	**C11 (mg/kg)**	**C12EO4-20 (mg/kg)**
Mean	254	279	359
Range	3.11 - 1250	3.55 - 1370	12.8 - 1500

$PNEC_{sediment}$ = (254 + 279 + 359)/3 = 297 mg/kg

$PNEC_{sediment}$ values determined by the equilibrium partitioning method, based on the deterministic method using the chronic *Daphnia magna* QSAR (Log Kow>5)

	C12EO1-3 (mg/kg)
Mean	6.35
Range	4.06 – 8.9

$PNEC_{sediment}$ = 6.0 mg/kg

Determination of $PNEC_{soil}$

The equilibrium partitioning calculation for $PNEC_{soil}$ has was carried out using the $PNEC_{aquatic}$ values determined by using the deterministic *Daphnia magna* QSAR with an application factor of 10. The results of this calculation are shown in Table 4.47 of the HERA report for each AE homologue. An additional application factor of 10 will be applied to the PNEC for any chemicals with a log Kow value >5. This affect the following AEs: C12EO1-3. A mean PNEC for this CASRN was calculated similar to the approach for $PNEC_{aquatic}$.

$PNEC_{soil}$ values determined by the equilibrium partitioning method, based on the deterministic method using the chronic *Daphnia magna* QSAR (Log Kow ≤5)

	C10 (mg/kg)	**C11 (mg/kg)**	**C12EO4-20 (mg/kg)**
Mean	206	226	247
Range	2.5 - 1012	2.9 - 1111	10.3 - 1219

$PNEC_{soil}$ = (206 + 226 + 247)/3 = 226 mg/kg

$PNEC_{soil}$ values determined by the equilibrium partitioning method, based on the deterministic method using the chronic *Daphnia magna* QSAR (Log Kow>5)

	C12EO1-3 (mg/kg)
Mean	5.1
Range	3.3 – 7.2

$PNEC_{soil}$= 5.1 mg/kg

PBT Assessment

C10-C12 alcohol ethoxylates are readily biodegradable; thus, they not meet the screening criteria for persistence.

Based on the information provided in the bioaccumulation section above, the C10-C12 alcohol ethoxylates do not meet the criteria for bioaccumulation.

The chronic Daphnia NOEC values for C10-C12 alcohol ethoxylates are >0.1 mg/L. Thus, C10-C12 alcohol ethoxylates do not meet the criteria for toxicity.

The overall conclusion is that C10-C12 alcohol ethoxylates is not a PBT substance.

Environmental Assessment

Calcium chloride
(CAS No. 10043-52-4)

Calcium chloride has been reviewed in the OECD-SIDS program (OECD, 202a,b).

Environmental Fate

Calcium chloride is soluble in water and its vapor pressure is negligible. This indicates that calcium chloride released into the environment is distributed into the water compartment in the form of calcium and chloride ions. Calcium chloride is not expected to be absorbed in soil due to its dissociation properties and high water solubility but may rather behave as free ions or may form stable inorganic or organic salts with other counter ions, leading to different fates between calcium and chloride ions in soil and water compartments in the environment. As for the behavior of calcium in soil, the calcium ion may bind to soil particulate or may form stable inorganic salts with sulfate and carbonate ions. The chloride ion is mobile in soil and eventually drains into surface water because it is readily dissolved in water.

Calcium chloride is not expected to undergo photolysis or biodegradation. The Fugacity model is not applied to estimate the distribution of this substance in the environment because the programs are designed for organic chemicals and not for inorganic salts. Considering its dissociation properties, calcium chloride *per se* is not expected to accumulate in living organisms.

Aquatic Toxicity

Several studies on acute toxicity to fish have been reported. The lowest 96-hour LC_{50} value was 4,630 mg/L in fathead minnow (*Pimephales promelas*). No chronic toxicity studies on fish conducted under standard guidelines have been reported.

There are seven acute toxicity data available for Daphnia. Two of these studies were conducted according to international or national guidelines, giving the 48-hour EC_{50} of 2,400 mg/L for *Daphnia magna* and the 48-hour LC_{50} of 1,830 mg/L for *Ceriodaphnia* sp. The lowest 48-hour EC_{50} was 1,062 mg/L for *Daphnia magna*. The chronic effect of 21-day exposure on reproduction of *Daphnia magna* has been investigated as a long-term study. The concentration required for 16% and 50% inhibition of reproduction (EC_{16} and EC_{50}) were 320 and 610 mg/L, respectively. The NOEC = $EC_{16}/2$ = 320/2 = 160 mg/L.

There is one study with fresh water algae, *Selenastrum capricornutum*, which was conducted according to OECD 201. The 72-hour EC_{50} and EC_{20} obtained on the basis of growth rate from the study were >4,000 and 2,700 mg/L, respectively. The 72-hour EC_{50} and EC_{20} obtained on the basis of biomass from the study were 2,900 and 1,000

mg/L, respectively. The NOECs are calculated as $EC_{20}/2$, which corresponds to 1,350 and 500 mg/L for growth rate and biomass, respectively.

Toxicity to Terrestrial Organisms

See Table 4-2 in OECD-SIDS SIAR (OECD, 2002b).

There are some studies that examined effects of deicing agents to plants and earthworm using calcium chloride, sodium chloride, CMA (calcium/magnesium acetate), urea, *etc.*. Although these studies were not conducted under the standard methods and were not necessarily providing reliable outcomes, they revealed a tendency to less damage to plants and earthworm from exposure to calcium chloride than to other deicing agents.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (4,630 mg/L), Daphnia (1,062 mg/L), and algae (2,900 mg/L). Results from a chronic Daphnia study (NOEC = 160 mg/L) and algae study (NOECs = 1,350 and 500 mg/L for growth rate and biomass, respectively) are also available. On the basis that the data consists of short-term results from three trophic levels and chronic studies on Daphnia and algae, an assessment factor of 50 has been applied to the lowest reported NOEC of 160 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 3.2 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Calcium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as calcium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of calcium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of calcium chloride is dominated by its water solubility. Sorption of calcium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Kow and Koc parameters do not readily apply to inorganics, such as calcium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, calcium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Calcium chloride is an organic salt that dissociates completely to calcium and chloride

ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both calcium and chloride ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Calcium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, calcium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on calcium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, calcium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that calcium chloride is not a PBT substance.

Environmental Assessment

Cocoamidopropyl betaine
(CAS No. 61789-40-0)

Cocoamidopropyl betaine has been reviewed in the OECD-SIDS program (OECD, 2006).

Cocamidopropyl betaines are mainly a mixture of C_{12}-C_{18} fatty acids from hydrolysis of coconut oil. Coconut oil has a mixed fatty acid composition, which varies slightly, as it is a natural product. Lauric acid - resulting in lauramidopropyl betaine - is the major ingredient of coconut oil. As the physical chemical properties of cocamidopropyl betaine are not fully available as measured values, calculated values of lauramidopropyl betaine (RCOOH=lauric acid, C_{12} fatty acid) - as the main component in the cocamidopropyl betaine - are indicated instead. If possible the calculated ranges for the cocamidopropyl betaine (C_{12} – C_{18}) are given. In terms of the environmental exposure assessment, the relevant calculated values of the respective betaine derived from the C_{18} fatty acid – Stearamidopropylbetaine are indicated. The characteristics of the stearamidopropylbetaine are regarded as to represent the most hydrophobic properties of the cocamidopropyl betaine.

Environmental Transport

Based on the calculation for caprylamidopropyl betaine (C8 fatty acid derivative) and stearamidopropyl betaine (C18 fatty acid derivative), cocamidopropyl betaine will be mainly distributed to the hydrosphere (59 - 100 %), and to a lesser extent to soil and sediment (0 - 20 % each). The Henry's law constants for alkylamidopropyl betaines calculated for every single fatty acid chain length indicate a very low potential for volatilization from surface waters under environmentally relevant conditions. The soil sorption coefficients (K_{OC}) calculated for the alkylamidopropyl betaines indicate a low to very high potential for sorption to organic matter of soils and sediments. The low sorption potential is confirmed by experimentally obtained values for laurylamidopropyl betaine (C12 derivative) and tetradecylamidopropyl betaine (C14 derivative) from the screening HPLC-method according to OECD Test Guideline 121. A high potential for sorption applies only for the alkylamidopropyl betaines with the C16 and C18 fatty acid chain length.

Biodegradation

Cocamidopropyl betaine can be considered as being readily biodegradable under aerobic conditions. In guideline tests biodegradation rates of 86 – 100 % after 28 days (OECD 301A/B/D/E), 90 – 93 % after 35 days (OECD 301B) and 100 % after 20 days (Directive 84/449/EEC, C.5) were determined with cocamidopropyl betaine. Under anaerobic

conditions, 80 – 90 % mineralization after 60 days or 56% after 56 days were observed for cocamidopropyl betaine.

Bioaccumulation

A low potential for bioaccumulation is to be expected for cocoamidopropyl betaines based on the calculated BCFs between 3 (with C8 fatty acid) and 71 (with C10 – C18 fatty acids).

Aquatic Toxicity

For cocoamidopropyl betaine, the lowest acute LC/EC_{50} values for fish, *Daphnia*, and algae are all in the range of 1.3 – 2 mg active substance/L. One long-term test with fish (according to OECD 215), and several chronic tests with *Daphnia* and algae were conducted on cocoamidopropyl betaine. The lowest NOECs are 0.16 mg active substance/L for fish (*Oncorhynchus mykiss*), 0.03 mg active substance/L for *Daphnia magna*, and 0.09 mg active substance/L for green algae (*Desmodesmus subspicatus*). These values were derived with analytical monitoring (photometric) except for the algae test. However, the effect values within the same species (*e.g.*, *Desmodesmus subspicatus*, *Daphnia magna*) have shown a high variability. Recent guideline studies performed in accordance with OECD 211 and 201 using state-of-the-art analytical monitoring and a quality of cocamidopropyl betaine currently commercialized, resulted in a lower aquatic toxicity. In these studies the lowest NOEC for *Daphnia* was determined to be 0.932 mg active substance/L. The lowest NOEC (72 hour, based on growth rate) for algae was determined to be 3.55 mg active substance/L (72-hour ErC_{50} = 9.86 mg active substance/L). This latter NOEC for algae is further supported by the similar NOEC of 3.53 mg active substance/L calculated using the geometric mean of all valid tests with this algae species. Furthermore, for algae a potential for recovery from the effect up to a concentration of 96 mg active substance/L has been observed.

Toxicity to Terrestrial Organisms

Two studies (without analytical monitoring) of effects on earthworms and higher plants showed low toxicity (no data given in the OECD-SIDS SIAP). Taking additionally into account that the adsorption potential of the main components of cocamidopropyl betaine (the C8 to C14 derivatives) is low, a risk for the terrestrial compartment is not expected.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. A recent state-of-the-art chronic study is available for invertebrates (lowest NOEC for Daphnia is 0.932 mg/L). A recent state-of-the-art OECD 211 study is also available with the lowest

NOEC (72 hour, based on growth rate) for algae was determined to be 3.55 mg/L. On the basis that the data consists of two chronic studies (Daphnia and algae), an assessment factor of 50 has been applied to the lowest reported NOEC of 0.932 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.019 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using PCKOCWIN v. 1.66 using specific betaine with C8, C10, C12, C14, C16, and C18 fatty acids. Using a Koc values of 264.7 to 120600 and a $PNEC_{aquatic}$ of 0.0.019 mg/L, the $PNEC_{sediment}$ was calculated to be 0.085 to 33.7 mg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using PCKOCWIN v. 1.66 using specific betaine with C8, C10, C12, C14, C16, and C18 fatty acids. Using a Koc values of 264.7 to 120,600 and a $PNEC_{aquatic}$ of 0.0.01 mg/L, the $PNEC_{soil}$ was calculated to be 0.066 to 29.8 mg/kg.

PBT Assessment

Cocoamidopropyl betaine is readily biodegradable and thus it does not meet the screening criteria for persistence.

The estimated log Kow values for cocoamidopropyl betaine (with C8 to C18 fatty acids) is -1.28 to 3.63, calculated using KOWWIN v1.67 (HERA, 2005). Thus, cocoamidopropyl betaine does not meet the screening criteria for bioaccumulation.

The lowest chronic NOEC for cocoamidopropyl betaine is >0.1 mg/L. Thus, cocoamidopropyl betaine does not meet the criteria for toxicity.

The overall conclusion is that cocoamidopropyl betaine is not a PBT substance.

OECD (2006). SIDS Initial Assessment Profile for Alkylamidopropyl betaines.

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Endo-1,4-beta-Mannanase
(CAS No. 37288-54-3)

No data could be located on endo-1,4-beta-mannanase. There is information, however, on α-amylases. α-Amylase catalyzes the endo-hydrolysis of 1,4-α-D-glycosidic linkages in polysaccharides like starches, glycogen, and oligosaccharides containing three or more 1,4-α-linked glucose units. Given the similarity of the substrates, amylases and endo-1,4-beta-mannanase would be expected to have similar physico-chemical properties relevant to evaluating their environmental fate and transport, and their aquatic toxicity potential.

The data on α-amylases have come from detergent amylases, the typical ones being *Bacillus*, which has an neutral isoelectric point and a broad pH optimum between pH 5 and 9. The enzyme is characterized by a molecular weight of 58 kD (HERA, 2005).

Biodegradation

Two different amylase enzymes were considered readily biodegradable based on the results of OECD 301E tests. In both tests, there was 99% DOC removal of the enzyme after 28 days. Likewise, endo-1,4-beta-mannanase is expected to be readily biodegradable (HERA, 2005).

Aquatic Toxicity

The 96-hour LC_{50} of α-amylase (Termamyl) to *Oncorhyncus mykiss* (rainbow trout) is >320 mg aep/L (HERA, 2005). The 48-hour LC_{50} of α-amylase to *Dapnia magna* is 450 mg aep/L (HERA, 2005). The 72-hour EC_{50} of α-amylase (Termamyl) to algae *Scenedesmus subspicatus* is 112 mg aep/L (HERA, 2005).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>320 mg aep/L), Daphnia (450 mg aep/L), and algae (112 mg aep/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 112 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.112 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.112 mg aep/L, the $PNEC_{sediment}$ was calculated to be 0.07 mg aeg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.112 mg aep/L, the $PNEC_{soil}$ was calculated to be 0.0019 mg aeg/kg.

PBT Assessment

Endo-1,4-beta-mannanase is expected to be readily biodegradable based on read-across to amylases. Thus, endo-1,4-beta-mannanase does not meet the screening criteria for persistence.

Based on the similarity to amylase, endo-1,4-beta-mannanase has a high molecular weight (20 to 80 kD), has hydrophilic properties (high water solubility, log Kow <0), and is readily metabolized in organisms by proteolytic enzymes or proteases. Thus, endo-1,4-beta-mannanase does not meet the screening criteria for bioaccumulation.

No chronic aquatic toxicity data exist for endo-1,4-beta-mannanase; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, endo-1,4-beta-mannanase does not meet the screening criteria for toxicity.

The overall conclusion is that endo-1,4-beta-mannanase is not a PBT substance.

Human and Environmental Risk Assessment (HERA) on Ingredients of Household Cleaning Products: α-amylase, CAS No. 9000-90-2; Cellulase (β-(1,4)-glucanase), CAS No. 9012-54-8; Lipase, 9001-62-1, 2005. http://www.heraproject.com

Environmental Assessment

Ethanol
(CAS No. 64-17-5)

Ethanol has been reviewed in the OECD-SIDS program (OECD, 2004a,b).

Environmental Transport

Fugacity-based modelling data show that ethanol released into the environment will become distributed mainly into air and water (OECD, 2004a,b).

Biodegradation

In aerobic conditions using adapted wastewater from domestic sewage, degradation was 74% after 5 days rising to 95% by day 15 and in similar conditions in synthetic seawater, ethanol was 45% degraded after 5 days rising to 75% by day 20 (Price, 1974).

Using a MITI protocol study, there was degradation of 89% after 14 days (>70% after 10 days, CERI, 2004) and (>90% within 10 days, Birch, 1991). Activated domestic sludges were capable of aerobically oxidizing ethanol, as measured by BOD, which was 37.3% of maximum after 1 day (Gerhold, 1966).

The rate of biodegradation in anaerobic conditions was calculated to be 17.9 ppm ethanol per day with a total methane recovery of 91% of the theoretical limit (Suflita, 1993). Biodegradation is the main method of removal of ethanol from water. Ethanol is stable to hydrolysis. Reaction with hydroxyl radicals in aquatic media will not likely be a significant process (Anbar, 1969).

Bioaccumulation

The bioconcentration factor (BCF) was estimated to be 3.16 L/kg using BCFBAF v. 3.01 (US EPA, 2011).

Aquatic Toxicity

The aquatic toxicity data in fish, invertebrates, and algae indicate a low order of acute toxicity with LC_{50}/EC_{50} values >1,000 mg/L (OECD, 2004a,b). The most sensitive species were algae, with a 96-hr EC_{50} for *Chlorella vulgaris* of 1,000 mg/L (El Jay, 1996).

Chronic toxicity studies in a variety of freshwater invertebrates show LC_{50} values of

>100 mg/L (Cowgill and Milazzo,1991). The lowest reported NOEC was 9.6 mg/L for *Cerodaphnia sp*.

A 5-day study using *Skeletonema costatum* gave a NOEC ranging from 3,240 to 5,400 mg/L based on cell count, with corresponding EC_{50} values of 10,943 - 11,619 mg/L. The authors commented that ethanol was used as a carbon source stimulating growth of the alga before inhibition began (Cowgill, 1989).

Toxicity to Terrestrial Plants

The 7-d NOEC values of higher (vascular) plants *Lemna gibba* and *L. minor* were 280 and 778 mg/L, respectively. The EC_{50} values for both plants were 4,432 mg/L (Cowgill, 1991).

Toxicity to Terrestrial Organisms

In the only study of the effect of ethanol on soil dwelling organisms found, the oligochaete worm *Eisenia foetida* showed a 48- hr LC_{50} of 0.1-1.0 mg/cm^2 loading on a filter paper test. The 'dosage', presented in terms of concentration in a given area of substrate is difficult to interpret but would have equated to the worms being exposed to a theoretical vapor concentration in the range 200-2000 mg/L (Roberts, 1984).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>1,000 mg/L), Daphnia (>1,000 mg/L), and algae (1,000 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 9.6 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported long-term NOEC of 9.6 mg/L for invertebrates. The $PNEC_{aquatic}$ is 0.96 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE (MCI method). Using a Koc of 1.0 and a $PNEC_{aquatic}$ of 0.96 mg/L, the $PNEC_{sediment}$ was calculated to be 0.61 mg/kg.

$PNEC_{soil}$: No relevant experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI method). Using a Koc of 1.0 and a $PNEC_{aquatic}$ of 0.96 mg/L, the $PNEC_{soil}$ was calculated to be 0.0128 mg/kg.

PBT Assessment

Ethanol is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on an experimental log Kow of -0.31 and a calculated BCF of 3.16, ethanol does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on ethanol show NOECs of >0.01 mg/L. Thus, ethanol does not meet the screening criteria for toxicity.

The overall conclusion is that ethanol is not a PBT substance.

Environmental Assessment

Ethoxylated Fatty Acid Ester II

This ethoxylated fatty acid ester is a hydrophilic, non-ionic surfactant used in pharmaceutical preparations, and cosmetics as an emulsifier, dispersant, or stabilizer, and as a food additive. It is considered a mixture and thus a UVCB substance (substance of unknown or variable composition, complex reaction products or biological materials).

The water solubility for this substance has been reported to be 50-100 g/L at 23^{o} C (source unknown). This is consistent with the estimated water solubility of 25 g/L at 25^{o}C from the WATERNT program in EPISUITE.

There are no experimental data on the Kow. An estimated Kow is difficult to obtain since this is a UVCB substance. A Kow of approximately 1.5-1.6 was calculated based on certain assumptions about the structure.

Biodegradation

This substance was reported to biodegrade in less than 5 days. For the purposes of this assessment, this ethoxylated fatty acid ester will be considered to be inherently biodegradable.

Aquatic Toxicity

Following 10 hours of exposure, invertebrate lethality was noted at concentrations of 1-5%, and an EC_{50} in algae was reported to be 100 mg/L.

The 96-hour LC_{50} in fish was estimated to be 815 mg/L (ECOSAR); the 48-hr LC_{50} in daphnia was estimated to be 1,980 mg/L (ECOSAR); and the 96-hr EC_{50} in green algae based on general population growth was estimated to be 970 mg/L (ECOSAR).

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

Using the EC_{50} of 100 mg/L in algae and an assessment factor of 1,000, the $PNEC_{aquatic}$ is 0.1 mg/L.

Environmental Assessment

Ethoxylated Sorbitan Monooelate
Polysorbate 80
(CAS No. 9005-65-6)

Ethoxylated sorbitan monooleate or polysorbate 80 is a hydrophilic, non-ionic surfactant used in pharmaceutical preparations, and cosmetics as an emulsifier, dispersant, or stabilizer, and as a food additive. It is a mixture of oleic esters of sorbitan and its anhydrides copolymerized with approximately 20 mol of ethylene oxide (Sweetman, 2002). Thus, polysorbate 80 is considered a UVCB substance (substance of unknown or variable composition, complex reaction products or biological materials).

The water solubility of ethoxylated sorbitan monooleate has been reported to be 50-100 g/L at 23ºC (source unknown). This is consistent with the estimated water solubility of 25 g/L at 25ºC from the WATERNT program in EPISUITE.

There are no experimental data on the Kow for ethoxylated sorbitan monooleate. An estimated Kow is difficult to obtain since this polysorbate 80 is a UVCB substance. Carlsson et al. (2006) calculated a Kow of approximately 1.5-1.6 assuming a linear polyethylene glycol chain bound to sorbitan monooleate

Biodegradation

Polysorbate 80 was been reported to biodegrade in less than 5 days (Baleux and Caumette, 1974). In their environmental risk assessment, Carlsson et al. (2006) considered polysorbate 80 to be inherently biodegradable.

Aquatic Toxicity

Following 10 hours of exposure, invertebrate lethality was noted at concentrations of 1-5% (Saski *et al.*, 1971), and an EC_{50} in algae was reported to be 100 mg/L (Nyberg, 1998).

The 96-hr LC_{50} in fish was estimated to be 815 mg/L (ECOSAR); the 48-hr LC_{50} in daphnia was estimated to be 1,980 mg/L (ECOSAR); and the 96-hr EC_{50} in green algae based on general population growth was estimated to be 970 mg/L (ECOSAR).

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

Carlsson *et al.* (2006) calculated the following PNECs for ethoxylated sorbitan monooleate (polysorbate 80) using the acute algal EC_{50} of 100 mg/L, and assessment factors in accordance with the EU TGD. Using an assessment factor of 1,000, the $PNEC_{aquatic}$ is 0.1 mg/L.

Environmental Assessment

Fatty Acid Ester

This fatty acid ester is a non-ionic surfactant-active agent that typically finds use as an emulsifier, stabilizer and thickener in foods, cosmetics, medical products, and lubricants, and other applications. It is approved by FDA as an indirect food additive.

Biodegradation

In an OECD 301C test, this fatty acid ester was degraded 62% in 28 days and did not meet the 10-day window. Thus, it is not readily biodegradable.

Aquatic Toxicity

This fatty acid ester caused no mortality in rainbow trout at nominal levels of 1,000 mg/L in an acute 96-hour fish toxicity study. The calculated water solubility of this fatty acid ester is 0.0191 mg/L. Thus, it appears that it would not be expected to cause acute toxicity at its water solubility limit.

The surrogate substance, has been evaluated in fish, daphnia and algae. The LC_{50} or EC_{50} value was reported to be greater than 1,000 mg/L [nominal loading concentrations in the water accommodated fraction (WAF) solutions tested] in all three aquatic species for this structurally analogous surrogate. The measured water solubility of the surrogate is <0.02 mg/L, which would suggest that this surrogate would not be expected to cause acute aquatic toxicity at its water solubility limit.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available on the fatty acid ester and its surrogate for all three tropic levels. It was concluded that this fatty acid ester would not be expected to cause acute toxicity at its water solubility limit of 0.0191 mg/L. On the basis that the data consists of short-term results from three trophic level, an assessment factor of 1,000 has been applied to the water solubility limit of 0.0191 mg/L. The $PNEC_{aquatic}$ is 1.91×10^{-5} mg/L or 0.0191 µg/L.

Environmental Assessment

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyanopsis tetragonolobus*. Structurally, it is a galactomannan (a polysaccharide) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum ranges from 200,000 to 300,000 daltons (Glickman, 1969).

Biodegradation

No information was found. Guar gum, being a polysaccharide composed of galactomannan, would be expected to be readily biodegradable.

Bioaccumulation

Not expected to bioaccumulate as a polysaccharide composed of galactomannans.

Aquatic Toxicity

The 48-hour LC_{50} for *Daphnia magna* was reported to be 42 mg/L (Biesinger *et al.*, 1976).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. An acute LC_{50} value is available for the invertebrate Daphnia (42 mg/L). On the basis that the data consists of only one short-term result from one trophic level, an assessment factor of 1,000 has been applied to the reported effect concentration of 42 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.042 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition

method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

No biodegradation was found on guar gum. However, guar gum is a naturally occurring polysaccharide which would be expected to readily biodegrade. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons, and it is also water soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The acute aquatic toxicity of guar gum is >0.1 mg/L. Thus, guar gum is not expected to meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

Environmental Assessment

Hydrocarbons, Terpene Processing By-products
(CAS No. 68956-56-9)

Terpenes and Terpenoids, Sweet Orange Oil
(CAS No. 68647-72-3)

CAS No. 68956-56-9 is a by-product of the manufacturing process in which high-quality gum turpentine oil or alpha pinene is synthesized into terpineol. It is largely composed of alpha terpinene, dl-limonene, cineol, gamma terpinene, terpinolene and other terpene hydrocarbons. The composition of CAS No. 68956-56-9 in the HPV Test Plan for Monoterpene Hydrocarbon Category is: 22-34% limonene, 22-33% terpinolene, 5-10% mycene, 18% limonene isomers, 10% other terpene hydrocarbons.

CAS No. 68647-72-3 is composed of 91-95% d-limonene, 1-3% beta-myrcene, and 1-2% alpha-pinene. (see HPV Test Plan for Monoterpene Hydrocarbon Category).

Biodegradation

Terpinolene was found to be biodegradable in two studies. In one study of inherent biodegradability, 80% biodegradation was reported using an OECD 302C guideline protocol after 28 and 31 days. In a study of ready biodegradability, 62.1% biodegradation was reported using an OECD 301B protocol after 28 days. One study of the ready biodegradability of terpinolene by OECD 301F reported it to be not readily biodegradable (51% after 28 days) but the authors concluded that the high vapor pressure and low water solubility of terpene hydrocarbons leads to volatilization in the upper parts of the test vessel, thereby, limiting aerobic biodegradation.

Limonene was readily biodegradable (41-98% degradation by biological oxygen demand in 14 days (OECD 301C).

Aquatic Toxicity

The 96-hour LC_{50}s in fathead minnows for limonene and terpinolene were reported to be 0.702 and 0.720 mg/L, respectively.

The 48-hour EC_{50} for limonene in *Daphnia pulex* was reported to be 69.6 mg/L. However, since the solubility of limonene is 13.8 mg/L at 25^{o}C, the actual test concentration is not known. The 96-hour LC_{50} value for limonene in *Daphnia magna* was reported to be 0.577 mg/L, while the 96-hour $EC_{50}$was 0.421 mg/L. When these tests were repeated using limonene from a different supplier, the 96-hour LC_{50} was 0.924 mg/L. The 48-hour LC_{50} for mycene in *Daphnia magna* was reported to be 31 mg/L and

is also considered unreliable given limits of solubility. For terpinolene, the 96-hour LC_{50} was reported to be 2.55 mg/L and the EC_{50} was reported to be 1.38 mg/L.

The 96-hour EC_{50}s for both limonene and terpinolene in green algae are >1.81 and >3.38 mg/L, respectively. Neither limonene nor terpinolene showed any significant inhibition at those test concentrations.

Toxicity to Terrestrial Organisms

The LC_{50} of *d*-limonene to earthworms (*Eisenia foetida* Savigny) is 6.0 ppm. The subacute dietary LC_{50} to Bobwhite quail (Colinus virginianus) is >5,620 ppm.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels for surrogates limonene and terpinolene. Acute $E(L)C_{50}$ values are available for fish (0.702 mg/L), Daphnia (0.421 mg/L), and algae (1.81 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.421 mg/L for Daphnia. The $PNEC_{aquatic}$ is 4.21×10^{-4} mg/L or 0.421 µg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE. Using a Koc of 6324 and a $PNEC_{aquatic}$ of 0.421 µg/L, the $PNEC_{sediment}$ was calculated to be 40 µg/kg (0.040 mg/kg).

$PNEC_{soil}$: Since there is limited experimental toxicity data on terrestrial organisms, the equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE. Using a Koc of 6324 and a $PNEC_{aquatic}$ of 0.421 µg/L, the $PNEC_{soil}$ was calculated to be 35 µg/kg (0.035 mg/kg).

PBT Assessment

This category of terpenes and terpenoids are considered to be readily biodegradable. Thus, terpenes and terpenoids do not meet the screening criteria for persistence.

The experimental log Kow values for d-limonene, terpinolene, beta-mycene and alpha-pinene are 4.38, 4.47, 4.44 and 4.17, respectively. The estimated BCF values using BCFFAF v. 3.01 for d-limonene, terpinolene, beta-mycene and alpha-pinene are 360.5, 413.3, 394.9, and 262 L/kg, respectively. Thus, this category of terpenes and terpenoids do not meet the screening criteria for bioaccumulation.

No chronic toxicity data exist terpenes and terpenoids; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, this category of terpenes and terpenoids do not meet the screening criteria for toxicity.

The overall conclusion is that this category of terpenes and terpenoids is not a PBT substance.

Environmental Assessment

Hydrochloric acid
(CAS No. 7647-01-0)

Hydrochloric acid has been reviewed in the OECD-SIDS program (OECD, 202a,b).

Environmental Fate and Transport

Hydrochloric acid is readily dissociated in water into hydrated protons and chloride ions.

The increase in the concentration of hydrochloric acid in water decreases the pH in the aquatic ecosystem. Generally, the buffer capacity to maintain the pH in the aquatic ecosystem is important and the equilibrium between CO_2, HCO_3^- and CO_3^{2-} in the aquatic ecosystem is mainly responsible for the buffer capacity of receiving water.

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

According to UNEP (1995), the mean, the 10th-percentile and the 90th-percentile of bicarbonate concentrations for 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania were 106, 20 and 195 mg/L, respectively. The buffering capacity for neutralization of receiving water with bicarbonate concentrations of 20, 106 and 195 mg/L is calculated to be 2.19, 11.60 and 21.3 mg/L, respectively.

Aquatic Toxicity

Several studies on the acute toxicity to fish have been published. The lowest 96-hour LC_{50} was reported to be 4.92 mg/L for *Cyprinus carpio* at pH 4.3 which was conducted according to OECD 203 guidelines (MLIT, 1999). The 96-hour LC_{50} for *Oncorhynchus mykiss* was 7.45 mg/L at pH 4.12 for hard water and 10.3 mg/L at pH 3.98 for soft water (Graham and Wood, 1981). The 96-hour LC_{50} in *Lepomis macrochirus* is 55.1 to 30.9 mg/L at pH 3.25 - 3.5; the low pH caused a reduction in the oxygen carrying capacity of hemoglobin and excessive secretion of mucus from the gills which in turn interfered with gas exchange (Ellgaard and Glimore, 1984).

Generally, the results of toxicity tests with acid or base depend on the buffer capacity of the test medium. Dechlorinated tap water was used as a test medium in the three tests described above. A 96-hour LC_{50} of 30.9 to 24.6 at pH 3.5-3.6 was obtained for *Lepomis macrochirus* using artificial water prepared from distilled water and analytical or reagent grade chemicals (Cairns and Scheier, 1959); other reported values are a 96-hour LC_{50} of 282 mg/L for *Gambusia affinis* (Wallen *et al.*, 1957) and a 16-hour LC_{100} value of 0.492 mg/L at pH 5.3 for the pike perch fry (*Lucioperca lucioperca*) conducted with pond water

(pH 6.0-8.2) are reported (Stangenberg, 1975). A 24-hr LC_{50} value of 60-80 mg/L for *Semotitus astromaculatus* with river water (pH 8.3) has also been reported. No long-term or chronic toxicity data on fish were located (Gillette *et al.*, 1952).

The 48-hour EC_{50} for *Daphnia magna* is 0.492 mg/L at pH 5.3 based on immobilization (MLIT, 1999). No long-term or chronic toxicity data on invertebrates have been reported. The 72-hour EC_{50} to *Selenastrum capriornutum* is 0.78 mg/L (pH 5.1) for biomass; 0.492 mg/L (pH 5.3) for growth rate; and the 72-hr-NOEC is 0.097 mg/L (pH 6.0) for biomass and growth rate (MLIT, 1999).

The hazard of hydrochloric acid for the environment is caused by the proton (pH effect). For this reason the effect of hydrochloric acid on the organisms depends on the buffer capacity of the aquatic ecosystem. Also, the variation in acute toxicity for aquatic organisms can be explained to a significant extent by the variation in buffer capacity of the test medium. For example, LC_{50} values of acute fish toxicity tests varied from 4.92 to 282 mg/L.

It is not considered useful to calculate a PNEC for hydrochloric acid because factors such as the buffer capacity, the natural pH, and the fluctuation of the pH are very specific for a certain ecosystem.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECS

$PNEC_{aquatic}$: Based on the information above, a $PNEC_{aquatic}$ was not derived for hydrochloric acid.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Kow and Koc parameters do not readily apply to inorganics, such as hydrochloric acid. Thus;, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of hydrochloric acid to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Sorption of hydrochloric acid should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as hydrochloric acid. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, hydrochloric acid is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Hydrochloric acid is an organic salt that dissociates completely to hydrogen and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and chloride ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Hydrogen and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, hydrochloric acid is not expected to bioaccumulate.

No chronic toxicity data exist on hydrochloric acid; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, hydrochloric acid does not meet the screening criteria for toxicity.

The overall conclusion is that hydrochloric acid is not a PBT substance.

Environmental Assessment

Monoethanolamine borate
(CAS No. 26038-87-9)

Monoethanolamine borate is also known as orthoboric acid, compound with 2-aminoethanol. It is a UVCB substance with the chemical formula: $C_2H_7NO.xBH_3O_3$.

Environmental Transport

Monoethanolamine (MEA) Polyborate 1:1 and MEA Polyborate 1:3 do not significantly adsorb to soil. The experimental log Koc was determined to be approximately 1.26.

Biodegradation

MEA Polyborate 1:1 was considered readily biodegradable in a modified Sturm test (OECD 301B). Degradation was 73% after 28 days.

MEA Polyborate 1:3 was considered readily biodegradable in a modified Sturm test (OECD 301B). Degradation was 75% after 28 days.

Aquatic Toxicity

The 96-hour LC_{50} in Carp for MEA Polyborate 1:3 is 617 mg/L.

The 48-hour EC_{50}s in *Daphnia magna* for MEA Polyborate 1:3 and MEA Polyborate 1:1 are 496 and 423 mg/L, respectively.

The 72-hour ErC_{50} in fresh water algae species *Pseudokirchneriella subcapitata* for MEA Polyborate 1:1 is 26 mg/L. The 72-hr EyC_{50} (yield inhibition) is 13 mg/L. The NOEC for growth rate reduction and yield inhibition is 3.2 mg/L. The 72-hr ErC_{50} in fresh water algae species *Pseudokirchneriella subcapitata* for MEA Polyborate 1:3 is 67 mg/L.

Toxicity to Sediment Organisms

No data are available.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (617 mg/L), Daphnia (423 mg/L), and algae (13 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 13 mg/L for algae. The $PNEC_{aquatic}$ is 0.013 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was experimentally determined to be approximately 18.20. Using a Koc of 18.20 and a $PNEC_{aquatic}$ of 0.013 mg/L, the $PNEC_{sediment}$ was calculated to be 0.012 mg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was experimentally determined to be approximately 18.20. Using a Koc of 18.20 and a $PNEC_{aquatic}$ of 0.013 mg/L, the $PNEC_{soil}$ was calculated to be 0.003 mg/kg (3.1 μg/kg).

PBT Assessment

Monoethanolamine borate is readily biodegradable and thus it does not meet the screening criteria for persistence.

Monoethanolamine borate is a UVCB substance and a log Kow cannot be accurately determined. For monoethanolamine itself, the measured log Kow and estimated BCF from BCFBAF v.3.01 are -1.6122 and 3.16 L/kg, respectively. The borate salt of monoethanolamine would not be expected to meet the screening criteria for bioaccumulation.

No chronic aquatic toxicity studies are available for monoethanolamine borate. The acute toxicity studies in fish, invertebrates and algae are >0.1 mg/L. Thus, monoethanolamine borate does not meet the criteria for toxicity.

The overall conclusion is that monoethanolamine borate is not a PBT substance.

Environmental Assessment

PEG Oleate Ester
[Poly(oxy-1,2-ethanediyl), .alpha.-hydro-.omega.-hydroxy-, (9Z)-9-octadecenoate]
(CAS No. 56449-46-8)

PEG oleate ester or polyethylene glycol oleate ester is an ethoxylated ester of oleic acid (http://legacy.library.ucsf.edu/tid/izs03c00/pdf); it is an UVCB substance with no defined ethylene oxide (EO) chain length. No data could be located for this particular substance.

An MSDS was found for BASF Cremophor® EL Castor Oil, which is ethoxylated castor oil. Castor oil contains 85-95% ricinoleic acid, 2-6% oleic acid, 1-5% linoleic acid; other fatty acids are <1%. Ricinoleic acid, a monounsaturated, 18-carbon fatty acid, is unusual in that it has a hydroxyl functional group on the 12th carbon. This functional group causes ricinoleic acid (and castor oil) to be unusually polar.

Information was also obtained from EPISuite v.4.10 (U.S. EPA, 2011) using PEG 18 oleate as a surrogate.

Biodegradation

BASF Cremophor® EL Castor Oil showed 90-100% degradation after 21 days in an OECD 302B study. It is biodegradable, but not readily biodegradable by OECD criteria.

PEG 18 oleate is predicted to not biodegrade fast by BIOWIN.

Aquatic Toxicity

BASF Cremophor® EL Castor Oil: The 48-hour LC_{50} in golden orfe is 448 mg/L. The 48-hour EC_{50} in *Daphnia* is >100 mg/L. The 72-hour EC_{50} in green algae is >93 mg/L.

The toxicity values for ethoxylated castor oil are in close agreement with those predicted for PEG 18 oleate by ECOSAR. For PEG 18 oleate, the estimated 96-hour LC_{50} in fish is 89 mg/L; the estimated 48-hour LC_{50} in *Daphnia* is 174 mg/L; and the 96-hour EC_{50} in green algae is 71 mg/L.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (448 mg/L), Daphnia (>100 mg/L), and algae (>93 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 93 mg/L for algae. The $PNEC_{aquatic}$ is 0.093 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE (log Kow method). Using a Koc of 13.5 and a $PNEC_{aquatic}$ of 0.093 mg/L, the $PNEC_{sediment}$ was calculated to be 0.077 mg/kg.

$PNEC_{soil}$: No adequate experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (log Kow Method). Using a Koc of 13.5 and a $PNEC_{aquatic}$ of 0.093 mg/L, the $PNEC_{soil}$ was calculated to be 0.017 mg/kg.

PBT Assessment

The results of BIOWIN for PEG 18 oleate are as follows: does not biodegrade fast (Biowin 2); recalcitrant (Biowin 3); and does not biodegrade fast (Biowin 6). Thus, using PEG 18 oleate as a surrogate, PEG oleate ester meets the screening criteria for persistence.

For PEG 18 oleate, the estimated log Kow is 2.3772 and the estimated BCF is 17.2. Thus, using PEG 18 oleate as a surrogate, PEG oleate ester does not meet the screening criteria for bioaccumulation.

No chronic toxicity studies could be located on ethoxylated castor oil or PEG 18 oleate; however, the acute toxicity data on ethoxylated castor oil show values of >1 mg/L. Thus, using ethoxylated castor oil and PEG 18 oleate as surrogates, PEG oleate ester does not meet the screening criteria for toxicity.

The overall conclusion is that PEG oleate ester is not a PBT substance.

Environmental Assessment

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium hydroxide (NaOH) will be found predominantly in the aquatic environment. NaOH is present in the environment as sodium (Na^+) and hydroxyl (OH^-) ions, which implies that it will not adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Measured concentrations in aquatic ecosystems
The concentration of hydroxyl ions in the environment has been determined very extensively via pH measurements. The pH is a very important parameter of aquatic ecosystems and it is a standard parameter of water quality monitoring programs. The most important freshwater aquatic ecosystems of the world revealed average annual pH values between 6.5 and 8.3 but lower and higher values have been measured in other aquatic ecosystems (UNEP, 1995). In aquatic ecosystems with dissolved organic acids a pH of less than 4.0 has been measured, while in waters with a high chlorophyll content the bicarbonate assimilation can result in pH values of higher than 9.0 at midday (UNEP, 1995). The pH of an aquatic ecosystem is mainly determined by geochemical, hydrological and/or biological processes.

Also sodium has been measured extensively in aquatic ecosystems. For example UNEP (1995) reported the concentration for a total number of 75 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th –percentile, mean and 90th-percentile were 1.5, 28 and 68 mg/l, respectively.

NaOH addition and buffer capacity
An addition of NaOH to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th– percentile, mean and 90th-percentile were 20, 106 and 195 mg/l, respectively.

Aquatic Toxicity

At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realized that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralized and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity *e.g.*, NH_3 is more toxic than NH_4^+.

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L . At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L. The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia* cf. *dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

No data are available on the effects of NaOH on algae.

Toxicity to Terrestrial Organisms

Toxicity tests, which determined the effects of NaOH on terrestrial organisms, are not available. Significant exposure of the terrestrial environment is not expected and for this reason there is no need to perform toxicity test with terrestrial organisms. The results of terrestrial toxicity tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil.

Determination of PNECs

In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available and the results of the tests are more or less consistent. Altogether they give a sufficient indication about acute toxicity levels of sodium hydroxide.

Furthermore acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterized by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.

Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,

- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and

- The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for NaOH there is a need to assess the environmental effect of an NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

$PNEC_{aquatic}$: Based on the information above, a PNEC was not derived for sodium hydroxide.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium hydroxide dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium hydroxide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium hydroxide to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium hydroxide is dominated by its water solubility.

Sorption of sodium hydroxide should probably be regarded as a reversible situation, i.e., the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium hydroxide Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium hydroxide is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium hydroxide is an organic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

Environmental Assessment

Sodium sulfate
(CAS No. 7757-82-6)

Sodium sulfate has been reviewed in the OECD-SIDS program (2005a,b).

Environmental Fate

Sodium sulfate is a solid inorganic salt that is highly soluble in water (161-190 g/L at 20^{o} C); with a melting point of 884^{o} C; and density of 2.7 g/cm^{3}. Sodium sulfate fully dissociates to sodium and sulfate ions in water.

Sulfates are not expected to bioaccumulate in the soil or in aqueous solution. Sodium and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. However, some plants (*e.g.* corn and *Kochia Scoparia*), are capable of accumulating sulfate to concentrations that are potentially toxic to ruminants.

In anaerobic environments sulfate is biologically reduced to (hydrogen) sulfide by sulfate reducing bacteria, or incorporated into living organisms as source of sulfur, and thereby included in the sulfur cycle.

Aquatic Toxicity

Algae were shown to be the most sensitive to sodium sulfate: the 120-hour EC_{50} is 1,900 mg/L. For invertebrates *(Daphnia magna)*, the 48-hour EC_{50} is 4,580 mg/L and fish appeared to be the least sensitive with a 96-hour LC_{50} of 7,960 mg/L for *Pimephales promelas*.

No data were found for chronic toxicity.

Toxicity to Sediment Organisms

The 96-hour LC_{50} of 660 mg/L was reported for *Trycorythus sp*.

Toxicity to Terrestrial Organisms

Sodium sulfate is not very toxic to terrestrial plants. *Picea banksiana* was the most sensitive species, an effect was seen at 1.4 g/L.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (7,960 mg/L), Daphnia (4,580 mg/L), and algae (1,900 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 1,900 mg/L for Daphnia. The $PNEC_{aquatic}$ is 1.9 mg/L.

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Sodium sulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium sulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium sulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium sulfate is dominated by its water solubility. Sorption of sodium sulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium sulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium sulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium sulfate is an organic salt that dissociates completely to sodium and sulfate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and sulfate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Sodium and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium sulfate is not expected to bioaccumulate.

No chronic toxicity data exist on sodium sulfate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium sulfate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium sulfate is not a PBT substance.

Environmental Assessment

Sodium sulfite
(CASRN 7757-83-7)

Sodium sulfite has been reviewed in the OECD-SIDS program (OECD, 2008a,b).

Environmental Fate

Sodium sulfite completely dissociates into the sodium and sulfite ions in aqueous solutions.

Sodium sulfite is a salt of sulfurous acid (H_2SO_3). Sulfurous acid dissociates in aqueous solutions (pKa_1 = 1.8; pKa_2 = 7.0 at 25°C). At neutral pH, a mixture of 50% sulfite (SO_3^{2-}) and 50% bisulfite (HSO_3^-) is present. At concentrations above 1M, bisulfite anions will dimerize with the elimination of water to form metabisulfite ($S_2O_5^{2-}$). At low concentrations, metabisulfite will hydrolyze to form bisulfite.

In surface waters, sulfite is oxidized to sulfate either catalytically by air oxygen or by microbial action. The half-life in deionized water was determined to be 77 hours. The presence of cations like iron, copper or manganese in the environment accelerates the oxidation rate significantly.

Aquatic Toxicity

For the interpretation of the test results the instability of the test solutions has to be considered. Sulfite is rapidly oxidized to sulfate, the reaction is accompanied with consumption of dissolved oxygen. Therefore, the observed effects can be caused either by sulfite toxicity or by lack of oxygen. The available results indicate that algae represent the most sensitive trophic level, followed by daphnids and fish.

Species	**Test Substance**	**96-hour LC_{50}***
Leuciscus idus	Sodium sulfite	215-464
Danio rerio	Dipotassium disulfite	570-1100**
Oncorhynchus mykiss	Sodium hydrogensulfite	>1,200
Oncorhynchus mykiss	Disodium disulfite	200-290
Leuciscus idus	Potassium sulfite	170-370

*Results are expressed as sodium sulfite.

**The referred concentrations are the sum of measured sulfite and sulfate concentrations. Assuming that the toxicity is caused exclusively by sulfite, the LC_{50} would be 12-220 mg/L (based on measurements after 96 h).

The 48-hour EC_{50} of sodium disulfite in *Daphnia magna* is 118 mg/L (expressed as Na_2SO_3) was obtained after 48 hours of exposure.

Species	Test Substance	Results	Endpoint
Chlamydomonas reinhardtii	Sodium sulfite	NOEC = 37.8 mg/L EC_{50} = 63-126 mg/L	Growth
Chlorella vulgaris	Sodium sulfite	NOEC = 37.8-63 mg/L EC_{50} = 63-126 mg/L	Growth
Scenedesmus basiliensis	Sodium sulfite	NOEC = 37.8-50.4 mg/L EC_{50} = 63-126 mg/L	Growth
Scenedesmus subspicatus	Sodium sulfite	EC_{20} = 52 mg/L EC_{50} = 77 mg/L	Growth

A long-term test on *Daphnia magna* was conducted using sodium disulfite as test substance. After 21 days of exposure, no effects were observed at all concentrations at either 1.3 or 13 mg/L (expressed as sodium sulfite). The NOEC is >13 mg/L.

Toxicity to Terrestrial Plants

In a study in which the effect of sulfite on the root growth of barley grains (*Hordeum vulgare*) was investigated, the roots were exposed to eight concentrations between 0.1 and 30 mM (pH 7) for 120 hours. At 0.1 mM slight stimulation of growth was observed, while at 0.5 mM root length decreased to ca. 6.1 cm (control ca. 6.7 cm, values taken from a graphic). 50% inhibition was reached at concentrations between 10 and 15 mM.

In another study, slices from leaves of *Vicia faba* in solutions containing various sodium sulfite concentrations (0.001-10 mM) was investigated. The oxygen uptake was stimulated at concentrations equal or lower than 0.1 mM (12.6 mg Na_2SO_3), higher concentrations had a dramatic inhibiting effect. The evolution of oxygen was inhibited by 20% at 0.01 mM (1.26 mg Na_2SO_3) and by 100% at 0.5 mM (63 mg Na_2SO_3).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (170 mg/L), Daphnia (118 mg/L), and algae (63 mg/L). Long-term results are available for Daphnia (21-day NOEC: >13 mg/L) and algae (EC_{20} = 52 mg/L). On the basis that the data consists of long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported NOEC concentration of 13 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.26 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium sulfite dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium sulfite. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium sulfite to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium sulfite is dominated by its water solubility. Sorption of sodium sulfite should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium sulfite. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium sulfite is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium sulfite is an organic salt that dissociates completely to sodium and sulfite ions in aqueous solutions. Sulfite is also naturally present in the environment, formed from the release of sulfur dioxide by natural and anthropogenic sources. Sulfite is rapidly oxidized to sulfate in water. Biodegradation is not applicable to these inorganic ions; sodium and sulfate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

The sulfite ion is rapidly oxidized to sulfate in water. Both sodium and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium sulfite is not expected to bioaccumulate.

No chronic toxicity data exist on sodium sulfite; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium sulfite does not meet the screening criteria for toxicity.

The overall conclusion is that sodium sulfite is not a PBT substance.

Environmental Assessment

Sodium thiosulfate
(CAS No. 7772-98-7)

Environmental Fate

Ammonium thiosulfate is an inorganic compound that dissociates completely in water. Thiosulfate is a metastable, moderately reducing oxyanion of sulfur. Chemical reactions (redox reactions) of thiosulfate generate chemical species of sulfur that differ in their oxidation state. The thiosulfate anion is only stable in neutral or alkaline media. It is unstable in acid media. In aqueous media, thiosulfate irreversibly disproportionates to sulfide and sulfate. The chemistry of sulfur in soils (and in water) is complex because of its many oxidation states. The terminal, thermodynamically-favored reaction product of thiosulfate is sulfate, except in highly reduced soils (U.S. EPA, 2007).

Aquatic Toxicity

No data are available for sodium thiosulfate. However, studies have been conducted on ammonium thiosulfate, which will be used as read-across to sodium thiosulfate.

The 96-hour LC_{50} of ammonium thiosulfate is 510 mg/L in *Lepomis macrochirus* and 770 mg/L in *Salmo gairdneri*. The 48-hour EC_{50} of ammonium thiosulfate in *Daphnia magna* is 230 mg/L. The 72-hour EC_{50} of ammonium thiosulfate in algae *Pseudokirchneriella subcapitata* is >100 mg/L (NOEC: 100 mg/L).

Toxicity to Terrestrial Plants

Seeds of corn were germinated on ammonium thiosulfate-spiked soil, and effects on germination, root growth and shoot growth were monitored for a 7-day exposure period. Root growth was the most sensitive endpoint, and resulted in a NOEC of 100 mg ATS/kg dry wt. Expressed as thiosulfate, this value becomes 75.7 mg thiosulfate/kg soil.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (510 mg/L), Daphnia (230 mg/L), and algae (100 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ is 0.1 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium thiosulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium thiosulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium thiosulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium thiosulfate is dominated by its water solubility. Sorption of sodium thiosulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium thiosulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium thiosulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium thiosulfate is an organic salt that dissociates completely to sodium and thiosulfate ions in aqueous solutions. Thiosulfate irreversibly disproportionates to sulfide and sulfate in aqueous media, with the terminal, thermodynamically-favored reaction product of thiosulfate being sulfate, except in highly reduced soils. Biodegradation is not applicable to these inorganic ions; sodium and sulfate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Both sodium and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium thiosulfate is not expected to bioaccumulate.

No chronic toxicity data exist on sodium thiosulfate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium thiosulfate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium thiosulfate is not a PBT substance.

Environmental Assessment

Sorbitan Monooelate
(CAS No. 1338-43-8)

Sorbitan fatty acid esters are non-ionic surfactant-active agents that typically find use as emulsifiers, stabilizers and thickeners in foods, cosmetics, medical products, lubricants and other applications (Andersen, 2002; Eisenhard, 1999). Sorbitan monooleate is approved by FDA as an indirect food additive.

The information in this toxicity profile was obtained from the U.S. EPA HPV Test Plan for Sorbitan Esters Category of the Aliphatic Esters Chemicals, November 26, 2003.

Biodegradation

In an OECD 301C test, sorbitan monooleate was degraded 62% in 28 days and did not meet the 10-day window. Thus, it is not readily biodegradable.

Aquatic Toxicity

Sorbitan monooleate caused no mortality in rainbow trout at nominal levels of 1,000 mg/L in an acute 96-hour fish toxicity study. The calculated water solubility of sorbitan monooleate is 0.0191 mg/L. Thus, it appears that sorbitan monooleate would not be expected to cause acute toxicity at its water solubility limit.

The surrogate substance, sorbitan fatty acid C6-10 tetraester (CAS NO. 228573-47-5) has been evaluated in fish, daphnia and algae. The LC_{50} or EC_{50} value was reported to be greater than 1,000 mg/L [nominal loading concentrations in the water accommodated fraction (WAF) solutions tested] in all three aquatic species for this structurally analogous surrogate. The measured water solubility of sorbitan fatty acid C6-10 tetraester is <0.02 mg/L, which would suggest that this surrogate sorbitan ester would not be expected to cause acute aquatic toxicity at its water solubility limit.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available on either sorbitan monoleate or its surrogate sorbitan fatty acid C6-C10 tetraester for all three tropic levels. It was

concluded that sorbitan monooleate would not be expected to cause acute toxicity at its water solubility limit of 0.0191 mg/L. On the basis that the data consists of short-term results from three trophic level, an assessment factor of 1,000 has been applied to the water solubility limit of 0.0191 mg/L. The $PNEC_{aquatic}$ is 1.91×10^{-5} mg/L or 0.0191 μg/L.

Environmental Assessment

Terpenes and Terpenoids
Terpenes and Terpenoids, Sweet Orange Oil
(CAS No. 68647-72-3)

The chemical category designated terpenes and terpenoids are hydrocarbons that can include C_{10} isomeric monocyclic terpene hydrocarbons (*d*-limonene, *dl*-limonene, and terpinolene) and two C_{10} acyclic terpene hydrocarbons (*beta*-myrcene and dihydromyrcene).

Terpenes and terpenoids, sweet orange oil (CAS No. 68647-72-3) is composed of 91-95% d-limonene, 1-3% beta-myrcene, and 1-2% alpha-pinene.

Biodegradation

Terpinolene was found to be biodegradable in two studies. In one study of inherent biodegradability, 80% biodegradation was reported using an OECD 302C guideline protocol after 28 and 31 days. In a study of ready biodegradability, 62.1% biodegradation was reported using an OECD 301B protocol after 28 days. One study of the ready biodegradability of terpinolene by OECD 301F reported it to be not readily biodegradable (51% after 28 days) but the authors concluded that the high vapor pressure and low water solubility of terpene hydrocarbons leads to volatilization in the upper parts of the test vessel, thereby, limiting aerobic biodegradation.

Limonene was readily biodegradable (41-98% degradation by biological oxygen demand in 14 days (OECD 301C).

Aquatic Toxicity

The 96-hour LC_{50}s in fathead minnows for limonene and terpinolene were reported to be 0.702 and 0.720 mg/L, respectively.

The 48-hour EC_{50} for limonene in *Daphnia pulex* was reported to be 69.6 mg/L. However, since the solubility of limonene is 13.8 mg/L at 25^{o}C, the actual test concentration is not known. The 96-hour LC_{50} value for limonene in *Daphnia magna* was reported to be 0.577 mg/L, while the 96-hour $EC_{50}$was 0.421 mg/L. When these tests were repeated using limonene from a different supplier, the 96-hour LC_{50} was 0.924 mg/L. The 48-hour LC_{50} for mycene in *Daphnia magna* was reported to be 31 mg/L and is also considered unreliable given limits of solubility. For terpinolene, the 96-hour LC_{50} was reported to be 2.55 mg/L and the EC_{50} was reported to be 1.38 mg/L.

The 96-hour EC_{50}s for both limonene and terpinolene in green algae are >1.81 and >3.38 mg/L, respectively. Neither limonene nor terpinolene showed any significant inhibition at those test concentrations.

Toxicity to Terrestrial Organisms

The LC_{50} of *d*-limonene to earthworms (*Eisenia foetida* Savigny) is 6.0 ppm. The subacute dietary LC_{50} to Bobwhite quail (Colinus virginianus) is >5,620 ppm.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels for surrogates limonene and terpinolene. Acute $E(L)C_{50}$ values are available for fish (0.702 mg/L), Daphnia (0.421 mg/L), and algae (1.81 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.421 mg/L for Daphnia. The $PNEC_{aquatic}$ is 4.21×10^{-4} mg/L or 0.421 µg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE. Using a Koc of 6324 and a $PNEC_{aquatic}$ of 0.421 µg/L, the $PNEC_{sediment}$ was calculated to be 40 µg/kg (0.040 mg/kg).

$PNEC_{soil}$: Since there is limited experimental toxicity data on terrestrial organisms, the equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE. Using a Koc of 6324 and a $PNEC_{aquatic}$ of 0.421 µg/L, the $PNEC_{soil}$ was calculated to be 35 µg/kg (0.035 mg/kg).

PBT Assessment

This category of terpenes and terpenoids are considered to be readily biodegradable. Thus, terpenes and terpenoids do not meet the screening criteria for persistence.

The experimental log Kow values for d-limonene, terpinolene, beta-mycene and alpha-pinene are 4.38, 4.47, 4.44 and 4.17, respectively. The estimated BCF values using BCFFAF v. 3.01 for d-limonene, terpinolene, beta-mycene and alpha-pinene are 360.5, 413.3, 394.9, and 262 L/kg, respectively. Thus, this category of terpenes and terpenoids do not meet the screening criteria for bioaccumulation.

No chronic toxicity data exist terpenes and terpenoids; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, this category of terpenes and terpenoids do not meet the screening criteria for toxicity.

The overall conclusion is that this category of terpenes and terpenoids is not a PBT substance.

Environmental Assessment

Tetrakis(hydroxymethyl)phosphonium sulfate
(CAS No. 55566-30-8))

Environmental Fate and Transport

Tetrakis(hydroxymethyl)phosphonium sulfate (THPS) has a high water solubility and very low volatility. Photodegradation and hydrolysis of THPS are significant abiotic degradation pathways in the environment. THPS binds poorly to environmental particulates and is, therefore, mobile.

THPS is inherently biodegradable. In an OECD 302B study, greater than 20% degradation occurred within a 28-day period (IPCS, 2000). Aquatic aerobic degradation of THPS was assessed in a soil/water system using U.S. EPA guidelines. The soil was dosed with THPS at 1 μg/g. Radiolabeled THPS was metabolized with 60% of applied radioactivity appearing as CO_2 within 7 days. Major metabolites were trihydroxymethyl phosphine oxide (THPO) and bishydroxymethyl phosphonic acid (BMPA), which were both found in the water; neither degradate reached a concentration of 10% of the applied dose (IPCS, 2000). A comparable study at the same initial concentration of THPS but under anaerobic conditions also showed 60% degradation within 30 days, and the same breakdown products were identified (IPCS, 2000).

Aquatic Toxicity

The acute 96-hour LC_{50} in *Oncorhynchus mykiss* (rainbow trout) is 119 mg/L (IPCS, 2000). The acute 96-hour LC_{50} in (*Lepomis macrochirus*) bluegill sunfish is 93 mg/L (IPCS, 2000). The acute 96-hour LC_{50} in (*Cyprinodon variegatus*) sheepshead minnow is 72 mg/L (IPCS, 2000).

The 48-hour LC_{50} in *Daphnia magna* is 19.4 mg/L (IPCS, 2000).

The 72-hour EC_{50}s in freshwater green algae *Selenastrum capricornutum* are 0.652 mg/L (growth rate) and 0.204 mg/L (biomass). The NOECs were 0.063 mg/L (IPCS, 2000).

Toxicity to Sediment Organisms

No data could be located for freshwater sediment organisms. A 10-day LC_{50} for *Corophium volutator* was reported to be 2,174 mg/kg dry sediment weight (IPCS, 2000).

Toxicity to Terrestrial Organisms

The LD_{50} to mallard duck (*Anas platyryncus*) is 311 mg/kg (IPCS, 2000). The dietary LC_{50}s to mallard ducks and bobwhite quail are 1,313 and 2,414 mg/kg diet, respectively (IPCS, 2000).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (72 mg/L), Daphnia (19.4 mg/L), and algae (0.204 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.204 mg/L for fish. The $PNEC_{aquatic}$ is calculated to be 0.0002 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on freshwater sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated to be 142.3. Using a Koc of 142.3 and a $PNEC_{aquatic}$ of 0.204 µg/L, the $PNEC_{sediment}$ was calculated to be 0.56 µg/kg.

$PNEC_{soil}$: No adequate experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated to be 142.3. Using a Koc of 142.3 and a $PNEC_{aquatic}$ of 0.204 µg/L, the $PNEC_{soil}$ was calculated to be 0.38 µg/kg.

PBT Assessment

The results of BIOWIN v4.10 for THPS are as follows: biodegrade fast (Biowin2); ultimate biodegradation timeframe is days-weeks (Biowin3); and biodegrades fast (Biowin 6). Thus, THPS does not meet the screening criteria for persistence.

The estimated log Kow for THPS using EPISUITE is -20.39. Hydrolysis is also indicated as a significant abiotic degradation process. Thus, THPS does not meet the screening criteria for bioaccumulation.

The NOEC from a 72-hour green algae study was reported to be 0.063 mg/L, which is <0.1 mg/L. Thus, THPS meets the criteria for toxicity.

The overall conclusion is that Tetrakis(hydroxylmethyl)phosphonium sulfate is not a PBT substance.

COFFEE EXTRACT

This dossier on coffee extract does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of coffee extract in its use in hydraulic fracturing fluids. The information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name: Coffee, bean, roasted, extract

CAS RN: 68916-18-7

Molecular formula: UVCB substance

Molecular weight: UVCB substance

Synonyms: Coffee extract; coffee, bean, roasted, extract

Table 1 shows all of the constituents found in roasted arabica and robusta coffees.

Table 1: Composition of Medium-Roasted Coffee (Clarke, 1987; IARC, 1991)

Components	**Typical average content (dry basis, %)**		**% extractable with water, 100°C[a]**
	Arabica	**Robusta**	
Alkaloids (caffeine)	1.3	2.4	75 - 100
Trigonelline (including roasted by-products)	1.0	0.7	85 - 100
Minerals (as oxide ash)	4.5	4.7	90
Acids			
Residual chlorogenic	2.5	3.8	100
Aquinic	0.8	1.0	100
Aliphatic	1.6	1.6	100
Sugars			
Sucrose	0.0	0.0	-
Reducing	0.3	0.3	100

Polysaccharides (unchanged from green)	33	37	10
Lignin	2.0	2.0	0
Pectins	3.0	3.0	-
Proteinaceous compounds			
Protein	10	10	15 – 20
Free amino acids	0.0	0.0	-
Lipids (coffee oil)	17	11	1
Caramelized or condensation products (*e.g.*, melanoidins) by difference	23	22.5	20-25
Volatile substances other than acids	0.1	0.1	40-80

[a]Maier (1981), for normal household brewing

II. PHYSICO-CHEMICAL PROPERTIES

Table 2: Overview of the Physico-chemical Properties of Coffee Extract

Property	**Value**	**Klimisch score**	**Reference**
Physical state at 20°C and 101.3 kPa	Viscous liquid	2	ECHA
Melting point	ca. -16.82 to -15.95°C	1	ECHA
Boiling point	>102.21°C	1	ECHA
Density	1.234 g/cm^3 @ 20°C	1	ECHA
Vapor pressure	21.8 Pa @ 20°C	1	ECHA
Partition coefficient (log K_{ow})	<0.36 @ 25°C	1	ECHA
Water solubility	2.85 mg/L @ 25°C	1	ECHA
Flash point	No flash to boiling.	1	ECHA
Auto flammability	>600°C	1	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Coffee extract is inherently biodegradable and is expected to have a low potential for bioaccumulation. The potential for adsorption is unknown; however, the low octanol water partition coefficient for coffee extract suggests that it is low. The acute toxicity by the oral and dermal routes is low.

B. Biodegradation

Coffee extract is inherently biodegradable. In an OECD 301D test, degradation was 50.2% after 28 days (ECHA) [Kl. score = 1].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for coffee extract. Coffee extract is an UVCB substance containing a wide range of different constituents (see Table 1); thus, a K_{oc} value cannot be calculated.

D. Bioaccumulation

No bioconcentration studies have been conducted on coffee extract. Coffee extract is not expected to bioaccumulate based on the experimental log K_{ow} of <0.36 (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The information on the human health hazard for coffee extract includes primarily data on caffeine, the pharmacologically active constituent of coffee extract, as well as the extract itself. Coffee extract is not irritating to the skin or eyes. Caffeine consumption up to 400 mg caffeine/day in healthy adults is not associated with overt, adverse cardiovascular effects, behavioral effects, reproductive and developmental effects, acute effects, or bone status. Also, consumption up to 300 mg caffeine/day in healthy pregnant women is generally not associated with adverse reproductive and developmental effects.

B. Pharmacokinetics

Caffeine is rapidly and completely adsorbed in humans, with approximately 99% absorbed within 45 minutes of consumption (Carillo and Benitez, 2000). Plasma caffeine levels may be influenced by the diet or route of exposure, but peak plasma levels occur approximately 15 to 120 minutes after consumption (Mandel, 2002; Beach *et al.*, 1984; Bonati *et al.*, 1984; Collomp *et al.*,

1991). Caffeine is water soluble and is rapidly distributed throughout the body, detected in all bodily fluids, including saliva, breast milk, urine and semen (Beach *et al.*, 1984). Caffeine elimination follows first-order kinetics (Newton *et al.*, 1981), with the plasma half-life of caffeine at approximately 3 to 6 hours in healthy adults and does not accumulate in body fat or other tissues (Kaplan *et al.*, 1997; Nawrot *et al.*, 2003). Caffeine is rapidly metabolized and excreted (1-3 mg/kg/minute) in the urine (Kaplan *et al.*, 1997), and varies between species, with a slightly different metabolic route noted in rats (Nawrot *et al.*, 2003).

C. Acute Toxicity

Animal Studies

The oral LD_{50} value of an aqueous extract of roasted and ground beans of *Coffea canephora robusta* containing 7.5% caffeine was between 2,000 and 5,000 mg/kg (ECHA) [Kl. score = 1].

No acute inhalation studies are available on coffee extract. The 4-hour LC_{50} value of a caffeine aerosol in rats is 4.94 mg/L (ECHA) [Kl. score = 2].

No acute dermal studies are available on coffee extract. The dermal LD_{50} value of an aqueous solution of caffeine in rats is >2,000 mg/kg (ECHA) [Kl. score = 2].

Human Studies

Studies in human have focused on caffeine, the pharmacologically active component in coffee. The fatal acute oral dose is estimated at 10 and 14 g (approximately 160 to 230 mg/kg for a 60 kg person) (Hodgman, 1998). The serum caffeine concentration is the most reliable indicator of potential caffeine toxicity, with a serum caffeine concentration >100 μg/ml considered lethal in humans (Mrvos *et al.*, 1989). Human caffeine consumption at up to 10 g has caused convulsions and vomiting, with recovery in six hours (Dreisbach, 1974). An acute dose of one gram caffeine can cause adverse effects, progressing from restlessness, nervousness, and irritability to delirium, emesis, neuromuscular tremors and convulsions (IOM, 2004). However, caffeine consumption through the day at up to 900 mg has been reported without adverse effects (Nawrot *et al.*, 2003).

D. Irritation

Coffee silverskin extracts was not considered a skin irritant when tested in an *in vitro* reconstructed human epidermis test (ECHA) [Kl. score = 1].

Coffee, bean, roasted, extract was not considered an eye irritant when tested in a bovine corneal opacity and permeability test (ECHA) [Kl. score = 1].

E. Sensitization

No studies are available.

F. Repeated Dose Toxicity

<u>Oral</u>

Male and female rats were given in their drinking water 0, 25, 50, or 100% with either instant or brewed coffee for 91 days. The average daily intakes of caffeine were 0, 20, 40, or 80 mg/kg-day for the brewed coffee and slightly lower intakes for the instant coffee. At study termination, the kidneys of the 100% male coffee groups had enlarged kidneys based on both absolute and relative weights. In the females, liver and kidneys were enlarged in all rats given brewed coffee, although the relative weights were significantly higher only in the 100% group. In the ≥50% instant coffee groups, both absolute and relative liver and kidney weights were increased, although there was no clear dose-response pattern. Histopathologic examination showed no treatment-related effects. In the absence of corresponding histopathologic changes, the liver and kidney weight changes were considered to be adaptive changes and not adverse. The NOAEL for this study is 100% coffee in drinking water, which corresponds to 80 mg/kg-day (Nolen, 1981; ECHA) [Kl. score = 2].

In an NTP study, male and female F344 rats were dosed by oral gavage with 0, 188, 375, 750, 1,500, or 3,000 ppm caffeine for 90 days. The average daily intakes were: 0, 19.7, 42, 85.4, 151, or 272 mg/kg-day for males; and 0, 23, 51, 104, 174, or 287 mg/kg-day for females). Body weight gain was reduced in all treated groups but was only significant in the 3,000 ppm animals (26% and 20% for males and females, respectively). Water consumption was decreased in the 3,000 ppm animals; it was increased in the 375 and 750 ppm groups. The only treatment-related effects observed was cellular enlargement in the salivary gland, which was dose-dependent. This effect in the salivary gland was considered an adaptive response as a result of the pharmacological effect of caffeine (sympathomimetic) and not an adverse effect. The NOAEL for this study is 1,500 ppm, which corresponds to 151 and 174 mg/kg-day for males and females, respectively (ECHA) [Kl. score = 2].

Inhalation

No studies are available.

Dermal

No studies are available.

G. Genotoxicity

In Vitro Studies

Instant and home brew coffees (caffeinated and decaffeinated) were evaluated for genotoxicity in an in vitro chromosomal aberration test using human lymphocytes with or without metabolic activation (S9 mix). Chromosomal aberrations were increased with all coffee samples with or without S9, although there was less of an increase with S9. Pure caffeine tested with or without S9 at doses equivalent to the levels in the caffeine-containing coffees did not induce a statistically significant increase in chromosomal aberrations (Aeschbacher et al., 1985; ECHA) [Kl. score 2].

Instant and home brew coffees (caffeinated and decaffeinated) were evaluated for mutagenicity in an in vitro bacterial reverse mutation assay with or without metabolic activation (S9 mix). The *S. typhimurium* strains were TA 98, TA 100, TA1535, TA 1537, and TA 1538. A mutagenic response was observed with TA 100 in the absence of S9, but not with S9. None of the other

strains showed a mutagenic response with or without S9 (Aeschbacher and Würzner, 1980; ECHA) [Kl. score = 2].

Five Americano coffees from selected coffee chains were evaluated for mutagenicity in an in vitro bacterial reverse mutation assay with or without metabolic activation (S9 mix). The *S. typhimurium* strains were TA 98, TA 100, and TA 1535. There were no mutagenic responses with or without metabolic activation (Liu et al., 2017; ECHA) [Kl. score = 2].

In Vivo Studies

Male Swiss OF-1 mice were dosed by oral gavage with 0, 500, 1,000, 2,000, or 3,000 mg/kg instant coffee for five consecutive days. There was no treatment-related increase in the frequency of micronuclei in bone marrow cells (Aeschbacher et. al., 1984 ECHA) [Kl. score = 2].

H. Carcinogenicity

No carcinogenicity studies are available.

I. Reproductive/Developmental Toxicity

Animal Studies

A one-generation reproductive toxicity study was conducted in rats. Male and female rats were given in their drinking water 0, 25, 50, or 100% with either instant or brewed coffee. The average daily intakes were 0, 20, 40, or 8 mg/kg-day for the brewed coffee and slightly lower intakes for the instant coffee. Exposure of parental animals were for 91 days and during mating. Exposure continued through the first gestation period and through weaning. Ten days later, the females were mated the second time and were sacrificed on GD 13 or 21. There were no indications of reproductive or developmental toxicity (Nolen, 1981; ECHA) [Kl. score = 2].

Human Studies

Studies in human have focused on caffeine, the pharmacologically active component in coffee. Studies that evaluated the potential teratogenicity of caffeine have been discussed in a review (Christian and Brent, 2001). In animal studies, caffeine administration to pregnant animals has been found to induce teratogenicity and toxic effects on the development of the fetuses only at doses that also caused toxic effects in the dams (Christian and Brent, 2001). Christian and Brent (2001) concluded that studies reporting positive teratogenic effects were administering large doses of caffeine that were far greater than human consumption and were providing the caffeine via gavage, which results in much higher peak serum caffeine levels and therefore overstates toxicity potential. Neither rodents nor humans could attain such peak exposures by consuming solutions of caffeine over several hours, the usual mode of human caffeine consumption.

There have been questions raised on whether high intake of coffee or caffeine may increase the risk of miscarriage. Caffeine crosses the placenta and increases maternal catecholamine levels (Goldstein and Warren, 1962). The American College of Obstetricians and Gynecologists (2010) have concluded the following: “Moderate caffeine consumption (less than 200 mg per day) does not appear to be a major contributing factor in miscarriage or preterm birth. The relationship of

caffeine to growth restriction remains undetermined. A final conclusion cannot be made at this time as to whether there is a correlation between high caffeine intake and miscarriage."

The American College of Obstetricians and Gynecologists (2010) have concluded that moderate caffeine consumption (<200 mg/day) does not appear to be a major contributing factor in miscarriage or preterm birth.

A recent systematic review of the potential adverse effects of caffeine consumptions in humans concluded that consumption up to 400 mg caffeine/day in healthy adults is not associated with reproductive and developmental effects. Also, consumption up to 300 mg caffeine/day in healthy pregnant women is generally not associated with adverse reproductive and developmental effects (Wikoff et al., 2017).

J. Human Studies

Caffeine is a stimulant and has been studied for its physiological and behavioral effects. Caffeine increases heart rate and blood pressure, increases diuresis, increases locomotion and alertness, and decreases sleepiness. Clinical studies indicate that doses <450 mg do not increase the risk or severity of cardiac arrhythmia, while acute doses of 150 mg caffeine may decrease heart rate (James, 1991; Green *et al.*, 1996; Myer, 1998). Studies evaluating effects of caffeine on cardiovascular health or serum cholesterol levels have not provided a consistent adverse effect with caffeine consumption (Nawrot *et al.*, 2003).

Nawrot *et al.* (2003) concluded in their review of the effects of caffeine on human health that "for the healthy adult population, moderate daily caffeine intake at a dose level up to 400 mg/day (equivalent to 6 mg/kg body weight/day in a 65-kg person) is not associated with adverse effects such as general toxicity, cardiovascular effects, effects on bone status and calcium balance (with consumption of adequate calcium), changes in adult behavior, increased incidence of cancer and effects on male fertility." It was indicated that habitual daily use of caffeine at greater than 500-600 mg/day (8.3 - 10 mg/kg) (4-7 cups of coffee or 7-9 cups of tea) could be considered a health risk. For women, caffeine intake greater than 400 mg/day (6.7 mg/kg) "may increase the risk of detrusor instability (unstable bladder) development in women" (Nawrot *et al.*, 2003).

A recent systematic review of the potential adverse effects of caffeine consumptions in humans also concluded that consumption up to 400 mg caffeine/day in healthy adults is not associated with overt, adverse cardiovascular effects, behavioral effects, acute effects or bone status (Wikoff et al., 2017).

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for coffee extract follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

<u>Oral</u>

A 90-day drinking water study on brewed and instant coffee reported no adverse effects up to 80 mg/kg-day (Nolen, 1982). A NTP 90-day oral gavage toxicity study in rats showed no adverse effects up to 174 mg/kg-day (NTP).

In two separate reviews (Nawrot et al., 2003; Wikoff et al., 2017) with the most recent one conducted using a systematic review approach (Wikoff et al., 2003), caffeine consumption in healthy adults up to 400 mg/day is not associated with any adverse health effects. Based on the acceptable daily intake of caffeine in coffee extract, the acceptable daily intake of caffeine of 400 mg/day will be used to derive the oral reference dose and drinking water guidance value for coffee extract.

Oral Reference Dose (oral RfD)

For a 70 kg person, the oral reference dose is 400/70 = 6 mg/kg-day.

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (5.7 x 70 x 0.1)/2 = <u>20 mg/L</u>

B. Cancer

No studies are available. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Coffee extract does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Coffee extract has a low acute toxicity concern for aquatic life.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on coffee extract.

Table 3: Acute Aquatic Toxicity Studies on Coffee Extract

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LL_{50}	>100 WAF	1	ECHA
Daphnia magna	48-hr EL_{50}	>100 WAF	1	ECHA
Pseudokirchneriella subcapitata	72-hr EL_{50}	>100 WAF (growth)	1	ECHA

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for coffee extract follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)L_{50}$ values are available for fish (>100 mg/L WAF), invertebrates (>100 mg/L WAF), and algae (>100 mg/L WAF). On the basis that the data consist of short-term results from three trophic levels, an assessment factor of 100 has been applied to the acute $E(L)L_{50}$ value of 100 mg/L WAF from fish, invertebrates, and algae. The $PNEC_{water}$ is 1 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. The $PNEC_{sed}$ was not calculated using the equilibrium partitioning method because the K_{oc} value cannot be determined.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. The $PNEC_{soil}$ was not calculated using the equilibrium partitioning method because the K_{oc} value cannot be determined.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008). Coffee extract is not readily biodegradable, but it does appear to be inherently biodegradable; thus, it is not expected to meet the screening criteria for persistence.

Based on a measured log K_{ow} of <0.36, coffee extract does not meet the screening criteria for bioaccumulation.

There are no chronic aquatic toxicity studies on coffee extract. The acute $E(L)L_{50}$ values for coffee extract are >1 mg/L for fish, invertebrates, and algae. Thus, coffee extract does not meet the screening criteria for toxicity.

The overall conclusion is that coffee extract is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water. If easy to do, remove contact lenses.

Skin Contact
Take off contaminated clothing immediately. Wash thoroughly with soap and water. Get medical attention if irritation develops and persists.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention.

Ingestion
Rinse mouth with water and then drink a glass of water. Get medical attention. Do not induce vomiting. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon oxides, nitrogen oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use personal protective clothing.

Environmental Precautions
Do not empty into drains.

Steps to be Taken if Material is Released or Spilled
For small amounts: Pick up with absorbent material. Dispose of contaminated material. For large amounts: pump off product.

D. STORAGE AND HANDLING

General Handling
No special measures necessary provided product is used correctly.

Storage
Keep container tightly closed and dry. Store in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure limit for coffee extract.

Engineering Controls
None

Personal Protection Equipment

Respiratory Protection: Respiratory protection not required.

Hand Protection: Wear chemical resistant protective gloves.

Skin Protection: Body protection must be chosen depending on activity and possible exposure.

Eye protection*:* Wear safety goggles with side shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Coffee extract is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

APPENDIX G.3 HALLIBURTON CLEANSTIMAU

Environmental Assessment

Aluminum sulfate
(CAS No. 10043-01-3)

This environmental assessment on aluminum sulfate has been extracted from the 2010 Priority Substances List Assessment Report. Follow-up to the State of the Science Report, 2000 for Aluminum Chloride, Aluminum Nitrate, Aluminum Sulphate, prepared by Environment Canada and Health Canada (Canada, 2010). The report can be downloaded from: http://www.ec.gc.ca/lcpe-cepa/default.asp?lang=En&n=491F0099-1

Aluminum sulfate, also know as alum, has the chemical formula is $Al_2(SO_4)_3$. It is often represented as $Al_2(SO_4)_3 \cdot 14H_2O$. It may be found in different hydrated forms. The commercial product, called cake alum or patent alum, is an octadecahydrate aluminum sulfate, $Al_2(SO_4)_3 \cdot 18H_2O$.

Aluminum sulfate is used primarily as a coagulant and flocculant in water and wastewater treatment.

Aluminum sulfate, which is highly soluble, will form various dissolved species on contact with water. A wide variety of environmental parameters will affect the speciation and solubility of aluminum. These parameters include pH, solution temperature, dissolved organic carbon (DOC) content, and the presence and concentrations of numerous ligands.

Aluminum in solution can be present in several different forms: as dissolved complexes, as "free" ions, in association with particles, as colloids or as solids in the process of precipitating. Two general types of ligands can form strong complexes with aluminum in solution: inorganic ligands such as sulfate, fluoride, phosphate, bicarbonate and hydroxide; and organic ligands such as oxalic, humic and fulvic acids. DOC will complex with aluminum in water, forming aluminum-organic complexes and reducing concentrations of monomeric forms of aluminum.

At low pH values, dissolved aluminum is present mainly in the "free" ion form (Al^{3+}). Hydrolysis occurs as pH rises, resulting in a series of less soluble hydroxide complexes (e.g., $Al(OH)^{2+}$, $Al(OH)_2^{+}$). Aluminum solubility is at a minimum near pH 6.5 at 20°C and then increases as the anion, $Al(OH)_4^-$, begins to form at higher pH (Driscoll and Schecher 1990; Witters et al. 1996). Thus, at 20°C and pH < 5.7, aluminum is present primarily in the forms Al^{3+} and $Al(OH)^{2+}$. In the pH range 5.7 to 6.7, aluminum hydroxide species dominate, including $Al(OH)^{2+}$ and $Al(OH)_2^{+}$, and then $Al(OH)_3$. Typically, at a pH of approximately 6.5, $Al(OH)_3$ predominates over all the other species. In this range, aluminum solubility is low, and availability to aquatic biota should also be low. At pH > 6.7, $Al(OH)_4^-$ becomes the dominant species.

For metals such as aluminum, the "free" or hydrated dissolved ions (i.e., Al^{3+}, $Al(OH)^{2+}$ and $Al(OH)_2^{+}$) are normally considered to be the principal bioavailable forms (Newman and Jagoe, 1994).

Bioaccumulation

Fish accumulate aluminum in and on the gill, and it has been suggested that the rate of transfer of aluminum into the body is either slow or negligible under natural environmental conditions (Spry and Wiener, 1991). The initial uptake of aluminum by fish occurs mainly on the gill mucous layer (Wilkinson and Campbell, 1993); both mucus and bound aluminum may be rapidly eliminated following exposure. Roy (1999) calculated the BCFs in fish to range from 400 to 1,365.

The BCF for *Daphnia magna* varied from 10,000 at pH 6.5 to 0 at pH 4.5, based on the results of Havas (1985). Most of the metal appears to be adsorbed to external surfaces and is not internalized (Havas 1985; Frick and Hermann 1990).

The accumulation of aluminum by the algae *Chlorella pyrenoidosa* increased with the concentration of inorganic monomeric aluminum (Parent and Campbell, 1994). A comparison of assays performed at different pH values but at the same concentration of aluminum showed suppression of that aluminum accumulation at low pH.

Aquatic Toxicity

There are several comprehensive reviews of the aquatic toxicity of aluminum (ATSDR, 2008; Bélanger *et al.*, 1999; Roy 1999). Below is a brief summary of the literature that is relevant for hydraulic fracturing fluids.

The primary target organ for aluminum in fish is the gills (Dussault *et al.*, 2001). Aluminum binds to the gill surface, causing swelling and fusion of the lamellae and increased diffusion distance for gas exchange (Karlsson-Norrgren *et al.*, 1986; Tietge *et al.*, 1988). The resulting damage leads to loss of membrane permeability, reduced ion uptake, loss of plasma ions, and changes in blood parameters relating to respiration. Fish death may result from ionoregulatory or respiratory failure, or a combination of both, depending upon the pH of the water and concentration of waterborne aluminum (Neville 1985; Booth *et al.*, 1988; Gensemer and Playle, 1999). Aluminum exposure may also disrupt ionic balance and osmoregulation in aquatic invertebrates (Otto and Svensson 1983).

Most aquatic toxicity studies involving aluminum have been conducted under conditions of low pH, and a number of these accounted for the solubility of the metal in the experimental design. The general conclusion of these studies is that aluminum toxicity is related to the concentration of dissolved inorganic monomeric aluminum (Roy 1999). At pH 6.0 to 6.5, there are few studies that provide effects estimates in terms of inorganic

monomeric aluminum. At pH6.0, a LOEC of 8µg/L (inorganic monomeric aluminum) for growth of the alga *C. pyrenoidosa* can be estimated from the data of Parent and Campbell (1994). Growth of the alga was reduced at this single exposure concentration in media without phosphate. This LOEC is, however, well within the likely range of natural concentrations of inorganic monomeric aluminum in surface water. In comparison, Neville (1985) observed that 75 µg Al/L (as inorganic monomeric aluminum) caused physiological distress to rainbow trout (*Oncorhynchus mykiss*) at pH 6.1 but not at pH 6.5.

At pH 6.5 to 8.0, there are also few effects data available. At neutral or near-neutral pH, aluminum has a tendency to precipitate, and the chemistry of these solutions is difficult to control. While the toxicity of alum in neutral-pH waters has been the subject of many studies, the results are unreliable, due to extreme variation between replicates of the same exposure concentration and between duplicate experiments. However, a No-Observed-Effect Concentration (NOEC) for respiratory activity at pH 6.5 is provided by the results of the study by Neville (1985), who found that rainbow trout tolerated 75 µg Al/L (as inorganic monomeric aluminum) during exposures at this pH. Wold *et al.* (2005) reported a LOEC of 0.05 mg/L Al for reduced survival and reproduction in *Daphnia pulex* exposed for 21 days to concentrations ranging from 0.05 to 0.50 mg Al/L (nominal) as aluminum sulfate. The test water was maintained at a pH of 7 ± 1, suggesting that the observed effects were due to the presence of aluminum hydroxide rather than the dissolved inorganic monomeric aluminum that is usually associated with toxicity.

At pH > 8.0, LOECs for survival of rainbow trout are ≥ 1.5 mg/L as total aluminum (Freeman and Everhart, 1971). In a more recent study, Gundersen *et al.* (1994) reported LC_{50}s for exposures of rainbow trout in the pH range 8.0–8.6. The LC_{50}s at all pHs were approximately the same value, ~ 0.6 mg/L (range: 0.36–0.79 mg/L) as dissolved aluminum (*i.e.*, filterable through a 0.4-µm filter), and were similar in both acute (96-hour) and longer- term (16-day) exposures at hardness levels ranging from 20 to 100 mg/L (as calcium carbonate). A NOEC for mortality of 0.06 mg dissolved Al/L can be derived from data given for one of the 16-day exposures conducted at 20 mg/L hardness and pH 8.0. Although these concentrations were measured as dissolved aluminum, it is probable that the monomeric aluminate ion, AlO_4^- predominated at this pH.

PNEC calculations

Dissolved inorganic monomeric aluminum is considered to have the highest bioavailability to aquatic species and to present the greatest risk of adverse effects to pelagic organisms.

The data from Neville (1985) provides a NOEC of 0.075 mg/L as inorganic monomeric aluminum, based on the absence of deleterious effects on ventilation and respiratory activity of rainbow trout at pH 6.5. This chronic toxicity value is considered valid for the pH range 6.5–8.0.

A second chronic toxicity value for alkaline conditions (pH > 8.0) is based on the work of Gundersen *et al.* (1994), who determined similar LC_{50}s (~0.6 mg dissolved Al/L) during several experiments in the pH range 8.0–8.6 and water hardness range 20 to 100 mg/L (as calcium carbonate). A NOEC for mortality of 0.06 mg dissolved Al/L can be derived for rainbow trout from data given for one of the 16-day exposures at 20 mg/L hardness and pH 8.0. The chemical concentrations in Gundersen *et al.* (1994) are expressed as "total" and "dissolved" aluminum; there was no attempt to identify the forms of dissolved aluminum present. At the experimental pH, it is probable that a good proportion of the dissolved aluminum was the monomeric aluminate ion as the predominant species.

It is possible that effects may be elicited at concentrations below that of the selected chronic toxicity value of 0.06 mg/L Wold *et al.* (2005) reported a 21-day LOEC for reduced survival and reproduction in *Daphnia pulex* at a lowest test concentration of 0.05 mg/L. Testing was conducted at a pH of 7 ± 1, suggesting that the observed effects were due to the presence of aluminum hydroxide rather than the dissolved inorganic monomeric aluminum that is usually associated with toxicity.

In determining Predicted No-Effect Concentrations (PNECs) for aluminum, the nature of the biological response was considered, since some organisms respond to a narrow aluminum concentration range. This results in an abrupt "threshold" where an evident biological response occurs, with no observable effects at slightly lower concentrations (Hutchinson *et al.* 1987; Roy and Campbell 1995). Consequently, since the chronic toxicity value chosen is a NOEC, the application factor used to derive a PNEC from the chronic toxicity value was 1.

The $PNEC_{aquatic}$ for Al is 0.06 mg/L.

PBT Assessment

Aluminum sulfate is an organic salt that dissociates in water to form sulfate ions and various species of dissolved aluminum. Biodegradation is not applicable to aluminum sulfate. Both sulfate and aluminum can be found naturally in the environment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Fish accumulate aluminum in and on the gill, and it has been suggested that the rate of transfer of aluminum into the body is either slow or negligible under natural environmental conditions. Sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, aluminum sulfate (or its dissolved species) is not expected to bioaccumulate.

The chronic NOEC value in fish for aluminum is <0.1 mg/L; thus, the dissolved aluminum from aluminum sulfate meets the screening criteria for toxicity.

The overall conclusion is that aluminum sulfate is not a PBT substance.

Environmental Assessment

Cellulase
(CAS No. 9012-54-8)

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity.

Biodegradation

Three different cellulase enzymes were considered readily biodegradable based on the results of OECD 301C and 301E tests (HERA, 2005). In an OECD 301E test, there was 84% DOC removal of the enzyme Carezyme after 28 days. In another OECD 301E test, there was 92% DOC removal of the enzyme Clazinase® after 28 days. In an OECD 301C test, BOD/COD was 78% after 28 days.

Aquatic Toxicity

The 96-hour LC_{50} of an alkaline cellulase to zebrafish (*Brachydanio rerio*) is 330 mg aep/L (HERA, 2005). The 48-hour EC_{50} of the same alkaline cellulase to *Daphnia magna* was reported to be >1,000 mg aep/L (HERA, 2005). The same alkaline cellulase was also tested in algae (*Scenedesmus subspicatus*), with a 72-hour EC_{50} of >1000 mg aep/L (HERA, 2005).

The 24- and 48-hour EC_{50} values of an alkaline cellulase (SP 227, Celluzyme) to *Daphnia magna* were reported to be >1,000 mg aep/L and approximately 1,000 mg aep/L respectively (HERA, 2005).

Two additional acute fish toxicity studies showed findings with LC_{50} values of >100 mg aep/L, but no references were provided (HERA, 2005).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (330 mg aep/L), Daphnia (>1,000 mg aep/L), and algae (1,000 mg aep/L). Although the HERA report provides information on two acute fish studies with LC_{50} values of >100 mg aep/L, no references were provided and were therefore excluded from the determination of PNECs. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 330 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.33 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{sediment}$ was calculated to be 0.21 mg aeg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{soil}$ was calculated to be 0.006 mg aeg/kg.

PBT Assessment

Cellulase is readily biodegradable and thus does not meet the screening criteria for persistence.

Cellulase has a high molecular weight (20 to 80 kD), has hydrophilic properties (high water solubility, log Kow <0), and is readily metabolized in organisms by proteolytic enzymes or proteases. Thus, it does not meet the screening criteria for bioaccumulation.

The acute $EC(L)_{50}$ of cellulase is >0.1 mg/L in fish, invertebrates and algae. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that cellulase is not a PBT substance.

Environmental Assessment

Lactose
(CAS No. 63-42-3)

Lactose is a disaccharide sugar composed of galactose and glucose. It is naturally synthesized in the mammary gland of virtually all mammals, occurring in milk at levels between 1 and 7%. Commercially, lactose is extracted from the whey of cow's milk (whey is the residual liquid of milk following cheese and casein production) and is purified extensively to remove fats, proteins, vitamins and minerals (Baldrick and Bamford, 1997; Goodhart, 1994).

Biodegradation

No biodegradation studies were found on lactose. The QSAR model BIOWIN estimates that the biodegradation of lactose would be fast, with primary degradation in hours-days and ultimate degradation in days-weeks (U.S. EPA, 2011).

Aquatic Toxicity

No aquatic toxicity studies were found on lactose.

Using ECOSAR, the 96-hour LC_{50} in fish was estimated to be 81,045 mg/L; the 48-hour LC_{50} in *Daphnia* was estimated to be 3,460,000 mg/L; and the 96-hour EC_{50} in green algae was estimated to be 583,000 mg/L (U.S. EPA, 2011).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: No experimental results are available for lactose. Acute $E(L)C_{50}$ estimates using the QSAR model ECOSAR are: fish (81,045 mg/L), Daphnia (3,460,000 mg/L), and algae (583,000 mg/L). On the basis that the data consists of short-term results from

three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 81,045 mg/L for fish. The $PNEC_{aquatic}$ is 81 mg/L.

PBT Assessment

No experimental biodegradation data are available on lactose. The QSAR model BIOWIN predict that lactose will biodegrade fast, with primary degradation in hours-days and ultimate degradation in days-weeks. Thus, lactose does not meet the screening criteria for persistence.

The estimated log K_{ow} and BCF for lactose is -5.03 and 3.162, respectively (U.S. EPA, 2011). Thus, lactose does not meet the screening criteria for bioaccumulation.

The estimated acute $EC(L)_{50}$ values of lactose indicate that it is non-toxic to fish, invertebrates and algae. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that lactose is not a PBT substance.

Environmental Assessment

Maltodextrin
(CAS No. 9050-36-6)

Maltodextrin is a nonsweet nutritive saccharide polymer that consists of D-glucose units linked primarily by $\alpha,1\rightarrow4$ bonds and that has a dextrose equivalent (D.E.) of <20. Typical commercial maltodextrins contain as few as three and as many as nineteen linked dextrose units. It is prepared as a white powder or concentrated solution by partial hydrolysis of corn starch, potato starch, or rice starch with safe and suitable acids and enzymes.

Biodegradation

No specific biodegradation studies could be found on maltodextrin. However, it is biopolymer that is readily broken down in the gastrointestinal tract of mammals by bacteria. Thus, it is expected to be readily biodegradable in the environment.

Aquatic Toxicity

No aquatic toxicity studies were found on maltodextrin. However, some of the smaller polymeric chains have molecular weights of <1,000 and are thus bioavailable. D-glucose, the monomeric units of maltodextrin, are found naturally in aquatic organisms and play a beneficial role. Thus, maltodextrin is not expected to be toxic to aquatic organisms.

Determination of PNECs

No aquatic toxicity data could be found on maltodextrin. Thus, PNECs were not determined.

PBT Assessment

Maltodextrin is expected to be readily biodegradable and thus would not be expected to meet the screening criteria for persistence.

The molecular weights of maltodextrin can be <1,000 and are thus bioavailable to aquatic organisms. Maltodextrin is water-soluble and composed of D-glucose monomeric units; which are naturally occurring in the body. Thus, maltodextrin is not likely to meet the screening criteria for bioaccumulation.

No aquatic toxicity data could be found on maltodextrin. However, D-glucose, the monomeric units of maltodextrin, are found naturally in aquatic organisms and play a beneficial role. Thus, maltodextrin is not expected to meet the screening criteria for toxicity.

The overall conclusion is that maltodextrin is not a PBT substance.

Environmental Assessment

Potassium chloride
(CAS No. 7447-40-7)

Potassium chloride (KCl) has been reviewed in the OECD-SIDS program (OECD, 2001a,b).

Environmental Fate

KCl is a solid inorganic salt that is highly soluble in water (342 g/L at 20^{o} C). Potassium chloride fully dissociates in aqueous solutions to K^+ and Cl^- ions.

KCl, either as an inorganic salt or as K^+ and Cl^- ions, is ubiquitous in the environment. There is no potential for bioaccumulation or bioconcentration. Potassium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated.

Aquatic Toxicity

In a guideline study, the 96-hour LC_{50} in *Pimephales promelas* was reported to be 880 mg/L (Mount *et al.*, 1997). The 48-hour LC_{50} values from two studies on *Lepomis macrochirus* (Patrick *et al.*, 1968; Trama, 1954), and one study each on *Oncorhyncus mykiss* and *Ictalurus punctatus* (Waller *et al.*, 1993) ranged from 720 to 2,010 mg/L.

In a guideline study, the 48-hour EC_{50}s in *Daphnia magna* and *Ceriodaphnia dubia* were 660 and 630 mg/L, respectively (Mount *et al.*, 1997; ECHA REACH database). The 48-hour EC_{50} in *Daphnia magna* in another study was also reported to be 177 mg/L (Biesinger and Christensen, 1972).

The toxicity of KCl has been investigated in one algae species (*Nitzschia linearis*), showing 120 hour-EC_{50} (growth rate) of 1,337 mg/L (Patrick *et al.*, 1968). The 72-hour EC_{50} to *Scenedesmus subspicatus* is >100 mg/L (growth rate), with a NOEC of $\geq$100 mg/L (ECHA REACH database).

In a fish early-life-stage test with the fathead minnow (*Pimephales promelas*), the 7-day NOEC is 500 mg/L (ECHA REACH database). A long term (21-day) study has been performed on *Daphnia magna* where effects on reproduction were investigated for several metals. A 16% impairment of reproduction (LOEC) was observed at a concentration of 53 mg/L of K +, equal to KCl concentration of 101 mg/L (Biesinger and Christensen, 1972).

Toxicity to Terrestrial Organisms

Potassium is one of the three major nutrients and chloride is an essential micronutrient for plants. No data could be located on the toxicity to terrestrial organisms.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (720 mg/L), Daphnia (177 mg/L), and algae (>100 mg/L). Although chronic studies has been conducted on fish and invertebrates, these tests are not valid for deriving PNECs (ECHA REACH database). On the basis of the short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ is determined to be 0.1 mg/L.

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Potassium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as potassium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of potassium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of potassium chloride is dominated by its water solubility. Sorption of potassium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as potassium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, potassium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Potassium chloride is an organic salt that dissociates completely to potassium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and chloride ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Potassium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, potassium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on potassium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, potassium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that potassium chloride is not a PBT substance.

Environmental Assessment

Shellac, Ammonium salt
(CAS No. 68308-35-8)

Lac is the hardened resinous secretion of the insesct *Kerria lacca* (Douglas, 1971; CIR, 1986). The secreted lac or sticklac contains lac resin, erythrolaccin, wax, inset debris, wood materials, sand, dust and water-soluble impurities. The semirefined seedlac of commerce is the yellowish granular material obtained from the processing of sticklac (Douglas, 1971; Misra and Sengupta, 1970; CIR, 1986).

Unrefined shellac can contain shellac wax and erythrolaccin (the yellow material), which both comprise about 6% of Shellac (CIR, 1986). The removal of these constituents yields lac resin that has a soft (30%) and hard (70%) components (CIR, 1986). Mild alkaline hydrolysis of this resin results in a complex mixture of hydroxyaliphatic and alicyclic acids and their polyesters. The composition of the mixture varies with the lac source and the time of collection (CIR, 1986).

The major component of the aliphatic fraction is aleuritic acid. The alicyclic fraction consists of sesquiterpenic acids, primarily jalaric acid and its derivatives. The native form of the pure lac resin molecule has a molecular weight of 2,095, which contains four terpene acids (mostly jalaric acid) and four aleuritic acid units in repeating ester linkage (Singh *et al.*, 1974). The proposed structure for lac resin respresents an average situation since the molecule may not always be homogenous with respect to sequence or ratio of jalaric acid to other sesquiterpenic acid substitutes (Singh *et al.*, 1974). The sesquiterpenic acids in lac resin are jalaric acid, shellolic acid, epishellolic acid, laksholic acid, and epilaksholic acid.

Aqueous shellac solutions can be prepared by neutralization with ethanolamines, alkalies, or borax (CIR, 1986).

Biodegradation

No data were found. As a natural resin, it is expected to be resistant to biodegradation.

Aquatic Toxicity

No data were found. Given that the molecular weight of the pure lac resin molecule is on average ~2,000 and that it is insoluble in water at environmentally relevant pHs, it is not expected to be bioavailable; this resin is thus expected to be non-toxic to aquatic organisms.

Toxicity to Sediment Organisms

No data were found.

Toxicity to Terrestrial Organisms

No data were found.

Determination of PNECs

PNECs were not determined since no aquatic toxicity data are available.

PBT Assessment

Shellac, ammonium salt is a natural resin and is not expected to readily biodegradable. Thus, it meets the screening criteria for persistence.

Shellac, ammonium salt has a high molecular weight (~2,000) and is insoluble in water at environmentally relevant pHs. It is not expected to be bioavailable and thus, it does not meet the screening criteria for bioaccumulation.

There are no aquatic toxicity in which to evaluate the aquatic toxicity of shellac, ammonium salt. It has, however, a high molecular weight (~2,000) and is also insoluble in water at environmentally relevant pHs; it is not expected to be bioavailable. Thus, shellac, ammonium salt is not expected to meet the screening criteria for toxicity.

The overall conclusion is that shellac, ammonium salt is not a PBT substance.

Environmental Assessment

Sodium Carboxymethyl Cellulose
(CAS No. 9004-32-4)

Sodium carboxycellulose is the sodium salt of carboxymethylcellulose. Carboxymethyl cellulose is a cellulose derivative with carboxymethyl groups (-CH_2COOH) bound to some of the hydroxyl groups of the glucopyranose monomers that make up the cellulose backbone.

Carboxymethyl cellulose (CMC) is a water-soluble semisynthetic polymer in which part of the hydroxyl groups of cellulose has been replaced at random by carboxymethyl groups. Carboxymethyl cellulose is therefore composed of eight different glucose units, namely one unsubstituted, three monosubstituted, three disubstituted, and one trisubstituted. The average number of carboxymethyl groups per glucose unit is denoted by the degree of substitution (DS). Carboxymethyl cellulose with a DS ranging from 0.4 to 1.3 has become the largest industrial cellulose ether because of its versatile applications in, for example, detergents and oil drilling. "

Biodegradation

Carboxymethyl cellulose (DS 0.7) showed 25% biodegradation after 28 days in a OECD 301A test. Thus, sodium carboxymethyl cellulose is not readily biodegradable. Other studies have also shown partial degradation of carboxymethyl cellulose in ready and inherent biodegradability tests.

Aquatic Toxicity

Carboxymethyl cellulose has been tested in several acute aquatic toxicity tests. The 96-hour LC_{50} for *Brachydanio rerio* is >2,500 mg/L; the 48-hour LC_{50} for *Daphnia magna* is >5,000 mg/L; and the 96-hrourEC_{50} for *Selenastrum capricornutum* is 500 mg/L.

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>2,500 mg/L), Daphnia (>5,000 mg/L), and algae (>500 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 500 mg/L for algae. The $PNEC_{aquatic}$ is 0.5 mg/L.

PBT Assessment

Sodium carboxymethyl cellulose is a water-soluble semisynthetic polymer and is not readily biodegradable. Thus, it meets the screening criteria for persistence.

Sodium carboxymethyl cellulose is a water-soluble semisynthetic polymer and is expected to have a molecular weight of >1,000 which limits its bioavailability to aquatic organisms. Thus, it is not expected to bioaccumulate.

The acute $EC(L)_{50}$ of sodium carboxymethylcellulose is >0.1 mg/L in fish, invertebrates and algae. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that sodium carboxymethylcellulose is not a PBT substance.

Environmental Assessment

Sodium chloride
(CAS No. 7647-14-5)

Sodium chloride will dissociate in aqueous solutions to sodium and chloride ions.

Determination of PNECs

$PNEC_{aquatic}$: Not determined.

$PNEC_{sediment}$: Sodium chloride dissociates completely in water with its environmental distribution dominated by its high water solubility. Kow and Koc are parameters that do not readily apply to inorganics, such as sodium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on its properties, no adsorption of sodium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: Sodium chloride dissociates completely in water with its environmental distribution idominated by its high water solubility. Kow and Koc are parameters that do not readily apply to inorganics, such as sodium chloride. Based on its properties, no adsorption of sodium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium chloride is an organic salt that dissociates completely to sodium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and chloride ions are also ubiquitous and are present in most water, soil and sediment. The persistent criteria is not considered applicable to this inorganic salt.

Sodium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on sodium chloride; the acute $EC(L)_{50}$s are expected to be >0.1 mg/L in fish, invertebrates and algae based on aquatic toxicity studies involving sodium and chloride ions. Thus, sodium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that sodium chloride is not a PBT substance.

Environmental Assessment

Sodium Lauryl Sulfate
(CAS No. 151-21-3)

Sodium lauryl sulfate has been reviewed in the OECD-SIDS program (IUCLID, 2007; OECD, 2007).

Environmental Fate and Transport

Sodium lauryl sulfate exhibits moderate sorption potential to sediments. The experimentally derived sediment-water coefficient (K_d) and sorption coefficient (K_{oc} for sodium lauryl sulfate are 70.2 – 99.1 and 316 – 446, respectively (Marchesi *et al.*, 1991).

Biodegradation

Sodium lauryl sulfate is readily biodegradable in standard ready tests (OECD 301D) that show 94-97% (Henkel KGaA, 1996; OECD, 2007) and ~85% (Fischer and Gerike, 1975) removal after 28 and 30 days, respectively. The 10-window was fulfilled in both tests. Alkyl sulfates with a chain length between 8 and 14 degraded to 90-100% after 8 days in an OECD 301E test (Sanchez-Leal *et al.*, 1991).

Bioaccumulation

The bioaccumulation of sodium lauryl sulfate is considered to be low based on the results of several studies. The BCFs for freshwater fish *Cyprinus carpio* and *Carassius auratus* were 2.1-5.3 (Wakabayashi *et al.*, 1978, 1980, 1981) and ~1.5 (Tovell *et al.*, 1975), respectively.

Aquatic Toxicity

The 48-hour LC_{50}s for *Oryzias latipes* was reported as a nominal value of 46 mg/L (Kikuchi and Wakabayashi, 1984) and as a measured value of 51 mg/L (Kikuchi *et al.*, 1976). In chronic studies, the lowest value was a 42-day NOEC for *Pimephales promelas* of >1.36 mg/L (OECD, 2007; Belanger *et al.*, 1995.

There are no reliable acute invertebrate studies conducted on sodium lauryl sulfate. The 24-hour EC_{50} nominal value for *Daphnia magna* for sodium tridecyl sulfate is 42 mg/L (Lundahl and Cabridenc, 1978). In another study, the 24-hour EC_{50} for *Daphnia magna* for sodium tridecyl sulfate was determined to 4.2 mg/L (Cognis, 2006). In a chronic study on sodium lauryl sulfate, the 7-day NOEC to *Ceriodaphnia dubia* was determined to be 0.88 mg/L (Dyer *et al.*, 1997).

The 72-hour EC_{50} values to algae *Desmodesmus subspicatus* are >120 mg/L for growth and 53 mg/L for biomass; the NOEC is 30 mg/L (Henkel KGaA, 1994). The 96-hour EC_{50} value to algae *Pseudokirchneriella subcapitata* is 117 mg/L based on growth (Nyholm and Damgaard, 1990).

Toxicity to Sediment Organisms

Three valid studies (two static and one semistatic) are available on the toxicity of sodium lauryl sulphate to benthic organisms. However, these studies were conducted in seawater without sediment.

Toxicity to Terrestrial Organisms

There are no valid studies.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (46 mg/L), Daphnia (4.2 mg/L), and algae (53 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 0.88 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported long-term NOEC of 0.88 mg/L for invertebrates. The $PNEC_{aquatic}$ is 0.09 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$.

PBT Assessment

Sodium lauryl sulfate is readily biodegradable and thus does not meet the screening criteria for persistence.

The experimental BCFs in freshwater fish are in the range of 1.5 to 5.3. Thus, sodium lauryl sulfate does not meet the criteria for bioaccumulation.

The lowest NOEC from a chronic invertebrate toxicity study is 0.88 mg/L. This value is >0.01 mg/L; thus, sodium lauryl sulfate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium lauryl sulfate is not a PBT substance.

Environmental Assessment

Sorbitan, monododecanoate poly(oxy-1,2-diethanediyl)
(CAS No. 9005-64-5)

Sorbitan, monododecanoate poly(oxy-1,2-diethanediyl) or PEG sorbitan monolaurate is a hydrophilic, nonionic surfactant that is also called Polysorbate 20 and Tweens 20. In this environmental assessment sorbitan, monododecanoate poly(oxy-1,2-diethanediyl) will be referred to as Polysorbate 20. Polysorbate 20 contains mainly the fatty acid lauric acid, but other fatty acids are also present. Thus, polysorbate 20 would be considered a UVCB substance (substance of unknown or variable composition, complex reaction products or biological materials).

Because no environmental fate and aquatic toxicity data were found on Polysorbate 20, information on Polysorbate 80 was used for this environmental assessment. QSAR modeling (EPISUITE) was also used based on the structural information on Polysorbate 20 provided in the Japanese Food Safety Commission Evaluation Report of Food Additives: Polysorbates (JFSC, 2007).

Biodegradation

Polysorbate 80 was been reported to biodegrade in less than 5 days (Baleux and Caumette, 1974). In their environmental risk assessment, Carlsson *et al.* (2006) considered Polysorbate 80 to be inherently biodegradable.

The QSAR model Biowin 2 predicts that Polysorbate 20 does not biodegrade fast, and Biowin 3 predicts that it is recalcitrant (U.S. EPA, 2011).

Bioaccumulation

Using QSAR modeling, the log K_{ow} of Polysorbate 20 was estimated to be -2.9 and the BCF is estimated to be 3.16 (U.S. EPA, 2011).

Aquatic Toxicity

No aquatic toxicity data was found for Polysorbate 20. For Polysorbate 80, invertebrate lethality was noted at concentrations of 1-5% following 10 hours of exposure (Saski *et al.*, 1971; cited in Carlsson *et al.*, 2006). An EC_{50} in algae was reported to be 100 mg/L for (Nyberg, 1998; cited in Carlsson *et al.*, 2006).

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: There are no experimental studies on Polysorbate 20. An acute $E(L)C_{50}$ value is available for algae (100 mg/L) on the structurally similar Polysorbate 80. On the basis that the only toxicity value is a short-term result from one trophic level, an assessment factor of 1,000 has been applied to the EC_{50} value of 100 mg/L for algae. The $PNEC_{aquatic}$ is 0.1 mg/L.

PBT Assessment

Using the QSAR model Biowin 2, Polysorbate 20 is predicted to not biodegrade fast; Biowin 3 predicts that Polysorbate 20 is recalcitrant. Thus, Polysorbate 20 meets the screening criteria for persistence.

Using QSAR modeling, the log K_{ow} of Polysorbate 20 was estimated to be -2.9 and the BCF is estimated to be 3.16. Thus, Polysorbate 20 is not expected to meet the screening criteria for bioaccumulation.

There are no toxicity data on Polysorbate 20; nor are there any chronic toxicity data on Polysorbate 80, which is structurally similar to Polysorbate 20. The acute algal EC_{50} value for Polysorbate 80 is >0.1 mg/L. Thus, Polysorbate 20 is not expected to meet the screening criteria for toxicity.

The overall conclusion is that Polysorbate 20 or sorbitan, monododecanoate poly(oxy-1,2-diethanediyl) is not a PBT substance.

Environmental Assessment

Sulfuric acid
(CAS No. 7664-93-9)

Sulfuric acid has been reviewed in the OECD-SIDS program (OECD, 2001).

Environmental Fate

Sulfuric acid (H_2SO_4) will dissociate completely in aqueous media at environmentally relevant pH to H^+ and SO_4^{2-}. The pK_a of sulfuric acid is 1.92.

Sulfates are not expected to bioaccumulate in the soil or in aqueous solution (OECD, 2005). Sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. However, some plants (*e.g.*, corn and *Kochia Scoparia*), are capable of accumulating sulfate to concentrations that are potentially toxic to ruminants (OECD, 2005).

In anaerobic environments sulfate is biologically reduced to (hydrogen) sulfide by sulfate reducing bacteria, or incorporated into living organisms as source of sulfur, and thereby included in the sulfur cycle (OECD, 2005).

Aquatic Toxicity

A review of the acute and chronic aquatic toxicity studies can be found in the OECD SIAR for sulfuric acid (OECD, 2001). The 24-hour LC_{50} in zebrafish (*Brachydanio rerio*) is 82 mg/L. In another study, the 48-hour LC_{50} in Bluegill sunfish (*Lepomis macrochirus*) was reported to be 16-28 mg/L at pH 3.25 to 3.5.

In a chronic toxicity study, the NOEC values for brook trout (*Salvelinus fontinalis*) are: 0.31 mg/L (pH 5.2) for embryo survival; 0.15 mg/L (pH 5.5) for time hatching, and 0.13 mg/L (pH 5.56) for weight of young fish.

The lowest 24-hour LC_{50} in *Daphnia magna* was reported to be 29 mg/L. In a chronic toxicity study, the 35-day NOEC for the midge *Tanytarsus dissimilis* is 0.15 mg/L (pH 5.5).

No standard algae growth studies could be found.

Toxicity to Sediment Organisms

No data are available.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (16 mg/L) and Daphnia (29 mg/L). Chronic toxicity studies are also available for fish and invertebrates, with comparable NOECs. On the basis that the data consists of short-term and long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported NOEC of 0.13 mg/L for fish. The $PNEC_{aquatic}$ value is 0.0026 mg/L (2.6 µg/L).

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Sulfuric acid dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sulfuric acid. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sulfuric acid to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of sulfuric acid is dominated by its water solubility. Sorption of sulfuric acid should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sulfuric acid. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sulfuric acid is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sulfuric acid is an organic salt that dissociates completely to hydrogen and sulfate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and sulfate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Hydrogen and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sulfuric acid is not expected to bioaccumulate.

Chronic toxicity studies have been conducted on sulfuric acid. The lowest NOEC was reported to be 0.13 mg/L in fish; this value is ~0.1 mg/L and thus meets the screening criteria for toxicity.

The overall conclusion is that sulfuric acid is not a PBT substance.

Environmental Assessment

Talc
(CAS No. 61789-40-0)

Talc is a mineral composed of hydrated magnesium silicate with the chemical formula $Mg_3Si4O_{10}(OH)_2$ or $H_2Mg_3(SiO_3)_4$. Talc is not soluble in water.

Biodegradation

As a mineral, talc does not biodegrade.

Aquatic Toxicity

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to aquatic organisms.

Toxicity to Sediment Organisms

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to sediment organisms.

Toxicity to Terrestrial Organisms

No data were found.

Determination of PNECs

PNEC values for talc cannot be calculated.

PBT Assessment

Talc is an inorganic mineral that is insoluble in water. Talc is not expected to be bioavailable to aquatic organisms; thus, it is does not meet the criteria for bioaccumulation or toxicity. Talc does not biodegrade in the environment. It is a naturally-occurring mineral and is persistent in the environment. However, for the purposes of this PBT assessment, it does not meet the criteria for persistence.

Environmental Assessment

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Limited toxicity information was located for this alkyl phosphonium salt.

Biodegradation

No data were found.

Aquatic Toxicity

Bellacide 350 MSDS: The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in Daphnia was reported to be 0.025 mg/L.

U.S. EPA OPP Pesticide Ecotoxicity Database: The 96-hour LC_{50}s in rainbow trout are 0.49 and 0.2 mg/L. The 96-hour LC_{50}s in Bluegill sunfish and common carp (*Cyprinus carpio*) are 0.06 and 0.09 mg/L, respectively. The 48-hour EC_{50} in Daphnia is 0.025 mg/L.

Toxicity to Sediment Organisms

No data were found.

Toxicity to Terrestrial Organisms

U.S. EPA OPP Pesticide Ecotoxicity Database: The 8-day dietary LC_{50} in Bobwhite Quail is 4,215 ppm, with a NOEL of 1,980 ppm. The 8-day dietary LC_{50} in Mallard Duck is 3,663 ppm, with a NOEL of 1,780 ppm. The 14-day oral gavage LD_{50} in Mallard Duck is 232 mg/kg, with a NOEL of 178 mg/kg.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.2 mg/L) and Daphnia (0.025 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.025 mg/L for Daphnia. The $PNEC_{aquatic}$ is calculated to be 2.5×10^{-5} mg/L (0.025 µg/L).

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$.

PBT Assessment

No information is available on biodegradation.

No information is available on bioaccumulation.

No chronic toxicity data are available for TTPC. The lowest acute $EC(L)_{50}$ of TTPC is 0.025 mg/L in invertebrates. Since this value is <0.1 mg/L, TTPC does meet the screening criteria for toxicity.

APPENDIX G.4 SCHLUMBERGER CLEARFRAC XT

Environmental Assessment

Acetic Acid
(CAS No. 64-19-7)

Acetic acid and its salts undergo dissociation in aqueous media into the acetate anion ($H_3C_2O_2^-$) and the respective cations (H^+, NH_4^+, Ca^{2+}, Mg^{2+}, Mn^{2+}, K^+, Na^+). The toxicity of each compound is driven by acetate, with the cations playing a minor role. The pH is 2.5 at 50 g/L and 20°C; and the pK_a is 4.76 at 20°C.

Environmental Transport

Level I fugacity modeling predicts that about 73% of any acetic acid released to the environment would partition to water, with the remainder partitioning into the air (U.S. HPVIS database).

Biodegradation

Acetic acid and its salts readily dissociate into their respective cations and the acetate anion; the anion acetate is readily biodegraded. In aerobic conditions using adapted wastewater from domestic sewage, degradation was 96% after 20 days (Price *et al.*, 1974). It was also shown to be readily biodegradable under anaerobic conditions using activated sludge (99% after 7 days) (Kameya *et al.*, 1995).

Aquatic Toxicity

The 96-hour LC_{50} in bluegill sunfish is 75 mg/L (Price *et al.*, 1974), and the 96-hour LC_{50} in mosquito fish is 251 mg/L (Wallen *et al.*, 1957). The 96-hour LC_{50} of 60% acetic acid in *Oncorhynchus mykiss* is 108 mg/L (64.8 mg acetic acid/L) (unpublished data, ECHA). In a chronic study with *Oncorhynchus mykiss*, the 21-day LC_{50} and NOEC for 60% acetic acid were 87 mg/L and 57.2 mg/L, respectively (unpublished data, ECHA). The 21-day LC_{50} and NOEC for 100% acetic acid were 52.2 mg/L and 34.3 mg/L, respectively (unpublished data, ECHA).

The 24-hour EC_{50} to Daphnia was reported to be 95 mg/L (un-neutralized) and 6,000 mg/L (neutralized to pH 8.0) (Bringmann and Kuehn, 1982). One other study showed the 48-hour EC_{50} to be 65 mg/L (Janssen *et al.*, 1993). In a chronic Daphnia study, the 21-day NOEC for reproduction was reported to be 22.7 mg/L for 100% acetic acid (unpublished data, ECHA). In another chronic Daphnia study, the 21-day NOEC for reproduction was 31.4 mg/L for 100% acetic acid (unpublished data, ECHA).

In an algae growth inhibition study, the reported nominal ErC_{50} to *Desmodesmus subspicatus* was 810.9 mg/L for 60% acetic acid (unpublished data, ECHA). The

reported nominal ErC_{50} was 486.5 mg/L for 100% acetic acid (unpublished data, ECHA). The toxicity threshold to algae after 8 days in a growth inhibition test was reported to be 4,000 mg/L (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (65 mg/L) and Daphnia (65 mg/L), and algae (487 mg/L). Long-term results are also available for fish (NOEC = 34 mg/L) and Daphnia (NOEC = 23 mg/L). On the basis that the data consists of short-term results from three trophic levels and two chronic study for fish and another chronic study for Daphnia, an assessment factor of 50 has been applied to the lowest NOEC of 23 mg/L for Daphnia. The $PNEC_{aquatic}$ was calculated to be 0.5 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Thus, the determination of the $PNEC_{sediment}$ is not possible. Based on its properties, no adsorption of acetic acid to sediment is to be expected and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Thus, the determination of the $PNEC_{soil}$ is not possible. Based on its properties, no adsorption of acetic acid to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

The acetate ion of acetic acid is readily biodegradable and thus it does not meet the screening criteria for persistence.

The log Kow for acetic acid is reported to be -0.17 (Verschueren, 1966). Acetate is also found in the body and is metabolized as part of the body's biochemical pathways. Thus,

acetic acid (specifically, the acetate ion) does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity data on acetic acid are >0.01 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

Environmental Assessment

Reaction mass of 5-chloro-2-methyl-4-isothiazolin-3-one and 2-methyl-2H-isothiazolin-3-one [3:1]
(CAS No. 55965-84-9)

Environmental Fate

5-Chloro-2-methyl-4-isothiazolin-3-one and 2-methyl-4-isothiazolin-3-one, the active ingredients in DOW™ CMIT/MIT antimicrobial products, have a low bioconcentration potential (tendency to accumulate in the food chain) and a high potential for mobility in soil. They are completely soluble in water. In the environment these compounds would tend to partition into water where they would rapidly biodegrade to non-persistent substances which are several orders of magnitude less toxic than parent compound. They would also be removed by common biological wastewater treatment facilities.

Biodegradation

The primary aerobic biodegradability of MIT has been examined in a river sediment-water system by use of a ^{14}C-labelled model compound. During the 7-day experiment ^{14}C-labelled MIT was rapidly metabolized as only 12.6% of the initial MIT was present after 24 hours of incubation at 25 The calculated half-life for the parent compound was 9.1 hours (Reynolds, 1994a). MIT was metabolized to several unidentified metabolites. One of the major metabolites reached a level corresponding to 18.2% of the ^{14}C added after 24 hours of incubation. This metabolite decreased to 6.8% after 7 days which indicates further transformation. Other metabolites tended to increase during the 7-day experiment. At the end of the experiment metabolites that were bound in the sediment corresponded to 55%, whereas $^{14}CO_2$ attained 9% of the added ^{14}C. Most of the formed metabolites have shorter chromatographic retention times than MI which indicates that they are polar compounds. On the basis of the identification of metabolites from transformation of 4,5-dichloro-2-(n-octyl)-4-isothiazolin-3-one, it has been proposed that MI is transformed via N-methyl malonamic acid, N-methyl acetamide, and malonic acid (Madsen, 2000).

The primary biodegradability of CMIT has been examined with the same type of sediment and water as described for MIT. The ^{14}C-labelled CMIT was rapidly metabolized as only 30% of the initial CMI remained after 24 hours of incubation at 25 The calculated half-life for the intact CMIT was 17.3 hours (Reynolds, 1994b). At the end of the 7-day experiment, the sediment bound metabolites corresponded to 57.1% of the added ^{14}C, whereas 2.8% of the added ^{14}C was released as $^{14}CO_2$. Due to the structural similarities of MI and CMIT, it is suggested that the major metabolites for the transformation of CMIT are the same as described for MIT.

MIT was tested in an OECD 301B test modified for low concentrations of ^{14}C-labelled

compounds. The accumulated $^{14}CO_2$ attained 54.1%, 55.8%, and 47.6% in the respective concentrations (0.1, 0.03 and 0.01 mg/l) after 29 days. During the 10-day window, 37%, 30% and 30%, respectively, of the initial MIT was mineralized to $^{14}CO_2$ (Bashir, 1998a).

CMIT was tested in an OECD 301B modified for low concentrations of ^{14}C-labelled compounds. The accumulated $^{14}CO_2$ attained 38.8%, 55.3%, and 62% in the respective concentrations (0.3, 0.1, and 0.03 mg/l) after 29 days. During the 10- day window, 25%, 40%, and 48%, respectively, of the initial CMIT was mineralized to $^{14}CO_2$. The ultimate biodegradability of CMIT exceeded the 60%-pass level for ready biodegradability at the lowest test concentration of 0.03 mg/L, but the pass level was not reached within the 10-day window Bashir, 1998b).

From Dow Chemicals MSDS for ROCIMA GT:
Biodegradation (aquatic metabolism): 5-Chloro-2-methyl-4-isothiazolin-3-one (CMIT): t ½ anaerobic = 0.2 day, t ½ aerobic = 0.38 – 1.3 days; 2-Methyl-4-isothiazolin-3-one (MIT): t ½ aerobic = 0.38 – 1.4 days.

Bioaccumulation

The bioaccumulation of CMIT in bluegill sunfish *(Lepomis macrochirus)* resulted in BCF values of 102, 114, and 67 at nominal concentrations of 0.02, 0.12, and 0.8 mg/L (Erikson *et al*. 1995). These BCF values are based on total accumulated ^{14}C and include both the parent compound and metabolites. The BCF for MIT has been determined to 2.3 at a nominal concentration of 0.12 mg/L (Erikson *et al*. 1995).

Aquatic Toxicity

From Dow Chemicals MSDS for ROCIMA GT:
The 96-hour LC_{50} for Bluegill sunfish (*Lepomis macrochirus*) is 0.28 mg/L, and the 96-hour LC_{50} for Rainbow trout (*Oncorhynchus mykiss*) is 0.188 mg/L. The 48-hour EC_{50} for *Daphnia magna* is 0.126 mg/L. The 72-hour ErC_{50} for algae (*Selenastrum capricornutum*) is 0.027 mg/L.

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.188 mg/L), Daphnia (0.126 mg/L), and algae (0.027 mg/L). On the basis that the data consists of short-term results from three trophic levels,

an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.027 mg/L for Daphnia. The $PNEC_{aquatic}$ is 2.7×10^{-5} mg/L or 0.027 µg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.025 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.022 µg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.007 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.0043 µg/kg.

PBT Assessment

The half-lives of CMIT and MIT is a river water-sediment system were 17.3 hours and 9.1 hours, respectively. Thus, CMIT/MIT do not meet the criteria for persistence.

The experimental BCF for CMIT is 67-114 in bluefish sunfish, and the BCF for MIT was determined to be 2.3. Thus, CMIT/MIT do not meet the criteria for bioaccumulation.

No chronic toxicity data are available for CMIT/MIT; however, the acute $E(L)C_{50}$ values for algae are >0.01 but <0.1 mg/L. Thus, CMIT/MIT meet the screening criteria for toxicity.

The overall conclusion is that CMIT/MIT mixture is not PBT substances.

Environmental Assessment

Choline chloride
Cholinium chloride
(CAS No. 67-48-1)

Choline chloride, also known as cholinium chloride, is quaternary amine salt. It dissociates in water into the corresponding positively charged quaternary hydroxyl alkylammonium ion and the negatively charged chloride ion.

Choline chloride has been reviewed in the OECD-SIDS program (OECD, 2004).

Environmental Fate and Transport

Results from Mackay Level I modeling indicate that choline chloride will be distributed completely into water (BASF AG, 2004).

Biodegradation

Choline chloride is readily biodegradable (93% within 14 days) in a MITI I-test (MITI, 1992). In another MITI-I test, biodegradation was $\geq$60%, indicating ready biodegradation (Tunkel *et al.*, 2000). A $BOD_5/ThOD_5$ ratio of 75% was obtained in a BOD_5 test performed according to DIN 38409 part 43 (BASF AG, 1984).

Bioaccumulation

No measured data on bioaccumulation of choline chloride are available. The experimental octanol-water partition coefficient (log K_{ow}) was determined to be -3.77. The estimated BCF using the equation log BCF = 0.85*logK_{ow} – 0.70 is 0.59. Therefore, bioaccumulation is not expected in aquatic organisms.

Aquatic Toxicity

The 96-hour fish LC_{50} value is >100 mg/L (nominal and measured) in *Oryzias latipes* (MOE Japan, 1999a), and the 48-hour in vertebrate EC_{50} is 349 mg/L (nominal and measured) in *Daphnia magna* (MOE Japan, 1999b). The 72-hour EC_{50} to *Pseudokirchneriella subcapitata* is >1,000 mg/L (nominal and measured) based on growth rate; the 72-hour NOEC is 32 mg/L (MOE Japan, 1999c).

In a 21-day *Daphnia magna* reproduction test, the nominal and measured NOEC was reported to be 30.2 mg/L (MOE Japan, 1999d).

Toxicity to Terrestrial Plants

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), invertebrates (349 mg/L), and algae (>1,000 mg/L). Results from chronic studies are available for invertebrates (21-day NOEC = 30.2 mg/L) and algae (72-hour NOEC = 32 mg/L). On the basis that the data consists of chronic studies on two trophic level (albeit not on the species with the lowest $E(L)C_{50}$), an assessment factor of 50 has been applied to the lowest reported NOEC of 30 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.6 mg/L.

PBT Assessment

Choline chloride is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of -3.77 and a calculated BCF of 0.59, choline chloride does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on choline chloride show NOECs of >0.01 mg/L. Thus, choline chloride does not meet the screening criteria for toxicity.

The overall conclusion is that choline chloride is not a PBT substance.

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Erucic amidopropyl dimethylbetaine
(CAS No. 149879-98-1)

No data were located on environmental fate/transport or aquatic toxicity. The QSAR models in EPI Suite™ (U.S. EPA, 2012) were used to estimate values for the environmental assessment.

Environmental Fate

A MacKay Level III fugacity model predicts a distribution of 51.8% to soil; 44.2% to sediment; 4.0% to water; and 0.0005% to air (U.S. EPA, 2012).

Biodegradation

Erucic amidopropyldimethyl betaine is predicted to biodegrade fast (Biowin 2) and in the timeframe of weeks-months (Biowin 3) (U.S. EPA, 2012).

Bioaccumulation

The estimated log K_{ow} of erucic amidopropyldimethyl betaine is estimated to be 5.38 (U.S. EPA, 2012). The BCF is estimated to be 70.8 (U.S. EPA, 2012).

Aquatic Toxicity

Using the QSAR model ECOSAR (neutral organic SAR), the 96-hour LC_{50} to fish is estimated to be 0.362 mg/L; the 48-hour LC_{50} to Daphnid is estimated to be 0.281 mg/L; and the 96-hour EC_{50} for algae is estimated to be 0.762 mg/L (U.S. EPA, 2012).

These values exceed the water solubility for erucic amidopropyldimethyl betaine, which is estimated to be 0.02368 mg/L (U.S. EPA, 2012).

Determination of PNECs

$PNEC_{aquatic}$: There are no experimental data on erucic amidopropyldimethyl betaine. Estimated acute $E(L)C_{50}$ values using the QSAR model ECOSAR (neutral organic SAR) are: fish (0.362 mg/L), Daphnia (0.281 mg/L), and algae (0.762 mg/L). These values exceed the water solubility for erucic amidopropyl betaine, which is estimated to be 0.02368 mg/L. Thus, the water solubility value will be used as the basis for the

$PNEC_{aquatic}$. Using as assessment factor of 1,000 since there are no experimental chronic data, the $PNEC_{aquatic}$ is 2.4×10^{-5} mg/L.

PBT Assessment

Erucic amidopropyldimethyl betaine is predicted to biodegrade fast (Biowin 2) and in the timeframe of weeks-months (Biowin 3). Thus, it does not meet the screening criteria for persistence.

The estimated log K_{ow} of erucic amidopropyldimethyl betaine is estimated to be 5.38. The BCF is calculated to be 70.8. Furthermore, erucic amidopropyldimethyl betaine is predicted to undergo biotransformation in aquatic organisms. Thus, erucic amidopropyldimethyl betaine does not meet the screening criteria for bioaccumulation.

No acute or chronic experimental aquatic toxicity was available for erucic amidopropyldimethyl betaine. Based on the QSAR model ECOSAR, the acute $E(L)C_{50}$ values are greater than the water solubility of erucic amidopropyldimethyl betaine, which is 0.02368 mg/L. Thus, chronic toxicity with a NOEC of <0.01 mg/L cannot be excluded. The ECOSAR model estimates ChVs of 0.051 and 0.065 for fish and daphnid, respectively. Since these values are >0.1 mg/L, erucic amidopropyldimethyl betaine meets the criteria for toxicity.

The overall conclusion is that erucic amidopropyldimethyl betaine is not a PBT substance.

Environmental Assessment

Hydrochloric acid
(CAS No. 7647-01-0)

Hydrochloric acid has been reviewed in the OECD-SIDS program (OECD, 202a,b).

Environmental Fate and Transport

Hydrochloric acid is readily dissociated in water into hydrated protons and chloride ions.

The increase in the concentration of hydrochloric acid in water decreases the pH in the aquatic ecosystem. Generally, the buffer capacity to maintain the pH in the aquatic ecosystem is important and the equilibrium between CO_2, HCO_3^- and CO_3^{2-} in the aquatic ecosystem is mainly responsible for the buffer capacity of receiving water.

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

According to UNEP (1995), the mean, the 10th-percentile and the 90th-percentile of bicarbonate concentrations for 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania were 106, 20 and 195 mg/L, respectively. The buffering capacity for neutralization of receiving water with bicarbonate concentrations of 20, 106 and 195 mg/L is calculated to be 2.19, 11.60 and 21.3 mg/L, respectively.

Aquatic Toxicity

Several studies on the acute toxicity to fish have been published. The lowest 96-hour LC_{50} was reported to be 4.92 mg/L for *Cyprinus carpio* at pH 4.3 which was conducted according to OECD 203 guidelines (MLIT, 1999). The 96-hour LC_{50} for *Oncorhynchus mykiss* was 7.45 mg/L at pH 4.12 for hard water and 10.3 mg/L at pH 3.98 for soft water (Graham and Wood, 1981). The 96-hour LC_{50} in *Lepomis macrochirus* is 55.1 to 30.9 mg/L at pH 3.25 - 3.5; the low pH caused a reduction in the oxygen carrying capacity of hemoglobin and excessive secretion of mucus from the gills which in turn interfered with gas exchange (Ellgaard and Glimore, 1984).

Generally, the results of toxicity tests with acid or base depend on the buffer capacity of the test medium. Dechlorinated tap water was used as a test medium in the three tests described above. A 96-hour LC_{50} of 30.9 to 24.6 at pH 3.5-3.6 was obtained for *Lepomis macrochirus* using artificial water prepared from distilled water and analytical or reagent grade chemicals (Cairns and Scheier, 1959); other reported values are a 96-hour LC_{50} of 282 mg/L for *Gambusia affinis* (Wallen *et al.*, 1957) and a 16-hour LC_{100} value of 0.492 mg/L at pH 5.3 for the pike perch fry (*Lucioperca lucioperca*) conducted with pond water

(pH 6.0-8.2) are reported (Stangenberg, 1975). A 24-hr LC_{50} value of 60-80 mg/L for *Semotitus astromaculatus* with river water (pH 8.3) has also been reported. No long-term or chronic toxicity data on fish were located (Gillette *et al.*, 1952).

The 48-hour EC_{50} for *Daphnia magna* is 0.492 mg/L at pH 5.3 based on immobilization (MLIT, 1999). No long-term or chronic toxicity data on invertebrates have been reported. The 72-hour EC_{50} to *Selenastrum capriornutum* is 0.78 mg/L (pH 5.1) for biomass; 0.492 mg/L (pH 5.3) for growth rate; and the 72-hr-NOEC is 0.097 mg/L (pH 6.0) for biomass and growth rate (MLIT, 1999).

The hazard of hydrochloric acid for the environment is caused by the proton (pH effect). For this reason the effect of hydrochloric acid on the organisms depends on the buffer capacity of the aquatic ecosystem. Also, the variation in acute toxicity for aquatic organisms can be explained to a significant extent by the variation in buffer capacity of the test medium. For example, LC_{50} values of acute fish toxicity tests varied from 4.92 to 282 mg/L.

It is not considered useful to calculate a PNEC for hydrochloric acid because factors such as the buffer capacity, the natural pH, and the fluctuation of the pH are very specific for a certain ecosystem.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECS

$PNEC_{aquatic}$: Based on the information above, a $PNEC_{aquatic}$ was not derived for hydrochloric acid.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Kow and Koc parameters do not readily apply to inorganics, such as hydrochloric acid. Thus;, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of hydrochloric acid to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Sorption of hydrochloric acid should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as hydrochloric acid. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, hydrochloric acid is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Hydrochloric acid is an organic salt that dissociates completely to hydrogen and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and chloride ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Hydrogen and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, hydrochloric acid is not expected to bioaccumulate.

No chronic toxicity data exist on hydrochloric acid; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, hydrochloric acid does not meet the screening criteria for toxicity.

The overall conclusion is that hydrochloric acid is not a PBT substance.

Environmental Assessment

2-Propanol or Isopropanol
(CAS No. 67-63-0)

2-Propanol or isopropanol has been reviewed in the OECD-SIDS program (OECD, 1997a,b).

Environmental Fate and Transport

Based on calculated results from a Level I fugacity model, isopropanol is expected to partition primarily to the aquatic compartment (77.7%) with the remainder to the air (22.3%) (OECD, 1977a,b).

Biodegradation

Aerobic biodegradation of isopropanol has been shown to occur rapidly under non-acclimated conditions, based on a result of 49% biodegradation from a 5-day BOD test (Bridie *et al.*, 1979). Additional biodegradation data developed using standardized test methods show that isopropanol is readily biodegradable in both freshwater and saltwater media (72 to 78% biodegradation in 20 days) (Price *et al.*, 1974).

Bioaccumulation

Bioconcentration of isopropanol in aquatic organisms is not expected to occur based on a measured log n-octanol/water partition coefficient (log Kow) of 0.05, a calculated bioconcentration factor of 1 for a freshwater fish, and the unlikelihood of constant, long-term exposures (OECD 1977a,b).

Aquatic Toxicity

The 96-hour LC_{50} in *Pimephales promelas* is 9,640 mg/L (Veith *et al.*, 1983). The 24-hour EC_{50} in *Daphnia magna* is >10,000 mg/L (Brinkmann and Kuehn, 1977). Chronic aquatic toxicity has also been shown to be of low concern, based on 16- and 21-day NOEC values of 141 and 30 mg/L, respectively, for the freshwater invertebrate *Daphnia magna* (Hermens *et al.*, 1985); OECD, 1977a,b). Toxicity of isopropanol to plants is expected to be low, based on a 7-day toxicity threshold value of 1,800 mg/L for a freshwater algae (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Plants

Toxicity of isopropanol to plants is expected to be low, based on an EC_{50} value of 2,100 mg/L from a lettuce seed germination test (Reynolds, 1977).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (9,640 mg/L) and invertebrates (>10,000 mg/L). Results from chronic studies are available for invertebrates (16- and 21-day NOECs for Daphnia are 141 and 30 mg/L, respectively). On the basis that the data consists of a chronic study on one trophic level, an assessment factor of 100 has been applied to the lowest reported NOEC of 30 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.3 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using EPISUITE. Using a Koc of 1.53 and a $PNEC_{aquatic}$ of 0.3 mg/L, the $PNEC_{sediment}$ was calculated to be 0.19 mg/kg.

$PNEC_{soil}$: Insufficient experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE. Using a Koc of 1.53 and a $PNEC_{aquatic}$ of 0.3 mg/L, the $PNEC_{soil}$ was calculated to be 0.0061 mg/kg.

PBT Assessment

Isopropanol is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of 0.05 and a calculated BCF of 1, isopropanol does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on isopropanol show NOECs of >0.01 mg/L. Thus, isopropanol does not meet the screening criteria for toxicity.

The overall conclusion is that isopropanol is not a PBT substance.

Environmental Assessment

Magnesium chloride
(CAS No. 7786-30-3)

Environmental Fate

Magnesium chloride dissociates completely in water to the Mg^{++} cation and the chloride anion (Cl^-).

Aquatic Toxicity

The 96-hour LC_{50} of magnesium chloride to *Pimephales promelas* is 541 mg of Mg/L (or 2,119.3 mg of $MgCl_2$/L).

The 48-hour LC_{50} for *Daphnia magna* is 140 mg Mg/L (or 548.4 mg of $MgCl_2$/L). In another study, the 48-hour LC_{50} to *Daphnia magna* and *Ceriodaphnia dubia* were 339 mg of Mg/L and 225 mg of Mg/L, respectively (or 1328 and 881.4 mg of $MgCl_2$/L, respectively).

The 72-hour EC_{50} of magnesium chloride for algae *Scenedesmus subspicatus* is >100 mg/L and the NOEC is 100 mg/L.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (2,119 mg/L as $MgCl_2$), Daphnia (548 mg/L as $MgCl_2$), and algae (100 mg/L $MgCl_2$). Even though a NOEC was obtained from the algae study, there were no chronic studies conducted on fish or Daphnia. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 0.1 mg/L. The $PNEC_{aquatic}$ is 0.1 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium chloride is dominated by its water solubility.

Sorption of magnesium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium chloride. Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium chloride is an organic salt that dissociates completely to magnesium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and chloride ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, magnesium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, maganesium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium chloride is not a PBT substance.

Environmental Assessment

Magnesium nitrate (CAS No. 10377-60-3)

Environmental Fate

Magnesium nitrate dissociates completely in water to Mg^{++} and the nitrate anion (NO_3^-).

Determination of PNECs

$PNEC_{aquatic}$: The ANZECC water quality guideline (2000) uses acute and chronic laboratory toxicity data for the derivation of "trigger values" for nitrate. The guideline summary for freshwaters is: *"A freshwater moderate reliability trigger value for nitrate toxicity as NO_3 (nitrate) of 700 µg/L was calculated using the statistical distribution method 95% protection and the default ACR."*

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium nitrate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium nitrate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium nitrate is dominated by its water solubility. Sorption of magnesium nitrate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium nitrate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium nitrate is an organic salt that dissociates completely to magnesium and nitrate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and nitrate ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium ions are essential to all living organisms and its intracellular and extracellular concentrations are actively regulated. Nitrates are ions that are very soluble in aqueous solutions. Thus, magnesium nitrate is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium nitrate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, maganesium nitrate does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium nitrate is not a PBT substance.

ANZECC & ARMCANZ (2000). Australian and New Zealand guidelines for fresh and marine water quality. National Water Quality Management Strategy Paper No 4, Australian and New Zealand Environment and Conservation Council & Agriculture and Resource Management Council of Australia and New Zealand, Canberra, Australia.

Environmental Assessment

Benzenesulfonic acid, 4-ethyenyl-, sodium salt, homopolymer (CAS No. 25704-18-1)

Acetic acid ethenyl ester, polymer with ethanol (CAS No. 25213-24-5)

Vinylidene chloride/methacrylate copolymer (CAS No. 25038-72-6)

Polyvinyl acetate, partially hydrolyzed (CAS No. 30443-60-5) THIS IS NOT THE CORRECT CASRN

All of these substances are polymers. Aquatic toxicity data was located for only for acetic acid, ethenyl ester, polymer with ethanol (CAS No. 25213-24-5) on a supplier's MSDS. However, all of the polymers listed above are expected to exhibit similar environmental fate and aquatic toxicity (Boethling and Nabholz, 1997).

Biodegradation

Generally, polymers are considered to be essentially non-biodegradable.

Bioaccumulation

Polymers are not generally absorbed through biological membranes to bioaccumulate in tissues.

Aquatic Toxicity

These polymers are not very insoluble in water and are expected to be essentially non-toxic to aquatic organisms.

The MSDS for DuPont's product ELVANOL 60-30, a polyvinyl alcohol with CAS No. 25213-24-5 (>93%) reported that concentrations of "ELVANOL" up to 10,000 mg of liter of water showed no mortality or other effect when tested on bluegill sunfish.

Determination of PNECs

$PNEC_{aquatic}$: Not determined.

PBT Assessment

These polymers are not expected to biodegrade and thus meets the criteria for persistence.

Polymers are not generally absorbed through biological membranes to bioaccumulate in tissues. Thus, these polymers do not meet the criteria for bioaccumulation.

The acute aquatic toxicity to fish (LC_{50} of >10,000 mg/L) for CASRN 25213-24-5 indicates that these polymers do not meet the criteria for toxicity.

Thus, these polymers are not considered to be PBT substances.

DuPont (2006) MSDS for “ELVANOL” 60-30, revised 27-Oct-2006.

Environmental Assessment

Sodium chloride
(CAS No. 7647-14-5)

Sodium chloride will dissociate in aqueous solutions to sodium and chloride ions.

Determination of PNECs

$PNEC_{aquatic}$: Not determined.

$PNEC_{sediment}$: Sodium chloride dissociates completely in water with its environmental distribution dominated by its high water solubility. Kow and Koc are parameters that do not readily apply to inorganics, such as sodium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on its properties, no adsorption of sodium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: Sodium chloride dissociates completely in water with its environmental distribution idominated by its high water solubility. Kow and Koc are parameters that do not readily apply to inorganics, such as sodium chloride. Based on its properties, no adsorption of sodium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium chloride is an organic salt that dissociates completely to sodium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and chloride ions are also ubiquitous and are present in most water, soil and sediment. The persistent criteria is not considered applicable to this inorganic salt.

Sodium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on sodium chloride; the acute $EC(L)_{50}$s are expected to be >0.1 mg/L in fish, invertebrates and algae based on aquatic toxicity studies involving sodium and chloride ions. Thus, sodium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that sodium chloride is not a PBT substance.

Environmental Assessment

Sodium chloroacetate
(CAS No. 3926-62-3)

Sodium chloroacetate has been reviewed in the OECD-SIDS program (OECD, 1994).

Biodegradation

In an OECD 301 C test, there was 91% degradation after 5.5 or 9 days with or without adaptation, respectively, indicating ready biodegradation (Solyom, 1981). In an OECD 302B test, there was 80% and 90% degradation after 5 and 6 days, respectively, indicating ready biodegradation (Hoechst AG, 1992).

Bioaccumulation

The calculated log P_{ow} is <0.2 (OECD, 1994).

Aquatic Toxicity

The 96-hour LC_{50} for Harlequin fish (*Rasbora heteromorpha*) is 1,400 mg/L (Martin, 1973), and the 48-hour LC_{50} for rainbow trout (*Oncorhynchus mykiss*) is 900 mg/L (U.S. EPA, 1993).

The 24-hour LC_{50} values for *Daphnia magna* are 800 mg/L (Bouonnet, 1988) and 427 mg/L (Hoechst AG, 1992).

The 72-hour EC_{50} for green algae (*Scenedesmus subspicatus*) is 0.033 mg/L based on biomass (Hoechst AG, 1992).

Toxicity to Terrestrial Organisms

The LD_{50} for bird (Hen) was reported to be 81 mg/kg (Hoechst AG, 1992). Administration of 50 mg/kg of sodium chloroacetate by stomach tube was not lethal to two geese; but 75 mg/kg, one week later, caused death within 46 hours in both birds. Symptoms, first occurring at 3 hours with 1,000 mg/kg included incoordination and convulsions. Death occurred withn 8.5 hours. Damage to the throat and gastrointestinal tract was seen at autopsy (Christiansen *et al.*, 1961).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (900 mg/L), Daphnia (427 mg/L), and algae (0.033 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.033 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 3.3×10^{-5} mg/L or 0.033 µg/L.

PBT Assessment

Sodium chloroacetate is readily biodegradable and thus it does not meet the screening criteria for persistence.

The estimated log Kow value for sodium chloroacetate is <0.2. Thus, it does not meet the screening criteria for bioaccumulation.

No chronic toxicity data exist for sodium chloroacetate. The lowest acute $E(L)C_{50}$ is 0.033 mg/L is greater than 0.01 mg/L but less than 0.1 mg/L. Thus, sodium chloroacetate meets the screening criteria for toxicity.

The overall conclusion is that sodium chloroacetate is not a PBT substance.

Environmental Assessment

Talc
(CAS No. 61789-40-0)

Talc is a mineral composed of hydrated magnesium silicate with the chemical formula $Mg_3Si4O_{10}(OH)_2$ or $H_2Mg_3(SiO_3)_4$. Talc is not soluble in water.

Biodegradation

As a mineral, talc does not biodegrade.

Aquatic Toxicity

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to aquatic organisms.

Toxicity to Sediment Organisms

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to sediment organisms.

Toxicity to Terrestrial Organisms

No data were found.

Determination of PNECs

PNEC values for talc cannot be calculated.

PBT Assessment

Talc is an inorganic mineral that is insoluble in water. Talc is not expected to be bioavailable to aquatic organisms; thus, it is does not meet the criteria for bioaccumulation or toxicity. Talc does not biodegrade in the environment. It is a naturally-occurring mineral and is persistent in the environment. However, for the purposes of this PBT assessment, it does not meet the criteria for persistence.

Environmental Assessment

Tetramethylammonium chloride
(CAS No. 75-57-0)

Environmental Fate

No measured data could be located on tetramethylammonium chloride.

The following information was obtained from EPISUITE v. 4.11 for this assessment (U.S. EPA, 2012). The water solubility was calculated to be 1 x 10^6 mg/L at 25^{o}C, and the octanol-water partition coefficient (log K_{ow}) was estimated to be -4.1817. A Mackay Level III model predicts that tetramethylammonim chloride will distribute 68.4% to soil, 31.6% to water, and 0.07% to sediment. Tetramethylammonium chloride is expected to biodegrade fast based on the Biowin 2 model and with an ultimate biodegradation timeframe of weeks based on the Biowin 3 model.

Bioaccumulation

No measured data could be located on tetramethylammonium chloride. The BCF was calculated to be 3.162, indicating a low bioaccumulation potential.

Aquatic Toxicity

A 96-hour LC_{50} for tetramethylammonium chloride xxxxxin fathead minnows has been reported to be 462 mg/L (ECOTOX).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. The acute 96-hour LC_{50} value for fish is 462 mg/L. Using an assessment factor of 1,000, the $PNEC_{aquatic}$ is 0.5 mg/L.

APPENDIX G.5 HALLIBURTON ALTERNATIVE FLUID SYSTEM

Environmental Assessment

Acetic Acid
(CAS No. 64-19-7)

Acetic acid and its salts undergo dissociation in aqueous media into the acetate anion ($H_3C_2O_2^-$) and the respective cations (H^+, NH_4^+, Ca^{2+}, Mg^{2+}, Mn^{2+}, K^+, Na^+). The toxicity of each compound is driven by acetate, with the cations playing a minor role. The pH is 2.5 at 50 g/L and 20°C; and the pK_a is 4.76 at 20°C.

Environmental Transport

Level I fugacity modeling predicts that about 73% of any acetic acid released to the environment would partition to water, with the remainder partitioning into the air (U.S. HPVIS database).

Biodegradation

Acetic acid and its salts readily dissociate into their respective cations and the acetate anion; the anion acetate is readily biodegraded. In aerobic conditions using adapted wastewater from domestic sewage, degradation was 96% after 20 days (Price *et al.*, 1974). It was also shown to be readily biodegradable under anaerobic conditions using activated sludge (99% after 7 days) (Kameya *et al.*, 1995).

Aquatic Toxicity

The 96-hour LC_{50} in bluegill sunfish is 75 mg/L (Price *et al.*, 1974), and the 96-hour LC_{50} in mosquito fish is 251 mg/L (Wallen *et al.*, 1957). The 96-hour LC_{50} of 60% acetic acid in *Oncorhynchus mykiss* is 108 mg/L (64.8 mg acetic acid/L) (unpublished data, ECHA). In a chronic study with *Oncorhynchus mykiss*, the 21-day LC_{50} and NOEC for 60% acetic acid were 87 mg/L and 57.2 mg/L, respectively (unpublished data, ECHA). The 21-day LC_{50} and NOEC for 100% acetic acid were 52.2 mg/L and 34.3 mg/L, respectively (unpublished data, ECHA).

The 24-hour EC_{50} to Daphnia was reported to be 95 mg/L (un-neutralized) and 6,000 mg/L (neutralized to pH 8.0) (Bringmann and Kuehn, 1982). One other study showed the 48-hour EC_{50} to be 65 mg/L (Janssen *et al.*, 1993). In a chronic Daphnia study, the 21-day NOEC for reproduction was reported to be 22.7 mg/L for 100% acetic acid (unpublished data, ECHA). In another chronic Daphnia study, the 21-day NOEC for reproduction was 31.4 mg/L for 100% acetic acid (unpublished data, ECHA).

In an algae growth inhibition study, the reported nominal ErC_{50} to *Desmodesmus subspicatus* was 810.9 mg/L for 60% acetic acid (unpublished data, ECHA). The

reported nominal ErC_{50} was 486.5 mg/L for 100% acetic acid (unpublished data, ECHA). The toxicity threshold to algae after 8 days in a growth inhibition test was reported to be 4,000 mg/L (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (65 mg/L) and Daphnia (65 mg/L), and algae (487 mg/L). Long-term results are also available for fish (NOEC = 34 mg/L) and Daphnia (NOEC = 23 mg/L). On the basis that the data consists of short-term results from three trophic levels and two chronic study for fish and another chronic study for Daphnia, an assessment factor of 50 has been applied to the lowest NOEC of 23 mg/L for Daphnia. The $PNEC_{aquatic}$ was calculated to be 0.5 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Thus, the determination of the $PNEC_{sediment}$ is not possible. Based on its properties, no adsorption of acetic acid to sediment is to be expected and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Thus, the determination of the $PNEC_{soil}$ is not possible. Based on its properties, no adsorption of acetic acid to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

The acetate ion of acetic acid is readily biodegradable and thus it does not meet the screening criteria for persistence.

The log Kow for acetic acid is reported to be -0.17 (Verschueren, 1966). Acetate is also found in the body and is metabolized as part of the body's biochemical pathways. Thus,

acetic acid (specifically, the acetate ion) does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity data on acetic acid are >0.01 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

Environmental Assessment

Alcohols, C6-C12, Ethoxylated Propoxylated
(CAS No. 68937-66-6)

No toxicity information could located on alcohols, C6-C12, ethoxylated propoxylated (CAS No. 68937-66-6). Toxicity information is available on alcohol ethoxylates. Alcohols, C6-C12, ethoxylated propoxylated is produced by the use of propylene oxide (PO) in addition to ethylene oxide (EO) during the alkoxylation of the alcohol(s). the PO is either incorporated randomly by alkoxylation within the epoxide mixture, or in a block by sequencing the addition of EO and PO to the reactor. Because of the similarity in structures, the toxicity data on the alcohol ethoxylates were used to read-across to alcohols, C6-C12, ethoxylated propoxylated.

Alcohol ethoxylates (AE) are a class of non-ionic surfactants that have the basic structure $C_{x-y}AE_n$. The subscript (x-y) following the 'C' indicates the range of carbon chain units. AEs with carbon unit range between C8 to C18 are most commonly used in household detergent products. The hydrocarbon chain can be either linear or branched. AEs also contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by the subscript (n) which indicates the average number of ethylene oxide units. In household products the average ethylene oxide chain length commonly ranges between 3 and 12 units.

The toxicity profile has been developed from a risk assessment report on alcohol ethoxylates ranging from C8 to C18 prepared by the household cleaning product and chemical industry (HERA, 2009).

Biodegradation

AE homologues with hydrocarbon chain lengths ranging from 8 to 18 and with 2 to >20 ethylene oxide units are readily biodegradable.

As a class, AE undergo rapid primary and ultimate biodegradation under both laboratory and field conditions. The biodegradability of the different AE homologues used in HERA applications is relatively unaffected by the alkyl carbon chain length and the number of EO units.

Proposed half-lives in river water at 12^{o}C: 4 to 24 hours (based on experimental data).

AE are also anaerobically biodegradable.

Bioaccumulation

The AE homologues used for domestic cleaning applications are very likely to have a log Kow value greater than 3.

The Danish EPA report on surfactants (Danish EPA, 2001) found that bioaccumulation of alkyl ethoxylates in aquatic organisms had been determined only for fish. The majority of the limited data were based on studies with 14C-labelled compounds that do not allow the distinction between the parent compound and metabolites, or material incorporated into the cells during growth. Because alcohol ethoxylates are metabolized in aquatic organisms (Danish EPA, 2001), the bioconcentration factor for the parent compound may well be overestimated in experiments in which 14C-labelled model surfactants are used. Tolls *et al.* (2000a,b) combined 14C-techniques and chemical analysis to determine the amount of AE actually present as the parent molecule in the fish. This showed that the parent AE (e.g. C13 EO8) was rapidly eliminated by transformation into metabolites, which were eliminated at a slower rate. The Danish EPA concluded that the data indicate that the more hydrophobic AE (e.g. C13 EO4, C14 EO4, and C16 EO8) have a moderate bioaccumulation potential (Danish EPA 2001). They also note that in the study by Tolls (1998) the BCF values ranged from < 5 to 387.5, whereas the uptake rates ($k1$) varied from 330 to 1660 (l x kg x d-1) and the elimination rates ($k2$) varied from 3.3 to 59 (d-1). The time to steady state and the BCF for AE increase with decreasing length of the ethoxylate chain (e.g., t95 for C13 EO8 = 2.4 h and BCF = 30-55, and t95 for C13 EO4 = 17.1 h and BCF = 233) (Danish EPA 2001).

Tolls *et al.* (2000a,b) concluded that the high values of the elimination rate constants suggest that fathead minnows efficiently biotransform AE, thereby preventing AE from attaining high concentrations in fish. They note that estimates of the bioconcentration potential of AE mixtures in influents and effluents of several wastewater treatment plants were similar to each other, implying that the bioconcentration potential was not significantly altered by the processes involved in wastewater treatment. These estimates of the bioconcentration potential were conservative and ranged around 140 L/kg.

Environment Canada and Health Canada (2006) has established that the degree of bioaccumulation expected from AE is well below the Canadian bioconcentration criterion of 5000. The sixteen measured BCF values for 15 AE homologues showed the lack of a linear relationship between alkyl or ethoxylate chain length and BCF, with the highest measured BCF value being under 800. Environment Canada (2006) concluded that it is evident that the AE metabolism rates prevent any significant accumulation. The data indicated that there may be an optimal structural combination of ethoxylate and alkyl chain lengths, at or around C14EO7, where BCF is maximized, but even the measured BCF for this chemical is well below the criterion of 5000. Thus Environment Canada (2006) concluded that ethoxylated aliphatic alcohols are not bioaccumulative.

Aquatic Toxicity

Acute aquatic effects data is presented in the HERA report only to establish that the essentially linear and branched AE used in household detergents are not more toxic than

the linear AE which have the same uses. The toxicity mechanism for AE is accepted to be non-polar narcosis, in which the AE homologues with longer hydrocarbon chains and higher log K_{ow} are more efficient at penetration of the cell membrane, and thus more toxic. However, the AE homologues must be sufficiently soluble in water to allow a toxic concentration to reach the target organism. For the long chain alcohols, generally the least soluble and the most toxic of the AE homologues, the long chain alcohol OECD-Screening Information Assessment Report (SIAR) (SIAR 2006) shows that the toxicity is restricted by solubility considerations at hydrocarbon chain lengths of 15 and above. Although the addition of ethylene oxide groups makes the other AE homologues more soluble, solubility considerations may reduce the toxicity of several higher hydrocarbon chain length and lower EO chain length AE. The available acute toxicity data follows this generally accepted pattern, and also indicates that the linear, essentially linear and branches AE are of similar toxicity.

Toxicity to Terrestrial Organisms

Acute soil toxicity measurements for both plants and soil invertebrates are available from standard tests carried out on commercial AE mixtures, which contain differing distributions of AE homologues. The available data are reviewed in the HERA report.

A range of chronic soil tests has been carried out for two pure AE homologues, C12EO4 and C16EO4. The two AE homologues chosen for the chronic tests span the hydrocarbon chain length range of high tonnage AE, and have an EO chain length value at which the toxicity is expected to be in the high range for each hydrocarbon chain length. The chronic tests, to assess the survival and reproduction of earthworms (*Eisenia fetida fetida)*, springtails (*Folsomia candida*), and nematodes (*Caenorhabditas elegans*), were carried out using a natural sandy loam soil, with an organic carbon content of 1.3%, which could be assumed to be free of pesticide. If an application factor of 10 were applied to the lowest chronic NOEC value to determine a PNEC, a PNEC of 22 mg/kg would result for C12EO4 and a PNEC of 46 mg/kg would result for the C16EO4 AE homologue. Comparison of the acute test data with the equilibrium partition soil PNEC values show very similar values. Thus, the chronic soil toxicity results for C12EO4 and C16EO4 support the validity of the PNEC values determined by equilibrium partitioning.

Information showing the relatively small difference between acute and chronic toxicity for soil organisms means that available single homologue acute data also supports the PNEC calculated by equilibrium partitioning from aquatic monitoring data. In addition, available data for AE mixtures is consistent with the equilibrium partitioning PNEC values.

Determination of $PNEC_{aquatic}$

The chronic *Daphnia magna* QSAR developed by Boeije *et al.* (2006) can be used, with an appropriate application factor, to determine the PNEC for each AE homologue. Of the three trophic level QSARs discussed here, the chronic *Daphnia magna* QSAR is the most

robust. The algal QSAR work by Wind and Belanger (2006) has shown that AE toxicity to algae, daphnia, and fish are of similar magnitude, while the chronic AE toxicity data given indicates that *Daphnia magna* are among the most sensitive invertebrates.

The PNEC values determined for each AE homologue using both the chronic *Daphnia magna* QSAR with an application factor of 10 given in Table 4.38 of the HERA report. For the *Daphnia magna* QSAR, the application factor of 10 is used as three chronic QSARs are available for AE homologues. The *Daphnia magna* QSAR has been chosen as it is the most robust of these three chronic QSARs, and has the most sensitive endpoint over much of the range of AE homologues.

The composition of alcohols, C6-C12, ethoxylated propoxylated (CAS No. 68937-66-6). For a comparable C6-C12 alcohol ethoxylate, a mean PNEC was calculated as follows: for each hydrocarbon number, the PNEC value AE for EO units 1 to 20 were average together, providing a mean value that covers the range of PNECs calculated for that hydrocarbon number. Each of these mean PNECs were then averaged together to cover all of the hydrocarbon chain lengths that may be included in alcohols, C6-C12, ethoxylated propoxylated, *i.e.* C6 to C12. It should be noted that the HERA document does not cover hydrocarbon numbers less that C8 and therefore PNEC values were not calculated for the C6 and C7 alcohol ethoxylates. Without knowing the hydrocarbon distribution in the supplier product, it is unclear how the limited data will influence the overall PNEC value for this substance.

$PNEC_{aquatic}$: Chronic Daphnia magna QSAR and an Application Factor of 10

	C8 + C9 (mg/L)	**C10 (mg/L)**	**C11 (mg/L)**	**C12 (mg/L)**
Mean	3.54	1.71	0.979	0.513
Range	0.171 – 11.9	0.118 – 6.23	0.0652 – 3.26	0.0358 – 1.7

$PNEC_{aquatic}$ (freshwater) = (3.54 + 1.71 + 0.979 + 0.513)/4 = 1.69 mg/L

PBT Assessment

Based on the alcohol ethoxylates, the alcohols, C6-C12, ethoxylated propoxylated are expected to be readily biodegradable; thus, they not meet the screening criteria for persistence.

Based on the information provided in the bioaccumulation section above on the alcohol ethoxylates, the alcohols, C6-C12, ethoxylated propoxylated are not be expected to meet the criteria for bioaccumulation.

The chronic Daphnia NOEC value for the C8-C12 alcohol ethoxylates is >0.1 mg/L. Thus, the alcohols, C6-C12, alcohols, ethoxylated propoxylated are not expected to meet the criteria for toxicity.

The overall conclusion is that alcohols, C6-C12, ethoxylated propoxylated (CAS No. 68937-66-6) is not a PBT substance.

Environmental Assessment

Alcohols, C10-C16, Ethoxylated Propoxylated
(CAS No. 69227-22-1)

No toxicity information could located on alcohols, C10-C16, ethoxylated propoxylated (CAS No. 69227-22-1). Toxicity information is available on alcohol ethoxylates. Alcohols, C10-C16, ethoxylated propoxylated is produced by the use of propylene oxide (PO) in addition to ethylene oxide (EO) during the alkoxylation of the alcohol(s). the PO is either incorporated randomly by alkoxylation within the epoxide mixture, or in a block by sequencing the addition of EO and PO to the reactor. Because of the similarity in structures, the toxicity data on the alcohol ethoxylates were used to read-across to alcohols, C10-C16, ethoxylated propoxylated.

Alcohol ethoxylates (AE) are a class of non-ionic surfactants that have the basic structure $C_{x\text{-}y}AE_n$. The subscript (x-y) following the 'C' indicates the range of carbon chain units. AEs with carbon unit range between C8 to C18 are most commonly used in household detergent products. The hydrocarbon chain can be either linear or branched. AEs also contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by the subscript (n) which indicates the average number of ethylene oxide units. In household products the average ethylene oxide chain length commonly ranges between 3 and 12 units.

The toxicity profile has been developed from a risk assessment report on alcohol ethoxylates ranging from C8 to C18 prepared by the household cleaning product and chemical industry (HERA, 2009).

Biodegradation

AE homologues with hydrocarbon chain lengths ranging from 8 to 18 and with 2 to >20 ethylene oxide units are readily biodegradable.

As a class, AE undergo rapid primary and ultimate biodegradation under both laboratory and field conditions. The biodegradability of the different AE homologues used in HERA applications is relatively unaffected by the alkyl carbon chain length and the number of EO units.

Proposed half-lives in river water at 12^{o}C: 4 to 24 hours (based on experimental data).

AE are also anaerobically biodegradable.

Bioaccumulation

The AE homologues used for domestic cleaning applications are very likely to have a log Kow value greater than 3.

The Danish EPA report on surfactants (Danish EPA, 2001) found that bioaccumulation of alkyl ethoxylates in aquatic organisms had been determined only for fish. The majority of the limited data were based on studies with 14C-labelled compounds that do not allow the distinction between the parent compound and metabolites, or material incorporated into the cells during growth. Because alcohol ethoxylates are metabolized in aquatic organisms (Danish EPA, 2001), the bioconcentration factor for the parent compound may well be overestimated in experiments in which 14C-labelled model surfactants are used. Tolls *et al.* (2000a,b) combined 14C-techniques and chemical analysis to determine the amount of AE actually present as the parent molecule in the fish. This showed that the parent AE (e.g. C13 EO8) was rapidly eliminated by transformation into metabolites, which were eliminated at a slower rate. The Danish EPA concluded that the data indicate that the more hydrophobic AE (e.g. C13 EO4, C14 EO4, and C16 EO8) have a moderate bioaccumulation potential (Danish EPA 2001). They also note that in the study by Tolls (1998) the BCF values ranged from < 5 to 387.5, whereas the uptake rates ($k1$) varied from 330 to 1660 (l x kg x d-1) and the elimination rates ($k2$) varied from 3.3 to 59 (d-1). The time to steady state and the BCF for AE increase with decreasing length of the ethoxylate chain (e.g., t95 for C13 EO8 = 2.4 h and BCF = 30-55, and t95 for C13 EO4 = 17.1 h and BCF = 233) (Danish EPA 2001).

Tolls *et al.* (2000a,b) concluded that the high values of the elimination rate constants suggest that fathead minnows efficiently biotransform AE, thereby preventing AE from attaining high concentrations in fish. They note that estimates of the bioconcentration potential of AE mixtures in influents and effluents of several wastewater treatment plants were similar to each other, implying that the bioconcentration potential was not significantly altered by the processes involved in wastewater treatment. These estimates of the bioconcentration potential were conservative and ranged around 140 L/kg.

Environment Canada and Health Canada (2006) has established that the degree of bioaccumulation expected from AE is well below the Canadian bioconcentration criterion of 5000. The sixteen measured BCF values for 15 AE homologues showed the lack of a linear relationship between alkyl or ethoxylate chain length and BCF, with the highest measured BCF value being under 800. Environment Canada (2006) concluded that it is evident that the AE metabolism rates prevent any significant accumulation. The data indicated that there may be an optimal structural combination of ethoxylate and alkyl chain lengths, at or around C14EO7, where BCF is maximized, but even the measured BCF for this chemical is well below the criterion of 5000. Thus Environment Canada (2006) concluded that ethoxylated aliphatic alcohols are not bioaccumulative.

Aquatic Toxicity

Acute aquatic effects data is presented in the HERA report only to establish that the essentially linear and branched AE used in household detergents are not more toxic than

the linear AE which have the same uses. The toxicity mechanism for AE is accepted to be non-polar narcosis, in which the AE homologues with longer hydrocarbon chains and higher log K_{ow} are more efficient at penetration of the cell membrane, and thus more toxic. However, the AE homologues must be sufficiently soluble in water to allow a toxic concentration to reach the target organism. For the long chain alcohols, generally the least soluble and the most toxic of the AE homologues, the long chain alcohol OECD-Screening Information Assessment Report (SIAR) (SIAR 2006) shows that the toxicity is restricted by solubility considerations at hydrocarbon chain lengths of 15 and above. Although the addition of ethylene oxide groups makes the other AE homologues more soluble, solubility considerations may reduce the toxicity of several higher hydrocarbon chain length and lower EO chain length AE. The available acute toxicity data follows this generally accepted pattern, and also indicates that the linear, essentially linear and branches AE are of similar toxicity.

Toxicity to Terrestrial Organisms

Acute soil toxicity measurements for both plants and soil invertebrates are available from standard tests carried out on commercial AE mixtures, which contain differing distributions of AE homologues. The available data are reviewed in the HERA report.

A range of chronic soil tests has been carried out for two pure AE homologues, C12EO4 and C16EO4. The two AE homologues chosen for the chronic tests span the hydrocarbon chain length range of high tonnage AE, and have an EO chain length value at which the toxicity is expected to be in the high range for each hydrocarbon chain length. The chronic tests, to assess the survival and reproduction of earthworms (*Eisenia fetida fetida)*, springtails (*Folsomia candida*), and nematodes (*Caenorhabditas elegans*), were carried out using a natural sandy loam soil, with an organic carbon content of 1.3%, which could be assumed to be free of pesticide. If an application factor of 10 were applied to the lowest chronic NOEC value to determine a PNEC, a PNEC of 22 mg/kg would result for C12EO4 and a PNEC of 46 mg/kg would result for the C16EO4 AE homologue. Comparison of the acute test data with the equilibrium partition soil PNEC values show very similar values. Thus, the chronic soil toxicity results for C12EO4 and C16EO4 support the validity of the PNEC values determined by equilibrium partitioning.

Information showing the relatively small difference between acute and chronic toxicity for soil organisms means that available single homologue acute data also supports the PNEC calculated by equilibrium partitioning from aquatic monitoring data. In addition, available data for AE mixtures is consistent with the equilibrium partitioning PNEC values.

Determination of $PNEC_{aquatic}$

The chronic *Daphnia magna* QSAR developed by Boeije *et al.* (2006) can be used, with an appropriate application factor, to determine the PNEC for each AE homologue. Of the three trophic level QSARs discussed here, the chronic *Daphnia magna* QSAR is the most

robust. The algal QSAR work by Wind and Belanger (2006) has shown that AE toxicity to algae, daphnia, and fish are of similar magnitude, while the chronic AE toxicity data given indicates that *Daphnia magna* are among the most sensitive invertebrates.

The PNEC values determined for each AE homologue using both the chronic *Daphnia magna* QSAR with an application factor of 10 given in Table 4.38 of the HERA report. For the *Daphnia magna* QSAR, the application factor of 10 is used as three chronic QSARs are available for AE homologues. The *Daphnia magna* QSAR has been chosen as it is the most robust of these three chronic QSARs, and has the most sensitive endpoint over much of the range of AE homologues.

The composition of alcohols, C6-C12, ethoxylated propoxylated (CAS No. 68937-66-6). For a comparable C6-C12 alcohol ethoxylate, a mean PNEC was calculated as follows: for each hydrocarbon number, the PNEC value AE for EO units 1 to 20 were average together, providing a mean value that covers the range of PNECs calculated for that hydrocarbon number. Each of these mean PNECs were then averaged together to cover all of the hydrocarbon chain lengths that may be included in alcohols, C6-C12, ethoxylated propoxylated, *i.e.* C6 to C12. It should be noted that the HERA document does not cover hydrocarbon numbers less that C8 and therefore PNEC values were not calculated for the C6 and C7 alcohol ethoxylates. Without knowing the hydrocarbon distribution in the supplier product, it is unclear how the limited data will influence the overall PNEC value for this substance.

$PNEC_{aquatic}$: Chronic Daphnia magna QSAR and an Application Factor of 10

	C10 (mg/L)	**C11 (mg/L)**	**C12 (mg/L)**	**C13 (mg/L)**	**C14 (mg/L)**	**C15 (mg/L)**	**C16 (mg/L)**
Mean	1.71	0.979	0.513	0.308	0.142	0.074	0.042
Range	0.118 – 6.23	0.0652 – 3.26	0.0358 – 1.7	0.0196 – 0.89	0.0107 – 0.465	0.00583 – 0.243	0.00316 – 0.127

$PNEC_{aquatic}$ (freshwater) = (1.71 + 0.979 + 0.513 + 0.308 + 0.142 + 0.074 + 0.042)/7 = 0.538 mg/L

PBT Assessment

Based on the alcohol ethoxylates, the alcohols, C10-C16, ethoxylated propoxylated are expected to be readily biodegradable; thus, they not meet the screening criteria for persistence.

Based on the information provided in the bioaccumulation section above on the alcohol ethoxylates, the alcohols, C10-C16, ethoxylated propoxylated are not be expected to meet the criteria for bioaccumulation.

The chronic Daphnia NOEC value for the C10-C16 alcohol ethoxylates is >0.1 mg/L. Thus, the alcohols, C10-C16, alcohols, ethoxylated propoxylated are not expected to meet the criteria for toxicity.

The overall conclusion is that alcohols, C10-C16, ethoxylated propoxylated (CAS No. 69227-22-1) is not a PBT substance.

Environmental Assessment

Choline chloride
Cholinium chloride
(CAS No. 67-48-1)

Choline chloride, also known as cholinium chloride, is quaternary amine salt. It dissociates in water into the corresponding positively charged quaternary hydroxyl alkylammonium ion and the negatively charged chloride ion.

Choline chloride has been reviewed in the OECD-SIDS program (OECD, 2004).

Environmental Fate and Transport

Results from Mackay Level I modeling indicate that choline chloride will be distributed completely into water (BASF AG, 2004).

Biodegradation

Choline chloride is readily biodegradable (93% within 14 days) in a MITI I-test (MITI, 1992). In another MITI-I test, biodegradation was $\geq$60%, indicating ready biodegradation (Tunkel *et al.*, 2000). A $BOD_5/ThOD_5$ ratio of 75% was obtained in a BOD_5 test performed according to DIN 38409 part 43 (BASF AG, 1984).

Bioaccumulation

No measured data on bioaccumulation of choline chloride are available. The experimental octanol-water partition coefficient (log K_{ow}) was determined to be -3.77. The estimated BCF using the equation log BCF = 0.85*logK_{ow} – 0.70 is 0.59. Therefore, bioaccumulation is not expected in aquatic organisms.

Aquatic Toxicity

The 96-hour fish LC_{50} value is >100 mg/L (nominal and measured) in *Oryzias latipes* (MOE Japan, 1999a), and the 48-hour in vertebrate EC_{50} is 349 mg/L (nominal and measured) in *Daphnia magna* (MOE Japan, 1999b). The 72-hour EC_{50} to *Pseudokirchneriella subcapitata* is >1,000 mg/L (nominal and measured) based on growth rate; the 72-hour NOEC is 32 mg/L (MOE Japan, 1999c).

In a 21-day *Daphnia magna* reproduction test, the nominal and measured NOEC was reported to be 30.2 mg/L (MOE Japan, 1999d).

Toxicity to Terrestrial Plants

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), invertebrates (349 mg/L), and algae (>1,000 mg/L). Results from chronic studies are available for invertebrates (21-day NOEC = 30.2 mg/L) and algae (72-hour NOEC = 32 mg/L). On the basis that the data consists of chronic studies on two trophic level (albeit not on the species with the lowest $E(L)C_{50}$), an assessment factor of 50 has been applied to the lowest reported NOEC of 30 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.6 mg/L.

PBT Assessment

Choline chloride is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of -3.77 and a calculated BCF of 0.59, choline chloride does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on choline chloride show NOECs of >0.01 mg/L. Thus, choline chloride does not meet the screening criteria for toxicity.

The overall conclusion is that choline chloride is not a PBT substance.

Environmental Assessment

Cocoamidopropyl betaine
(CAS No. 61789-40-0)

Cocoamidopropyl betaine has been reviewed in the OECD-SIDS program (OECD, 2006).

Cocamidopropyl betaines are mainly a mixture of C_{12}-C_{18} fatty acids from hydrolysis of coconut oil. Coconut oil has a mixed fatty acid composition, which varies slightly, as it is a natural product. Lauric acid - resulting in lauramidopropyl betaine - is the major ingredient of coconut oil. As the physical chemical properties of cocamidopropyl betaine are not fully available as measured values, calculated values of lauramidopropyl betaine (RCOOH=lauric acid, C_{12} fatty acid) - as the main component in the cocamidopropyl betaine - are indicated instead. If possible the calculated ranges for the cocamidopropyl betaine (C_{12} – C_{18}) are given. In terms of the environmental exposure assessment, the relevant calculated values of the respective betaine derived from the C_{18} fatty acid – Stearamidopropylbetaine are indicated. The characteristics of the stearamidopropylbetaine are regarded as to represent the most hydrophobic properties of the cocamidopropyl betaine.

Environmental Transport

Based on the calculation for caprylamidopropyl betaine (C8 fatty acid derivative) and stearamidopropyl betaine (C18 fatty acid derivative), cocamidopropyl betaine will be mainly distributed to the hydrosphere (59 - 100 %), and to a lesser extent to soil and sediment (0 - 20 % each). The Henry's law constants for alkylamidopropyl betaines calculated for every single fatty acid chain length indicate a very low potential for volatilization from surface waters under environmentally relevant conditions. The soil sorption coefficients (K_{OC}) calculated for the alkylamidopropyl betaines indicate a low to very high potential for sorption to organic matter of soils and sediments. The low sorption potential is confirmed by experimentally obtained values for laurylamidopropyl betaine (C12 derivative) and tetradecylamidopropyl betaine (C14 derivative) from the screening HPLC-method according to OECD Test Guideline 121. A high potential for sorption applies only for the alkylamidopropyl betaines with the C16 and C18 fatty acid chain length.

Biodegradation

Cocamidopropyl betaine can be considered as being readily biodegradable under aerobic conditions. In guideline tests biodegradation rates of 86 – 100 % after 28 days (OECD 301A/B/D/E), 90 – 93 % after 35 days (OECD 301B) and 100 % after 20 days (Directive 84/449/EEC, C.5) were determined with cocamidopropyl betaine. Under anaerobic

conditions, 80 – 90 % mineralization after 60 days or 56% after 56 days were observed for cocamidopropyl betaine.

Bioaccumulation

A low potential for bioaccumulation is to be expected for cocoamidopropyl betaines based on the calculated BCFs between 3 (with C8 fatty acid) and 71 (with C10 – C18 fatty acids).

Aquatic Toxicity

For cocoamidopropyl betaine, the lowest acute LC/EC_{50} values for fish, *Daphnia*, and algae are all in the range of 1.3 – 2 mg active substance/L. One long-term test with fish (according to OECD 215), and several chronic tests with *Daphnia* and algae were conducted on cocoamidopropyl betaine. The lowest NOECs are 0.16 mg active substance/L for fish (*Oncorhynchus mykiss*), 0.03 mg active substance/L for *Daphnia magna*, and 0.09 mg active substance/L for green algae (*Desmodesmus subspicatus*). These values were derived with analytical monitoring (photometric) except for the algae test. However, the effect values within the same species (*e.g.*, *Desmodesmus subspicatus*, *Daphnia magna*) have shown a high variability. Recent guideline studies performed in accordance with OECD 211 and 201 using state-of-the-art analytical monitoring and a quality of cocamidopropyl betaine currently commercialized, resulted in a lower aquatic toxicity. In these studies the lowest NOEC for *Daphnia* was determined to be 0.932 mg active substance/L. The lowest NOEC (72 hour, based on growth rate) for algae was determined to be 3.55 mg active substance/L (72-hour ErC_{50} = 9.86 mg active substance/L). This latter NOEC for algae is further supported by the similar NOEC of 3.53 mg active substance/L calculated using the geometric mean of all valid tests with this algae species. Furthermore, for algae a potential for recovery from the effect up to a concentration of 96 mg active substance/L has been observed.

Toxicity to Terrestrial Organisms

Two studies (without analytical monitoring) of effects on earthworms and higher plants showed low toxicity (no data given in the OECD-SIDS SIAP). Taking additionally into account that the adsorption potential of the main components of cocamidopropyl betaine (the C8 to C14 derivatives) is low, a risk for the terrestrial compartment is not expected.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. A recent state-of-the-art chronic study is available for invertebrates (lowest NOEC for Daphnia is 0.932 mg/L). A recent state-of-the-art OECD 211 study is also available with the lowest

NOEC (72 hour, based on growth rate) for algae was determined to be 3.55 mg/L. On the basis that the data consists of two chronic studies (Daphnia and algae), an assessment factor of 50 has been applied to the lowest reported NOEC of 0.932 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.019 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated using PCKOCWIN v. 1.66 using specific betaine with C8, C10, C12, C14, C16, and C18 fatty acids. Using a Koc values of 264.7 to 120600 and a $PNEC_{aquatic}$ of 0.0.019 mg/L, the $PNEC_{sediment}$ was calculated to be 0.085 to 33.7 mg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using PCKOCWIN v. 1.66 using specific betaine with C8, C10, C12, C14, C16, and C18 fatty acids. Using a Koc values of 264.7 to 120,600 and a $PNEC_{aquatic}$ of 0.0.01 mg/L, the $PNEC_{soil}$ was calculated to be 0.066 to 29.8 mg/kg.

PBT Assessment

Cocoamidopropyl betaine is readily biodegradable and thus it does not meet the screening criteria for persistence.

The estimated log Kow values for cocoamidopropyl betaine (with C8 to C18 fatty acids) is -1.28 to 3.63, calculated using KOWWIN v1.67 (HERA, 2005). Thus, cocoamidopropyl betaine does not meet the screening criteria for bioaccumulation.

The lowest chronic NOEC for cocoamidopropyl betaine is >0.1 mg/L. Thus, cocoamidopropyl betaine does not meet the criteria for toxicity.

The overall conclusion is that cocoamidopropyl betaine is not a PBT substance.

Environmental Assessment

Coffee Beans (Roasted and Ground)

The composition of a medium-roasted coffee (Clarke, 1987; IARC, 1991) is shown in the table below:

Components	Typical avg content (dry basis, %)		% extractable with water, 100°C[a]
	Arabica	Robusta	
Alkaloids (caffeine)	1.3	2.4	75 - 100
Trigonelline (including roasted by-products)	1.0	0.7	85 - 100
Minerals (as oxide ash)	4.5	4.7	90
Acids			
Residual chlorogenic	2.5	3.8	100
Aquinic	0.8	1.0	100
Aliphatic	1.6	1.6	100
Sugars			
Sucrose	0.0	0.0	-
Reducing	0.3	0.3	100
Polysaccharides (unchanged from green)	33	37	10
Lignin	2.0	2.0	0
Pectins	3.0	3.0	-
Proteinaceous compounds			
Protein	10	10	15 – 20
Free amino acids	0.0	0.0	-
Lipids (coffee oil)	17	11	1
Caramelized or condensation products (*e.g.*, melanoidins) by difference	23	22.5	20-25
Volatile substances other than acids	0.1	0.1	40-80

[a]Maier (1981), for normal household brewing

The environmental assessment will focus on caffeine.

Caffeine (CAS No. 58-08-2) is an alkaloid. The chemical names for caffeine are 1,3,7-trimethyl-2,6-dioxopurine; 1,3,7-trimethylxanthine; 2,7-dihydro-1,3,7-trimethyl-1H-purine-2,6-dione; and 7-methyltheophylline. Caffeine has been reviewed in the OECD-SIDS program (OECD, 2002a,b) and has been registered in the EU under the REACH legislation (ECHA REACH database).

Caffeine is soluble in water with a solubility limit of 20 g/L at 20°C. The measured octanol-water coefficient (log K_{ow}) is -0.091. A Mackay Level I fugacity model predicts that caffeine will distribute almost entirely into water (99.99%). One biodegradation study was found on caffeine, but findings have not been considered valid due to the large variability in the results (OECD, 2002a,b). The structural analogue of caffeine, theophylline (CAS No. 58-55-9) which differs from caffeine in the absence of a methyl group at the 7- position, has been tested for ready biodegradation in an OECD 301A test (OECD, 2002a,b). There was 90-100% degradation after 22 days, with >90% at the end of the 10-day window, indicating ready biodegradation. Thus, caffeine would be expected to biodegrade rapidly in the environment.

Acute toxicity guideline studies have been conducted in fish, invertebrates and algae (OECD, 2002a,b; ECHA REACH database). A 96-hour LC_{50} in *Leuciscus idus* was reported to be 87 mg/L; the 48-hour EC_{50} in *Daphnia magna* was reported to be 182 mg/L. and the ErC_{50} in *Scenedesmus subspicatus* was reported to be >100 mg/L. Based on the lowest acute toxicity value of 87 mg/L in fish, caffeine is considered to be harmful to aquatic organisms. Using an assessment factor of 1,000, a $PNEC_{aquatic}$ is determined to be 0.087 mg/L.

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Ethylene glycol
(CAS No. 107-21-1)

Ethylene glycol has been reviewed in the OECD-SIDS program (OECD, 2004a,b)

Environmental Transport

A Mackay Level III fugacity model predicts that ethylene glycol will distribute 45.6% to water, 52.3% to soil, 2.02% to air, and <0.1% to sediment (OECD, 2004a,).

Biodegradation

Ethylene glycol is readily biodegradable both aerobically and anaerobically. There was 97% degradation after 20 days in a BOD test (OECD, 2004a,b), and 96% degradation after 28 days in an OECD 301D test (OECD, 2004a,b).

The aerobic degradation of ethylene glycol was measured from grab river water samples at 4, 8, and 20^{o}C (Evans and David, 1974). At 20^{o}C, ethylene glycol was completely degraded in three days in all river waters tested, and at 8^{o}C degradation was complete within 14 days. Degradation at 4^{o}C was substantially slower, with degradation of less than 20% after 14 days in river samples with limited suspended matter and a starting concentration of 10 mg/L.

Bioaccumulation

The log K_{ow} of ethylene glycol was measured as -1.36 (Hansch *et al.*, 1989). The BCF for ethylene glycol in golden ide (*Leuciscus idus melanotus*) after three days of exposure was determined to be 10 (Freitag *et al.*, 1985).

Aquatic Toxicity

The 96-hour LC_{50} values to fry, juvenile, and subadult fathead minnows (*Pimephales promelas*) are 53,000, 49,000 and 57,000 mg/L, respectively (Mayes *et al.*, 1983). The 96-hour LC_{50} values to fathead minnows (*Pimephales promelas*) was also reported to be 72,860 mg/L (Pillard, 1995). The 96-hour LC_{50} to rainbow trout (*Oncorhynchus mykiss*) is 22,810 mg/L (OECD, 2004b). In a 12-day chronic study, the NOEC to rainbow trout (*Oncorhynchus mykiss*) was reported to be 14,692 mg/L (OECD, 2004b).

The 48-hour LC_{50} to *Daphnia magna* is 46,300 mg/L (Gersich *et al.*, 1986). The 48-hour EC_{50} values to *Ceriodaphnia dubia-affinis* and *Daphnia magna* are 10,000 and 51,000 mg/L at 24^{o}C, respectively; and 25,800 and 46,300 mg/L at 24^{o}C, respectively (Cowgill

et al., 1985). The NOEC for a 7-day reproduction test to *Ceriodaphnia dubia* is 3,469 mg/L (OECD, 2004b).

The 96-hour EC_{50} to green algae (*Selenastrum capricornutum*) is 10,940 mg/L based on cell growth; the NOEC is 10,000 mg/L (Pillard and DuFresne, 1999).

Toxicity to Sediment Organisms

No data were located.

Toxicity to Terrestrial Organisms

A mallard duck receiving 1.1 mL/kg ethylene glycol recovered, but ducks (1/dose) receiving 2.3, 4.5, 8.9, 13.3, and 17.8 mL/kg died (Stowe *et al.*, 1981). Ethylene glycol (0.1 mL/chicken egg) significantly decreased hatchability relative to controls and significantly increased embryonic mortality during weeks 1 and 3 (Ameenuddin and Suude, 1984). Doses of 0, 0.05, 0.1, and 0.15 ml/egg resulted in hatchability of approximately 82, 75, 45 and 45%, respectively.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (22,810 mg/L), Daphnia (10,000 mg/L), and algae (10,940 mg/L). NOEC values are available for fish (14,692 mg/L), invertebrates (3,469 mg/L), and algae (10,000 mg/L). On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 3,469 mg/L for invertebrates. The $PNEC_{aquatic}$ is 347 mg/L.

PBT Assessment

Ethylene glycol is readily biodegradable and thus does not meet the screening criteria for persistence.

The octanol-water coefficient (log K_{ow}) for ethylene glycol is -1.36. The measured BCF in fish is 10. Thus, ethylene glycol does not meet the criteria for bioaccumulation.

The chronic toxicity data on ethylene glycol show NOECs of >0.01 mg/L. Thus, ethylene glycol does not meet the screening criteria for toxicity.

The overall conclusion is that ethylene glycol is not a PBT substance.

Environmental Assessment

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyanopsis tetragonolobus*. Structurally, it is a galactomannan (a polysaccharide) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum ranges from 200,000 to 300,000 daltons (Glickman, 1969).

Biodegradation

No information was found. Guar gum, being a polysaccharide composed of galactomannan, would be expected to be readily biodegradable.

Bioaccumulation

Not expected to bioaccumulate as a polysaccharide composed of galactomannans.

Aquatic Toxicity

The 48-hour LC_{50} for *Daphnia magna* was reported to be 42 mg/L (Biesinger *et al.*, 1976).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. An acute LC_{50} value is available for the invertebrate Daphnia (42 mg/L). On the basis that the data consists of only one short-term result from one trophic level, an assessment factor of 1,000 has been applied to the reported effect concentration of 42 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.042 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition

method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

No biodegradation was found on guar gum. However, guar gum is a naturally occurring polysaccharide which would be expected to readily biodegrade. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons, and it is also water soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The acute aquatic toxicity of guar gum is >0.1 mg/L. Thus, guar gum is not expected to meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

Environmental Assessment

Hemicellulase
(CAS No. 9025-56-3)

Hemicellulases are a group of enzymes that break down hemicellulose, which are polysaccharides that are present in cell walls of all terrestrial plants. These polysaccharides have a β-(1→4)-linked backbone and are composed of pentoses (xylose, arabinoses), hexoses (mannose, glucose, galactose), and sugar acids. Unlike cellulose which are polysaccharides consisting of linear chains of several hundred to over ten thousand β-(1→4) linked D-glucoses, hemicelluloses are not chemically homogeneous. The best characterized hemicellulases are the 1,4- β -D-xylanases and, in particular, those derived from fungal sources presumably because their substrates, xylans, constitute the largest proportion of hemicelluloses in pasture plants.

No toxicity information could be located on hemicellulases; however, mammalian toxicity information were found on the cellulase enzymes (HERA report, 2005). Cellulases cleave the ß-1,4-glycosidic bonds in cellulose, and are used in the pulp and paper industry, the textile industry, and in detergents to remove deposits and stains.

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity. For the purposes of risk assessment, the structure of hemicellulases would be expected to be similar to that of cellulases, given that hemicellulases and cellulases are both enzyme families that hydrolyze polysaccharides, although differing in their substrates. Thus, the toxicity data on cellulases will be used as read-across to hemicellulases.

Biodegradation

Three different cellulase enzymes were considered readily biodegradable based on the results of OECD 301C and 301E tests (HERA, 2005). In an OECD 301E test, there was 84% DOC removal of the enzyme Carezyme after 28 days. In another OECD 301E test, there was 92% DOC removal of the enzyme Clazinase® after 28 days. In an OECD 301C test, BOD/COD was 78% after 28 days. Likewise, hemicellulase is expected to be readily biodegradable.

Aquatic Toxicity

The 96-hour LC_{50} of an alkaline cellulase to zebrafish (*Brachydanio rerio*) is 330 mg aep/L (HERA, 2005). The 48-hour EC_{50} of the same alkaline cellulase to *Daphnia magna* is >1,000 mg aep/L (HERA, 2005). The same alkaline cellulase was also tested in algae (*Scenedesmus subspicatus*), with a 72-hour EC_{50} of >1000 mg aep/L (HERA,

2005).

The 24- and 48-hour EC_{50} values of an alkaline cellulase (SP 227, Celluzyme) to *Daphnia magna* are >1,000 mg aep/L and approximately 1,000 mg aep/L respectively (HERA, 2005).

Two additional acute fish toxicity studies showed findings with LC_{50} values of >100 mg aep/L, but no references were provided (HERA, 2005).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (330 mg aep/L), Daphnia (>1,000 mg aep/L), and algae (1,000 mg aep/L). Although the HERA report provides information on two acute fish studies with LC_{50} values of >100 mg aep/L, no references were provided and were therefore excluded from the determination of PNECs. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 330 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.33 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{sediment}$ was calculated to be 0.21 mg aeg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{soil}$ was calculated to be 0.006 mg aeg/kg.

PBT Assessment

Hemicellulase is expected to be readily biodegradable based on read-across to cellulases. Thus, hemicellulase does not meet the screening criteria for persistence.

Based on the similarity to cellulase, hemicellulase has a high molecular weight (20 to 80 kD), has hydrophilic properties (high water solubility, log Kow <0), and is readily metabolized in organisms by proteolytic enzymes or proteases. Thus, hemicellulose does not meet the screening criteria for bioaccumulation.

The acute $EC(L)_{50}$ of hemicellulase is >0.1 mg/L in fish, invertebrates and algae. Thus, hemicellulase does not meet the screening criteria for toxicity.

The overall conclusion is that hemicellulase is not a PBT substance.

Environmental Assessment

Maltodextrin
(CAS No. 9050-36-6)

Maltodextrin is a nonsweet nutritive saccharide polymer that consists of D-glucose units linked primarily by $\alpha,1\rightarrow4$ bonds and that has a dextrose equivalent (D.E.) of <20. Typical commercial maltodextrins contain as few as three and as many as nineteen linked dextrose units. It is prepared as a white powder or concentrated solution by partial hydrolysis of corn starch, potato starch, or rice starch with safe and suitable acids and enzymes.

Biodegradation

No specific biodegradation studies could be found on maltodextrin. However, it is biopolymer that is readily broken down in the gastrointestinal tract of mammals by bacteria. Thus, it is expected to be readily biodegradable in the environment.

Aquatic Toxicity

No aquatic toxicity studies were found on maltodextrin. However, some of the smaller polymeric chains have molecular weights of <1,000 and are thus bioavailable. D-glucose, the monomeric units of maltodextrin, are found naturally in aquatic organisms and play a beneficial role. Thus, maltodextrin is not expected to be toxic to aquatic organisms.

Determination of PNECs

No aquatic toxicity data could be found on maltodextrin. Thus, PNECs were not determined.

PBT Assessment

Maltodextrin is expected to be readily biodegradable and thus would not be expected to meet the screening criteria for persistence.

The molecular weights of maltodextrin can be <1,000 and are thus bioavailable to aquatic organisms. Maltodextrin is water-soluble and composed of D-glucose monomeric units; which are naturally occurring in the body. Thus, maltodextrin is not likely to meet the screening criteria for bioaccumulation.

No aquatic toxicity data could be found on maltodextrin. However, D-glucose, the monomeric units of maltodextrin, are found naturally in aquatic organisms and play a beneficial role. Thus, maltodextrin is not expected to meet the screening criteria for toxicity.

The overall conclusion is that maltodextrin is not a PBT substance.

Environmental Assessment

Polyethylene Glycol
(CAS No. 25322-68-3)

Polyethylene glycols (PEGs) are water-soluble linear polymers formed by the addition reaction of ethylene oxide to an ethylene glycol equivalent. The general formula for polyethylene glycol is: $H-(OCH_2CH_2)_n-OH$ where "n" is the average number of repeating oxyethylene groups. PEGs are available in average molecular weights ranging from 200 to 8000.

No information on the aquatic toxicity and environmental fate and transport could be located for the PEGs. There are, however, data available on tetraEG and pentaEG, both being major constituents of the low molecular weight PEG 200. PEG 200 is a mixture consisting of ethylene glycols with an average molecular weight of approximately 200; there is an average of 4 oxyethylene units, but the range is from 2 to 8 oxyethylene units. The approximate composition of PEG 200 is as follows: 3% diethylene glycol (DEG), 17% triethylene glycol (TEG), 29% tetraEG, 25% pentaEG, 16% hexaEG, 8% heptaEG, and 2% octaEG (Bailey and Koleske, 1966).

Environmental Fate and Transport

PEG is a water-soluble polymer with molecular weights ranging from 200 to 8,000. PEG 200 consists of approximately 29% tetraEG and 25% pentaEG. A Mackay III fugacity model predicts that tetraEG and pentaEG will essentially distribute to water (45.3%) to soil (54.6%) (OECD, 2004).

Biodegradation

Both tetraEG and pentaEG are inherently biodegradable. For tetraEG, there was 22% degradation after 20 days in a BOD test and 40% degradation after 28 days in an OECD 301D test (Waggy *et al.*, 1994). For pentaEG, there was 34% degradation after 20 days in a BOD test (OECD, 2004).

Bioaccumulation

The log K_{ow} values for the PEG polymers were not found. Log K_{ow} and BCF values were estimated for tetraEG and pentaEG, the major constituents of the low molecular weight PEG 200. The log K_{ow} values for tetraEG and pentaEG were estimated to be -2.0 and -2.3, respectively, using EPISUITE v.4.11. The BCF values were estimated to be 3.16 for both tetraEG and pentaEG.

Aquatic Toxicity

No aquatic toxicity data were found on the PEG polymers. However, data are available on tetraEG and pentaEG.

For tetraEG, the acute 96-hour LC_{50} to fathead minnows (*Pimephales promelas*) is >10,000 mg/L (OECD, 2004), and the acute 48-hour LC_{50} to *Daphnia magna* is 7,746 mg/L (OECD, 2004).

For pentaEG, the acute 96-hour LC_{50} to fathead minnows (*Pimephales promelas*) is >50,000 mg/L (OECD, 2004); the acute 48-hour LC_{50} to *Daphnia magna* is >20,000 mg/L (OECD, 2004); and the 72-hour EC_{50} to algae *Pseudokirchneriella subcapitata* is >100 mg/L; the NOEC is 100 mg/L (OECD, 2004).

A 7-day LC_{50} for triethylene glycol in guppies was reported to be 63,000 mg/L (Könemann, 1981).

Toxicity to Terrestrial Organisms

No data were located on either PEG 200 or on the higher ethylene glycols, such as tetraEG and pentaEG.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels for PEG 200 constituents tetraEG and pentaEG. Acute $E(L)C_{50}$ values are available for fish (>10,000 mg/L), Daphnia (7,746 mg/L), and algae (>100 mg/L). Chronic toxicity data on pentaEG are available for algae (NOEC = 100 mg/L); and a chronic fish toxicity study has been conducted on triethylene glycol (NOEC = 63,000 mg/L), which is also found in PEG 200 but at lower concentrations than either tetraEG or pentaEG. On the basis that the data consists of short-term results from three trophic levels and long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported short-term EC_{50} of 100 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 2.0 mg/L.

PBT Assessment

No biodegradation data could be found on the PEG polymers. PEG is a water-soluble polymer, with molecular weights ranging from 200 to 8,000. The high molecular weight PEGs would be expected to meet the screening criteria for persistence. TetraEG and pentaEG are major constituents of the low molecular weight PEG 200. Biowin 2 predicts that both tetraEG and pentaEG will not biodegrade fast and Biowin 3 predicts the ultimate biodegradation timeframe is in weeks. Thus, the low molecular weight PEGs do not meet the screening criteria for persistence.

No information on log K_{ow} or BCF could be found on the PEG polymers. The molecular weights of PEGs range from 200 to 8,000. The high molecular weight PEGs would not be expected to bioaccumulate due to limitations in bioavailability because of the size of the polymer. TetraEG and pentaEG are major constituents of the low molecular weight PEG 200. The log K_{ow} values for tetraEG and penta were estimated to be -2.0 and -2.3, respectively; the BCF values were estimated to be 3.16 for both tetraEG and pentaEG. Thus, the low molecular weight PEGs are also not expected to meet the criteria for bioaccumulation.

No aquatic toxicity data could be located for the PEG polymers. The molecular weights of PEGs range from 200 to 8,000. The high molecular PEGs are not expected to meet the screening criteria of toxicity because the molecular size would limit bioavailability. TetraEG and pentaEG are major constituents of the low molecular weight PEG 200. There are no chronic aquatic toxicity on tetraEG or pentaEG; however, the acute aquatic toxicity is >0.1 mg/L. Thus, the low molecular weight PEGs are also not expected to meet the screening criteria for toxicity.

The overall conclusion is that the polyethylene glycol polymers are not PBT substances.

Environmental Assessment

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium hydroxide (NaOH) will be found predominantly in the aquatic environment. NaOH is present in the environment as sodium (Na^+) and hydroxyl (OH^-) ions, which implies that it will not adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Measured concentrations in aquatic ecosystems
The concentration of hydroxyl ions in the environment has been determined very extensively via pH measurements. The pH is a very important parameter of aquatic ecosystems and it is a standard parameter of water quality monitoring programs. The most important freshwater aquatic ecosystems of the world revealed average annual pH values between 6.5 and 8.3 but lower and higher values have been measured in other aquatic ecosystems (UNEP, 1995). In aquatic ecosystems with dissolved organic acids a pH of less than 4.0 has been measured, while in waters with a high chlorophyll content the bicarbonate assimilation can result in pH values of higher than 9.0 at midday (UNEP, 1995). The pH of an aquatic ecosystem is mainly determined by geochemical, hydrological and/or biological processes.

Also sodium has been measured extensively in aquatic ecosystems. For example UNEP (1995) reported the concentration for a total number of 75 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th –percentile, mean and 90th-percentile were 1.5, 28 and 68 mg/l, respectively.

NaOH addition and buffer capacity
An addition of NaOH to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th– percentile, mean and 90th-percentile were 20, 106 and 195 mg/l, respectively.

Aquatic Toxicity

At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realized that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralized and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity *e.g.*, NH_3 is more toxic than NH_4^+.

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L . At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L. The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia* cf. *dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

No data are available on the effects of NaOH on algae.

Toxicity to Terrestrial Organisms

Toxicity tests, which determined the effects of NaOH on terrestrial organisms, are not available. Significant exposure of the terrestrial environment is not expected and for this reason there is no need to perform toxicity test with terrestrial organisms. The results of terrestrial toxicity tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil.

Determination of PNECs

In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available and the results of the tests are more or less consistent. Altogether they give a sufficient indication about acute toxicity levels of sodium hydroxide.

Furthermore acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterized by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.

Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,

- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and

- The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for NaOH there is a need to assess the environmental effect of an NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

$PNEC_{aquatic}$: Based on the information above, a PNEC was not derived for sodium hydroxide.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium hydroxide dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium hydroxide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium hydroxide to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium hydroxide is dominated by its water solubility.

Sorption of sodium hydroxide should probably be regarded as a reversible situation, i.e., the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium hydroxide Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium hydroxide is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium hydroxide is an organic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

Environmental Assessment

Tetrakis(hydroxymethyl)phosphonium sulfate
(CAS No. 55566-30-8))

Environmental Fate and Transport

Tetrakis(hydroxymethyl)phosphonium sulfate (THPS) has a high water solubility and very low volatility. Photodegradation and hydrolysis of THPS are significant abiotic degradation pathways in the environment. THPS binds poorly to environmental particulates and is, therefore, mobile.

THPS is inherently biodegradable. In an OECD 302B study, greater than 20% degradation occurred within a 28-day period (IPCS, 2000). Aquatic aerobic degradation of THPS was assessed in a soil/water system using U.S. EPA guidelines. The soil was dosed with THPS at 1 μg/g. Radiolabeled THPS was metabolized with 60% of applied radioactivity appearing as CO_2 within 7 days. Major metabolites were trihydroxymethyl phosphine oxide (THPO) and bishydroxymethyl phosphonic acid (BMPA), which were both found in the water; neither degradate reached a concentration of 10% of the applied dose (IPCS, 2000). A comparable study at the same initial concentration of THPS but under anaerobic conditions also showed 60% degradation within 30 days, and the same breakdown products were identified (IPCS, 2000).

Aquatic Toxicity

The acute 96-hour LC_{50} in *Oncorhynchus mykiss* (rainbow trout) is 119 mg/L (IPCS, 2000). The acute 96-hour LC_{50} in (*Lepomis macrochirus*) bluegill sunfish is 93 mg/L (IPCS, 2000). The acute 96-hour LC_{50} in (*Cyprinodon variegatus*) sheepshead minnow is 72 mg/L (IPCS, 2000).

The 48-hour LC_{50} in *Daphnia magna* is 19.4 mg/L (IPCS, 2000).

The 72-hour EC_{50}s in freshwater green algae *Selenastrum capricornutum* are 0.652 mg/L (growth rate) and 0.204 mg/L (biomass). The NOECs were 0.063 mg/L (IPCS, 2000).

Toxicity to Sediment Organisms

No data could be located for freshwater sediment organisms. A 10-day LC_{50} for *Corophium volutator* was reported to be 2,174 mg/kg dry sediment weight (IPCS, 2000).

Toxicity to Terrestrial Organisms

The LD_{50} to mallard duck (*Anas platyryncus*) is 311 mg/kg (IPCS, 2000). The dietary LC_{50}s to mallard ducks and bobwhite quail are 1,313 and 2,414 mg/kg diet, respectively (IPCS, 2000).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (72 mg/L), Daphnia (19.4 mg/L), and algae (0.204 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.204 mg/L for fish. The $PNEC_{aquatic}$ is calculated to be 0.0002 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on freshwater sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was calculated to be 142.3. Using a Koc of 142.3 and a $PNEC_{aquatic}$ of 0.204 µg/L, the $PNEC_{sediment}$ was calculated to be 0.56 µg/kg.

$PNEC_{soil}$: No adequate experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated to be 142.3. Using a Koc of 142.3 and a $PNEC_{aquatic}$ of 0.204 µg/L, the $PNEC_{soil}$ was calculated to be 0.38 µg/kg.

PBT Assessment

The results of BIOWIN v4.10 for THPS are as follows: biodegrade fast (Biowin2); ultimate biodegradation timeframe is days-weeks (Biowin3); and biodegrades fast (Biowin 6). Thus, THPS does not meet the screening criteria for persistence.

The estimated log Kow for THPS using EPISUITE is -20.39. Hydrolysis is also indicated as a significant abiotic degradation process. Thus, THPS does not meet the screening criteria for bioaccumulation.

The NOEC from a 72-hour green algae study was reported to be 0.063 mg/L, which is <0.1 mg/L. Thus, THPS meets the criteria for toxicity.

The overall conclusion is that Tetrakis(hydroxylmethyl)phosphonium sulfate is not a PBT substance.

APPENDIX G.6 SCHLUMBERGER YF120FLEX WITH J318 SYSTEM

Environmental Assessment

Reaction mass of 5-chloro-2-methyl-4-isothiazolin-3-one and 2-methyl-2H-isothiazolin-3-one [3:1]
(CAS No. 55965-84-9)

Environmental Fate

5-Chloro-2-methyl-4-isothiazolin-3-one and 2-methyl-4-isothiazolin-3-one, the active ingredients in DOW™ CMIT/MIT antimicrobial products, have a low bioconcentration potential (tendency to accumulate in the food chain) and a high potential for mobility in soil. They are completely soluble in water. In the environment these compounds would tend to partition into water where they would rapidly biodegrade to non-persistent substances which are several orders of magnitude less toxic than parent compound. They would also be removed by common biological wastewater treatment facilities.

Biodegradation

The primary aerobic biodegradability of MIT has been examined in a river sediment-water system by use of a ^{14}C-labelled model compound. During the 7-day experiment ^{14}C-labelled MIT was rapidly metabolized as only 12.6% of the initial MIT was present after 24 hours of incubation at 25□C. The calculated half-life for the parent compound was 9.1 hours (Reynolds, 1994a). MIT was metabolized to several unidentified metabolites. One of the major metabolites reached a level corresponding to 18.2% of the ^{14}C added after 24 hours of incubation. This metabolite decreased to 6.8% after 7 days which indicates further transformation. Other metabolites tended to increase during the 7-day experiment. At the end of the experiment metabolites that were bound in the sediment corresponded to 55%, whereas $^{14}CO_2$ attained 9% of the added ^{14}C. Most of the formed metabolites have shorter chromatographic retention times than MI which indicates that they are polar compounds. On the basis of the identification of metabolites from transformation of 4,5-dichloro-2-(n-octyl)-4-isothiazolin-3-one, it has been proposed that MI is transformed via N-methyl malonamic acid, N-methyl acetamide, and malonic acid (Madsen, 2000).

The primary biodegradability of CMIT has been examined with the same type of sediment and water as described for MIT. The ^{14}C-labelled CMIT was rapidly metabolized as only 30% of the initial CMI remained after 24 hours of incubation at 25□C. The calculated half-life for the intact CMIT was 17.3 hours (Reynolds, 1994b). At the end of the 7-day experiment, the sediment bound metabolites corresponded to 57.1% of the added ^{14}C, whereas 2.8% of the added ^{14}C was released as $^{14}CO_2$. Due to the structural similarities of MI and CMIT, it is suggested that the major metabolites for the transformation of CMIT are the same as described for MIT.

MIT was tested in an OECD 301B test modified for low concentrations of ^{14}C-labelled compounds. The accumulated $^{14}CO_2$ attained 54.1%, 55.8%, and 47.6% in the respective concentrations (0.1, 0.03 and 0.01 mg/l) after 29 days. During the 10-day window, 37%, 30% and 30%, respectively, of the initial MIT was mineralized to

$^{14}CO_2$ (Bashir, 1998a).

CMIT was tested in an OECD 301B modified for low concentrations of ^{14}C-labelled compounds. The accumulated $^{14}CO_2$ attained 38.8%, 55.3%, and 62% in the respective concentrations (0.3, 0.1, and 0.03 mg/l) after 29 days. During the 10- day window, 25%, 40%, and 48%, respectively, of the initial CMIT was mineralized to $^{14}CO_2$. The ultimate biodegradability of CMIT exceeded the 60%-pass level for ready biodegradability at the lowest test concentration of 0.03 mg/L, but the pass level was not reached within the 10-day window Bashir, 1998b).

From Dow Chemicals MSDS for ROCIMA GT:
Biodegradation (aquatic metabolism): 5-Chloro-2-methyl-4-isothiazolin-3-one (CMIT): t ½ anaerobic = 0.2 day, t ½ aerobic = 0.38 – 1.3 days; 2-Methyl-4-isothiazolin-3-one (MIT): t ½ aerobic = 0.38 – 1.4 days.

Bioaccumulation

The bioaccumulation of CMIT in bluegill sunfish *(Lepomis macrochirus)* resulted in BCF values of 102, 114, and 67 at nominal concentrations of 0.02, 0.12, and 0.8 mg/L (Erikson *et al*. 1995). These BCF values are based on total accumulated ^{14}C and include both the parent compound and metabolites. The BCF for MIT has been determined to 2.3 at a nominal concentration of 0.12 mg/L (Erikson *et al*. 1995).

Aquatic Toxicity

From Dow Chemicals MSDS for ROCIMA GT:
The 96-hour LC_{50} for Bluegill sunfish (*Lepomis macrochirus*) is 0.28 mg/L, and the 96-hour LC_{50} for Rainbow trout (*Oncorhynchus mykiss*) is 0.188 mg/L. The 48-hour EC_{50} for *Daphnia magna* is 0.126 mg/L. The 72-hour ErC_{50} for algae (*Selenastrum capricornutum*) is 0.027 mg/L.

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.188 mg/L), Daphnia (0.126 mg/L), and algae (0.027 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.027 mg/L for Daphnia. The $PNEC_{aquatic}$ is 2.7×10^{-5} mg/L or 0.027 µg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was

calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.025 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.022 µg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.007 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.0043 µg/kg.

PBT Assessment

The half-lives of CMIT and MIT is a river water-sediment system were 17.3 hours and 9.1 hours, respectively. Thus, CMIT/MIT do not meet the criteria for persistence.

The experimental BCF for CMIT is 67-114 in bluefish sunfish, and the BCF for MIT was determined to be 2.3. Thus, CMIT/MIT do not meet the criteria for bioaccumulation.

No chronic toxicity data are available for CMIT/MIT; however, the acute $E(L)C_{50}$ values are <0.1 mg/L. Thus, CMIT/MIT meet the screening criteria for toxicity.

The overall conclusion is that the CMIT/MIT mixture is not a PBT substance.

Environmental Assessment

Amorphous/Non-crystalline Silica
(CAS No. 7631-86-9[1])

Silica Gel
(CAS No. 112926-00-8)

Amorphous Silica and silica gel have been reviewed in the OECD-SIDS program (OECD, 2004a,b).

The CAS No. 7631-86-9 is the general CAS registry number for silicon dioxide which includes all forms of silicas (*e.g.*, also crystalline and natural forms). Only the silica sub-classes, the synthetic amorphous silicas, are subject of this assessment.

Synthetic amorphous silica and silicates are in powder form which have a low water solubility, based on the sum of soluble SiO_2 and cations (water-soluble fraction): ≤70 mg/l (SAS), approx. 70 – 80 mg/l (NAS), and approx. 260 mg/l (CS) at 20 °C.

Environmental Fate and Transport

Silicon oxides are the most abundant compounds in the earth's crust mass. Synthetic amorphous silica and silicates are released into the environment are expected to be distributed mainly into soils and sediments, weakly into water and probably not at all in the air due to their physico-chemical properties, particularly low water solubility and very low vapor pressure.

Synthetic amorphous silica and silicates released into the environment are expected to combine indistinguishably with the soil or sediment due to their similarity with inorganic soil/sediment matter and will be subjected to natural processes under environmental conditions (cation exchange, dissolution, sedimentation).

Biodegradation is not applicable to these inorganic substances. The bioavailable form of synthetic amorphous silica and silicates is the dissolved form which exists exclusively as monosilicic $[Si(OH)_4]$ acid under environmental pH. In analogy to the general chemical reaction of weak acids and salts of weak acids with water, the water-soluble fraction of silica acts as a weak acid and, therefore, will tend to lower the pH value, while that of a silicate acts as a base tending to bind protons and, thus, raise the pH value by forming hydroxyl ions. But pH shifts which are measurable at high loadings under laboratory conditions are not expected to occur from the anthropogenic deposition in the aquatic environment of synthetic amorphous silicas due to low aquatic releases and sufficient natural buffer capacities. Finally, these materials are supposed to combine indistinguishably with the soil layer or sediment due to their chemical similarity with inorganic soil matter.

Dissolved silica can be actively assimilated by some marine and terrestrial organisms as normal natural processes mainly related to structural function.

Aquatic Toxicity

Studies on fish, Daphnia and algae using excess loadings of SAS or NAS showed no acute toxicity, although physical effects on Daphnia were observed in tests using unfiltered test medium. Test results, based on loading rates, are as follows: 96-hour LL_0 *(Brachydanio rerio)* is 10,000 mg/L for SAS and NAS; 24-hour EL_{50} *(Daphnia magna)* >10,000 mg/L for SAS; 72-hour NOEL *(Scenedesmus subspicatus)* is 10,000 mg/L for NAS.

There are no chronic aquatic toxicity data, but due to the known inherent physico-chemical properties, absence of acute toxic effects as well as the ubiquitous presence of silica/silicates in the environment, there is no evidence of harmful long-term effects arising from exposure to synthetic amorphous silica/silicates.

Toxicity to Terrestrial Organisms

No data are available.

PBT Assessment

Noncrystalline silica (silica gel) is silicon dioxide, an inorganic compound which is ubiquitous in the environment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

A log Kow is not applicable to noncrystalline silica. Noncrystalline silica (silica gel), as a stable crystalline solid, is expected to have negligible uptake through the gill or gut of aquatic organisms. Thus, noncrystalline silica (silica gel) is not expected to bioaccumulate.

No chronic toxicity data exist on noncrystalline silica or silica gel; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, noncrystalline silica (silica gel) does not meet the screening criteria for toxicity.

The overall conclusion is that noncrystalline silica (silica gel) is not a PBT substance.

Environmental Assessment

Choline chloride
Cholinium chloride
(CAS No. 67-48-1)

Choline chloride, also known as cholinium chloride, is a quaternary amine salt. It dissociates in water into the corresponding positively charged quaternary hydroxyl alkylammonium ion and the negatively charged chloride ion.

Choline chloride has been reviewed in the OECD-SIDS program (OECD, 2004).

Environmental Fate and Transport

Results from Mackay Level I modeling indicate that choline chloride will be distributed completely into water (BASF AG, 2004).

Biodegradation

Choline chloride is readily biodegradable (93% within 14 days) in a MITI I-test (MITI, 1992). In another MITI-I test, biodegradation was $\geq$60%, indicating ready biodegradation (Tunkel *et al.*, 2000). A $BOD_5/ThOD_5$ ratio of 75% was obtained in a BOD_5 test performed according to DIN 38409 part 43 (BASF AG, 1984).

Bioaccumulation

No measured data on bioaccumulation of choline chloride are available. The experimental octanol-water partition coefficient (log K_{ow}) was determined to be -3.77. The estimated BCF using the equation log BCF = 0.85*logK_{ow} – 0.70 is 0.59. Therefore, bioaccumulation is not expected in aquatic organisms.

Aquatic Toxicity

The 96-hour fish LC_{50} value is >100 mg/L (nominal and measured) in *Oryzias latipes* (MOE Japan, 1999a), and the 48-hour EC_{50} is 349 mg/L (nominal and measured) in *Daphnia magna* (MOE Japan, 1999b). The 72-hour EC_{50} to algae *Pseudokirchneriella subcapitata* is >1,000 mg/L (nominal and measured) based on growth rate; the 72-hour NOEC is 32 mg/L (MOE Japan, 1999c).

In a 21-day *Daphnia magna* reproduction test, the nominal and measured NOEC was reported to be 30.2 mg/L (MOE Japan, 1999d).

Toxicity to Terrestrial Plants

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), invertebrates (349 mg/L), and algae (>1,000 mg/L). Results from chronic studies are available for invertebrates (21-day NOEC = 30.2 mg/L) and algae (72-hour NOEC = 32 mg/L). On the basis that the data consists of chronic studies on two trophic level (albeit not on the species with the lowest $E(L)C_{50}$), an assessment factor of 50 has been applied to the lowest reported NOEC of 30 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.6 mg/L.

PBT Assessment

Choline chloride is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of -3.77 and a calculated BCF of 0.59, choline chloride does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on choline chloride show NOECs of >0.1 mg/L. Thus, choline chloride does not meet the screening criteria for toxicity.

The overall conclusion is that choline chloride is not a PBT substance.

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Diammonium peroxidisulfate
Ammonium persulfate
(CAS No. 7727-54-0)

Diammonium peroxisulfate or ammonium persulfate has been reviewed in the OECD-SIDS program (OECD, 2005a,b).

Environmental Fate

The inorganic persulfates are soluble in water (≥ 60 g/L) and their vapor pressures are negligible. Ammonium persulfate will be distributed into the water compartment in the ionic form of the ammonium cation and persulfate anion. Ammonium persulfate is expected to degrade in the environment mainly via hydrolysis, but metal catalyzed decomposition, and reactions with organic chemicals in the soil or water also are possible.

Persulfates are not expected to adsorb to soil due to its dissociation properties, instability (hydrolysis) and high water solubility. Persulfates should behave as free ions or decompose into sulfate ions. In soils, upon decomposition, the cation could form more stable sulfate or bisulfate salts.

Persulfates are not expected to bioaccumulate in the soil or in aqueous solution. They will decompose into inorganic sulfate or bisulfate.

Aquatic Toxicity

The 96-hour LC_{50} values for ammonium persulfate to fish are from 76 to 323 mg/L. The acute toxicity EC_{50} values for invertebrates are from 120 to 391 mg/L. The 72-hour EC_{50} values for ammonium persulfate to algae are 83.7 mg/L.

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (76 mg/L), Daphnia (120 mg/L), and algae (84 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 76 mg/L for fish. The $PNEC_{aquatic}$ is 0.076 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Diammonium peroxidisulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc do not readily

apply to inorganics, such as diammonium peroxidisulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of diammonium peroxidisulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of diammonium peroxidisulfate is dominated by its water solubility. Sorption of diammonium peroxidisulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Kow and Koc parameters do not readily apply to inorganics, such as diammonium peroxidisulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, diammonium peroxidisulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Ammonium persulfate is an organic salt that dissociates completely to ammonium and sulfate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both ammonium and sulfate ions are ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Ammonium and sulfate ions are present in all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, ammonium persulfate is not expected to bioaccumulate.

No chronic toxicity data exist on ammonium persulfate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, ammonium persulfate does not meet the screening criteria for toxicity.

The overall conclusion is that ammonium persulfate is not a PBT substance.

Environmental Assessment

Diatomaceous Earth
(CAS No. 61790-53-2)

Uncalcined diatomaceous earth (CAS No. 61790-53-2) typically contains around 1% crystalline silica. When diatomaceous earth is subjected to pressure or is processed ("calcined") at temperatures above 1000°C some of the amorphous silica is converted to crystalline silica in the form of cristobalite. Calcined diatomaceous earth can contain anywhere from 1% to 75% cristobalite.

Diatomaceous earth and crystalline silica are naturally occurring minerals that are insoluble in water.

The are persistent in the environment.

Diatomaceous earth and crystalline silica as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Diatomaceous earth and crystalline silica, quartz are not considered to be PBT substances.

Environmental Assessment

Glycerine
(CAS No. 56-81-5)

Glycerine is also known as glycerol or 1,2,3-propanetriol.

Biodegradation

In an OECD 301 D test, degradation was 57% after 5 days, 84% after 15 days, and 92% after 30 days. Thus, glycerine is readily biodegradable (OECD 2002).

Bioaccumulation

Glycerine is not expected to bioaccumulate. The measured octanol-water partition coefficient (log K_{ow}) is -1.76 (OECD 2002). The calculated bioconcentration factor is 3.162 using EPIWIN vs. 3.04 (OECD 2002).

Aquatic Toxicity

The 24-hour LC_{50} to goldfish (*Carassius auratus*) was reported to be >5,000 mg/L (Bridie 1979). The 48-hour LC_0 to golden orfe (*Leuciscus idus*) is 250 mg/L (OECD 2002).

The 24-hour EC_{50} to *Daphnia magna* is >10,000 mg/L (OECD 2002).

An 8-day test with green algae (*Scenedesmus quadricauda*) showed no toxicity, with an EC_0 of >10,000 mg/L(Bringmann 1980; OECD 2002).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels, although the data on algae cannot be used for determining a PNEC value. Acute $E(L)C_{50}$ values are available for fish (5,000 mg/L) and *Daphnia* (>10,000 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 5,000 mg/L for fish. The $PNEC_{aquatic}$ is 5 mg/L.

PBT Assessment

Glycerine is readily biodegradable and thus does not meet the screening criteria for persistence.

The measured log K_{ow} for glycerine is -1.76 and the calculated BCF is 3.162. Thus glycerine does not meet the screening criteria for bioaccumulation.

No chronic toxicity studies are available for glycerine. However, the lowest acute toxicity value (LC_{50}) value is >0.1 mg/L. Thus glycerol does not meet the screening criteria for toxic.

The overall conclusion is that glycerine is not a PBT substance.

Environmental Assessment

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyanopsis tetragonolobus*. Structurally, it is a galactomannan (a polysaccharide) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum ranges from 200,000 to 300,000 daltons (Glickman, 1969).

Biodegradation

No information was found. Guar gum, being a polysaccharide composed of galactomannan, would be expected to be readily biodegradable.

Bioaccumulation

Not expected to bioaccumulate as a polysaccharide composed of galactomannans.

Aquatic Toxicity

The 48-hour LC_{50} for *Daphnia magna* was reported to be 42 mg/L (Biesinger *et al.*, 1976).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. An acute LC_{50} value is available for the invertebrate Daphnia (42 mg/L). On the basis that the data consists of only one short-term result from one trophic level, an assessment factor of 1,000 has been applied to the reported effect concentration of 42 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.042 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

No biodegradation was found on guar gum. However, guar gum is a naturally occurring polysaccharide which would be expected to readily biodegrade. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons, and it is also water soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The acute aquatic toxicity of guar gum is >0.1 mg/L. Thus, guar gum is not expected to meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

Environmental Assessment

Hydrochloric acid
(CAS No. 7647-01-0)

Hydrochloric acid has been reviewed in the OECD-SIDS program (OECD, 202a,b).

Environmental Fate and Transport

Hydrochloric acid is readily dissociated in water into hydrated protons and chloride ions.

The increase in the concentration of hydrochloric acid in water decreases the pH in the aquatic ecosystem. Generally, the buffer capacity to maintain the pH in the aquatic ecosystem is important and the equilibrium between CO_2, HCO_3^- and CO_3^{2-} in the aquatic ecosystem is mainly responsible for the buffer capacity of receiving water.

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

According to UNEP (1995), the mean, the 10th-percentile and the 90th-percentile of bicarbonate concentrations for 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania were 106, 20 and 195 mg/L, respectively. The buffering capacity for neutralization of receiving water with bicarbonate concentrations of 20, 106 and 195 mg/L is calculated to be 2.19, 11.60 and 21.3 mg/L, respectively.

Aquatic Toxicity

Several studies on the acute toxicity to fish have been published. The lowest 96-hour LC_{50} was reported to be 4.92 mg/L for *Cyprinus carpio* at pH 4.3 which was conducted according to OECD 203 guidelines (MLIT, 1999). The 96-hour LC_{50} for *Oncorhynchus mykiss* was 7.45 mg/L at pH 4.12 for hard water and 10.3 mg/L at pH 3.98 for soft water (Graham and Wood, 1981). The 96-hour LC_{50} in *Lepomis macrochirus* is 55.1 to 30.9 mg/L at pH 3.25 - 3.5; the low pH caused a reduction in the oxygen carrying capacity of hemoglobin and excessive secretion of mucus from the gills which in turn interfered with gas exchange (Ellgaard and Glimore, 1984).

Generally, the results of toxicity tests with acid or base depend on the buffer capacity of the test medium. Dechlorinated tap water was used as a test medium in the three tests described above. A 96-hour LC_{50} of 30.9 to 24.6 at pH 3.5-3.6 was obtained for *Lepomis macrochirus* using artificial water prepared from distilled water and analytical or reagent grade chemicals (Cairns and Scheier, 1959); other reported values are a 96-hour LC_{50} of 282 mg/L for *Gambusia affinis* (Wallen *et al.*, 1957) and a 16-hour LC_{100} value of 0.492 mg/L at pH 5.3 for the pike perch fry (*Lucioperca lucioperca*) conducted with pond water (pH 6.0-8.2) are reported (Stangenberg, 1975). A 24-hr LC_{50} value of 60-80 mg/L for *Semotitus astromaculatus* with river water (pH 8.3) has also been reported. No long-term or chronic toxicity data on fish

were located (Gillette *et al.*, 1952).

The 48-hour EC_{50} for *Daphnia magna* is 0.492 mg/L at pH 5.3 based on immobilization (MLIT, 1999). No long-term or chronic toxicity data on invertebrates have been reported. The 72-hour EC_{50} to *Selenastrum capriornutum* is 0.78 mg/L (pH 5.1) for biomass; 0.492 mg/L (pH 5.3) for growth rate; and the 72-hr-NOEC is 0.097 mg/L (pH 6.0) for biomass and growth rate (MLIT, 1999).

The hazard of hydrochloric acid for the environment is caused by the proton (pH effect). For this reason the effect of hydrochloric acid on the organisms depends on the buffer capacity of the aquatic ecosystem. Also, the variation in acute toxicity for aquatic organisms can be explained to a significant extent by the variation in buffer capacity of the test medium. For example, LC_{50} values of acute fish toxicity tests varied from 4.92 to 282 mg/L.

It is not considered useful to calculate a PNEC for hydrochloric acid because factors such as the buffer capacity, the natural pH, and the fluctuation of the pH are very specific for a certain ecosystem.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECS

$PNEC_{aquatic}$: Based on the information above, a $PNEC_{aquatic}$ was not derived for hydrochloric acid.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Kow and Koc parameters do not readily apply to inorganics, such as hydrochloric acid. Thus;, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of hydrochloric acid to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Sorption of hydrochloric acid should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as hydrochloric acid. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, hydrochloric acid is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Hydrochloric acid is an organic salt that dissociates completely to hydrogen and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and chloride ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Hydrogen and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, hydrochloric acid is not expected to bioaccumulate.

No chronic toxicity data exist on hydrochloric acid; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, hydrochloric acid does not meet the screening criteria for toxicity.

The overall conclusion is that hydrochloric acid is not a PBT substance.

Environmental Assessment

Magnesium chloride
(CAS No. 7786-30-3)

Environmental Fate

Magnesium chloride dissociates completely in water to the Mg^{++} cation and the chloride anion (Cl^-).

Aquatic Toxicity

The 96-hour LC_{50} of magnesium chloride to *Pimephales promelas* is 541 mg of Mg/L (or 2,119.3 mg of $MgCl_2$/L).

The 48-hour LC_{50} for *Daphnia magna* is 140 mg Mg/L (or 548.4 mg of $MgCl_2$/L). In another study, the 48-hour LC_{50} to *Daphnia magna* and *Ceriodaphnia dubia* were 339 mg of Mg/L and 225 mg of Mg/L, respectively (or 1328 and 881.4 mg of $MgCl_2$/L, respectively).

The 72-hour EC_{50} of magnesium chloride for algae *Scenedesmus subspicatus* is >100 mg/L and the NOEC is 100 mg/L.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (2,119 mg/L as $MgCl_2$), Daphnia (548 mg/L as $MgCl_2$), and algae (100 mg/L $MgCl_2$). Even though a NOEC was obtained from the algae study, there were no chronic studies conducted on fish or Daphnia. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 0.1 mg/L. The $PNEC_{aquatic}$ is 0.1 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium chloride is dominated by its water solubility. Sorption of magnesium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium chloride.

Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium chloride is an organic salt that dissociates completely to magnesium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and chloride ions are ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, magnesium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, magnesium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium chloride is not a PBT substance.

Environmental Assessment

Magnesium nitrate (CAS No. 10377-60-3)

Environmental Fate

Magnesium nitrate dissociates completely in water to Mg^{++} and the nitrate anion (NO_3^-).

Determination of PNECs

$PNEC_{aquatic}$: The ANZECC water quality guideline (2000) uses acute and chronic laboratory toxicity data for the derivation of "trigger values" for nitrate. The guideline summary for freshwaters is: *"A freshwater moderate reliability trigger value for nitrate toxicity as NO_3 (nitrate) of 700 µg/L was calculated using the statistical distribution method 95% protection and the default ACR."*

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium nitrate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium nitrate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium nitrate is dominated by its water solubility. Sorption of magnesium nitrate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium nitrate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium nitrate is an organic salt that dissociates completely to magnesium and nitrate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and nitrate ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium ions are essential to all living organisms and its intracellular and extracellular concentrations are actively regulated. Nitrates are ions that are very

soluble in aqueous solutions. Thus, magnesium nitrate is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium nitrate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, magnesium nitrate does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium nitrate is not a PBT substance.

Environmental Assessment

Vinylidene chloride/methacrylate copolymer (CAS No. 25038-72-6)

Biodegradation

Generally, polymers are considered to be essentially non-biodegradable.

Bioaccumulation

Polymers are not generally absorbed through biological membranes to bioaccumulate in tissues.

Aquatic Toxicity

This polymer is insoluble in water and is expected to be essentially non-toxic to aquatic organisms.

Determination of PNECs

$PNEC_{aquatic}$: Not determined.

PBT Assessment

Based on the information above, vinylidene chloride/methylacrylate copolymer is not considered to be a PBT substance.

Environmental Assessment

Potassium borate
Dipotassium tetraborate
(CAS No. 1332-77-0)

Toxicity data on borax and boric acid will be used to read across to potassium borate ($B_4K_2O_7$). The rationale is as follows:

Borax is also known as sodium borate, sodium tetraborate, or disodium tetraborate. With water content, borax can refer to a group of compounds that differ in their crystal water content, but typically it is disodium tetraborate decahydrate with the chemical structure ($Na_2B_4O_7 \bullet 10H_2O$). Borax is moderately soluble in water, with the main species in freshwater being the borate ion $[B(OH)_4]^-$ and boric acid $B(OH)_3$, depending on the pH. The relative proportion of boric acid and borate ions is controlled by pH: $B(OH)_3 + 2H_2O \Leftrightarrow [B(OH)_4]^- + H_3O^-$. In dilute aqueous solutions, boric acid does not dissociate at pH <7; at pH values between 7 and 11, both boric acid and borate ions are present. In dilute aqueous solutions and physiological conditions, the predominant species present is un-dissociated boric acid. So, the consideration of boric acid addresses the relevant environmental stability properties for borates.

Exposure to borates are often expressed in terms of boron (B) equivalents based on the fraction of boron in the source substance on a molecular weight basis. The B equivalents used are a generic designation rather than a designation of the element boron. The factors for converting disodium tetraborate decahydrate and boric acid to B-equivalents are 0.113 and 0.175, respectively.

In natural waters, boron forms stable species and exists primarily as un-dissociated boric acid [$B(OH)_3$] and complex polyanions (*e.g.,* $B(OH)_4^-$). These forms of boron are highly soluble and not easily removed from solution by natural mechanisms. Borate and boric acid are in equilibrium depending on the pH of the water. At an acidic pH, boron exists in solution mainly as un-dissociated boric acid, whereas at alkaline pH it is present as borate ions.

Environmental Fate

At noted above, disodium tetraborate decahydrate will yield boric acid upon dissolution in water (or borate anion in higher pH conditions). Boric acid is a persistent molecule, not subject to hydrolysis, photodegradation or biodegradation.

Many mineral contain boron, which is present as the sodium or calcium borate salt. Thus, boron is ubiquitous and widely distributed in the environment. It is present in rocks, soil and water and is released into the environment primarily from the weathering of rock and soil, volatilization of sea water, and anthropogenic activity.

Bioaccumulation

The WHO (1998) review of boron noted that "highly water soluble materials are unlikely to bioaccumulate to any significant degree and that borate species are all present essentially as un-dissociated and highly soluble boric acid at neutral pH". A BCF of <0.1 was reported in Chinook salmon fed boron-supplemented diets for 60 to 90 days (Hamilton and Wiedmeyer, 1990).

Some bioconcentration is expected in terrestrial plants since boron is a critical element to terrestrial plants and is incorporated into the cell wall structure. However, the phytotoxicity of boron limits the potential for excessive accumulation beyond "normal" plant tissue concentrations (Austria, 2008). Terrestrial non-predatory organisms, such as Mallard ducks, did not accumulate boron (BCF <0.1) when fed a plant diet of 1,600 mg-B/kg for up to 48 days (Pendleton *et al.*, 1995).

Toxicity

There are many ecotoxicity laboratory and field tests that have been conducted on boron (which includes boric acid and borates). Overall, the studies show that boron does not fulfill the criteria of Toxicity in a PBT assessment with regards to aquatic organisms. The data were reviewed in the "Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for Boron" (CCME, 2009), which is summarized below:

"Primary acute toxicity data for vertebrates were available for early life stages of four fish species. Endpoints ranged from a 3 day NOEC (teratogenesis at hatching) of 0.109 mg/L for embryo- hatching stage largemouth bass (Black *et al.* 1993) to a 7 day EC_{50} (embryo test) of 969 mg/L for rainbow trout (MELP, 1996). Secondary and unclassified toxicity data were similar to the reported primary data with effect concentrations ranging between 4.6 and 3,145 mg/L."

"Primary acute toxicity data for invertebrates were available for four species. The 48 hour LC_{50} concentrations ranged from 21.3 mg/L for neonate water fleas (MELP, 1996) to 1,376 mg/L for larval midge (Maier and Knight, 1991). Secondary, unclassified and unacceptable toxicity data were similar to the reported primary data with effect concentrations ranging between 1 and 2,797 mg/L."

"Primary chronic toxicity data for vertebrates were available for three fish species." If the outliers are excluded, "effect concentrations ranged from a 36 day LOEC (mortality) of 1.34 mg/L for embryo-larval rainbow trout to a 32 day LC_{50} of 138 mg/L for rainbow trout (Black *et al.*, 1993). Lower effect concentrations (0.01 mg/L) for embryo-larval rainbow trout were observed in the unclassified toxicity studies (Birge and Black, 1977)."

"Primary chronic toxicity data for invertebrates were available for two species. Effect concentrations ranged between a 21 day LOEC (mean brood size) of 13 mg/L to a 21 day LC_{50} of 53.2 mg/L for the water flea (Lewis and Valentine, 1981). Effect concentrations for additional unclassified studies differed from those reported by the primary studies, with a range of <0.38 to ~266 mg/L."

"Primary chronic toxicity data were available for 4 to 7 day old green algae (*Selenastrum capricornutum*) (MELP, 1997). The lowest reported effect concentration for algae exposed to boron was a 72 hour LOEC of 12.3 mg/L. Effect concentrations of secondary and unclassified toxicity data ranged from 1 to ~171 mg/L."

Determination of PNECs

$PNEC_{aquatic}$: There are many ecotoxicity laboratory and field tests that have been conducted on boron (which includes boric acid and borates). Both acute and chronic toxicity studies are available for three trophic levels. A Canadian Water Quality Guidelines for the Protection of Aquatic Life of 1.5 mg/L was derived for long–term exposure to boron (CCME, 2009). Thus, the $PNEC_{aquatic}$ for disodium tetraborate decahydrate is 1.5 mg-B/L.

It should be noted, however, that Australia and New Zealand adopted a freshwater high reliability trigger value for boron of 0.37 mg-B/L (ANZECC, 2000).

The factor for converting dipotassium tetraborate to B-equivalents is 0.185.

PBT Assessment

Disodium tetraborate decahydrate is a persistent molecule, not subject to hydrolysis, photodegradation or biodegradation. Thus, it meets the criteria for persistence.

Disodium tetraborate decahydrate is a water-soluble substance that is not expected to bioaccumulate. Limited data indicate that bioaccumulation (BCF values are low) is not significant in aquatic and terrestrial food chains. Thus, it does not meet the criteria for bioaccumulation.

Overall, the aquatic toxicity studies show that boron does not fulfill the criteria of toxicity. However, there are human health concerns and boric acid (and borates) are considered reproductive toxicants; they have, for instance, been classified in the EU as known or presumed human reproductive toxicants (Category 1B). Thus, disodium tetraborate decahydrate meets the PBT criteria of toxicity.

The overall conclusion is that disodium tetraborate decahydrate is not a PBT substance.

Environmental Assessment

Potassium hydroxide
(CAS No. 1310-58-3)

Potassium hydroxide (KOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Environmental Fate

The high water solubility and low vapor pressure indicate that potassium hydroxide (KOH) will be found predominantly in the aquatic environment. KOH is present in the environment as potassium (K^+) and hydroxyl (OH^-) ions, which implies that it will not adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Measured concentrations in aquatic ecosystems
The concentration of hydroxyl ions in the environment has been determined very extensively via pH measurements. The pH is a very important parameter of aquatic ecosystems and it is a standard parameter of water quality monitoring programs. The most important freshwater aquatic ecosystems of the world revealed average annual pH values between 6.5 and 8.3 but lower and higher values have been measured in other aquatic ecosystems (UNEP, 1995). In aquatic ecosystems with dissolved organic acids a pH of less than 4.0 has been measured, while in waters with a high chlorophyll content the bicarbonate assimilation can result in pH values of higher than 9.0 at midday (UNEP, 1995). The pH of an aquatic ecosystem is mainly determined by geochemical, hydrological and/or biological processes.

Potassium has been measured extensively in aquatic ecosystems. UNEP (1995) reported the concentration for a total number of 75 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th –percentile, mean and 90th-percentile were 0.8, 3.2 and 6.0 mg/l, respectively.

KOH addition and buffer capacity
An addition of KOH to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th– percentile, mean and 90th-percentile were 20, 106 and 195 mg/l, respectively.

Aquatic Toxicity

At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realized that the results of toxicity tests with KOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralized and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) KOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity ***e.g.***, NH_3 is more toxic than NH_4^+.

The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 80 mg/L. At 56 mg/L, no effects on the fish were observed. The pH was 10.3 at 100 mg/L.

Several studies have been conducted using NaOH. The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L (equivalent KOH: 224 mg/L). At 100 mg/L (equivalent KOH: 140 mg/L), which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L (equivalent KOH: 265 mg/L). The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L.

No toxicity studies on invertebrates are available. For NaOH, the 48-hour LC_{50} is 40 mg/L (equivalent KOH: 56 mg/L) for *Ceriodaphnia* cf. *dubia*.

No data are available on the effects of KOH on algae.

Toxicity to Terrestrial Organisms

Significant exposure of the terrestrial environment is not expected and for this reason there is no need to perform toxicity test with terrestrial organisms. The results of terrestrial toxicity tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil.

Determination of PNECs

In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with KOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with KOH are not available there is no need for additional testing with KOH. A significant number of acute toxicity tests are available and the results of the tests are more or less consistent. Altogether they give a sufficient indication about acute toxicity levels of potassium hydroxide.

Furthermore acute toxicity data cannot be used to derive a PNEC or a PNEC added for potassium hydroxide. Aquatic ecosystems are characterized by an alkalinity/pH

and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.

Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for KOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,

- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and

- The change in pH due to an anthropogenic KOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for KOH there is a need to assess the environmental effect of an KOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

$PNEC_{aquatic}$: Based on the information above, a PNEC was not derived for potassium hydroxide.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Potassium hydroxide dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as potassium hydroxide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of potassium hydroxide to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of potassium hydroxide is dominated by its water solubility. Sorption of potassium hydroxide should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as potassium hydroxide Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, potassium hydroxide is not expected to significantly

adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Potassium hydroxide is an organic salt that dissociates completely to potassium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Potassium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, potassium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on potassium hydroxide; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, potassium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that potassium hydroxide is not a PBT substance.

Environmental Assessment

Talc
(CAS No. 61789-40-0)

Talc is a mineral composed of hydrated magnesium silicate with the chemical formula $Mg_3Si4O_{10}(OH)_2$ or $H_2Mg_3(SiO_3)_4$. Talc is not soluble in water.

Biodegradation

As a mineral, talc does not biodegrade.

Aquatic Toxicity

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to aquatic organisms.

Toxicity to Sediment Organisms

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to sediment organisms.

Toxicity to Terrestrial Organisms

No data were found.

Determination of PNECs

PNEC values for talc cannot be calculated.

PBT Assessment

Talc is an inorganic mineral that is insoluble in water. Talc is not expected to be bioavailable to aquatic organisms; thus, it is does not meet the criteria for bioaccumulation or toxicity. Talc does not biodegrade in the environment. It is a naturally-occurring mineral and is persistent in the environment. However, for the purposes of this PBT assessment, it does not meet the criteria for persistence.

Environmental Assessment

Triethanolamine
(CAS No. 102-71-6)

Environmental Fate

Triethanolamine was completely degraded after incubation in municipal activated sludge for 1 or 5 days (West and Gonsior, 1996). The rate constants in all test batches for degradation and mineralization were reported to be >0.359. Thus, triethanolamine can be considered to be readily biodegradable.

In an OECD 301E test, there was 96% degradation after 19 days, indicating ready biodegradation (ECHA).

Bioaccumulation

Triethanolamine has been tested in a bioconcentration: flow-through fish (OECD 305) test using *Cyprinus carpio*. The BCF was determined to be <0.4 and <3.9 at triethanolamine concentrations of 2.5 and 0.25 mg/L, respectively (ECHA).

Aquatic Toxicity

The 96-hour LC_{50} to fathead minnow (*Pimephales promelas*) is 11,800 mg/L (ECHA). The 48-hour EC_{50} to *Ceriodaphnia dubia* is 610 mg/L (Warne and Schifko, 1999).

In a 21-day *Daphnia* reproduction test, the NOEC for reproduction rate was 125 mg/L, and the NOEC for reproduction on the appearance of first offspring was 250 mg/L (Kuehn *et al.*, 1989).

The 72-hour EC_{50} to algae *Desmodesmus subspicatus* is 512 mg/L [neutralized media] and 216 mg/L [un-neutralized media] (ECHA).

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (11,800 mg/L), *Daphnia* (610 mg/L), and algae (512 mg/L). A long-term (chronic) study is available for invertebrates (21-day NOEC = 125 mg/L). On the basis that the data consists of a chronic study on one trophic level, an assessment factor of 100 has been applied to the lowest reported NOEC of 125 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 1.25 mg/L.

PBT Assessment

Triethanolamine is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The BCF values for triethanolamine in fish was <3.9; thus, it does not meet the criteria for bioaccumulation.

The NOEC for triethanolamine in a 21-day *Daphnia* reproduction test is 125 mg/L, which is >0.1 mg/L. Thus, triethanolamine does not meet the screening criteria for toxicity.

The overall conclusion is that triethanolamine is not a PBT substance.

APPENDIX G.7 SCHLUMBERGER SAPPHIRE LF

Environmental Assessment

Reaction mass of 5-chloro-2-methyl-4-isothiazolin-3-one and 2-methyl-2H-isothiazolin-3-one [3:1]
(CAS No. 55965-84-9)

Environmental Fate

5-Chloro-2-methyl-4-isothiazolin-3-one and 2-methyl-4-isothiazolin-3-one, the active ingredients in DOW™ CMIT/MIT antimicrobial products, have a low bioconcentration potential (tendency to accumulate in the food chain) and a high potential for mobility in soil. They are completely soluble in water. In the environment these compounds would tend to partition into water where they would rapidly biodegrade to non-persistent substances which are several orders of magnitude less toxic than parent compound. They would also be removed by common biological wastewater treatment facilities.

Biodegradation

The primary aerobic biodegradability of MIT has been examined in a river sediment-water system by use of a ^{14}C-labelled model compound. During the 7-day experiment ^{14}C-labelled MIT was rapidly metabolized as only 12.6% of the initial MIT was present after 24 hours of incubation at 25□C. The calculated half-life for the parent compound was 9.1 hours (Reynolds, 1994a). MIT was metabolized to several unidentified metabolites. One of the major metabolites reached a level corresponding to 18.2% of the ^{14}C added after 24 hours of incubation. This metabolite decreased to 6.8% after 7 days which indicates further transformation. Other metabolites tended to increase during the 7-day experiment. At the end of the experiment metabolites that were bound in the sediment corresponded to 55%, whereas $^{14}CO_2$ attained 9% of the added ^{14}C. Most of the formed metabolites have shorter chromatographic retention times than MI which indicates that they are polar compounds. On the basis of the identification of metabolites from transformation of 4,5-dichloro-2-(n-octyl)-4-isothiazolin-3-one, it has been proposed that MI is transformed via N-methyl malonamic acid, N-methyl acetamide, and malonic acid (Madsen, 2000).

The primary biodegradability of CMIT has been examined with the same type of sediment and water as described for MIT. The ^{14}C-labelled CMIT was rapidly metabolized as only 30% of the initial CMI remained after 24 hours of incubation at 25□C. The calculated half-life for the intact CMIT was 17.3 hours (Reynolds, 1994b). At the end of the 7-day experiment, the sediment bound metabolites corresponded to 57.1% of the added ^{14}C, whereas 2.8% of the added ^{14}C was released as $^{14}CO_2$. Due to the structural similarities of MI and CMIT, it is suggested that the major metabolites for the transformation of CMIT are the same as described for MIT.

MIT was tested in an OECD 301B test modified for low concentrations of ^{14}C-labelled compounds. The accumulated $^{14}CO_2$ attained 54.1%, 55.8%, and 47.6% in the respective concentrations (0.1, 0.03 and 0.01 mg/l) after 29 days. During the 10-day window, 37%, 30% and 30%, respectively, of the initial MIT was mineralized to

$^{14}CO_2$ (Bashir, 1998a).

CMIT was tested in an OECD 301B modified for low concentrations of ^{14}C-labelled compounds. The accumulated $^{14}CO_2$ attained 38.8%, 55.3%, and 62% in the respective concentrations (0.3, 0.1, and 0.03 mg/l) after 29 days. During the 10- day window, 25%, 40%, and 48%, respectively, of the initial CMIT was mineralized to $^{14}CO_2$. The ultimate biodegradability of CMIT exceeded the 60%-pass level for ready biodegradability at the lowest test concentration of 0.03 mg/L, but the pass level was not reached within the 10-day window Bashir, 1998b).

From Dow Chemicals MSDS for ROCIMA GT:
Biodegradation (aquatic metabolism): 5-Chloro-2-methyl-4-isothiazolin-3-one (CMIT): t ½ anaerobic = 0.2 day, t ½ aerobic = 0.38 – 1.3 days; 2-Methyl-4-isothiazolin-3-one (MIT): t ½ aerobic = 0.38 – 1.4 days.

Bioaccumulation

The bioaccumulation of CMIT in bluegill sunfish *(Lepomis macrochirus)* resulted in BCF values of 102, 114, and 67 at nominal concentrations of 0.02, 0.12, and 0.8 mg/L (Erikson *et al*. 1995). These BCF values are based on total accumulated ^{14}C and include both the parent compound and metabolites. The BCF for MIT has been determined to 2.3 at a nominal concentration of 0.12 mg/L (Erikson *et al*. 1995).

Aquatic Toxicity

From Dow Chemicals MSDS for ROCIMA GT:
The 96-hour LC_{50} for Bluegill sunfish (*Lepomis macrochirus*) is 0.28 mg/L, and the 96-hour LC_{50} for Rainbow trout (*Oncorhynchus mykiss*) is 0.188 mg/L. The 48-hour EC_{50} for *Daphnia magna* is 0.126 mg/L. The 72-hour ErC_{50} for algae (*Selenastrum capricornutum*) is 0.027 mg/L.

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.188 mg/L), Daphnia (0.126 mg/L), and algae (0.027 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 0.027 mg/L for Daphnia. The $PNEC_{aquatic}$ is 2.7×10^{-5} mg/L or 0.027 µg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was

calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.025 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{sediment}$ was calculated to be 0.022 µg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was calculated using EPISUITE (MCI Method). CMIT: Using a Koc of 19.38 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.007 µg/kg. MIT: Using a Koc of 12.08 and a $PNEC_{aquatic}$ of 0.027 µg/L, the $PNEC_{soil}$ was calculated to be 0.0043 µg/kg.

PBT Assessment

The half-lives of CMIT and MIT is a river water-sediment system were 17.3 hours and 9.1 hours, respectively. Thus, CMIT/MIT do not meet the criteria for persistence.

The experimental BCF for CMIT is 67-114 in bluefish sunfish, and the BCF for MIT was determined to be 2.3. Thus, CMIT/MIT do not meet the criteria for bioaccumulation.

No chronic toxicity data are available for CMIT/MIT; however, the acute $E(L)C_{50}$ values are <0.1 mg/L. Thus, CMIT/MIT meet the screening criteria for toxicity.

The overall conclusion is that the CMIT/MIT mixture is not a PBT substance.

Environmental Assessment

Choline chloride
Cholinium chloride
(CAS No. 67-48-1)

Choline chloride, also known as cholinium chloride, is a quaternary amine salt. It dissociates in water into the corresponding positively charged quaternary hydroxyl alkylammonium ion and the negatively charged chloride ion.

Choline chloride has been reviewed in the OECD-SIDS program (OECD, 2004).

Environmental Fate and Transport

Results from Mackay Level I modeling indicate that choline chloride will be distributed completely into water (BASF AG, 2004).

Biodegradation

Choline chloride is readily biodegradable (93% within 14 days) in a MITI I-test (MITI, 1992). In another MITI-I test, biodegradation was ≥60%, indicating ready biodegradation (Tunkel *et al.*, 2000). A $BOD_5/ThOD_5$ ratio of 75% was obtained in a BOD_5 test performed according to DIN 38409 part 43 (BASF AG, 1984).

Bioaccumulation

No measured data on bioaccumulation of choline chloride are available. The experimental octanol-water partition coefficient (log K_{ow}) was determined to be -3.77. The estimated BCF using the equation log BCF = 0.85*logK_{ow} – 0.70 is 0.59. Therefore, bioaccumulation is not expected in aquatic organisms.

Aquatic Toxicity

The 96-hour fish LC_{50} value is >100 mg/L (nominal and measured) in *Oryzias latipes* (MOE Japan, 1999a), and the 48-hour EC_{50} is 349 mg/L (nominal and measured) in *Daphnia magna* (MOE Japan, 1999b). The 72-hour EC_{50} to algae *Pseudokirchneriella subcapitata* is >1,000 mg/L (nominal and measured) based on growth rate; the 72-hour NOEC is 32 mg/L (MOE Japan, 1999c).

In a 21-day *Daphnia magna* reproduction test, the nominal and measured NOEC was reported to be 30.2 mg/L (MOE Japan, 1999d).

Toxicity to Terrestrial Plants

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), invertebrates (349 mg/L), and algae (>1,000 mg/L). Results from chronic studies are available for invertebrates (21-day NOEC = 30.2 mg/L) and algae (72-hour NOEC = 32 mg/L). On the basis that the data consists of chronic studies on two trophic level (albeit not on the species with the lowest $E(L)C_{50}$), an assessment factor of 50 has been applied to the lowest reported NOEC of 30 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.6 mg/L.

PBT Assessment

Choline chloride is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of -3.77 and a calculated BCF of 0.59, choline chloride does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on choline chloride show NOECs of >0.1 mg/L. Thus, choline chloride does not meet the screening criteria for toxicity.

The overall conclusion is that choline chloride is not a PBT substance.

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Diammonium peroxidisulfate
Ammonium persulfate
(CAS No. 7727-54-0)

Diammonium peroxisulfate or ammonium persulfate has been reviewed in the OECD-SIDS program (OECD, 2005a,b).

Environmental Fate

The inorganic persulfates are soluble in water (≥ 60 g/L) and their vapor pressures are negligible. Ammonium persulfate will be distributed into the water compartment in the ionic form of the ammonium cation and persulfate anion. Ammonium persulfate is expected to degrade in the environment mainly via hydrolysis, but metal catalyzed decomposition, and reactions with organic chemicals in the soil or water also are possible.

Persulfates are not expected to adsorb to soil due to its dissociation properties, instability (hydrolysis) and high water solubility. Persulfates should behave as free ions or decompose into sulfate ions. In soils, upon decomposition, the cation could form more stable sulfate or bisulfate salts.

Persulfates are not expected to bioaccumulate in the soil or in aqueous solution. They will decompose into inorganic sulfate or bisulfate.

Aquatic Toxicity

The 96-hour LC_{50} values for ammonium persulfate to fish are from 76 to 323 mg/L. The acute toxicity EC_{50} values for invertebrates are from 120 to 391 mg/L. The 72-hour EC_{50} values for ammonium persulfate to algae are 83.7 mg/L.

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (76 mg/L), Daphnia (120 mg/L), and algae (84 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 76 mg/L for fish. The $PNEC_{aquatic}$ is 0.076 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Diammonium peroxidisulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc do not readily

apply to inorganics, such as diammonium peroxidisulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of diammonium peroxidisulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of diammonium peroxidisulfate is dominated by its water solubility. Sorption of diammonium peroxidisulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Kow and Koc parameters do not readily apply to inorganics, such as diammonium peroxidisulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, diammonium peroxidisulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

Environmental Assessment

Diatomaceous Earth
(CAS No. 61790-53-2)

Uncalcined diatomaceous earth (CAS No. 61790-53-2) typically contains around 1% crystalline silica. When diatomaceous earth is subjected to pressure or is processed ("calcined") at temperatures above 1000°C some of the amorphous silica is converted to crystalline silica in the form of cristobalite. Calcined diatomaceous earth can contain anywhere from 1% to 75% cristobalite.

Diatomaceous earth and crystalline silica are naturally occurring minerals that are insoluble in water.

The are persistent in the environment.

Diatomaceous earth and crystalline silica as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Diatomaceous earth and crystalline silica, quartz are not considered to be PBT substances.

Environmental Assessment

Magnesium chloride
(CAS No. 7786-30-3)

Environmental Fate

Magnesium chloride dissociates completely in water to the Mg^{++} cation and the chloride anion (Cl^-).

Aquatic Toxicity

The 96-hour LC_{50} of magnesium chloride to *Pimephales promelas* is 541 mg of Mg/L (or 2,119.3 mg of $MgCl_2$/L).

The 48-hour LC_{50} for *Daphnia magna* is 140 mg Mg/L (or 548.4 mg of $MgCl_2$/L). In another study, the 48-hour LC_{50} to *Daphnia magna* and *Ceriodaphnia dubia* were 339 mg of Mg/L and 225 mg of Mg/L, respectively (or 1328 and 881.4 mg of $MgCl_2$/L, respectively).

The 72-hour EC_{50} of magnesium chloride for algae *Scenedesmus subspicatus* is >100 mg/L and the NOEC is 100 mg/L.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (2,119 mg/L as $MgCl_2$), Daphnia (548 mg/L as $MgCl_2$), and algae (100 mg/L $MgCl_2$). Even though a NOEC was obtained from the algae study, there were no chronic studies conducted on fish or Daphnia. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ was calculated to be 0.1 mg/L. The $PNEC_{aquatic}$ is 0.1 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium chloride is dominated by its water solubility. Sorption of magnesium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium chloride.

Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium chloride is an organic salt that dissociates completely to magnesium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and chloride ions are ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, magnesium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, magnesium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium chloride is not a PBT substance.

Reference

Environmental Assessment

Magnesium nitrate (CAS No. 10377-60-3)

Environmental Fate

Magnesium nitrate dissociates completely in water to Mg^{++} and the nitrate anion (NO_3^-).

Determination of PNECs

$PNEC_{aquatic}$: The ANZECC water quality guideline (2000) uses acute and chronic laboratory toxicity data for the derivation of "trigger values" for nitrate. The guideline summary for freshwaters is: *"A freshwater moderate reliability trigger value for nitrate toxicity as NO_3 (nitrate) of 700 µg/L was calculated using the statistical distribution method 95% protection and the default ACR."*

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Magnesium nitrate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of magnesium nitrate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of magnesium nitrate is dominated by its water solubility. Sorption of magnesium nitrate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as magnesium nitrate. Thus, the equilibrium partitioning methods cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, magnesium nitrate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Magnesium nitrate is an organic salt that dissociates completely to magnesium and nitrate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both magnesium and nitrate ions are also ubiquitous and are present in most water, soil and sediment. Thus, the persistent criteria is not considered applicable to this inorganic salt.

Magnesium ions are essential to all living organisms and its intracellular and extracellular concentrations are actively regulated. Nitrates are ions that are very

soluble in aqueous solutions. Thus, magnesium nitrate is not expected to bioaccumulate.

No chronic toxicity data exist on magnesium nitrate; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, magnesium nitrate does not meet the screening criteria for toxicity.

The overall conclusion is that magnesium nitrate is not a PBT substance.

Environmental Assessment

Vinylidene chloride/methacrylate copolymer (CAS No. 25038-72-6)

Biodegradation

Generally, polymers are considered to be essentially non-biodegradable.

Bioaccumulation

Polymers are not generally absorbed through biological membranes to bioaccumulate in tissues.

Aquatic Toxicity

This polymer is insoluble in water and is expected to be essentially non-toxic to aquatic organisms.

Determination of PNECs

$PNEC_{aquatic}$: Not determined.

PBT Assessment

Based on the information above, vinylidene chloride/methylacrylate copolymer is not considered to be a PBT substance.

Reference

Boethling, R.S. and Nabholz, J.V. (1997). Environmental Assessment of Polymers under the U.S. Toxic Substances Control Act. In: Ecological Assessment of Polymers Strategies for Product Stewardship and Regulatory Programs (Hamilton, J.D. and Sutcliffe, R. eds.), pp. 187-234, Van Nostrand Reinhold.

Environmental Assessment

Sodium Carboxymethyl Cellulose
(CAS No. 9004-32-4)

Sodium carboxycellulose is the sodium salt of carboxymethylcellulose. Carboxymethyl cellulose is a cellulose derivative with carboxymethyl groups (-CH_2COOH) bound to some of the hydroxyl groups of the glucopyranose monomers that make up the cellulose backbone.

Carboxymethyl cellulose (CMC) is a water-soluble semisynthetic polymer in which part of the hydroxyl groups of cellulose has been replaced at random by carboxymethyl groups. Carboxymethyl cellulose is therefore composed of eight different glucose units, namely one unsubstituted, three monosubstituted, three disubstituted, and one trisubstituted. The average number of carboxymethyl groups per glucose unit is denoted by the degree of substitution (DS). Carboxymethyl cellulose with a DS ranging from 0.4 to 1.3 has become the largest industrial cellulose ether because of its versatile applications in, for example, detergents and oil drilling.

Biodegradation

Carboxymethyl cellulose (DS 0.7) showed 25% biodegradation after 28 days in a OECD 301A test. Thus, sodium carboxymethyl cellulose is not readily biodegradable. Other studies have also shown partial degradation of carboxymethyl cellulose in ready and inherent biodegradability tests.

Aquatic Toxicity

Carboxymethyl cellulose has been tested in several acute aquatic toxicity tests. The 96-hour LC_{50} for *Brachydanio rerio* is >2,500 mg/L; the 48-hour LC_{50} for *Daphnia magna* is >5,000 mg/L; and the 96-hour EC_{50} for *Selenastrum capricornutum* is 500 mg/L.

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>2,500 mg/L), Daphnia (>5,000 mg/L), and algae (>500 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 500 mg/L for algae. The $PNEC_{aquatic}$ is 0.5 mg/L.

PBT Assessment

Sodium carboxymethyl cellulose is a water-soluble semisynthetic polymer and is not readily biodegradable. Thus, it meets the screening criteria for persistence.

Sodium carboxymethyl cellulose is a water-soluble semisynthetic polymer and is expected to have a molecular weight of >1,000 which limits its bioavailability to aquatic organisms. Thus, it is not expected to bioaccumulate.

The acute $EC(L)_{50}$ of sodium carboxymethylcellulose is >0.1 mg/L in fish, invertebrates and algae. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that sodium carboxymethylcellulose is not a PBT substance.

Reference

Van Ginkel, C.G., and Gayton, S. (1996). The biodegradability and nontoxicity of carboxymethyl cellulose (DS 0.7) and intermediates. Environ. Toxicol. Chem. 15: 270-274.

Environmental Assessment

Talc
(CAS No. 61789-40-0)

Talc is a mineral composed of hydrated magnesium silicate with the chemical formula $Mg_3Si4O_{10}(OH)_2$ or $H_2Mg_3(SiO_3)_4$. Talc is not soluble in water.

Biodegradation

As a mineral, talc does not biodegrade.

Aquatic Toxicity

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to aquatic organisms.

Toxicity to Sediment Organisms

No data were found. As an insoluble mineral, talc is not expected to be bioavailable; therefore, it is not expected to toxic to sediment organisms.

Toxicity to Terrestrial Organisms

No data were found.

Determination of PNECs

PNEC values for talc cannot be calculated.

PBT Assessment

Talc is an inorganic mineral that is insoluble in water. Talc is not expected to be bioavailable to aquatic organisms; thus, it is does not meet the criteria for bioaccumulation or toxicity. Talc does not biodegrade in the environment. It is a naturally-occurring mineral and is persistent in the environment. However, for the purposes of this PBT assessment, it does not meet the criteria for persistence.

Environmental Assessment

Triethanolamine
(CAS No. 102-71-6)

Environmental Fate

Triethanolamine was completely degraded after incubation in municipal activated sludge for 1 or 5 days (West and Gonsior, 1996). The rate constants in all test batches for degradation and mineralization were reported to be >0.359. Thus, triethanolamine can be considered to be readily biodegradable.

In an OECD 301E test, there was 96% degradation after 19 days, indicating ready biodegradation (ECHA).

Bioaccumulation

Triethanolamine has been tested in a bioconcentration: flow-through fish (OECD 305) test using *Cyprinus carpio*. The BCF was determined to be <0.4 and <3.9 at triethanolamine concentrations of 2.5 and 0.25 mg/L, respectively (ECHA).

Aquatic Toxicity

The 96-hour LC_{50} to fathead minnow (*Pimephales promelas*) is 11,800 mg/L (ECHA). The 48-hour EC_{50} to *Ceriodaphnia dubia* is 610 mg/L (Warne and Schifko, 1999).

In a 21-day *Daphnia* reproduction test, the NOEC for reproduction rate was 125 mg/L, and the NOEC for reproduction on the appearance of first offspring was 250 mg/L (Kuehn *et al.*, 1989).

The 72-hour EC_{50} to algae *Desmodesmus subspicatus* is 512 mg/L [neutralized media] and 216 mg/L [un-neutralized media] (ECHA).

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (11,800 mg/L), *Daphnia* (610 mg/L), and algae (512 mg/L). A long-term (chronic) study is available for invertebrates (21-day NOEC = 125 mg/L). On the basis that the data consists of a chronic study on one trophic level, an assessment factor of 100 has been applied to the lowest reported NOEC of 125 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 1.25 mg/L.

PBT Assessment

Triethanolamine is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The BCF values for triethanolamine in fish was <3.9; thus, it does not meet the criteria for bioaccumulation.

The NOEC for triethanolamine in a 21-day *Daphnia* reproduction test is 125 mg/L, which is >0.1 mg/L. Thus, triethanolamine does not meet the screening criteria for toxicity.

The overall conclusion is that triethanolamine is not a PBT substance.

APPENDIX G.8 HALLIBURTON – WELL RM 08-14-3

Environmental Assessment

Acetic Acid
(CAS No. 64-19-7)

Acetic acid and its salts undergo dissociation in aqueous media into the acetate anion ($H_3C_2O_2^-$) and the respective cations (H^+, NH_4^+, Ca^{2+}, Mg^{2+}, Mn^{2+}, K^+, Na^+). The toxicity of each compound is driven by acetate, with the cations playing a minor role. The pH is 2.5 at 50 g/L and 20°C; and the pK_a is 4.76 at 20°C.

Environmental Transport

Level I fugacity modeling predicts that about 73% of any acetic acid released to the environment would partition to water, with the remainder partitioning into the air (U.S. HPVIS database).

Biodegradation

Acetic acid and its salts readily dissociate into their respective cations and the acetate anion; the anion acetate is readily biodegraded. In aerobic conditions using adapted wastewater from domestic sewage, degradation was 96% after 20 days (Price *et al.*, 1974). It was also shown to be readily biodegradable under anaerobic conditions using activated sludge (99% after 7 days) (Kameya *et al.*, 1995).

Aquatic Toxicity

The 96-hour LC_{50} in bluegill sunfish is 75 mg/L (Price *et al.*, 1974), and the 96-hour LC_{50} in mosquito fish is 251 mg/L (Wallen *et al.*, 1957). The 96-hour LC_{50} of 60% acetic acid in *Oncorhynchus mykiss* is 108 mg/L (64.8 mg acetic acid/L) (unpublished data, ECHA). In a chronic study with *Oncorhynchus mykiss*, the 21-day LC_{50} and NOEC for 60% acetic acid were 87 mg/L and 57.2 mg/L, respectively (unpublished data, ECHA). The 21-day LC_{50} and NOEC for 100% acetic acid were 52.2 mg/L and 34.3 mg/L, respectively (unpublished data, ECHA).

The 24-hour EC_{50} to Daphnia was reported to be 95 mg/L (un-neutralized) and 6,000 mg/L (neutralized to pH 8.0) (Bringmann and Kuehn, 1982). One other study showed the 48-hour EC_{50} to be 65 mg/L (Janssen *et al.*, 1993). In a chronic Daphnia study, the 21-day NOEC for reproduction was reported to be 22.7 mg/L for 100% acetic acid (unpublished data, ECHA). In another chronic Daphnia study, the 21-day NOEC for reproduction was 31.4 mg/L for 100% acetic acid (unpublished data, ECHA).

In an algae growth inhibition study, the reported nominal ErC_{50} to *Desmodesmus subspicatus* was 810.9 mg/L for 60% acetic acid (unpublished data, ECHA). The

reported nominal ErC_{50} was 486.5 mg/L for 100% acetic acid (unpublished data, ECHA). The toxicity threshold to algae after 8 days in a growth inhibition test was reported to be 4,000 mg/L (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (65 mg/L) and Daphnia (65 mg/L), and algae (487 mg/L). Long-term results are also available for fish (NOEC = 34 mg/L) and Daphnia (NOEC = 23 mg/L). On the basis that the data consists of short-term results from three trophic levels and two chronic study for fish and another chronic study for Daphnia, an assessment factor of 50 has been applied to the lowest NOEC of 23 mg/L for Daphnia. The $PNEC_{aquatic}$ was calculated to be 0.5 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Thus, the determination of the $PNEC_{sediment}$ is not possible. Based on its properties, no adsorption of acetic acid to sediment is to be expected and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Thus, the determination of the $PNEC_{soil}$ is not possible. Based on its properties, no adsorption of acetic acid to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

The acetate ion of acetic acid is readily biodegradable and thus it does not meet the screening criteria for persistence.

The log Kow for acetic acid is reported to be -0.17 (Verschueren, 1966). Acetate is also found in the body and is metabolized as part of the body's biochemical pathways. Thus,

acetic acid (specifically, the acetate ion) does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity data on acetic acid are >0.01 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

Environmental Assessment

Crystalline Silica, Quartz
(CAS No. 14808-60-7)

Crystalline Silica, Cristobalite
(CAS No. 14464-46-1)

Silica is an off-white granule that occurs naturally in various crystalline and amorphous or other non-crystalline forms. Crystalline silica is characterized by silicon dioxide (SiO_2) molecules oriented in fixed, periodic patterns to form stable crystals. The primary crystalline form of silica is quartz. Other crystalline forms of silica include cristobalite, tripoli and tridymite.

Crystalline silica, quartz and crystalline silica, cristobalite are naturally occurring minerals that are insoluble in water.

They are persistent in the environment.

Crystalline silica, quartz, and crystalline silica, cristobalite as minerals, are not expected to bioaccumulate or be toxic to aquatic organisms because of their water insolubility and lack of bioavailability.

Crystalline silica, quartz and crystalline silica, cristobalite are not considered to be PBT substances.

Environmental Assessment

Diethanolamine
(CAS No. 111-42-2)

Environmental Fate

In an OECD 301F test, there was 50% degradation after 7 days, 80% after 14 days, and 93% after 28 days (OECD 2007). In modified OECD 301E screening tests using river or pond water, there was 93% and 97% degradation (measured as DOC removal) after 28 days (OECD 2007). Results from other biodegradation tests (ready, inherent, and one simulation test according to OECD 303A) indicate that diethanolamine is easily eliminated from sewage treatment plants as well as from surface water. The results of these tests indicate that diethanolamine is readily biodegradable.

Bioaccumulation

The BCF calculated from a QSAR model by Zhao *et al.* (2008) was 4 L/kg (ECHA). The BCF calculated from U.S. EPA EPIWIN is 3.16 L/kg (OECD 2007).

Aquatic Toxicity

The 96-hour LC_{50} values for fathead minnows are 1,480 mg/L [fry], 1,550 mg/L [juvenile], and 1,370 mg/L [subadults]; the geometric mean of the 96-hour LC_{50} values is 1,460 mg/L (Mayes *et al.* 1983). The 48-hour LC_{50} to *Lepomis macrochirus* is 1,850 mg/L (Turnbull *et al*. 1954).

The 48-hour EC_{50} values to *Ceriodaphnia dubia* are 89.9 ml/L and 30.1 mg/L at 20°C. and 24°C., respectively (Cowgill *et al.* 1985). The 48-hour EC_{50} to *Daphnia magna* was reported to be 55 mg/L (LeBlanc 1980) and 171 mg/L (Zurita *et al.* 2005).

The NOEC from a 21-day *Daphnia* reproduction study is 0.78 mg/L (ECHA; OECD 2007).

The 96-hour EC_{50} to *Pseudokirchnerella subcapitata* is 9.7 mg/L based on growth rate and 2 mg/L based on yield; the 96-hour NOEC is 0.6 mg/L for yield (ECHA). However, the test concentrations were not confirmed by chemical analysis.

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (1,460 mg/L), *Daphnia* (30 mg/L), and algae (2 mg/L). A long-term (chronic) study is available for invertebrates (21-day NOEC = 0.78 mg/L). On the basis that the data consists of two chronic studies on two trophic levels, an assessment factor of 50 has been applied to the NOEC of 0.78 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 0.0156 mg/L.

PBT Assessment

Diethanolamine is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The estimated BCF values for diethanolamine calculated from QSAR models are 4 and 3.16 L/kg; thus, it does not meet the criteria for bioaccumulation.

The NOEC for diethanolamine in a 21-day *Daphnia* reproduction test is 0.78 mg/L, which is >0.1 mg/L. Thus, diethanolamine does not meet the screening criteria for toxicity.

The overall conclusion is that diethanolamine is not a PBT substance.

Environmental Assessment

Disodium Octaborate Tetrahydrate
(CAS No. 12280-03-4)

Data on borax and boric acid will be used to read across to disodium octaborate tetrahydrate ($Na_2B_8O_{13}\bullet 4H_2O$). The rationale is as follows:

Borax is also known as sodium borate, sodium tetraborate, or disodium tetraborate. With water content, borax can refer to a group of compounds that differ in their crystal water content, but typically it is disodium tetraborate decahydrate with the chemical structure ($Na_2B_4O_7\bullet 10H_2O$). Borax is moderately soluble in water, with the main species in freshwater being the borate ion $[B(OH)_4]^-$ and boric acid $B(OH)_3$, depending on the pH. The relative proportion of boric acid and borate ions is controlled by pH: $B(OH)_3 + 2H_2O \Leftrightarrow [B(OH)_4]^- + H_3O^-$. In dilute aqueous solutions, boric acid does not dissociate at pH <7; at pH values between 7 and 11, both boric acid and borate ions are present. In dilute aqueous solutions and physiological conditions, the predominant species present is un-dissociated boric acid. So, the consideration of boric acid addresses the relevant environmental stability properties for borates.

Exposure to borates are often expressed in terms of boron (B) equivalents based on the fraction of boron in the source substance on a molecular weight basis. The B equivalents used are a generic designation rather than a designation of the element boron. The factors for converting disodium tetraborate decahydrate (or disodium octaborate tetrahydrate) and boric acid to B-equivalents are 0.113 and 0.175, respectively.

In natural waters, boron forms stable species and exists primarily as un-dissociated boric acid [$B(OH)_3$] and complex polyanions (*e.g.*, $B(OH)_{4^-}$). These forms of boron are highly soluble and not easily removed from solution by natural mechanisms. Borate and boric acid are in equilibrium depending on the pH of the water. At an acidic pH, boron exists in solution mainly as un-dissociated boric acid, whereas at alkaline pH it is present as borate ions.

Environmental Fate

At noted above, disodium tetraborate decahydrate will yield boric acid upon dissolution in water (or borate anion in higher pH conditions). Boric acid is a persistent molecule, not subject to hydrolysis, photodegradation or biodegradation.

Many mineral contain boron, which is present as the sodium or calcium borate salt. Thus, boron is ubiquitous and widely distributed in the environment. It is present in rocks, soil and water and is released into the environment primarily from the weathering of rock and soil, volatilization of sea water, and anthropogenic activity.

Bioaccumulation

The WHO (1998) review of boron noted that "highly water soluble materials are unlikely to bioaccumulate to any significant degree and that borate species are all present essentially as un-dissociated and highly soluble boric acid at neutral pH". A BCF of <0.1 was reported in Chinook salmon fed boron-supplemented diets for 60 to 90 days (Hamilton and Wiedmeyer, 1990).

Some bioconcentration is expected in terrestrial plants since boron is a critical element to terrestrial plants and is incorporated into the cell wall structure. However, the phytotoxicity of boron limits the potential for excessive accumulation beyond "normal" plant tissue concentrations (Austria, 2008). Terrestrial non-predatory organisms, such as Mallard ducks, did not accumulate boron (BCF <0.1) when fed a plant diet of 1,600 mg-B/kg for up to 48 days (Pendleton *et al.*, 1995).

Toxicity

There are many ecotoxicity laboratory and field tests that have been conducted on boron (which includes boric acid and borates). Overall, the studies show that boron does not fulfill the criteria of Toxicity in a PBT assessment with regards to aquatic organisms. The data were reviewed in the "Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for Boron" (CCME, 2009), which is summarized below:

"Primary acute toxicity data for vertebrates were available for early life stages of four fish species. Endpoints ranged from a 3 day NOEC (teratogenesis at hatching) of 0.109 mg/L for embryo- hatching stage largemouth bass (Black *et al.* 1993) to a 7 day EC_{50} (embryo test) of 969 mg/L for rainbow trout (MELP, 1996). Secondary and unclassified toxicity data were similar to the reported primary data with effect concentrations ranging between 4.6 and 3,145 mg/L."

"Primary acute toxicity data for invertebrates were available for four species. The 48 hour LC_{50} concentrations ranged from 21.3 mg/L for neonate water fleas (MELP, 1996) to 1,376 mg/L for larval midge (Maier and Knight, 1991). Secondary, unclassified and unacceptable toxicity data were similar to the reported primary data with effect concentrations ranging between 1 and 2,797 mg/L."

"Primary chronic toxicity data for vertebrates were available for three fish species." If the outliers are excluded, "effect concentrations ranged from a 36 day LOEC (mortality) of 1.34 mg/L for embryo-larval rainbow trout to a 32 day LC_{50} of 138 mg/L for rainbow trout (Black *et al.*, 1993). Lower effect concentrations (0.01 mg/L) for embryo-larval rainbow trout were observed in the unclassified toxicity studies (Birge and Black, 1977)."

"Primary chronic toxicity data for invertebrates were available for two species. Effect concentrations ranged between a 21 day LOEC (mean brood size) of 13 mg/L to a 21 day LC_{50} of 53.2 mg/L for the water flea (Lewis and Valentine, 1981). Effect concentrations

for additional unclassified studies differed from those reported by the primary studies, with a range of <0.38 to ~266 mg/L."

"Primary chronic toxicity data were available for 4 to 7 day old green algae (*Selenastrum capricornutum*) (MELP, 1997). The lowest reported effect concentration for algae exposed to boron was a 72 hour LOEC of 12.3 mg/L. Effect concentrations of secondary and unclassified toxicity data ranged from 1 to ~171 mg/L."

Determination of PNECs

$PNEC_{aquatic}$: There are many ecotoxicity laboratory and field tests that have been conducted on boron (which includes boric acid and borates). Both acute and chronic toxicity studies are available for three trophic levels. A Canadian Water Quality Guidelines for the Protection of Aquatic Life of 1.5 mg/L was derived for long–term exposure to boron (CCME, 2009). Thus, the $PNEC_{aquatic}$ for disodium octaborate tetrahydrate is 1.5 mg-B/L.

It should be noted, however, that Australia and New Zealand adopted a freshwater high reliability trigger value for boron of 0.37 mg-B/L (ANZECC, 2000).

The factor for converting disodium octaborate tetrahydrate to B-equivalents is 0.113.

PBT Assessment

Disodium octaborate tetrahydrate is a persistent molecule, not subject to hydrolysis, photodegradation or biodegradation. Thus, it meets the criteria for persistence.

Disodium octaborate tetrahydrate is a water-soluble substance that is not expected to bioaccumulate. Limited data indicate that bioaccumulation (BCF values are low) is not significant in aquatic and terrestrial food chains. Thus, it does not meet the criteria for bioaccumulation.

Overall, the aquatic toxicity studies show that boron does not fulfill the criteria of toxicity. However, there are human health concerns and boric acid (and borates) are considered reproductive toxicants; they have, for instance, been classified in the EU as known or presumed human reproductive toxicants (Category 1B). Thus, disodium octaborate tetrahydrate meets the PBT criteria of toxicity.

The overall conclusion is that disodium octaborate tetrahydrate is not a PBT substance.

Environmental Assessment

Ethylene glycol
(CAS No. 107-21-1)

Ethylene glycol has been reviewed in the OECD-SIDS program (OECD, 2004a,b)

Environmental Transport

A Mackay Level III fugacity model predicts that ethylene glycol will distribute 45.6% to water, 52.3% to soil, 2.02% to air, and <0.1% to sediment (OECD, 2004a,).

Biodegradation

Ethylene glycol is readily biodegradable both aerobically and anaerobically. There was 97% degradation after 20 days in a BOD test (OECD, 2004a,b), and 96% degradation after 28 days in an OECD 301D test (OECD, 2004a,b).

The aerobic degradation of ethylene glycol was measured from grab river water samples at 4, 8, and 20^{o}C (Evans and David, 1974). At 20^{o}C, ethylene glycol was completely degraded in three days in all river waters tested, and at 8^{o}C degradation was complete within 14 days. Degradation at 4^{o}C was substantially slower, with degradation of less than 20% after 14 days in river samples with limited suspended matter and a starting concentration of 10 mg/L.

Bioaccumulation

The log K_{ow} of ethylene glycol was measured as -1.36 (Hansch *et al.*, 1989). The BCF for ethylene glycol in golden ide (*Leuciscus idus melanotus*) after three days of exposure was determined to be 10 (Freitag *et al.*, 1985).

Aquatic Toxicity

The 96-hour LC_{50} values to fry, juvenile, and subadult fathead minnows (*Pimephales promelas*) are 53,000, 49,000 and 57,000 mg/L, respectively (Mayes *et al.*, 1983). The 96-hour LC_{50} values to fathead minnows (*Pimephales promelas*) was also reported to be 72,860 mg/L (Pillard, 1995). The 96-hour LC_{50} to rainbow trout (*Oncorhynchus mykiss*) is 22,810 mg/L (OECD, 2004b). In a 12-day chronic study, the NOEC to rainbow trout (*Oncorhynchus mykiss*) was reported to be 14,692 mg/L (OECD, 2004b).

The 48-hour LC_{50} to *Daphnia magna* is 46,300 mg/L (Gersich *et al.*, 1986). The 48-hour EC_{50} values to *Ceriodaphnia dubia-affinis* and *Daphnia magna* are 10,000 and 51,000 mg/L at 24^{o}C, respectively; and 25,800 and 46,300 mg/L at 24^{o}C, respectively (Cowgill

et al., 1985). The NOEC for a 7-day reproduction test to *Ceriodaphnia dubia* is 3,469 mg/L (OECD, 2004b).

The 96-hour EC_{50} to green algae (*Selenastrum capricornutum*) is 10,940 mg/L based on cell growth; the NOEC is 10,000 mg/L (Pillard and DuFresne, 1999).

Toxicity to Sediment Organisms

No data were located.

Toxicity to Terrestrial Organisms

A mallard duck receiving 1.1 mL/kg ethylene glycol recovered, but ducks (1/dose) receiving 2.3, 4.5, 8.9, 13.3, and 17.8 mL/kg died (Stowe *et al.*, 1981). Ethylene glycol (0.1 mL/chicken egg) significantly decreased hatchability relative to controls and significantly increased embryonic mortality during weeks 1 and 3 (Ameenuddin and Suude, 1984). Doses of 0, 0.05, 0.1, and 0.15 ml/egg resulted in hatchability of approximately 82, 75, 45 and 45%, respectively.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (22,810 mg/L), Daphnia (10,000 mg/L), and algae (10,940 mg/L). NOEC values from long-term studies are available for fish (14,692 mg/L), invertebrates (3,469 mg/L), and algae (10,000 mg/L). On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 3,469 mg/L for invertebrates. The $PNEC_{aquatic}$ is 347 mg/L.

PBT Assessment

Ethylene glycol is readily biodegradable and thus does not meet the screening criteria for persistence.

The octanol-water coefficient (log K_{ow}) for ethylene glycol is -1.36. The measured BCF in fish is 10. Thus, ethylene glycol does not meet the criteria for bioaccumulation.

The chronic toxicity data on ethylene glycol show NOECs of >0.01 mg/L. Thus, ethylene glycol does not meet the screening criteria for toxicity.

The overall conclusion is that ethylene glycol is not a PBT substance.

Environmental Assessment

Hemicellulase
(CAS No. 9025-56-3)

Hemicellulases are a group of enzymes that break down hemicellulose, which are polysaccharides that are present in cell walls of all terrestrial plants. These polysaccharides have a β-(1→4)-linked backbone and are composed of pentoses (xylose, arabinoses), hexoses (mannose, glucose, galactose), and sugar acids. Unlike cellulose which are polysaccharides consisting of linear chains of several hundred to over ten thousand β-(1→4) linked D-glucoses, hemicelluloses are not chemically homogeneous. The best characterized hemicellulases are the 1,4- β -D-xylanases and, in particular, those derived from fungal sources presumably because their substrates, xylans, constitute the largest proportion of hemicelluloses in pasture plants.

No toxicity information could be located on hemicellulases; however, mammalian toxicity information were found on the cellulase enzymes (HERA report, 2005). Cellulases cleave the ß-1,4-glycosidic bonds in cellulose, and are used in the pulp and paper industry, the textile industry, and in detergents to remove deposits and stains.

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity. For the purposes of risk assessment, the structure of hemicellulases would be expected to be similar to that of cellulases, given that hemicellulases and cellulases are both enzyme families that hydrolyze polysaccharides, although differing in their substrates. Thus, the toxicity data on cellulases will be used as read-across to hemicellulases.

Biodegradation

Three different cellulase enzymes were considered readily biodegradable based on the results of OECD 301C and 301E tests (HERA, 2005). In an OECD 301E test, there was 84% DOC removal of the enzyme Carezyme after 28 days. In another OECD 301E test, there was 92% DOC removal of the enzyme Clazinase® after 28 days. In an OECD 301C test, BOD/COD was 78% after 28 days. Likewise, hemicellulase is expected to be readily biodegradable.

Aquatic Toxicity

The 96-hour LC_{50} of an alkaline cellulase to zebrafish (*Brachydanio rerio*) is 330 mg aep/L (HERA, 2005). The 48-hour EC_{50} of the same alkaline cellulase to *Daphnia magna* is >1,000 mg aep/L (HERA, 2005). The same alkaline cellulase was also tested in algae (*Scenedesmus subspicatus*), with a 72-hour EC_{50} of >1000 mg aep/L (HERA,

2005).

The 24- and 48-hour EC_{50} values of an alkaline cellulase (SP 227, Celluzyme) to *Daphnia magna* are >1,000 mg aep/L and approximately 1,000 mg aep/L respectively (HERA, 2005).

Two additional acute fish toxicity studies showed findings with LC_{50} values of >100 mg aep/L, but no references were provided (HERA, 2005).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (330 mg aep/L), Daphnia (>1,000 mg aep/L), and algae (1,000 mg aep/L). Although the HERA report provides information on two acute fish studies with LC_{50} values of >100 mg aep/L, no references were provided and were therefore excluded from the determination of PNECs. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 330 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.33 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{sediment}$ was calculated to be 0.21 mg aeg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{soil}$ was calculated to be 0.006 mg aeg/kg.

PBT Assessment

Hemicellulase is expected to be readily biodegradable based on read-across to cellulases. Thus, hemicellulase does not meet the screening criteria for persistence.

Based on the similarity to cellulase, hemicellulase has a high molecular weight (20 to 80 kD), has hydrophilic properties (high water solubility, log Kow <0), and is readily metabolized in organisms by proteolytic enzymes or proteases. Thus, hemicellulose does not meet the screening criteria for bioaccumulation.

The acute $EC(L)_{50}$ of hemicellulase is >0.1 mg/L in fish, invertebrates and algae. Thus, hemicellulase does not meet the screening criteria for toxicity.

The overall conclusion is that hemicellulase is not a PBT substance.

Environmental Assessment

Hydroxypropyl Guar Gum
(CAS No. 39421-75-5)

No data could be located on hydroxypropyl guar gum; information in this assessment will be read-across from guar gum.

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyamopsis tetragonolobus*. Structurally, it is a galactomannan (high molecular weight carbohydrate polymer) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum ranges from 200,000 to 300,000 daltons (Glickman, 1969).

Biodegradation

No information was found. Guar gum, being a polysaccharide composed of galactomannan, would be expected to be readily biodegradable.

Bioaccumulation

Not expected to bioaccumulate as a polysaccharide composed of galactomannans.

Aquatic Toxicity

The 48-hour LC_{50} for *Daphnia magna* was reported to be 42 mg/L (Biesinger *et al.*, 1976).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. An acute LC_{50} value is available for the invertebrate Daphnia (42 mg/L). On the basis that the data consists of only one short-term result from one trophic level, an assessment factor of

1,000 has been applied to the reported effect concentration of 42 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.042 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

No biodegradation was found on guar gum. However, guar gum is a naturally occurring polysaccharide which would be expected to readily biodegrade. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons, and it is also water soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The acute aquatic toxicity of guar gum is >0.1 mg/L. Thus, guar gum is not expected to meet the screening criteria for toxicity.

The overall conclusion is that guar gum, and therefore hydroxypropyl guar gum, is not a PBT substance.

Environmental Assessment

Lactose
(CAS No. 63-42-3)

Lactose is a disaccharide sugar composed of galactose and glucose. It is naturally synthesized in the mammary gland of virtually all mammals, occurring in milk at levels between 1 and 7%. Commercially, lactose is extracted from the whey of cow's milk (whey is the residual liquid of milk following cheese and casein production) and is purified extensively to remove fats, proteins, vitamins and minerals (Baldrick and Bamford, 1997; Goodhart, 1994).

Biodegradation

No biodegradation studies were found on lactose. The QSAR model BIOWIN estimates that the biodegradation of lactose would be fast, with primary degradation in hours-days and ultimate degradation in days-weeks (U.S. EPA, 2011).

Aquatic Toxicity

No aquatic toxicity studies were found on lactose.

Using ECOSAR, the 96-hour LC_{50} in fish was estimated to be 81,045 mg/L; the 48-hour LC_{50} in *Daphnia* was estimated to be 3,460,000 mg/L; and the 96-hour EC_{50} in green algae was estimated to be 583,000 mg/L (U.S. EPA, 2011).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: No experimental results are available for lactose. Acute $E(L)C_{50}$ estimates using the QSAR model ECOSAR are: fish (81,045 mg/L), Daphnia (3,460,000 mg/L), and algae (583,000 mg/L). On the basis that the data consists of short-term results from

three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 81,045 mg/L for fish. The $PNEC_{aquatic}$ is 81 mg/L.

PBT Assessment

No experimental biodegradation data are available on lactose. The QSAR model BIOWIN predict that lactose will biodegrade fast, with primary degradation in hours-days and ultimate degradation in days-weeks. Thus, lactose does not meet the screening criteria for persistence.

The estimated log K_{ow} and BCF for lactose is -5.03 and 3.162, respectively (U.S. EPA, 2011). Thus, lactose does not meet the screening criteria for bioaccumulation.

The estimated acute $EC(L)_{50}$ values of lactose indicate that it is non-toxic to fish, invertebrates and algae. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that lactose is not a PBT substance.

Environmental Assessment

Monoethanolamine borate
(CAS No. 26038-87-9)

Monoethanolamine borate is also known as orthoboric acid, compound with 2-aminoethanol. It is a UVCB substance with the chemical formula: $C_2H_7NO.xBH_3O_3$.

Environmental Transport

Monoethanolamine (MEA) Polyborate 1:1 and MEA Polyborate 1:3 do not significantly adsorb to soil. The experimental log Koc was determined to be approximately 1.26.

Biodegradation

MEA Polyborate 1:1 was considered readily biodegradable in a modified Sturm test (OECD 301B). Degradation was 73% after 28 days.

MEA Polyborate 1:3 was considered readily biodegradable in a modified Sturm test (OECD 301B). Degradation was 75% after 28 days.

Aquatic Toxicity

The 96-hour LC_{50} in Carp for MEA Polyborate 1:3 is 617 mg/L.

The 48-hour EC_{50}s in *Daphnia magna* for MEA Polyborate 1:3 and MEA Polyborate 1:1 are 496 and 423 mg/L, respectively.

The 72-hour ErC_{50} in fresh water algae species *Pseudokirchneriella subcapitata* for MEA Polyborate 1:1 is 26 mg/L. The 72-hr EyC_{50} (yield inhibition) is 13 mg/L. The NOEC for growth rate reduction and yield inhibition is 3.2 mg/L. The 72-hr ErC_{50} in fresh water algae species *Pseudokirchneriella subcapitata* for MEA Polyborate 1:3 is 67 mg/L.

Toxicity to Sediment Organisms

No data are available.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (617 mg/L), Daphnia (423 mg/L), and algae (13 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 13 mg/L for algae. The $PNEC_{aquatic}$ is 0.013 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was experimentally determined to be approximately 18.20. Using a Koc of 18.20 and a $PNEC_{aquatic}$ of 0.013 mg/L, the $PNEC_{sediment}$ was calculated to be 0.012 mg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was experimentally determined to be approximately 18.20. Using a Koc of 18.20 and a $PNEC_{aquatic}$ of 0.013 mg/L, the $PNEC_{soil}$ was calculated to be 0.003 mg/kg (3.1 μg/kg).

PBT Assessment

Monoethanolamine borate is readily biodegradable and thus it does not meet the screening criteria for persistence.

Monoethanolamine borate is a UVCB substance and a log Kow cannot be accurately determined. For monoethanolamine itself, the measured log Kow and estimated BCF from BCFBAF v.3.01 are -1.6122 and 3.16 L/kg, respectively. The borate salt of monoethanolamine would not be expected to meet the screening criteria for bioaccumulation.

No chronic aquatic toxicity studies are available for monoethanolamine borate. The acute toxicity studies in fish, invertebrates and algae are >0.1 mg/L. Thus, monoethanolamine borate does not meet the criteria for toxicity.

The overall conclusion is that monoethanolamine borate is not a PBT substance.

Environmental Assessment

Amorphous/Non-crystalline Silica
(CAS No. 7631-86-9[1])

Silica Gel
(CAS No. 112926-00-8)

Amorphous Silica and silica gel have been reviewed in the OECD-SIDS program (OECD, 2004a,b).

The CAS No. 7631-86-9 is the general CAS registry number for silicon dioxide which includes all forms of silicas (*e.g.*, also crystalline and natural forms). Only the silica sub-classes, the synthetic amorphous silicas, are subject of this assessment.

Synthetic amorphous silica and silicates are in powder form which have a low water solubility, based on the sum of soluble SiO_2 and cations (water-soluble fraction): ≤70 mg/l (SAS), approx. 70 – 80 mg/l (NAS), and approx. 260 mg/l (CS) at 20 °C.

Environmental Fate and Transport

Silicon oxides are the most abundant compounds in the earth's crust mass. Synthetic amorphous silica and silicates are released into the environment are expected to be distributed mainly into soils and sediments, weakly into water and probably not at all in the air due to their physico-chemical properties, particularly low water solubility and very low vapor pressure.

Synthetic amorphous silica and silicates released into the environment are expected to combine indistinguishably with the soil or sediment due to their similarity with inorganic soil/sediment matter and will be subjected to natural processes under environmental conditions (cation exchange, dissolution, sedimentation).

Biodegradation is not applicable to these inorganic substances. The bioavailable form of synthetic amorphous silica and silicates is the dissolved form which exists exclusively as monosilicic [$Si(OH)_4$] acid under environmental pH. In analogy to the general chemical reaction of weak acids and salts of weak acids with water, the water-soluble fraction of silica acts as a weak acid and, therefore, will tend to lower the pH value, while that of a silicate acts as a base tending to bind protons and, thus, raise the pH value by forming hydroxyl ions. But pH shifts which are measurable at high loadings under laboratory conditions are not expected to occur from the anthropogenic deposition in the aquatic environment of synthetic amorphous silicas due to low aquatic releases and sufficient natural buffer capacities. Finally, these materials are supposed to combine indistinguishably with the soil layer or sediment due to their chemical similarity with inorganic soil matter.

Dissolved silica can be actively assimilated by some marine and terrestrial organisms as normal natural processes mainly related to structural function.

Aquatic Toxicity

Studies on fish, Daphnia and algae using excess loadings of SAS or NAS showed no acute toxicity, although physical effects on Daphnia were observed in tests using unfiltered test medium. Test results, based on loading rates, are as follows: 96-hour LL_0 *(Brachydanio rerio)* is 10,000 mg/L for SAS and NAS; 24-hour EL_{50} *(Daphnia magna)* >10,000 mg/L for SAS; 72-hour NOEL *(Scenedesmus subspicatus)* is 10,000 mg/L for NAS.

There are no chronic aquatic toxicity data, but due to the known inherent physico-chemical properties, absence of acute toxic effects as well as the ubiquitous presence of silica/silicates in the environment, there is no evidence of harmful long-term effects arising from exposure to synthetic amorphous silica/silicates.

Toxicity to Terrestrial Organisms

No data are available.

PBT Assessment

Noncrystalline silica (silica gel) is silicon dioxide, an inorganic compound which is ubiquitous in the environment. It is persistent in the environment.

A log Kow is not applicable to noncrystalline silica. Noncrystalline silica (silica gel), as a stable crystalline solid, is expected to have negligible uptake through the gill or gut of aquatic organisms. Thus, noncrystalline silica (silica gel) is not expected to bioaccumulate.

No chronic toxicity data exist on noncrystalline silica or silica gel; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, noncrystalline silica (silica gel) does not meet the screening criteria for toxicity.

The overall conclusion is that noncrystalline silica (silica gel) is not a PBT substance.

Environmental Assessment

Sodium carbonate
(CAS No. 497-19-8)

Sodium carbonate has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Sodium carbonate is a strong alkaline compound with a pH of 11.6 for a 0.1M aqueous solution (The Merck Index, 1983; Johnson and Swanson, 1987). The pKa of CO_3^{2-} is 10.33, which means that at a pH of 10.33 both carbonate and bicarbonate are present in equal amounts.

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium carbonate will be found predominantly in the aquatic environment. In water, sodium carbonate dissociates into sodium (Na^+) and carbonate (CO_3^{2-}) and both ions will not adsorb on particulate matter or surfaces and will not accumulate in living tissues. Addition of potassium carbonate to water will result in an increase in alkalinity and a tendency to raise the pH value. The carbonate ions will react with water, resulting in the formation of bicarbonate (HCO_3^-) and hydroxide (OH^-), until an equilibrium is established.

Background concentration of carbonate
If carbonate (CO_3^{2-}) is dissolved in water a re-equilibration takes place according to the following equations:

$HCO_3^- \rightleftharpoons CO_3^{2-} + H^+$ pKa=10.33
$CO_2 + H_2O \rightleftharpoons HCO_3^- + H^+$ pKa = 6.35

Only a small fraction of the dissolved CO_2 is present as H_2CO_3, the major part is present as CO_2. The amount of CO_2 in water is in equilibrium with the partial pressure of CO_2 in the atmosphere. The CO_2/ HCO_3^-/ CO_3^{2-} equilibria are the major buffer of the pH of freshwater and seawater throughout the world.

Based on the above equations, CO_2 is the predominant species at a pH smaller than 6.35, while HCO_3^- is the predominant species at a pH in the range of 6.35-10.33 and CO_3^{2-} is the predominant species at a pH higher than 10.33.

The natural concentration of CO_2/ HCO_3^-/ CO_3^{2-} in freshwater is influenced by geochemical and biological processes. Many minerals are deposited as salts of the carbonate ion and for this reason the dissolution of these minerals is a continuous source of carbonate in freshwater. Carbon dioxide is produced in aquatic ecosystems from microbial decay of organic matter. On the other hand plants utilize dissolved carbon dioxide for the synthesis of biomass (photosynthesis). Because many factors influence the

natural concentration of CO_2/ HCO_3^-/ CO_3^{2-} in freshwater, significant variations of the concentrations do occur.

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th – percentile, mean and 90th-percentile were 20, 106 and 195 mg/L, respectively.

Aquatic Toxicity

The acute 96-hour LC_{50} to three sizes of Bluegill sunfish (*Lepomis macrochirus*) exposed to sodium carbonate is 300 mg/L for all sizes. The acute 96-hour LC_{50} to mosquitofish (*Gambusia affinis*) is 740 mg/L. The acute 48-hour EC_{50} value to the invertebrate *Ceriodaphnia* cf. *dubia* is from 200 to 227 mg/L.

Toxicity to Terrestrial Organisms

Toxicity tests which determined the effect of sodium carbonate on terrestrial organisms are not available. The results of the tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil. Furthermore, carbonates are natural components of soil minerals.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (300 mg/L) and *Ceriodaphnia* (200 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 200 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.2 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium carbonate dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium carbonate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium carbonate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium carbonate is dominated by its water solubility. Sorption of sodium carbonate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not

readily apply to inorganics, such as sodium carbonate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium carbonate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

Environmental Assessment

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium hydroxide (NaOH) will be found predominantly in the aquatic environment. NaOH is present in the environment as sodium (Na^+) and hydroxyl (OH^-) ions, which implies that it will not adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Measured concentrations in aquatic ecosystems
The concentration of hydroxyl ions in the environment has been determined very extensively via pH measurements. The pH is a very important parameter of aquatic ecosystems and it is a standard parameter of water quality monitoring programs. The most important freshwater aquatic ecosystems of the world revealed average annual pH values between 6.5 and 8.3 but lower and higher values have been measured in other aquatic ecosystems (UNEP, 1995). In aquatic ecosystems with dissolved organic acids a pH of less than 4.0 has been measured, while in waters with a high chlorophyll content the bicarbonate assimilation can result in pH values of higher than 9.0 at midday (UNEP, 1995). The pH of an aquatic ecosystem is mainly determined by geochemical, hydrological and/or biological processes.

Also sodium has been measured extensively in aquatic ecosystems. For example UNEP (1995) reported the concentration for a total number of 75 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th –percentile, mean and 90th-percentile were 1.5, 28 and 68 mg/l, respectively.

NaOH addition and buffer capacity
An addition of NaOH to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th– percentile, mean and 90th-percentile were 20, 106 and 195 mg/l, respectively.

Aquatic Toxicity

At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realized that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralized and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity *e.g.*, NH_3 is more toxic than NH_4^+.

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L . At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L. The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia* cf. *dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

No data are available on the effects of NaOH on algae.

Toxicity to Terrestrial Organisms

Toxicity tests, which determined the effects of NaOH on terrestrial organisms, are not available. Significant exposure of the terrestrial environment is not expected and for this reason there is no need to perform toxicity test with terrestrial organisms. The results of terrestrial toxicity tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil.

Determination of PNECs

In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available and the results of the tests are more or less consistent. Altogether they give a sufficient indication about acute toxicity levels of sodium hydroxide.

Furthermore acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterized by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.

Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,

- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and

- The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for NaOH there is a need to assess the environmental effect of an NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

$PNEC_{aquatic}$: Based on the information above, a PNEC was not derived for sodium hydroxide.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium hydroxide dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium hydroxide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium hydroxide to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium hydroxide is dominated by its water solubility.

Sorption of sodium hydroxide should probably be regarded as a reversible situation, i.e., the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium hydroxide Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium hydroxide is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium hydroxide is an organic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

Environmental Assessment

Triethanolamine
(CAS No. 102-71-6)

Environmental Fate

Triethanolamine was completely degraded after incubation in municipal activated sludge for 1 or 5 days (West and Gonsior, 1996). The rate constants in all test batches for degradation and mineralization were reported to be >0.359. Thus, triethanolamine can be considered to be readily biodegradable.

In an OECD 301E test, there was 96% degradation after 19 days, indicating ready biodegradation (ECHA).

Bioaccumulation

Triethanolamine has been tested in a bioconcentration: flow-through fish (OECD 305) test using *Cyprinus carpio*. The BCF was determined to be <0.4 and <3.9 at triethanolamine concentrations of 2.5 and 0.25 mg/L, respectively (ECHA).

Aquatic Toxicity

The 96-hour LC_{50} to fathead minnow (*Pimephales promelas*) is 11,800 mg/L (ECHA). The 48-hour EC_{50} to *Ceriodaphnia dubia* is 610 mg/L (Warne and Schifko, 1999).

In a 21-day *Daphnia* reproduction test, the NOEC for reproduction rate was 125 mg/L, and the NOEC for reproduction on the appearance of first offspring was 250 mg/L (Kuehn *et al.*, 1989).

The 72-hour EC_{50} to algae *Desmodesmus subspicatus* is 512 mg/L [neutralized media] and 216 mg/L [un-neutralized media] (ECHA).

Toxicity to Terrestrial Organisms

No data were available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (11,800 mg/L), *Daphnia* (610 mg/L), and algae (512 mg/L). A long-term (chronic) study is available for invertebrates (21-day NOEC = 125 mg/L).

On the basis that the data consists of a chronic study on one trophic level, an assessment factor of 100 has been applied to the lowest reported NOEC of 125 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 1.25 mg/L.

PBT Assessment

Triethanolamine is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The BCF values for triethanolamine in fish was <3.9; thus, it does not meet the criteria for bioaccumulation.

The NOEC for triethanolamine in a 21-day *Daphnia* reproduction test is 125 mg/L, which is >0.1 mg/L. Thus, triethanolamine does not meet the screening criteria for toxicity.

The overall conclusion is that triethanolamine is not a PBT substance.

Environmental Assessment

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Limited information was located for this alkyl phosphonium salt.

Hydrolysis
TTPC is stable in water over a wide range of pH values (BuruEnergy).

Photolysis
TTPC is not susceptible to photolysis (BuruEnergy).

Biodegradation
TTPC was not readily biodegradable in an OECD 301 test (BuruEnergy).

In a die-away [simulation] test (using activated sludge) with radiolabelled TTPC for 168 hours at 0.31 mg/L, the first-order rate constant was 0.69/hour and the half-life was 6.6 hours. After 24 and 168 hours, degradation was >81% and >98%, respectively (BuruEnergy).

TTPC was evaluation in simulation tests over a 40-day period using double ^{14}C labeled TTPC. In activated sludge, there was >40% degradation after 30 days with 50 ppb TTPC and >30% degradation after 7 days with 5 ppb TTPC. In river water, there was >20% after 35 days with 5 ppb TTPC. In sea water, there was >30% degradation after 35 days with 5 ppb TTPC (BuruEnergy).

Adsorption/Desorption
The soil adsorption/desorption of TTPC was tested with three soils differing in sand/silt/clay content, by running an aqueous solution of radiolabelled TTPC through a column of soil. Soil adsorption ranged from 93-96% (BuruEnergy).

Bioaccumulation
The octanol-water coefficient (K_{ow}) was determined experimentally to be 2.45 from an OECD 107 test (BuruEnergy).

Aquatic Toxicity

Bellacide 350 MSDS: The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L.

U.S. EPA OPP Pesticide Ecotoxicity Database (wit study details): The 96-hour LC_{50}s in

rainbow trout are 0.49 and 0.2 mg/L. The 96-hour LC_{50}s in Bluegill sunfish and common carp (*Cyprinus carpio*) are 0.06 and 0.09 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* is 0.025 mg/L.

Environmental Properties of Proposed Biocide BE-9 (Document from BuruEnergy)
The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L. The 72-hour EC_{50} in green algae *Selenastrum capricornutum* was reported to be 0.019 mg/L.

Toxicity to Sediment Organisms

No data were found.

Toxicity to Terrestrial Organisms

U.S. EPA OPP Pesticide Ecotoxicity Database: The 8-day dietary LC_{50} in Bobwhite Quail is 4,215 ppm, with a NOEL of 1,980 ppm. The 8-day dietary LC_{50} in Mallard Duck is 3,663 ppm, with a NOEL of 1,780 ppm. The 14-day oral gavage LD_{50} in Mallard Duck is 232 mg/kg, with a NOEL of 178 mg/kg.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.2 mg/L), Daphnia (0.025 mg/L), and algae (0.019 mg/L). While the lowest acute value is 0.019 mg/L, it has only been reported in summary document from BuruEnergy and needs to be substantiated. For the purposes of PNEC determination, the acute EC_{50} value for Daphnia will be used. It should be noted that the two values are very similar.

On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the effect concentration of 0.025 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is calculated to be 2.5×10^{-5} mg/L (0.025 μg/L).

PBT Assessment

TTPC is not readily biodegradable. In a simulation test using river water, there was >20% after 35 days. Thus, TTPC appears to meet the screening criteria for persistence.

The octanol-water coefficient (K_{ow}) for TTPC is 2.45. Thus, TTPC does not meet the screening criteria for bioaccumulation.

No chronic toxicity data are available for TTPC. The lowest acute $EC(L)_{50}$ of TTPC is 0.025 mg/L in invertebrates. Since this value is <0.1 mg/L, TTPC does meet the screening criteria for toxicity.

Environmental Assessment

Ulexite
(CAS No. 1319-33-1)

Ulexite is a structurally complex mineral with the chemical structure ($NaCaB_5O_6(OH)_6 \bullet 5H_2O$). It is slightly soluble in water. One of the uses of ground alexite is in agricultural applications as a source of slow-release boron. No environmental fate or aquatic toxicity exist for ulexite. However, for the purposes of this assessment, data on borax and boric acid will be used to read across to ulexite. The rationale is as follows:

Borax is also known as sodium borate, sodium tetraborate, or disodium tetraborate. With water content, borax can refer to a group of compounds that differ in their crystal water content, but typically it is disodium tetraborate decahydrate with the chemical structure ($Na_2B_4O_7 \bullet 10H_2O$). Borax is moderately soluble in water, with the main species in freshwater being the borate ion $[B(OH)_4]^-$ and boric acid $B(OH)_3$, depending on the pH. The relative proportion of boric acid and borate ions is controlled by pH: $B(OH)_3 + 2H_2O \Leftrightarrow [B(OH)_4]^- + H_3O^-$. In dilute aqueous solutions, boric acid does not dissociate at pH <7; at pH values between 7 and 11, both boric acid and borate ions are present. In dilute aqueous solutions and physiological conditions, the predominant species present is un-dissociated boric acid. So, the consideration of boric acid addresses the relevant environmental stability properties for borates.

Exposure to borates are often expressed in terms of boron (B) equivalents based on the fraction of boron in the source substance on a molecular weight basis. The B equivalents used are a generic designation rather than a designation of the element boron. The factors for converting disodium tetraborate decahydrate, boric acid, and ulexite to B-equivalents are 0.113, 0.175, and 0.133, respectively.

In natural waters, boron forms stable species and exists primarily as un-dissociated boric acid [$B(OH)_3$] and complex polyanions (*e.g.,* $B(OH)_{4-}$). These forms of boron are highly soluble and not easily removed from solution by natural mechanisms. Borate and boric acid are in equilibrium depending on the pH of the water. At an acidic pH, boron exists in solution mainly as un-dissociated boric acid, whereas at alkaline pH it is present as borate ions.

<u>Environmental Fate</u>

At noted above, disodium tetraborate decahydrate will yield boric acid upon dissolution in water (or borate anion in higher pH conditions). Boric acid is a persistent molecule, not subject to hydrolysis, photodegradation or biodegradation.

Many mineral contain boron, which is present as the sodium or calcium borate salt. Thus, boron is ubiquitous and widely distributed in the environment. It is present in

rocks, soil and water and is released into the environment primarily from the weathering of rock and soil, volatilization of sea water, and anthropogenic activity.

Bioaccumulation

The WHO (1998) review of boron noted that "highly water soluble materials are unlikely to bioaccumulate to any significant degree and that borate species are all present essentially as un-dissociated and highly soluble boric acid at neutral pH". A BCF of <0.1 was reported in Chinook salmon fed boron-supplemented diets for 60 to 90 days (Hamilton and Wiedmeyer, 1990).

Some bioconcentration is expected in terrestrial plants since boron is a critical element to terrestrial plants and is incorporated into the cell wall structure. However, the phytotoxicity of boron limits the potential for excessive accumulation beyond "normal" plant tissue concentrations (Austria, 2008). Terrestrial non-predatory organisms, such as Mallard ducks, did not accumulate boron (BCF <0.1) when fed a plant diet of 1,600 mg-B/kg for up to 48 days (Pendleton *et al.*, 1995).

Toxicity

There are many ecotoxicity laboratory and field tests that have been conducted on boron (which includes boric acid and borates). Overall, the studies show that boron does not fulfill the criteria of Toxicity in a PBT assessment with regards to aquatic organisms. The data were reviewed in the "Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for Boron" (CCME, 2009), which is summarized below:

"Primary acute toxicity data for vertebrates were available for early life stages of four fish species. Endpoints ranged from a 3 day NOEC (teratogenesis at hatching) of 0.109 mg/L for embryo- hatching stage largemouth bass (Black *et al.* 1993) to a 7 day EC_{50} (embryo test) of 969 mg/L for rainbow trout (MELP, 1996). Secondary and unclassified toxicity data were similar to the reported primary data with effect concentrations ranging between 4.6 and 3,145 mg/L."

"Primary acute toxicity data for invertebrates were available for four species. The 48 hour LC_{50} concentrations ranged from 21.3 mg/L for neonate water fleas (MELP, 1996) to 1,376 mg/L for larval midge (Maier and Knight, 1991). Secondary, unclassified and unacceptable toxicity data were similar to the reported primary data with effect concentrations ranging between 1 and 2,797 mg/L."

"Primary chronic toxicity data for vertebrates were available for three fish species." If the outliers are excluded, "effect concentrations ranged from a 36 day LOEC (mortality) of 1.34 mg/L for embryo-larval rainbow trout to a 32 day LC_{50} of 138 mg/L for rainbow

trout (Black *et al.*, 1993). Lower effect concentrations (0.01 mg/L) for embryo-larval rainbow trout were observed in the unclassified toxicity studies (Birge and Black, 1977)."

"Primary chronic toxicity data for invertebrates were available for two species. Effect concentrations ranged between a 21 day LOEC (mean brood size) of 13 mg/L to a 21 day LC_{50} of 53.2 mg/L for the water flea (Lewis and Valentine, 1981). Effect concentrations for additional unclassified studies differed from those reported by the primary studies, with a range of <0.38 to ~266 mg/L."

"Primary chronic toxicity data were available for 4 to 7 day old green algae (*Selenastrum capricornutum*) (MELP, 1997). The lowest reported effect concentration for algae exposed to boron was a 72 hour LOEC of 12.3 mg/L. Effect concentrations of secondary and unclassified toxicity data ranged from 1 to ~171 mg/L."

Determination of PNECs

$PNEC_{aquatic}$: There are many ecotoxicity laboratory and field tests that have been conducted on boron (which includes boric acid and borates). Both acute and chronic toxicity studies are available for three trophic levels. A Canadian Water Quality Guidelines for the Protection of Aquatic Life of 1.5 mg/L was derived for long–term exposure to boron (CCME, 2009). Thus, the $PNEC_{aquatic}$ for disodium octaborate tetrahydrate is 1.5 mg-B/L.

It should be noted, however, that Australia and New Zealand adopted a freshwater high reliability trigger value for boron of 0.37 mg-B/L (ANZECC, 2000).

The factor for converting ulexite to B-equivalents is 0.133.

PBT Assessment

Ulexite is a persistent molecule, not subject to hydrolysis, photodegradation or biodegradation. Thus, it meets the criteria for persistence.

Ulexite is slightly water-soluble substance that is not expected to bioaccumulate. Limited data indicate that bioaccumulation (BCF values are low) is not significant in aquatic and terrestrial food chains. Thus, it does not meet the criteria for bioaccumulation.

Overall, the aquatic toxicity studies show that boron does not fulfill the criteria of toxicity. However, there are human health concerns and boric acid (and borates) are considered reproductive toxicants; they have, for instance, been classified in the EU as known or presumed human reproductive toxicants (Category 1B). Thus, ulexite meets the PBT criteria of toxicity.

The overall conclusion is that ulexite is not a PBT substance.

APPENDIX G.9 FLUOROSCEIN DYE

Environmental Assessment

Potassium chloride
(CAS No. 7447-40-7)

Potassium chloride (KCl) has been reviewed in the OECD-SIDS program (OECD, 2001a,b).

Environmental Fate

KCl is a solid inorganic salt that is highly soluble in water (342 g/L at 20^{o} C). Potassium chloride fully dissociates in aqueous solutions to K^+ and Cl^- ions.

KCl, either as an inorganic salt or as K^+ and Cl^- ions, is ubiquitous in the environment. There is no potential for bioaccumulation or bioconcentration. Potassium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated.

Aquatic Toxicity

In a guideline study, the 96-hour LC_{50} in *Pimephales promelas* was reported to be 880 mg/L (Mount *et al.*, 1997). The 48-hour LC_{50} values from two studies on *Lepomis macrochirus* (Patrick *et al.*, 1968; Trama, 1954), and one study each on *Oncorhyncus mykiss* and *Ictalurus punctatus* (Waller *et al.*, 1993) ranged from 720 to 2,010 mg/L.

In a guideline study, the 48-hour EC_{50}s in *Daphnia magna* and *Ceriodaphnia dubia* were 660 and 630 mg/L, respectively (Mount *et al.*, 1997; ECHA REACH database). The 48-hour EC_{50} in *Daphnia magna* in another study was also reported to be 177 mg/L (Biesinger and Christensen, 1972).

The toxicity of KCl has been investigated in one algae species (*Nitzschia linearis*), showing 120 hour-EC_{50} (growth rate) of 1,337 mg/L (Patrick *et al.*, 1968). The 72-hour EC_{50} to *Scenedesmus subspicatus* is >100 mg/L (growth rate), with a NOEC of $\geq$100 mg/L (ECHA REACH database).

In a fish early-life-stage test with the fathead minnow (*Pimephales promelas*), the 7-day NOEC is 500 mg/L (ECHA REACH database). A long term (21-day) study has been performed on *Daphnia magna* where effects on reproduction were investigated for several metals. A 16% impairment of reproduction (LOEC) was observed at a concentration of 53 mg/L of K +, equal to KCl concentration of 101 mg/L (Biesinger and Christensen, 1972).

Toxicity to Terrestrial Organisms

Potassium is one of the three major nutrients and chloride is an essential micronutrient for plants. No data could be located on the toxicity to terrestrial organisms.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (720 mg/L), Daphnia (177 mg/L), and algae (>100 mg/L). Although chronic studies has been conducted on fish and invertebrates, these tests are not valid for deriving PNECs (ECHA REACH database). On the basis of the short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ is determined to be 0.1 mg/L.

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Potassium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as potassium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of potassium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of potassium chloride is dominated by its water solubility. Sorption of potassium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as potassium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, potassium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Potassium chloride is an organic salt that dissociates completely to potassium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and chloride ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Potassium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, potassium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on potassium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, potassium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that potassium chloride is not a PBT substance.

Environmental Assessment

Sodium Fluorescein
[D&C Yellow No. 8; Acid Yellow 73]
(CAS No. 518-47-8)

Biodegradation

In a modified OECD 302B test using an activated sludge inoculum, sodium fluorescein showed <25% elimination in 42 days with no indication of biodegradation (Pagga and Brown 1986).

Bioaccumulation

The estimated BCF for sodium fluorescein based on an estimated log K_{ow} of 3.35 is 75 (EPA 2012).

Aquatic Toxicity

The 48-hour LC_{50} in Oryzias latipes (medaka fish) was reported to be 3,000 mg/L (Tonogai *et al.* 1979). The 48-hour LC_{50} to *Daphnia pulex* neonates (<24 hours old) is 337 mg/L (Walthall and Stark 1999).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for two trophic levels. Acute LC_{50} values are available for fish (3,000 mg/L) and the invertebrate *Daphnia* (337 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the reported lowest effect concentration of 337 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 0.34 mg/L.

PBT Assessment

Sodium fluorescein is not biodegradable and thus it meets the screening criteria for persistence.

The estimated BCF for sodium fluorescein based on an estimated log K_{ow} of 3.35 is 75 (EPA 2012). Thus, sodium fluorescein would not be expected to meet the screening criteria for bioaccumulation.

No chronic aquatic toxicity studies are available for sodium fluorescein. The acute toxicity studies in fish and invertebrates are >0.1 mg/L. Thus, sodium fluorescein does not meet the criteria for toxicity.

The overall conclusion is that sodium fluorescein is not a PBT substance.

Environmental Assessment

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Limited information was located for this alkyl phosphonium salt.

Hydrolysis
TTPC is stable in water over a wide range of pH values (BuruEnergy).

Photolysis
TTPC is not susceptible to photolysis (BuruEnergy).

Biodegradation
TTPC was not readily biodegradable in an OECD 301 test (BuruEnergy).

In a die-away [simulation] test (using activated sludge) with radiolabelled TTPC for 168 hours at 0.31 mg/L, the first-order rate constant was 0.69/hour and the half-life was 6.6 hours. After 24 and 168 hours, degradation was >81% and >98%, respectively (BuruEnergy).

TTPC was evaluation in simulation tests over a 40-day period using double ^{14}C labeled TTPC. In activated sludge, there was >40% degradation after 30 days with 50 ppb TTPC and >30% degradation after 7 days with 5 ppb TTPC. In river water, there was >20% after 35 days with 5 ppb TTPC. In sea water, there was >30% degradation after 35 days with 5 ppb TTPC (BuruEnergy).

Adsorption/Desorption
The soil adsorption/desorption of TTPC was tested with three soils differing in sand/silt/clay content, by running an aqueous solution of radiolabelled TTPC through a column of soil. Soil adsorption ranged from 93-96% (BuruEnergy).

Bioaccumulation
The octanol-water coefficient (K_{ow}) was determined experimentally to be 2.45 from an OECD 107 test (BuruEnergy).

Aquatic Toxicity

Bellacide 350 MSDS: The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L.

U.S. EPA OPP Pesticide Ecotoxicity Database (wit study details): The 96-hour LC_{50}s in

rainbow trout are 0.49 and 0.2 mg/L. The 96-hour LC_{50}s in Bluegill sunfish and common carp (*Cyprinus carpio*) are 0.06 and 0.09 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* is 0.025 mg/L.

Environmental Properties of Proposed Biocide BE-9 (Document from BuruEnergy)
The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L. The 72-hour EC_{50} in green algae *Selenastrum capricornutum* was reported to be 0.019 mg/L.

Toxicity to Sediment Organisms

No data were found.

Toxicity to Terrestrial Organisms

U.S. EPA OPP Pesticide Ecotoxicity Database: The 8-day dietary LC_{50} in Bobwhite Quail is 4,215 ppm, with a NOEL of 1,980 ppm. The 8-day dietary LC_{50} in Mallard Duck is 3,663 ppm, with a NOEL of 1,780 ppm. The 14-day oral gavage LD_{50} in Mallard Duck is 232 mg/kg, with a NOEL of 178 mg/kg.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.2 mg/L), Daphnia (0.025 mg/L), and algae (0.019 mg/L). While the lowest acute value is 0.019 mg/L, it has only been reported in summary document from BuruEnergy and needs to be substantiated. For the purposes of PNEC determination, the acute EC_{50} value for Daphnia will be used. It should be noted that the two values are very similar.

On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the effect concentration of 0.025 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is calculated to be 2.5×10^{-5} mg/L (0.025 μg/L).

PBT Assessment

TTPC is not readily biodegradable. In a simulation test using river water, there was >20% after 35 days. Thus, TTPC appears to meet the screening criteria for persistence.

The octanol-water coefficient (K_{ow}) for TTPC is 2.45. Thus, TTPC does not meet the screening criteria for bioaccumulation.

No chronic toxicity data are available for TTPC. The lowest acute $EC(L)_{50}$ of TTPC is 0.025 mg/L in invertebrates. Since this value is <0.1 mg/L, TTPC does meet the screening criteria for toxicity.

APPENDIX G.10 CONDOR ENERGY SYSTEMS

Environmental Assessment

2-Ethoxynaphthalene
(CAS No. 93-18-5)

Biodegradation

There are no biodegradation studies on 2-ethoxynaphthalene. A biodegradation study on 1-methoxynapthalene (method not specified) showed 0% degradation (measured as BOD) and 4% (measured by HPLC) after 28 days (ECHA) [Kl. score = 4]. Thus, 2-ethoxynaphthalene is not expected to be readily biodegradable.

Bioaccumulation

No bioconcentration studies have been conducted on 2-ethoxynaphthalene. 2-Ethoxynaphthalene is unlikely to bioaccumulate based on the experimental log K_{ow} of 3.748 (ECHA) [Kl. score = 1] and a calculated BCF of 136.6 (ECHA).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on 2-ethoxynaphthalene.

Table 1: Acute Aquatic Toxicity Studies on 2-Ethoxynaphthalene

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oryzias latipes	48-hr LC_{50}	11.1	2	ECHA
Daphnia magna	48-hr EC_{50}	3.9	2	ECHA
Daphnia pulex	48-hr EC_{50}	4.04	2	ECHA
Desmodesmus subspicatus	72-hr EC_{50}	4.93	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (11.1 mg/L), *Daphnia* (3.9 mg/L), and algae (4.93 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 3.9 mg/L for *Daphnia*. The $PNEC_{water}$ is 0.04 mg/L.

PBT Assessment

2-Ethoxynaphthalene is not readily biodegradable; thus, it does not meet the screening criteria for persistence.

No bioconcentration studies are available for 2-ethyoxynaphthalene. The measured log K_{ow} for cinnamaldehyde is 3.748; thus, 2-ethoxynaphthalene does not meet the screening criteria for bioaccumulation.

There are no chronic toxicity studies on 2-ethoxynaphthalene. The acute E(L)C_{50} values for 2-ethoxynaphthalene in fish, invertebrates, and algae are >1 mg/L. Thus, 2-ethoxynaphthalene does not meet the screening criteria for toxicity.

The overall conclusion is that 2-ethoxynaphthalene is not a PBT substance.

Environmental Assessment

2-Mercaptoethyl alcohol
(CAS No. 60-24-2)

Biodegradation

In an OECD 310 test, biodegradation was 69% after 60 days (ECHA) [Kl. score = 1]. In an OECD 301A test, biodegradation was <10% after 28 days (ECHA) [Kl. score = 1]. In an OECD 301C test, biodegradation was ≥15% and ≤21% after 28 days (ECHA) [Kl. score = 2]. In an OECD 302 C test, biodegradation was 90% after 28 days (ECHA) [Kl. score = 2].

In an OECD 309 test, the mineralization of 2-ME in surface water was determined in a GLP-compliant study following OECD guideline 309. Mineralization was a significant route of degradation and activity recovered as CO_2 increased to >60% after 14 days of incubation at two different test concentrations. Three major transformation products were detected which exceeded 10% of applied activity at both test concentrations. Transformation product M-1 reached a maximum of 26% after 4 hours (0.17 days) at the low-test concentration and a maximum of 13% after 8 hours (0.33 days) at the high-test concentration, and then decreased to non-detectable amounts after 6 days of incubation (both concentrations). Transformation product M-3 reached a maximum of 36% (low test concentration) and 30% (high test concentration after 2 days and then decreased to 14% after 9 days of incubation (low test concentration) and to <5% after 14 days of incubation (high test concentration). Transformation product M-6C reached a maximum of 41% (low test concentration) and 39% (high test concentration) after 4 hours (0.17 days) and then decreased to non-detectable amounts after 6 days of incubation. It was concluded that 2-mercaptoethanol degrades quickly in water, with a half-life of 0.079 days, and no parent compound was detected in the water layers of both test concentrations after 1 day of incubation. Based on the results of the OECD 309 study, the substance degrades in the aquatic environment to a level of >70% within a 28-day period and therefore, the substance is considered to be rapidly biodegradable (ECHA) [Kl. score = 1].

Bioaccumulation

No bioconcentration studies have been conducted on 2-mercaptoethanol. 2-Mercaptoethanol is not expected to bioaccumulate based on the experimental log K_{ow} of -0.056 at pH 7 (ECHA) [Kl. score = 2].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on salts of 2-ME.

Table 1: Acute Aquatic Toxicity Studies on Salts of 2-Mercaptoethyl Alcohol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Leuciscus idus	96-hr LC_{50}	37	2	ECHA
Daphnia magna	48-hr EC_{50}	0.4	2	ECHA

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Desmodesmus subspicatus	96-hr EC_{50} NOEC	19 1.7	1	ECHA

The 21-day NOEC from a *Daphnia* reproduction test was determined to be >0.063 mg/L (ECHA) [Kl. score = 1].

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (37 mg/L), *Daphnia* (0.4 mg/L), and algae (19 mg/L). Results from chronic toxicity studies are available for invertebrates (>0.063 mg/L) and algae (1.7 mg/L). On the basis that the data consists of short-term results from three trophic levels and long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported NOEC value of 0.063 mg/L for *Daphnia*. The $PNEC_{water}$ is 0.0013 mg/L.

PBT Assessment

2-ME is readily biodegradable in the aquatic environment; thus, it does not meet the screening criteria for persistence.

No bioconcentration studies are available for formic acid. The measured log K_{ow} for 2-ME is -0.056; thus, 2-ME does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on 2-ME show a NOEC of <0.1 mg/L. Thus, 2-ME meets the screening criteria for toxicity.

The overall conclusion is that 2-ME is not a PBT substance.

References

ECHA. ECHA REACH database: http://echa.europa.eu/information-on-chemicals/registered-substances.

Environmental Assessment
Acetic acid

(CAS No. 64-19-7)

Acetic acid readily dissociates in aqueous media to the acetate ($H_3C2O_2^-$) and hydrogen (H^+) ions. The toxicity is driven by acetate, with the hydrogen ion playing a minor role. The pK_a is 4.76 at 20°C.

Biodegradation

Acetic acid was readily biodegradable in a non-acclimated freshwater study. Degradation was 96% after 20 days (Price et al., 1974; ECHA) [Kl. score = 2]. Acetic acid is also readily biodegradable under anaerobic conditions (Kameya et al., 1995) [Kl. score = 2].

Bioaccumulation

There are no bioaccumulation studies on acetic acid. Bioaccumulation of acetic acid is not expected to occur because acetic acid dissociates completely in aqueous solution to acetate and its hydrogen ion. Both ions are ubiquitous in the environment. Acetate is naturally found in eukaryotic and prokaryotic cells and is involved in their biochemical pathways.

Aquatic Toxicity

Table 1 presents the results of acute aquatic toxicity studies on acetic acid and potassium acetate.

Table 1: Acute Aquatic Toxicity Studies on Acetic acid and Potassium Acetate

Test Substance	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Potassium acetate	*Oncorhynchus mykiss*	96-h LC_{50}	>300.82*	2	ECHA
Potassium acetate	*Danio rerio*	96-h LC_{50}	>300.82*	2	ECHA
Acetic acid	*Oncorhynchus mykiss*	96-h LC_{50}	64.8 (measured)	4	ECHA
Acetic acid	*Oncorhynchus mykiss*	96-h LC_{50}	31.3 – 67.6	4	ECHA
Potassium acetate	*Daphnia magna*	48-h EC_{50}	>300.82*	2	ECHA
Acetic acid	*Daphnia magna*	48-h EC_{50}	79.5	4	ECHA

Test Substance	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
			(measured)		
Acetic acid	*Daphnia magna*	48-h EC_{50}	18.9 (measured)	4	ECHA
Acetic acid	*Desmodesmus subspicatus*	72-h EC_{50}	486.5	4	ECHA

*As the acetate ion.

In a 21-day fish (*Oncorhynchus mykiss*) chronic study, the measured NOEC values for 60% and 100% acetic acid were 57.2 and 34.3 mg/L, respectively (ECHA). [Kl. score = 4]

In a 21-day *Daphnia* reproduction study, the measured NOEC for 60% and 100% acetic acid were 80 and 31.4 mg/L, respectively (ECHA). [Kl. score = 4]

In a 21-day *Daphnia* reproduction study, the measured NOEC for 100% acetic acid was 22.7 mg/L (ECHA). [Kl. score = 4]

Terrestrial Toxicity

No data are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. For the acute toxicity studies, data are available on both acetic acid and potassium acetate; both substances dissociate completely in aqueous media to the acetate anion and the corresponding cations (H^+ and K^+). The toxicity of these substances is expected to be driven by the acetate ion, with the cations having a minor role. The toxicity data on potassium acetate are preferred because of the absence of a potential pH change from the dissociated H^+ ion of acetic acid. For the chronic toxicity studies, only acetic acid has been tested for two trophic levels: fish and invertebrates. These studies will not be used to derive the PNEC value; however, an assessment factor of 100 will be applied to the lowest acute $E(L)C_{50}$ values.

From the potassium acetate studies, acute $E(L)C_{50}$ values (adjusted for acetic acid) are available for fish (300.82 mg/L) and *Daphnia* (300.82 mg/L). By applying an assessment factor of 100 to the $E(L)C_{50}$ value of 300.82 mg/L from either fish or *Daphnia*, the $PNEC_{aquatic}$ for acetic acid is 3.0 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 1.9 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.82/1280) \times 1000 \times 3.0$
$= 1.9$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [(0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [(0.2 \times 0.04/1000 \times 2400]$
$= 0.82$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 1.0 \times 0.04$
$= 0.04$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for acetic acid calculated from EPISUITE™ using the MCI is 1.0 L/kg .
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.04 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.02/1500) \times 1000 \times 3.0$
$= 0.04$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 1.0 \times 0.02$
$= 0.02$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for acetic acid calculated from EPISUITE™ using the MCI is 1.0 L/kg .
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

PBT Assessment

Acetic acid is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Bioaccumulation of acetic acid is not expected to occur because acetic acid dissociates completely in aqueous media to acetate and its hydrogen ion. Both ions are ubiquitous in the environment. Acetate is naturally found in eukaryotic and prokaryotic cells and is involved in their biochemical pathways. The log K_{ow} for acetic acid is -0.17. Thus, acetic acid does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity studies on acetic acid are >0.1 mg/L. The $E(L)C_{50}$ values for potassium acetate are >1 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

Environmental Assessment

Acrylamide/sodium acrylate copolymer (anionic polyacrylamide) (CAS No. 25085-02-3)

Polyacrylamide polymers can exist in cationic, anionic, or non-ionic forms, depending on their ionic charge. The non-ionic form of polyacrylamide is generated from the basic polymerization of acrylamide. Anionic polyacrylamide polymer can then be formed from the hydrolysis of the acrylamide homopolymer either simultaneously during the polymerization process or as a subsequent step (Zheng et al., 2013). Anionic polyacrylamide polymer can also be formed from the copolymerization of acrylamide and acrylic acid (Lyons and Vasconellos, 1997; Zheng et al., 2013). The molecular weight of polyacrylamide co-polymers uses as flocculents are 1,000,000 to >50,000,000 (Lyons and Vasconcellos, 1997.

Environmental Fate

No studies on the environmental fate of anionic polyacrylamide are available. As a high-molecular-weight polymer, it is not expected to biodegrade or bioaccumulate (Lyons and Vasconcellos, 1997). The environmental fate of anionic polyacrylamide will be determined primarily by adsorption (Lyons and Vasconcellos, 1997).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on the powder form of anionic polyacrylamides, respectively. The data were reported in a table as LC_{50} values with no details on the individual studies.

Table 1: Acute Aquatic Toxicity Studies on Anionic Polyacrylamide* in Powder Form

*Acrylic acid-acrylamide copolymers with molecular weights of >1,000,000.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for two trophic levels. Acute LC_{50} values are available for fish (>100 mg/L) and invertebrates (470 mg/L). On the basis that the data consist of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest LC_{50} value of 100 mg/L for fish. The $PNEC_{water}$ is 0.1 mg/L.

$PNEC_{sediment}$: There are no toxicity data for sediment-dwelling organisms. The K_{ow} and K_{oc} have not been experimentally derived for anionic polyacrylamide; these values cannot be estimated using QSAR models because of the high molecular weight of anionic polyacrylamide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sed}$.

$PNEC_{soil}$: There are no toxicity data for soil-dwelling organisms. The K_{ow} and K_{oc} have not been experimentally derived for anionic polyacrylamide; these values cannot be estimated using QSAR models because of the high molecular weight of anionic polyacrylamide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$.

PBT Assessment

Anionic polyacrylamide is a large molecular weight, water-soluble polymer. It is not expected to be readily biodegradable; thus, it meets the screening criteria for persistence.

Pharmacokinetic studies showed that anionic polyacrylamide was not bioavailable to rats when ingested; this is most likely due to its large size (high molecular weight) and presumed resistance to breakdown in the gastrointestinal tract. Anionic polyacrylamide is thus not expected to be bioavailable to aquatic or terrestrial organisms. It is not expected to meet the criteria for bioaccumulation.

No chronic aquatic toxicity data are available on polyacrylamide. The acute LC_{50} values in fish and invertebrates are >1 mg/L. Thus, it does not meet the criteria for toxicity.

The overall conclusion is that anionic polyacrylamide is not a PBT substance.

Environmental Assessment

Ammonium persulfate
(CAS No. 7727-54-0)

Environmental Fate

Ammonium persulfate dissociates in aqueous media to the ammonium cation (NH_4^+) and persulfate anion ($S_2O_8^{2-}$) (OECD 2005a and 2005b; ECHA). The persulfate anion will readily hydrolyze (decompose) into sulfate ions.

The rates of hydrolysis are expected to be similar for sodium persulfate, potassium persulfate, and ammonium persulfate. The rates of decomposition (hydrolysis) were measured at 50°C at various pHs. The half-lives increased from 20 hours at pH 1 to 210 hours at pH 10 (Koltoff and Miller, 1951).

Biodegradation is not applicable to inorganic compounds. Ammonium persulfate is not expected to bioaccumulate; it will dissociate (and decompose) to ions that are ubiquitous in the environment. Ammonium persulfate is not expected to absorb to soil or sediment because of its dissociation properties, instability (hydrolysis), and high water solubility.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on ammonium persulfate.

Table 1: Acute Aquatic Toxicity Studies on Ammonium Persulfate

Test Species	**Endpoint**	**Results (mg/L)**	**Klimisch score**	**Reference**
Oncorhynchus mykiss	96-h LC_{50}	76.3	1	ECHA
Daphnia magna	48-h EC_{50}	120	1	ECHA
Selenastrum capricornutum	72-h EC_{50}	83.7	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (76.3 mg/L), *Daphnia* (120 mg/L), and algae (83.7 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 76.3 mg/L for fish. The $PNEC_{water}$ is 0.8 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Ammonium persulfate dissociates completely in water; its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as ammonium persulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on its properties, no adsorption of ammonium persulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of ammonium persulfate is dominated by its water solubility. Sorption of ammonium persulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{oc} and K_{ow} parameters do not readily apply to inorganics, such as ammonium persulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, ammonium persulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Ammonium persulfate is an inorganic compound that dissociates completely to ammonium and persulfate ions in aqueous solutions. Persulfate ions are further hydrolysed to sulphate ions. Biodegradation is not applicable to these compounds. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to ammonium persulfate or its dissociated compounds.

Ammonium persulfate is an inorganic compound that dissociates completely in water to ionic compounds that are ubiquitous in the environment. Thus, ammonium persulfate is not expected to bioaccumulate.

There are no chronic aquatic toxicity data on ammonium persulfate. The acute $E(L)C_{50}$ values for fish, invertebrates, and algae are >1 mg/L. Thus, ammonium persulfate does not meet the criteria for toxicity.

The overall conclusion is that ammonium persulfate is not a PBT substance.

Environmental Assessment

2-Propenoic acid, homopolymer, ammonium salt
(CAS No. 9003-03-6)

No information could be located on 2-propenoic acid, homopolymer, ammonium salt (ammonium polyacrylate). Therefore, data on sodium polyacrylates will be used to read-across to ammonium polyacrylate.

Sodium polyacrylates are polymers that range in molecular weight (MW) from 1,000 to 78,000 (HERA, 2014). The sodium polyacrylates mostly used in detergents have a typical molecular weight of approximately 4,500 (HERA, 2014).

Biodegradation

Sodium polyacrylates are not readily biodegradable, but are partly accessible to ultimate biodegradation particularly under long incubation conditions. Sodium polyacrylates with MW of <2,000 are partly biodegradable under the conditions of soil and sediment inoculation. Test results with activated sludge inoculum indicate different elimination degrees, apparently due to adsorption and precipitation processes. The removal degrees of different sodium polyacrylates show no clear relationship between elimination extent and molecular weight (HERA, 2014).

Bioaccumulation

No experimental studies are available on sodium polyacrylates. Estimated bioconcentration factors based on octanol-water coefficients are not appropriate since the molecular weights of these polymers are higher than the molecular weight range for the QSAR models. Due to their high molecular weights, sodium polyacrylates are not expected to bioaccumulate. In addition, these water-soluble polymers can form insoluble calcium salts in natural waters, suggesting that bioaccumulation is unlikely.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on sodium polyacrylates.

Table 1: Acute Aquatic Toxicity Studies on Sodium Polyacrylates

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference

Table 2 lists the results of chronic aquatic toxicity studies on sodium polyacrylates.

Table 2: Chronic Aquatic Toxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
4,500	*Pimephales promelas*	32-d NOEC	56	2	HERA, 2014
4,500	*Brachydanio rerio*	28-d NOEC	>450	1	HERA, 2014
78,000	*Brachydanio rerio*	14-d NOEC	>400	2	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	450	1	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	58	1	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	12	2	HERA, 2014
78,000	*Daphnia magna*	21-d NOEC	100	2	HERA, 2014
4,500	*Scenedesmus subspicatus*	96-hr NOEC	180	2	HERA, 2014
78,000	*Scenedesmus subspicatus*	96-hr NOEC	32.8	2	HERA, 2014

There is considerable variability in the chronic aquatic toxicity results for *Daphnia magna* for sodium polyacrylates with the same molecular weight of 4,500. This was discussed in HERA (2014) and was explained by the solubility of sodium polyacrylates in water. In distilled water, the solubility of sodium polyacrylates with the molecular weight of 4,500 is >400 mg/L; however, under test conditions water solubility will decrease due to the presence of Ca^{++} and Mg^{++} (as measured by water hardness). In a study by BASF (reviewed in HERA, 2014), the water solubility of sodium polyacrylate (MW 4,500) was determined with radiolabelled compounds in a test system with a calcium concentration of 70 mg/L, which corresponds to the mean water hardness to the media used in an OECD TG 202 test. Under these conditions, the water solubility of sodium polyacrylate was 1.3 mg/L after 24 hours. So, one explanation for the variability of the chronic *Daphnia* studies may be due to differences in water hardness.

Toxicity to Sediment Organisms

The 96-hr EC_0 to *Chironomus riparius* (larvae) is >4,500 mg/kg sediment dry weight (HERA, 2014).

Terrestrial Toxicity

The results of terrestrial toxicity studies on sodium polyacrylate polymers are listed below in Table 3.

Table 3: Terrestrial Toxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
4,500	*Eisenia foetida*	14-d EC_0	1,000	1	HERA, 2014

*Soil organisms.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>200 mg/L), invertebrates (>200 mg/L), and plants (40 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 12 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 12 mg/L for invertebrates. The $PNEC_{water}$ is 1.2 mg/L.

$PNEC_{sediment}$: Experimental results are available for one trophic level. There were no visual signs of toxicity to *Chironomus riparius* (larvae) at the highest concentration tested (>4,500 mg/kg sediment dry weight) (HERA, 2014). The EC_0 is considered to be above 4,500 mg/kg and an assessment factor cannot apply. Thus, the equilibrium partitioning method will be used to determine the $PNEC_{sed}$. The HERA (2014) risk assessment calculated a $PNEC_{sed}$ of 130 mg/kg sediment wet weight using the default of 0.05 as the weight fraction of organic carbon in sediment according to the EU Technical Guidance Document (TGD) (EU, 2003).

$PNEC_{soil}$: Experimental results are available for three trophic levels. An acute LC_{50} value is available for earthworms (1,000 mg/kg soil dry weight). A 21-day NOEC for *Brassica rapa* was reported to be 1,000 mg/kg soil dry weight. Results from two long-term studies are available for soil microorganisms, with the NOECs for nitrogen and carbon transformation being >2,500 mg/kg soil dry weight. On the basis that the data consists of short-term tests, as well as one long-term test from one trophic level, an assessment factor of 100 has been applied to the lowest reported long-term NOEC of >2,500 mg/kg soil dry weight. The $PNEC_{soil}$ is 25 mg/kg soil dry weight.

PBT Assessment

The sodium polyacrylates are not readily biodegradable; thus, they meet the screening criteria for persistence.

The sodium polyacrylates are expected to have high molecular weights and are not expected to be bioavailable. Thus, these polymers do not meet the criteria for bioaccumulation.

Chronic NOECs for fish, daphnia and algae are available for sodium polyacrylates, and the NOEC values are >0.1 mg/L. Thus, sodium polyacrylates do not meet the screening criteria for toxicity.

The overall conclusion is that sodium polyacrylates are not PBT substances.

Environmental Assessment

Ammonium sulfate
(CAS No. 7783-20-2)

Environmental Fate

Ammonium sulfate dissociates in aqueous media to ammonium (NH_4^+) and sulfate (SO_4^{2-}) ions in water.

Biodegradation is not applicable to inorganic compounds. Ammonium sulfate is not expected to bioaccumulate; it will dissociate to ions that are ubiquitous in the environment. Ammonium sulfate is not expected to absorb to soil or sediment because of its dissociation properties and high water solubility.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on salts of ammonium sulfate.

Table 1: Acute Aquatic Toxicity Studies on Ammonium Sulfate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LC_{50}	53	1	ECHA
Ceriodaphnia acanthina	48-hr EC_{50}	121.7	1	ECHA

The 30-d EC_{10} for ammonium sulfate to *Lepomis macrochirus* is 5.29 mg/L (ECHA) [Kl. score = 1].

The 10-wk EC_{10} for ammonium sulfate to *Hyalella azteca* in a reproduction test is 3.12 mg/L (ECHA) [Kl. score = 1].

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (53 mg/L) and *Daphnia* (122 mg/L). Results from chronic studies are also available for two trophic levels, with the lowest EC_{10} being 3.12 for invertebrates. On the basis that the data consists of short-term results from two trophic levels and long-term results from two trophic level, an assessment factor of 50 has been applied to the NOEC value of 3.12 mg/L for fish. The $PNEC_{water}$ is 0.06 mg/L.

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Ammonium sulfate dissociates completely in water; its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as ammonium sulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on its properties, no adsorption of ammonium sulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of ammonium sulfate is dominated by its water solubility. Sorption of ammonium sulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as ammonium sulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, ammonium sulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Ammonium sulfate is an organic salt that dissociates completely to ammonium and sulfate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both ammonium and sulfate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to ammonium sulfate or its dissociated ions.

Ammonium and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, ammonium sulfate is not expected to bioaccumulate.

The NOECs from a chronic toxicity studies on ammonium sulfate are >0.1 mg/L, and the acute $E(L)C_{50}$ values for fish and *Daphnia* are >1 mg/L. Thus, ammonium sulfate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium sulfate is not a PBT substance.

Environmental Assessment

Alpha-Amylase
[α-Amylase]
(CAS No. 9000-90-2)

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. α-Amylases are enzymes that catalyze the endo-hydrolysis of 1,4-α-D-glycosidic linkages in polysaccharide, such as starches, glycogen, and oligosaccharides containing three or more 1,4-α-linked glucose units. (HERA, 2005).

Biodegradation

In an OECD 301 E test, degradation was 95% after 7 days and 99% after 28 days (ECHA) [Kl. score = 1]. Thus, alpha-amylase is readily biodegradable.

Bioaccumulation

No bioconcentration studies have been conducted on alpha-amylase. Alpha-Amylases are not expected to bioaccumulate due to their high molecular weight (40,000 to 50,000 daltons [Yutani, 1973]) and their octanol-water partition coefficient (log K_{ow} is <-1.3, [ECHA]). Moreover, alpha-amylases are rapidly biotransformation in an organism to lower molecular-weight protein fragments by proteolytic enzymes (proteases), and eventually to the basic amino acids by peptidase enzymes.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on alpha-amylase.

Table 1: Acute Aquatic Toxicity Studies on alpha-Amylase

Test Species	Endpoint	Results (mg aep*/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LC_{50}	>100	1	ECHA
Daphnia magna	48-hr EC_{50}	212	1	ECHA
Desmodesmus subspicatus	72-hr EC_{50} NOEC	5.2 2.6	1	ECHA

*active enzyme protein.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg aep/L), *Daphnia* (212 mg aep/L), and algae (5.2 mg aep/L).

On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 5.2 mg/L for algae. The $PNEC_{water}$ is 0.05 mg/L.

PBT Assessment

Alpha-Amylase is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Alpha-Amylase has a high molecular weight (20 to 80 kD), hydrophilic properties (high water solubility, log K_{ow} <-1.3), and is readily biotransformed in organisms by proteases and peptidases. Thus, alpha-amylase does not meet the screening criteria for bioaccumulation.

There are no chronic toxicity studies on alpha-amylase. The acute $E(L)C_{50}$ values for alpha-amylase are >1 mg/L in fish, invertebrates, and algae. Thus, alpha-amylase does not meet the criteria for toxicity.

The overall conclusion is that alpha-amylase is not a PBT substances.

Environmental Assessment

Alcohols, C9-11, ethoxylated
(CAS No. 68439-46-3)

Alcohol ethoxylates (AE) are a class of non-ionic surfactants that have the basic structure $C_{x-y}AE_n$. The subscript (x-y) following the 'C' indicates the range of carbon chain units. The hydrocarbon chain can be either linear or branched. AEs also contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by the subscript (n) which indicates the average number of ethylene oxide units. In household products the average ethylene oxide chain length commonly ranges between 3 and 12 units.

Biodegradation

The alcohols, C9-11, ethoxylated are readily biodegradable. In an ISO 14593 test, degradation of $C_{9-11}AE_{2.5}$ was 72% in 28 days (ECHA) [Kl. score = 2]. In another ISO 14593 test, degradation of $C_{9-11}AE_3$ was essentially 100% (measured as CO_2 evolution) in 28 days (ECHA) [Kl. score = 2].

Bioaccumulation

The BCF-values for alcohol ethoxylates in fathead minnows have been reported to range from <5 to 387.5 (Toll et al., 2000). The uptake rates varied from 330 to 1660 (L x kg/d) and elimination rates varied from 3.3 to 59 per day (Toll et al., 2000). Toll et al. (2000) concluded that the high values of elimination rate constants suggested that the tested fathead minnow efficiently biotransformed alcohol ethoxylates, thereby preventing them from attaining high concentrations in fish.

Aquatic Toxicity

In developing a water quality guideline for alcohol ethoxylates (ANZECC, 2000), the toxicity data was normalized for a specific alkyl chain length or a specific number of ethoxylate (EO) groups. The NOECs listed below were normalized to an alkyl chain length of C13.3 and EO of 8.2.

Freshwater fish: 2 species, 720 to 1,500 μg/L.

Freshwater crustaceans: 2 species, 590 to 860 μg/L.

Freshwater rotifers: 1 species, *Brachionus calyciflorus,* 1,300 μg/L.

Freshwater algae, diatoms and blue-green algae: 6 species, 200 to 8,700 μg/L.

Freshwater mesocosms: Four NOEC data for multiple species tests were 80, 80, 320, and 330 μg/L, although replication was insufficient to meet OECD (1992) requirements. Normalized data were 380, 380, 320, and 1,520 μg/L.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: The ANZECC water quality guideline (2000) for freshwater is: **"A high reliability trigger value of 140 μg/L was derived for AE (normalized data) using the statistical distribution method with 95% protection."**

PBT Assessment

Alcohols C9-11, ethoxylated is readily biodegradable and thus does not meet the screening criteria for persistence.

The bioconcentration factors (BCF) in fish for alcohols, C9-11, ethoxylated has been reported to range from <5 to 387.5. Thus, alcohols, C9-11, ethoxylated does not meet the screening criteria for bioaccumulation.

The NOEC values for alcohols ethoxylates are <1 mg/L. Thus, alcohols, C9-11, ethoxylated meets the screening criteria for toxicity.

The overall conclusion is that alcohols, C9-11, ethoxylated is not a PBT substance.

Environmental Assessment

Castor Oil, Ethoxylated
(CAS No. 61791-12-6)

Biodegradation

Castor oil, ethoxylated is readily biodegradable, based on the results of a study involving biodegradation of aliphatic-based surfactants in reactors by activated sludge method. Castor oil, ethoxylated was one of the ingredients of the surfactants. There was 90% degradation, as indicated by TOC removal, after 5 days. The reactor approached ultimate BOD after about 20 days incubation. Based on comparison with the ThOD of the feed, 100% biodegradation was achieved under the BOD test conditions (ECHA) [Kl. score = 2].

Bioaccumulation

No bioconcentration studies have been conducted on castor oil, ethoxylated. Castor oil, ethoxylated is not expected to bioaccumulate based on the experimental log K_{ow} of 1.33 (ECHA) [Kl. score = 1].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies of castor oil, ethoxylated.

Table 1: Acute Aquatic Toxicity Studies on Castor Oil, Ethoxylated

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rerio	96-hr LC_{50}	>45	1	ECHA
Daphnia magna	48-hr EC_{50}	>100	4	ECHA
Desmodesmus subspicatus	72-hr EC_{50}	>93	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (45 mg/L), *Daphnia* (100 mg/L), and algae (93 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 45 mg/L for fish. The $PNEC_{water}$ is 0.45 mg/L.

PBT Assessment

Castor oil, ethoxylated is readily biodegradable and thus does not meet the screening criteria for persistence.

No bioconcentration studies are available for cinnamaldehyde. The measured log K_{ow} for castor oil, ethoxylated is 1.33; thus, castor oil, ethoxylated does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for castor oil, ethoxylated in fish, invertebrates, and algae are >1 mg/L. Thus, castor oil, ethoxylated does not meet the screening criteria for toxicity.

The overall conclusion is that castor oil, ethoxylated is not a PBT substance.

Environmental Assessment

N-benzyl-alkylpyridium chloride
(CAS No. 68909-18-2)

N-benzyl-alkylpyridium chloride is a UVCB substance.

Biodegradation

No data are available.

Bioaccumulation

No bioconcentration studies have been conducted on N-benzyl alkylpyridium chloride. N-benzyl alkylpyridium chloride is not expected to bioaccumulate based on the experimental log K_{ow} of 3 (ECHA) [Kl. score = 1].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on salts of N-benzyl-alkylpyridium chloride.

Table 1: Acute Aquatic Toxicity Studies on N-benzylalkylpyridium chloride

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Daphnia magna	48-hr EC_{50}	3.1	1	ECHA
Pseudokirchneriella subcapitata	72-hr EC_{50} NOEC	0.47 0.02	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for *Daphnia* (3.1 mg/L), and algae (0.47 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 0.47 mg/L for algae. The $PNEC_{water}$ is 0.005 mg/L.

PBT Assessment

No data are available on the persistence of N-benzyl alkylpyridium chloride.

No bioconcentration studies are available for N-benzyl alkylpyridium chloride. The measured log K_{ow} for N-benzyl alkylpyridium chloride is 3; thus, N-benzyl alkylpyridium chloride does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for N-benzyl alkylpyridium chloride in algae is <1 mg/L. Thus, N-benzyl alkylpyridium chloride meets the screening criteria for toxicity.

The overall conclusion is that N-benzyl alkylpyridium chloride is not a PBT substance.

Environmental Assessment

Cinnamaldehyde
(CAS No. 104-55-2)

Biodegradation

In an OECD 301B test, degradation of cinnamaldehyde was 89% after 7 days, 94% after 14 days, and 100% after 28 days, indicating ready biodegradation (ECHA) [Kl. score = 2]. In an OECD 301D test, biodegradation was 24.98% after 5 days. The BOD_5 value was 0.635 mg O_2/mg (ECHA) [Kl. score = 1].

Bioaccumulation

No bioconcentration studies have been conducted on cinnamaldehyde. Cinnamaldehyde is not expected to bioaccumulate based on the experimental log K_{ow} of 2.107 (ECHA) [Kl. score = 1].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on cinnamaldehyde.

Table 1: Acute Aquatic Toxicity Studies on Cinnamaldehyde.

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Brachydanio rerio	96-hr LC_{50}	4.15	1	ECHA
Poecilia reticulata	96-hr LC_{50}	>3.5	1	ECHA
Daphnia magna	48-hr EC_{50}	3.21	1	ECHA
Desmodesmus subspicatus	72-hr EC_{50}	31.6	1	ECHA
Chlorella vulgaris	72-hr EC_{50}	16.09	1	ECHA

In a OECD 210 chronic fish toxicity study, the 28-day LOEC to *Oryzias latipes* was 66.08 mg/L (ECHA) [Kl. score = 2].

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (4.15 mg/L), *Daphnia* (3.21 mg/L), and algae (16.09 mg/L). Results from

a chronic fish study are available, with a LOEC of 66.08 mg/L. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported E(L)C_{50} value of 4.15 mg/L for fish. The $PNEC_{water}$ is 0.04 mg/L.

PBT Assessment

Cinnamaldehyde is readily biodegradable and thus does not meet the screening criteria for persistence.

No bioconcentration studies are available for cinnamaldehyde. The measured log K_{ow} for cinnamaldehyde is 2.107; thus, cinnamaldehyde does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for cinnamaldehyde in algae is <1 mg/L. Thus, cinnamaldehyde meets the screening criteria for toxicity.

The overall conclusion is that cinnamaldehyde is not a PBT substance.

ECHA. ECHA REACH database: http://echa.europa.eu/information-on-chemicals/registered-substances.

Environmental Assessment

Diethylene Glycol
(CAS No. 111-46-6)

Biodegradation

Diethylene glycol is readily biodegradable. In an OECD 301B test, there was 70-80% and 90-100% degradation after 28 days, as determined by CO_2 evolution and DOC removal respectively (ECHA) [Kl. score = 2]. In an OECD 301A test, there was 90-100% degradation after 28 days, although the 10-day window was missed (ECHA) [Kl. score = 1]. In a modified MITI I test (OECD 301C), there was up to 92% degradation after 28 days (ECHA) [Kl. score = 2].

Bioaccumulation

Diethylene glycol has low potential to bioaccumulate. In a three-day bioaccumulation fish study with *Leuciscus idus melanotus*, the BCF was determined to be 100 (Freitag *et al.*, 1985) [Kl. score = 2]. The calculated log K_{ow} for diethylene glycol is -1.98 (Verschueren, 1993).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on diethylene glycol.

Table 1: Acute Aquatic Toxicity Studies on Diethylene Glycol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-h LC_{50}	75,200	2	ECHA
Oncorhynchus mykiss	96-h LC_{50}	66,000	2	ECHA
Daphnia magna	24-h EC_{50}	>10,000	2	ECHA
Daphnia magna	48-h EC_{50}	65,980	2	ECHA
Daphnia magna	48-h EC_{50}	62,630	2	ECHA
Scenedesmus quadricauda	8-d TGK	2,700	2	ECHA

Terrestrial Toxicity

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (66,000 mg/L), and *Daphnia* (>10,000 mg/L). Results from a chronic algae study is available on diethylene glycol (2,700 mg/L). On the basis that the data consists of short-term results from two trophic levels and a long-term result from one trophic level, an assessment factor of 100 has been applied to the lowest reported value, which is the chronic value for algae. The $PNEC_{aquatic}$ is 27 mg/L.

PBT Assessment

Diethylene glycol has been shown to be readily biodegradable; thus, it does not meet the screening criteria for persistence.

The calculated log K_{ow} is -1.98, and the experimental BCF is 100. Thus, diethylene glycol does not meet the screening criteria for bioaccumulation.

The lowest chronic toxicity value for diethylene glycol is >0.1 mg/L. Thus, diethylene glycol does not meet the criteria for toxicity.

The overall conclusion is that diethylene glycol is not a PBT substance.

Environmental Assessment

Distillates, Petroleum, Hydrotreated Light
(CAS No. 64742-47-8)

Distillates, petroleum, hydrotreated light (CAS No. 64742-47-8) is defined as follows:

"A complex combination of hydrocarbons obtained by treating a petroleum fraction with hydrogen in the presence of a catalyst. It consists of hydrocarbons having carbon numbers predominantly in the range of C9 through C16 and boiling in the range of approximately 150ºC to 290ºC. (302ºF to 554ºF)."

Biodegradation

Distillates, petroleum, hydrotreated light is inherently biodegradable. In an OECD 301F test, kerosene (CAS No. 64742-47-8) was degraded 58.6% after 28 days (ECHA) [Kl. score = 1]. In an OECD 301F test, a solvent, naphtha (petroleum), heavy aromatic (CAS No. 64742-94-5) was degraded 48% after 10 days and 61% after 28 days (ECHA) [Kl. score = 1].

Bioaccumulation

Distillates, petroleum, hydrotreated light is a UVCB substance. Standard tests for this endpoint are intended for single substances and are not appropriate for this complex substance. This endpoint can be calculated for representative hydrocarbon structures using the BCFWIN v2.16 model within EPISUITE as input to the hydrocarbon block method incorporated into the PETRORISK model. The predicted BCFs for hydrocarbons are generally overly conservative since biotransformation is not quantitatively taken into account. Therefore, indirect exposure and resulting risk estimates predicted by PETRORISK are likely to be overestimated (ECHA). An evaluation of representative hydrocarbon structures indicates that some structures meet the Bioaccumulative criterion.

Aquatic Toxicity

The acute toxicity of petroleum streams similar to distillates, petroleum, hydrotreated light (CAS No. 64742-47-8) are shown in Table 1.

Table 1: Acute Toxicity of Petroleum Streams Similar to Distillates, Petroleum, Hydrotreated Light (CAS No. 64742-47-8) [ECHA]

Test Substance	Test Species	Endpoint	Results (mg/L) [WAF]	Kl. score
solvent, naphtha (petroleum), heavy aromatic kerosene (CAS No. 64742-94-5)	*Oncorhynchus mykiss*	96-h LL_{50}	2 to 5	1
kerosene (petroleum), hydrodesulferized (CAS No. 64742-81-0)	*Oncorhynchus mykiss*	96-h LL_{50}	20	1
kerosene, petroleum, sweetened (CAS No. 91770-14-9)	*Oncorhynchus mykiss*	96-h LL_{50}	18	1

Test Substance	Test Species	Endpoint	Results (mg/L) [WAF]	Kl. score
solvent, naphtha (petroleum), heavy aromatic kerosene (CAS No. 64742-94-5)	*Daphnia magna*	48-h EL_{50}	3 to 10	1
kerosene (petroleum), hydrodesulferized (CAS No. 64742-81-0)	*Daphnia magna*	48-h EL_{50}	1.4	1
kerosene, petroleum, sweetened (CAS No. 91770-14-9)	*Daphnia magna*	48-h EL_{50}	21	1
solvent, naphtha (petroleum), heavy aromatic kerosene (CAS No. 64742-94-5)	*Raphidocelis subcaptata*	72-h EL_{50} NOEL	1 to 3 1	1
kerosene (petroleum), hydrodesulferized (CAS No. 64742-81-0)	*Selenastrum capricornutum*	96-h EL_{50} NOEL	6.2 0.4	1
kerosene, petroleum, sweetened (CAS No. 91770-14-9)	*Selenastrum capricornutum*	96-h EL_{50} NOEL	4.3 0.2	1

The 21-day NOEC of hydrodesulfurized kerosene to *Daphnia magna* was 0.48 mg/L [WAF] (ECHA) [Kl. score = 1].

Terrestrial Toxicity

No studies are available.

Determination of PNECs

$PNEC_{water}$: Substance is a hydrocarbon with a complex, unknown or variable composition. Conventional methods of deriving PNECs are not appropriate.

PBT Assessment

Distillates, petroleum, hydrotreated light (CAS No. 64742-47-8) is inherently biodegradable. Thus, it meets the criteria for persistence.

The ECHA database for distillates, petroleum hydrotreated light (CAS No. 64742-47-8) states that some structures meet the criterion for bioaccumulation.

The ECHA database for distillates, petroleum hydrotreated light (CAS No. 64742-47-8) states that structures do not meet the criterion for toxicity.

Toxicity

The overall conclusion is that distillates, petroleum, hydrotreated light (CAS No. 64742-47-8) is not a PBT substance.

Reference

ECHA. ECHA REACH database: http://echa.europa.eu/information-on-chemicals/registered-substances.

Environmental Assessment

Ethoxylated C11 alcohol
(CAS No. 34398-01-1)

Alcohol ethoxylates (AE) are a class of non-ionic surfactants that have the basic structure $C_{x-y}AE_n$. The subscript (x-y) following the 'C' indicates the range of carbon chain units. The hydrocarbon chain can be either linear or branched. AEs also contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by the subscript (n) which indicates the average number of ethylene oxide units. In household products the average ethylene oxide chain length commonly ranges between 3 and 12 units.

Biodegradation

The alcohols, C9-11, ethoxylated are readily biodegradable. In an ISO 14593 test, degradation of $C_{9-11}AE_{2.5}$ was 72% in 28 days (ECHA) [Kl. score = 2]. In another ISO 14593 test, degradation of $C_{9-11}AE_3$ was essentially 100% (measured as CO_2 evolution) in 28 days (ECHA) [Kl. score = 2].

Bioaccumulation

The BCF-values for alcohol ethoxylates in fathead minnows have been reported to range from <5 to 387.5 (Toll et al., 2000). The uptake rates varied from 330 to 1660 (L x kg/d) and elimination rates varied from 3.3 to 59 per day (Toll et al., 2000). Toll et al. (2000) concluded that the high values of elimination rate constants suggested that the tested fathead minnow efficiently biotransformed alcohol ethoxylates, thereby preventing them from attaining high concentrations in fish.

Aquatic Toxicity

In developing a water quality guideline for alcohol ethoxylates (ANZECC, 2000), the toxicity data was normalized for a specific alkyl chain length or a specific number of ethoxylate (EO) groups. The NOECs listed below were normalized to an alkyl chain length of C13.3 and EO of 8.2.

Freshwater fish: 2 species, 720 to 1,500 μg/L.

Freshwater crustaceans: 2 species, 590 to 860 μg/L.

Freshwater rotifers: 1 species, *Brachionus calyciflorus,* 1,300 μg/L

Freshwater algae, diatoms and blue-green algae: 6 species, 200 to 8,700 μg/L.

Freshwater mesocosms: 4 NOEC data for multiple species tests were 80, 80, 320, and 330 μg/L, although replication was insufficient to meet OECD (1992) requirements. Normalized data were 380, 380, 320, and 1,520 μg/L.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: The ANZECC water quality guideline (2000) for freshwater is: **"A high reliability trigger value of 140 μg/L was derived for AE (normalized data) using the statistical distribution method with 95% protection."**

PBT Assessment

Ethoxylated C11 alcohol is readily biodegradable and thus does not meet the screening criteria for persistence.

The bioconcentration factors (BCF) in fish for ethoxylated C11 alcohol has been reported to range from <5 to 387.5. Thus, ethoxylated C11 alcohol does not meet the screening criteria for bioaccumulation.

The NOEC values for alcohols ethoxylates are <1 mg/L. Thus, ethoxylated C11 alcohol meets the screening criteria for toxicity.

The overall conclusion is that ethoxylated C11 alcohol is not a PBT substance.

Environmental Assessment

Polyoxyethylene-polyoxypropylene Block Copolymer
(CAS No. 9003-11-6)

The generic CAS RN 9003-11-6 refers to polymers that are synthetic block copolymers of ethylene oxide and propylene oxide. There are over 50 various amphiphilic nonionic block polymers of hydrophobic propylene oxide (PO) and hydrophilic ethylene oxide (EO) (CIR, 2008). These copolymers consist of a central polyoxypropylene molecule, flanked on both sides by two hydrophilic polyoxyethylene chains. These copolymers are also known as Poloxamers. The average molecular weights of several Poloxamer products are as follows: 2,090-2360 for Poloxamer 124; 7,680-9,510 for Poloxamer 188; and 9,840-14,600 for Poloxamer 407 (CIR, 2008).

Environmental Fate

No studies are available.

The following information is from the Dow Chemical Company's Product Safety Assessment document (Dow, 2014) on their EO/PO copolymer products with CASRN 9003-11-6 and 53637-25-5:

> Polyglycol EP Series Polymers are non-volatile (do not evaporate) and vary in water solubility. If released to water or soil, they would tend to remain in and be transported with the surface or ground water to which they are emitted, and will be adsorbed to soil and sediment particles. Polyglycol EP Series Polymers are unlikely to persist in the environment, as all products are known or expected to be either readily biodegradable (>65% biodegraded in 28 days per OECD 301F test) or inherently biodegradable according to Organisation for Economic and Co-operation and Development (OECD) test guidelines. As such, these products will be efficiently removed during treatment in biological wastewater-treatment facilities.

These products are not expected to accumulate in the food chain (low bioconcentration potential).

Aquatic Toxicity

No studies are available.

The following information is from the Dow Chemical Company's Product Safety Assessment document on their EO/PO copolymer products with CASRN 9003-11-6 and 53637-25-5 (Dow, 2014):

> [EO/PO copolymers] are practically non-toxic to aquatic organisms (LC_{50}/EC_{50} >100 mg/L for the most sensitive species tested) on an acute basis.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: No experimental studies were found. However, Dow Chemical's Product Safety Assessment document on their EO/PO copolymers indicates that acute toxicity testing has been conducted on these copolymers and the $E(L)C_{50}$ value for the most sensitive species is >100 mg/L. On the basis of the short-term results, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L. The $PNEC_{water}$ is 0.1 mg/L.

$PNEC_{sediment}$: A $PNEC_{sed}$ was not calculated for EO/PO copolymer. There are no experimental toxicity data on sediment organisms and a K_{oc} value EO/PO copolymer is unavailable for calculating the $PNEC_{sed}$ using the equilibrium partition method. A K_{oc} value for the EO/PO polymers has not been determined experimentally, and QSAR models are invalid for high molecular weight polymers, such as EO/PO polymers.

$PNEC_{soil}$: A $PNEC_{soil}$ was not calculated for EO/PO copolymer. There are no experimental toxicity data on soil organisms and a K_{oc} value EO/PO copolymer is unavailable for calculating the $PNEC_{soil}$ using the equilibrium partition method. A K_{oc} value for the EO/PO polymers has not been determined experimentally, and QSAR models are invalid for high molecular weight polymers, such as EO/PO polymers.

PBT Assessment

EO/PO copolymers are either readily biodegradable or inherently biodegradable; thus, they do not meet the screening criteria for persistence.

EO/PO copolymers are expected to have high molecular weights and are not expected to be bioavailable. Thus, these copolymers do not meet the criteria for bioaccumulation.

There are no chronic aquatic toxicity studies on the EO/PO copolymers. However, the acute $E(L)C_{50}$ on these copolymers are >1 mg/L in aquatic organisms based on information from Dow Chemical's Product Safety Assessment (Dow, 2014). EO/PO copolymers also have a high molecular weight and are not expected to be bioavailable. Thus, they do not meet the screening criteria for toxicity.

The overall conclusion is that EO/PO copolymers are not PBT substances.

Environmental Assessment

Ethylene Glycol
(CAS No. 107-21-1)

Biodegradation

Ethylene glycol was readily biodegradable in an OECD 301A test. After 10 days, degradation was 90-100% (ECHA) [Kl. score = 1]. There was 97% degradation after 20 days in a BOD test; and 96% degradation after 28 days in an OECD 301D test (Waggy et al., 1994; OECD, 2004a,b) [Kl. score = 2].

The aerobic degradation of ethylene glycol was measured from grab river water samples at 4, 8, and 20°C. At 20°C, ethylene glycol was completely degraded in three days in all river waters tested; at 8°C, degradation was complete within 14 days. Degradation at 4°C was substantially slower, with degradation of <20% after 14 days in river samples with limited suspended matter and a starting concentration of 10 mg/L (Evans and David, 1974).

Adsorption/Desorption

No experimental data are available for ethylene glycol. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} values from the molecular connectivity index (MCI) and from the log K_{ow} are 1 and 0.2239 L/kg, respectively.

Bioaccumulation

The calculated log K_{ow} for ethylene glycol is -1.36 (ECHA). The BCF for ethylene glycol in golden ide (*Leuciscus idus melanotus*) after three days of exposure was determined to be 10 (Freitag *et al.*, 1985).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies conducted on ethylene glycol.

Table 1: Acute Aquatic Toxicity Studies on Ethylene Glycol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-h LC_{50}	>72,860	1	Pillard (1995)
Oncorhynchus mykiss	96-h LC_{50}	22,810 24,591	2	OECD (2004a,b)
Daphnia magna	48-h EC_{50}	>100	1	ECHA
Daphnia magna	48-h EC_{50}	46,300	2	Gersich et al. (1986)

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference

Pimephales promelas	7-day NOEC	15,380	2	Pillard (1995)
Ceriodaphnia dubia	7-day NOEC (reproduction)	8,590	2	Pillard (1995)

Terrestrial Toxicity

No guideline studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (22,810 mg/L), *Daphnia* (>100 mg/L), and algae (10,940 mg/L). NOEC values from long-term studies are available for fish (15,380 mg/L), invertebrates (8,590 mg/L), and algae (10,000 mg/L). On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported $E(L)C_{50}$ value of 100 mg/L for fish. The $E(L)C_{50}$ value is used because the value for fish is lower than the NOEC values for all three trophic levels. The $PNEC_{aquatic}$ is 10 mg/L.

$PNEC_{sediment}$: There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 6.4 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.82/1280) \times 1000 \times 10$
$= 6.4$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [(0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [(0.2 \times 0.04/1000 \times 2400]$
$= 0.82$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 1 \times 0.04$
$= 0.04$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for ethylene glycol calculated from EPISUITE™ using the MCI is 1 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

$PNEC_{soil}$: There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is <u>0.13 mg/kg soil dry weight</u>.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.02/1500) \times 1000 \times 10$
$= 0.13$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 1 \times 0.02$
$= 0.02$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for ethylene glycol calculated from EPISUITE™ using the MCI is 1 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

PBT Assessment

Ethylene glycol is readily biodegradable and thus does not meet the screening criteria for persistence.

The measured BCF in fish is 10. Thus, ethylene glycol does not meet the criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity studies on ethylene glycol are >0.1 mg/L. The acute E(L)C_{50} values from the acute aquatic toxicity studies on ethylene glycol are >1 mg/L. Thus, ethylene glycol does not meet the criteria for toxicity.

The overall conclusion is that ethylene glycol is not a PBT substance.

Environmental Assessment

Formic acid
(CAS No. 64-18-6)

Biodegradation

In an OECD 301C test, biodegradation was 100% after 14 days, indicating that formic acid is readily biodegradable (ECHA) [Kl. score = 2].

Bioaccumulation

No bioconcentration studies have been conducted on sodium erythrobate. Sodium erythrobate is not expected to bioaccumulate based on the experimental log K_{ow} of -2.1 at pH 7 (ECHA).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on salts of formic acid.

Table 1: Acute Aquatic Toxicity Studies on Salts of Formic Acid

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Brachydanio rerio	96-hr LC_{50}	130*	1	ECHA
Daphnia magna	48-hr EC_{50}	365*	1	ECHA
Pseudokirchneriella subcapitata	72-hr EC_{50}	1,240**	1	ECHA

*Potassium formate
**Ammonium formate

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (130 mg/L), *Daphnia* (365 mg/L), and algae (1,240 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 100 mg/L for fish. The $PNEC_{aquatic}$ is 1.0 mg/L.

PBT Assessment

Formic acid is readily biodegradable; thus, it does not meet the screening criteria for persistence.

No bioconcentration studies are available for formic acid. The measured log K_{ow} for formic acid is -2.1 at pH 7; thus, formic acid does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for formic acid in fish, invertebrates, and algae are >1 mg/L. Thus, formic acid does not meet the screening criteria for toxicity.

The overall conclusion is that formic acid is not a PBT substance.

Environmental Assessment

Glutaraldehyde
(CAS No. 111-30-8)

Biodegradation

Glutaraldehyde was considered readily biodegradable in an OECD 301A (DOC die away test). Degradation was 90-100% in 28 days (ECHA). [Kl. score = 1]

In a simulation test involving aerobic sewage treatment [activated sludge units] (OECD TG 303A), glutaraldehyde degraded 97% after 73 days based on DOC removal (ECHA). [Kl. score = 1]

In an aerobic aquatic metabolism test, [^{14}C]-glutaraldehyde had a half-life of 10.6 hours in the water/sediment system. A minor transformation product was glutaric acid: the maximum yield was 18.9 to 21.5% at 12 hours, which then declined rapidly to 10.1 to 11% by 24 hours; and was not observed at the end of the study period in the aqueous phase (ECHA). [Kl. score = 1]

In an anaerobic aquatic metabolism test, [^{14}C]-glutaraldehyde was rapidly metabolised with the first-order half-life being 7.7 hours. Glutaraldehyde was transformed to 5-hydroxypentanal (ca 37% of applied radioactivity) on day 1; after that, it declined to <10%; it was not detected at all after 30 days. The second stable transformation product was 1,5-pentanediol (35% of radioactivity on Day 1), which accounted for 70% of the radioactivity at the end of the test. A minor transformation product was a compound formed via Aldol condensation, cyclisation and dehydration. This compound accounted for about 10-20% of total radioactivity from day 1 onwards (ECHA). [Kl. score = 1]

In an aerobic soil metabolism test, the half-life of the degradation of [^{14}C]-glutaraldehyde was calculated to be 1.7 days, indicating rapid degradation in soil by microbial biotransformation. Degradation products were measured but not identified. (ECHA). [Kl. score = 1]

Adsorption/Desorption

The organic carbon/water partition coefficients (K_{oc}) values were determined for sediment and four types of soil. The values are as follows: 120 for sediment; 210 for sandy loam; 500 for silty clay loam; 340 for silt loam; and 460 for loamy sand (ECHA; Leung, 2001). [Kl. score = 1]

Bioaccumulation

Glutaraldehyde is not expected to bioaccumulate. The measured log Pow at pH 5, 7 and 9 are -0.41, -0.36 and -0.80, respectively (ECHA).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies conducted on glutaraldehyde.

Table 1: Acute Aquatic Toxicity Studies on Glutaraldehyde

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Bluegill sunfish	96-hr LC_{50}	13	2	ECHA
Oncorhynchus mykiss	96-hr LC_{50}	10	2	ECHA
Daphnia magna	48-hr LC_{50}	14.87	2	ECHA
Daphnia magna	48-hr LC_{50}	14	2	ECHA
Scenedesmus subspicatus	72-hr EC_{50}	0.375 (biomass) 0.6 (growth rate) 0.025 (NOEC)	1	ECHA
Scenedesmus subspicatus	72-hr EC_{50}	0.92 (growth rate) 0.61(biomass) 0.33 (NOEC)	2	ECHA; Leung, 2001
Scenedesmus subspicatus	72-hr EC_{50}	0.61 (growth rate)	2	ECHA

The chronic aquatic toxicity studies conducted on glutaraldehyde are listed in Table 2.

Table 2: Chronic Aquatic Toxicity Studies on Glutaraldehyde

Test Species	Endpoint	Results (mg/L)	Kl. score	Reference
Oncorhynchus mykiss	97-day (OECD 210)	LOEC = 5 NOEC = 1.6	1	ECHA
Daphnia magna	21-day	NOEC = 5	1	ECHA

Terrestrial Toxicity

Table 3 lists the results of toxicity studies conducted on glutaraldehyde with earthworms, soil microorganisms, and birds.

Table 3: Terrestrial Toxicity Studies on Glutaraldehyde

Test Species (method)	Endpoint	Results	Kl. score	Reference
Earthworm *Eisenia fetida* (OECD 207)	14-d LC_{50}	>500 mg/kg soil dw	1	ECHA
Soil microorganisms* (OECD 216)	28-d EC_{50} 28-d EC_{10}	360 mg/kg soil dw 11.5 mg/kg soil dw	1	ECHA
Soil microorganisms* (OECD 217)	28-d EC_{50} 28-d EC_{10}	>593 mg/kg soil dw 1.5 mg/kg soil dw	1	ECHA
Mallard ducks	Single-dose (oral gavage) LC_{50}	206 mg/kg	2	ECHA
Mallard ducks	5-d (dietary) NOEC	>2,500 ppm	1	ECHA

*organic carbon content of soil = 1.34% dry weight

Glutaraldehyde has also been evaluated in a terrestrial plants test: seedling emergence and seedling growth test (OECD TG 208). The test material contained 48.9% glutaraldehyde. The results are as follows:

Avena sativa (oats): 19-day EC_{50} value is >1,000 mg/kg soil dry weight based on emergence rate, dry weight and shoot length. The NOECs for *Avena sativa* (oats) were $\geq$1,000 mg/kg dry weight on all three parameters tested.

Brassica napus (rapeseed): 19-day EC_{50} is >1,000 mg/kg soil dry weight based on emergence rate and shoot length and 994 mg/kg soil dry weight based on dry weight. The NOECs were $\geq$1,000, 500, and 250 mg/kg soil dry weight for emergence rate, dry matter, and shoot length, respectively.

Vicia sativa (vetch): 19-day EC_{50} is >1,000 mg/kg soil dry weight based on emergence rate and shoot length, and 901 mg/kg soil dry weight based on dry weight. The NOECs were $\geq$1,000, 125, and 125 mg/kg soil dry weight for emergence rate, dry matter, and shoot length, respectively (ECHA). [Kl. score = 1]

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (10 mg/L), *Daphnia* (14 mg/L), and algae (0.375 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 0.025 mg/L for algae. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 0.025 mg/L for algae. The $PNEC_{water}$ is 0.0025 mg/L.

$PNEC_{sediment}$: There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.006 mg/kg wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (3.1/1280) \times 1000 \times 0.0025$
$= 0.006$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [(0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [(0.2 \times 4.8)/1000 \times 2400]$
$= 3.1$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{0c} \times f_{oc}$
$= 120 \times 0.04$
$= 4.8$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for glutaraldehyde in sediment is 120.
F_{oc} = fraction of organic carbon suspended sediment = 0.04 [default].

$PNEC_{soil}$: Experimental results are available for three trophic level. An acute LC_{50} value is available for earthworms (>500 mg/kg). Results from long-term studies are available for two trophic levels, with the lowest NOEC or EC_{10} being 1.5 mg/kg soil dry weight for soil organisms.

The EC_{10} value is corrected for bioavailability of glutaraldehyde in soil by normalising the organic carbon content in the soil using the following equation:

$EC_{10(std)} = EC_{10(exp)} \times Fom_{soil(std)}/Fom_{soil(exp)}$

Where:
$Fom_{soil(std)}$ = 1% (www.scew.gov.au/node/941)
$Fom_{soil(exp)}$ = 1.34% (see Table 3)

$EC_{10(std)}$ = 1.5 mg/kg x 1/1.34 = 1.12 mg/kg

On the basis that the data consists of one short-term from one trophic level and two long-term results from two additional levels, an assessment factor of 50 has been applied to the lowest

reported long-term EC_{10} of 1.12 mg/kg soil dry weight [corrected for organic carbon content] for soil organisms. The $PNEC_{soil}$ is 0.02 mg/kg soil dry weight.

PBT Assessment

Glutaraldehyde is readily biodegradable and therefore does not meet the screening criteria for persistence.

The log P_{ow} for glutaraldehyde at different pH values ranges from -0.36 to -0.80. Therefore, glutaraldehyde does not meet the screening criteria for bioaccumulation.

Chronic NOECs for fish, daphnia and algae are available for glutaraldehyde, and the NOEC values are >0.01 mg/L. Therefore, glutaraldehyde does not meet the screening criteria for toxic.

The overall conclusion is that glutaraldehyde is not a PBT substance.

Environmental Assessment

Glycerol
(CAS No. 56-81-5)

Biodegradation

Glycerolwas readily biodegradable in an OECD 301D test. Degradation was 57% after 5 days, 84% after 15 days, and 92% after 30 days (OECD, 2002) [Kl. score = 2].

Adsorption/Desorption

No experimental data are available for glycerol. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} value from log K_{ow} is 0.1345 L/kg. The estimated K_{oc} value from the molecular connectivity index (MCI) is 1 L/kg.

Bioaccumulation

No bioconcentration studies have been conducted on glycerol. Glycerol is not expected to bioaccumulate based on the experimental log K_{ow} of -1.75 (ECHA).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on glycerol.

Table 1: Acute Aquatic Toxicity Studies on Glycerol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-h LC_{50}	54,000	2	ECHA
Sheepshead minnow	96-h LC_{50}	>11,000	2	ECHA
Daphna magna	24-h EC_{50}	>10,000	2	ECHA
Scenedesmus quadricauda	8-d EC_0	>10,000	2	Bringmann and Kuehn, 1980; OECD, 2002

No chronic toxicity studies are available.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels, although the data on algae cannot be used for determining a PNEC value. Acute $E(L)C_{50}$ values are available for fish (>11,000 mg/L) and *Daphnia* (>10,000 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 10,000 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 10 mg/L.

$PNEC_{sediment}$: There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 6.4 mg/kg sediment wet weight.

The calculations are as follows:

$$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$$
$$= (0.82/1280) \times 1000 \times 10$$
$$= 6.4$$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{solid}]$$
$$= 0.8 + [0.2 \times 0.04/1000 \times 2400]$$
$$= 0.82$$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$$Kp_{sed} = K_{oc} \times f_{oc}$$
$$= 1 \times 0.04$$
$$= 0.04$$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for glycerol calculated from EPISUITE™ using MCI is 1 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

$PNEC_{soil}$: There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.13 mg/kg soil dry weight.

The calculations are as follows:

$$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$$

= (0.02/1500) x 1000 x 10
= 0.13

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
= 1 x 0.02
= 0.02

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for glycerol calculated from EPISUITE™ using MCI is 1 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

PBT Assessment

Glycerol is readily biodegradable and thus does not meet the screening criteria for persistence.

No bioconcentration studies are available for glycerol. The measured log K_{ow} for glycerol is -1.75; thus, glycerine does not meet the screening criteria for bioaccumulation.

The acute $E(L)C_{50}$ values for glycerol in fish, invertebrates, and algae are >1 mg/L. Thus, glycerol does not meet the screening criteria for toxicity.

The overall conclusion is that glycerol is not a PBT substance.

Environmental Assessment

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is a resinous material derived from milled endosperm from guar beans of the legume *Cyamopsis tetragonolobus*. Structurally, it is a galactomannan (high molecular weight carbohydrate polymer) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The molecular weight of guar gum is 200,000 to 300,000 daltons (Glicksman, 1969).

Environmental Fate

Guar gum is a carbohydrate polymer consisting of D-mannose and D-galactose sugars from the guar plant or cluster bean. It is expected to be readily biodegradable and not bioaccumulate.

Aquatic Toxicity

The 96-hour LC_{50} for *Oncorhynchus mykiss* is 218 mg/L (Biesinger *et al.*, 1976). [Kl. score = 2]

The 48-hour and 96-hour LC_{50} values for *Daphnia magna* are 42 mg/L and <6.2 mg/L, respectively (Biesinger *et al.*, 1976). [Kl. score = 2]

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for two trophic levels. The acute $E(L)C_{50}$ values are available for fish (218 mg/L) and *Daphnia* (<6.2 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 6.2 mg/L for *Daphnia*. The $PNEC_{water}$ is 0.006 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The K_{ow} and K_{oc} of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The K_{ow} and K_{oc} of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Guar gum is a naturally occurring polysaccharide from the guar plant or cluster bean; it expected to be readily biodegradable. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons and is water-soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The 96-hour LC_{50} value for *Daphnia* is <6.2 mg/L. Thus, guar gum may potentially meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

Environmental Assessment

Hemicellulase
(CAS No. 9025-56-3)

Hemicellulases are a group of enzymes that break down hemicellulose, which are polysaccharides that are present in cell walls of all terrestrial plants. These polysaccharides have a β-(1→4)-linked backbone and are composed of pentoses (xylose, arabinoses), hexoses (mannose, glucose, galactose), and sugar acids. Unlike cellulose which are polysaccharides consisting of linear chains of several hundred to over ten thousand β-(1→4) linked D-glucoses, hemicelluloses are not chemically homogeneous. The best characterized hemicellulases are the 1,4- β -D-xylanases and, in particular, those derived from fungal sources presumably because their substrates, xylans, constitute the largest proportion of hemicelluloses in pasture plants.

No toxicity information could be located on hemicellulases; however, mammalian toxicity information was found on the cellulase enzymes (HERA, 2005). Cellulases cleave the ß-1,4-glycosidic bonds in cellulose, and are used in the pulp and paper industry, the textile industry, and in detergents to remove deposits and stains. The molecular weight of cellulase is 20,000 to 80,000 daltons.

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity. For the purposes of risk assessment, the structure of hemicellulases would be expected to be similar to that of cellulases, given that hemicellulases and cellulases are both enzyme families that hydrolyze polysaccharides, although differing in their substrates. Thus, the toxicity data on cellulases will be used as read-across to hemicellulases.

Biodegradation

A cellulase enzyme was readily biodegradable in an OECD 301F test. There was ~10% degradation after one day; ~60% after 5 days; and 129% after 28 days (ECHA). [Kl. score = 1]

Three different cellulase enzymes were considered readily biodegradable based on the results of OECD 301C and 301E tests (HERA, 2005) [Kl. scores = 1]. In an OECD 301E test, there was 84% DOC removal of the enzyme Carezyme after 28 days. In another OECD 301E test, there was 92% DOC removal of the enzyme Clazinase® after 28 days. In an OECD 301C test, BOD/COD was 78% after 28 days (HERA, 2005).

Bioaccumulation

No bioaccumulation studies have been conducted on cellulase enzymes. Cellulase enzymes are not expected to bioaccumulate due to their high molecular weight and their octanol-water partition coefficient (log K_{ow} is <1.3). Moreover, cellulases are rapidly biotransformed in an organism to lower molecular-weight protein fragments by proteolytic enzymes (proteases), and eventually to the basic amino acids by peptidase enzymes.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on cellulase enzyme.

Table 1: Acute Aquatic Toxicity Studies on Cellulase Enzyme

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-h LC_{50}	>100* >52.1**	1	ECHA
Brachydanio rerio	96-h LC_{50}	330*	4	HERA (2005)
Daphnia magna	48-h EC_{50}	>100* >52.1**	1	ECHA
Daphnia magna	48-h EC_{50}	>1,000**	4	HERA (2005)
Daphnia magna	48-h EC_{50}	1,000**	4	HERA (2005)
Pseudokirchneriella subcapitata	72-h EC_{50}	>100* >52.1**	1	ECHA
Scenedesmus subspicatus	72-h EC_{50}	>1,000**	4	HERA (2005)

*Total organic solids.
**Active enzyme protein.

No chronic studies are available.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>52.1 mg aep/L), *Daphnia* (>52.1 mg aep/L), and algae (>52.1 mg aep/L). No chronic toxicity studies are available. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 52.1 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.5 mg/L.

$PNEC_{sediment}$: There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.3 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.825/1280) \times 1000 \times 0.5$
$= 0.3$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{solid}]$
$= 0.8 + [0.2 \times 0.052/1000 \times 2400]$
$= 0.825$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 1.3 \times 0.04$
$= 0.052$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for cellulase enzymes is calculated to be <1.3 L/kg (HERA, 2005).
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

$PNEC_{soil}$: There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is <u>0.009 mg/kg soil dry weight</u>.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.026/1500) \times 1000 \times 0.5$
$= 0.009$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 1.3 \times 0.02$
$= 0.026$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for cellulase enzymes is calculated to be <1.3 L/kg (HERA, 2005).
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

PBT Assessment

Hemicellulase enzyme is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Hemicellulase enzyme has a high molecular weight (20 to 80 kD), hydrophilic properties (high water solubility, log K_{ow} <1.3), and is readily biotransformed in organisms by proteases and peptidases. Thus, hemicellulase enzyme does not meet the screening criteria for bioaccumulation.

There are no chronic toxicity studies on the cellulase enzyme. The acute E(L)C_{50} values for cellulase are >1 mg/L in fish, invertebrates, and algae. Thus, hemicellulase enzyme does not meet the criteria for toxicity.

The overall conclusion is that hemicellulase enzyme is not a PBT substance.

Environmental Assessment

1,6-Hexanediol
(CAS No. 629-11-8)

Biodegradation

1,6-Hexanediol is readily biodegradable. In an OECD 301 C test, degradation was 98% (DOC removal) and 95% (O_2 consumption) after 28 days (ECHA) [Kl. score = 2]. In an OECD 301 A test, degradation was >90% (DOC removal) after 7 days (ECHA) [Kl. score = 2].

Bioaccumulation

No bioconcentration studies have been conducted on 1,6-hexanediol. 1,6-Hexanediol is not expected to bioaccumulate based on the experimental log K_{ow} of 0 (ECHA) [Kl. score = 2].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on salts of 1,6-hexanediol.

Table 1: Acute Aquatic Toxicity Studies on 1,6-Hexanediol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Leuciscus idus	96-hr LC_{50}	4,640 – 10,000	2	ECHA
Daphnia magna	48-hr EC_{50}	>500	2	ECHA
Desmodesmus subspicatus	72-hr EC_{50}	5,940	2	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (4,640 – 10,000 mg/L), *Daphnia* (>500 mg/L), and algae (5,940 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 500 mg/L for *Daphnia*. The $PNEC_{water}$ is 5.0 mg/L.

PBT Assessment

1,6-Hexanediol is readily biodegradable and thus does not meet the screening criteria for persistence.

No bioconcentration studies are available for 1,6-hexanediol. The measured log K_{ow} for 1,6-hexanediol is 0; thus, 1,6-hexanediol does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for 1,6-hexanediol in fish, invertebrates, and algae are >1 mg/L. Thus, 1,6-hexanediol does not meet the screening criteria for toxicity.

The overall conclusion is that 1,6-hexanediol is not a PBT substance.

Environmental Assessment

Hydrochloric acid
(CAS No. 7647-01-0)

Hydrochloric acid can exist in a gaseous phase at room temperature and pressure. Hydrochloric acid is also very soluble in water and is a strong acid that dissociates completely in water to hydrogen (H^+) and chloride (Cl^-) ions.

Environmental Fate

Due to its high water solubility and low vapour pressure, hydrochloric acid will be found predominantly in the aquatic environment where it dissociates completely to hydrogen (H^+) and chloride (Cl^-) ions. Both ions are ubiquitous in the environment (UNEP, 1995).

The addition of hydrochloric acid to an aquatic ecosystem may decrease the pH depending on the buffer capacity of the receiving water. In general, the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

A release of hydrochloric acid into the aquatic environment from the use of HCl could potentially increase the chloride concentration and decrease the pH in the aquatic environment. Table 1 shows the amount of hydrochloric acid that would need to be added to bicarbonate solutions to obtain pH values of 6.0 and 4.0. The UNEP (1995) study reported that the 10th percentile, mean, and the 90th percentile of bicarbonate concentrations in 77 rivers in North America, South America, Asia, Africa, Europe, and Oceania were 20, 106, and 195 mg/L, respectively. The data show that the decrease in pH depends on the buffer capacity (bicarbonate concentration) of the receiving water. The calculated values in Table 2 were confirmed experimentally.

Table 1: Buffer capacity to maintain the pH based on bicarbonate concentration from UNEP monitoring data (de Groot and van Dijk, 2002; taken from OECD, 2002b)

Initial concentration of HCO_3^-	**Final pH**	**Concentration of HCl required to obtain the final pH value**
		Calculated [mg/L]
20 mg/LHCO_3^- (10th percentile 77 rivers)	6.0	8.28
	4.0	11.9
106 mg/L HCO_3^- (mean value of 77 rivers)	6.0	43.9
	4.0	63.2
195 mg/L HCO_3^- (90th percentile 77 rivers)	6.0	80.7
	4.0	116.3

H^+ and Cl^- ions will not adsorb on the particulate matter or surfaces and will not accumulate in living tissues (OECD, 2002a,b).

Aquatic Toxicity

The acute aquatic toxicity studies on hydrochloric acid are listed in Table 2.

Table 2: Acute Aquatic Toxicity Studies on Hydrochloric Acid

Test Species	Endpoint	Results	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LC_{50}	pH 4.12 (hard water) pH 3.98 (soft water)	2	ECHA; OECD 2002a,b
Lepomis macrochirus	96-hr LC_{50}	pH 3.25 – 3.5	2	ECHA; OECD 2002a,b
Daphnia magna	48-hr EC_{50}	pH 4.92	1	ECHA
Chlorella vulgaris	72-hr EC_{50} 72-hr NOEC	pH 4.7 [growth rate] pH 4.82 [biomass] pH 5 [yield/growth rate	1	ECHA

No chronic studies are available.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

PNEC values were not derived from hydrochloric acid because factors such as the buffer capacity, the natural pH, and the fluctuation of the pH are very specific for a certain ecosystem.

PBT Assessment

Hydrochloric acid is an inorganic salt that dissociates completely to hydrogen and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and chloride ions are also ubiquitous and are present in water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Hydrogen and chloride ions are essential to all living organisms, and their intracellular, and extracellular concentrations are actively regulated. Thus, hydrochloric acid is not expected to bioaccumulate.

No chronic toxicity data exist on hydrochloric acid; however, the acute $E(L)C_{50}$ values are >1 mg/L in fish, invertebrates and algae. Thus, hydrochloric acid does not meet the screening criteria for toxicity.

The overall conclusion is that hydrochloric acid is not a PBT substance.

Environmental Assessment

Isopropanol
(CAS No. 67-63-0)

Biodegradation

Aerobic biodegradation of isopropanol has been shown to occur rapidly under non-acclimated conditions, based on a result of 49% biodegradation from a 5-day BOD test (Bridie *et al.*, 1979). Additional biodegradation data developed using standardized test methods show that isopropanol is readily biodegradable in both freshwater and saltwater media (72 to 78% biodegradation in 20 days) (Price *et al.*, 1974).

Adsorption/Desorption

No experimental data are available for isopropanol. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} value from log K_{ow} is 3.478 L/kg. The estimated K_{oc} value from the molecular connectivity index (MCI) is 1.53 L/kg.

Bioaccumulation

Bioconcentration of isopropanol in aquatic organisms is not expected to occur based on a measured log K_{ow} of 0.05 (ECHA).

Aquatic Toxicity

The 96-hour LC_{50} in *Pimephales promelas* is 9,640 mg/L (Veith *et al.*, 1983) [Kl score = 2]. The 24-hour EC_{50} in *Daphnia magna* is >10,000 mg/L (Brinkmann and Kuehn, 1977) [Kl. score = 2]. The 7-day toxicity threshold value for a freshwater algae was determined to be 1,800 mg/L (Brinkmann and Kuehn, 1980) [Kl. score = 2].

The 16- and 21-day NOEC values for *Daphnia magna* were 141 and 30 mg/L, respectively (Hermens *et al.*, 1985; OECD, 1977a,b) [Kl. score = 4].

Terrestrial Toxicity

An EC_{50} value of 2,100 mg/L was determined from a lettuce seed germination test (Reynolds, 1977) [Kl. score = 2].

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (9,640 mg/L) and invertebrates (>10,000 mg/L). Results from chronic studies are available for invertebrates (16- and 21-day NOECs for *Daphnia* are 141 and 30 mg/L, respectively). On the basis that the data consists of a chronic study on one trophic level, an assessment factor of 100 has been applied to the lowest reported NOEC of 30 mg/L for *Daphnia*. The $PNEC_{water}$ is 0.3 mg/L.

$PNEC_{sediment}$: There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.2 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.87/1280) \times 1000 \times 0.3$
$= 0.2$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed})1000 \times BD_{solid}]$
$= 0.8 + [0.2 \times 0.14/1000 \times 2400]$
$= 0.87$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 3.478 \times 0.04$
$= 0.14$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for isopropanol calculated from EPISUITE™ using Log K_{ow} is 3.478.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

$PNEC_{soil}$: There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.014 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.07/1500) \times 1000 \times 0.3$
$= 0.014$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 3.478 \times 0.02$
$= 0.07$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for isopropanol calculated from EPISUITE™ using K_{ow} is 3.478.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

PBT Assessment

Isopropanol is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Based on a measured log K_{ow} of 0.05 and a calculated BCF of 1, isopropanol does not meet the screening criteria for bioaccumulation.

The chronic toxicity data on isopropanol show a NOEC of >0.1 mg/L. The acute $E(L)C_{50}$ values for isopropanol in fish, invertebrates, and algae are >1 mg/L. Thus, isopropanol does not meet the screening criteria for toxicity.

The overall conclusion is that isopropanol is not a PBT substance.

Environmental Assessment

Methanol
(CAS No. 67-56-1)

Biodegradation

Methanol is readily biodegradable. In a closed bottle test using seawater, there was 84% and 95% degradation after 10 and 20 days, respectively (Price et al., 1974; ECHA). [Kl. score = 2]

In a soil test using [^{14}C]-methanol, there was 53.4% degradation under aerobic conditions after 5 days, as measured by CO_2 evolution; and 46.3% degradation under anaerobic conditions after 5 days, as measured by CO_2 evolution (Scheunert et al., 1987; ECHA). [Kl. score = 2]

Adsorption/Desorption

The adsorption of methanol was investigated in three different soil types at 6°C (Lokke, 1984; ECHA). There was slight adsorption with the sandy soils tested (percentage organic matter of 0.09% and 0.1% in the samples) and with the clay soil (percentage organic matter was 0.22%). Methanol solutions of concentrations of 0.1, 1.0, 9, and 90 mg/L were used in one-hour exposure adsorption studies; the K_{oc} values were between 0.13 and 0.61 for all soil types and at all concentrations.

Bioaccumulation

The BCF of methanol in *Cyprinus carpio* was determined to be 1.0 (Gluth et al. 1985); in *Leuciscus idus*, the BCF was <10 (Hansch and Leo, 1985; Freitag et al. 1985).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies conducted on methanol.

Table 1: Acute Aquatic Toxicity Studies on Methanol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Bluegill	96-hr LC_{50}	15,400	1	Poirer et al. 1986
Salmo gairdneri	96-hr LC_{50}	20,100	1	Call et al., 1983

Daphnia magna	48-hr EC_{50}	>10,000	2	Kuehn et al., 1989

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Selenastrum capricornutum	96-hr EC_{50}	~22,000	2	Cho et al., 2008; ECHA
Chlorella pyrenoidosa	10-14 d EC_{50}	28,400	2	Stratton and Smith, 1988

No adequate chronic studies were identified.

Terrestrial Toxicity

The terrestrial toxicity studies on methanol are listed below in Table 2.

Table 2: Terrestrial Toxicity Studies on Methanol

Test Species (Method)	Endpoint	Results (mg/kg soil dw)	Klimisch score	Reference
Earthworm *Eisenia fetida* (OECD 222)	35-d EC_{50} 63-d EC_{50}	17,199 26,646	2	ECHA
Folsomia candida (OECD 232)	28-d EC_{25} 28-d NOEC* (reproduction)	2,842 1,000	1	ECHA
Hordeum vulgare (OECD 208)	14-d EC_{50} 14-d NOEC* (seedling emergence)	15,492 12,000	1	ECHA
	14-d EC_{25} 14-d NOEC* (shoot dry mass)	2,538 1,555		
	14-d EC_{25} 14-d NOEC* (root dry mass)	2,823 2,592		
	14-d EC_{25} 14-d NOEC* (shoot length)	4,885 2,592		
	14-d EC_{25} 14-d NOEC* (root length)	5,752 4,320		

* Since only EC_{25} values were available from the test results, NOECs were derived graphically from the representing treatment means.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (15,400 mg/L), *Daphnia* (>10,000 mg/L), and algae (22,000 mg/L). There are no well-conducted long-term studies on methanol. Therefore, an assessment of 1,000 has been applied to the lowest reported effect concentration of 10,000 mg/L for *Daphnia*. The $PNEC_{water}$ is 10 mg/L.

$PNEC_{sediment}$: There are no adequate toxicity studies on sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 6.3 mg/kg wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.81/1280) \times 1000 \times 10$
$= 6.3$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{soilid}]$
$= 0.8 + [0.2 \times 0.02/1000 \times 2400]$
$= 0.81$

Where:
Kp = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 0.61 \times 0.04$
$= 0.02$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for methanol is 0.61.
F_{oc} = fraction of organic carbon suspended sediment = 0.04 [default].

$PNEC_{soil}$: Experimental results from chronic studies are available for three trophic levels. The lowest NOEC is 1,000 mg/kg soil dry weight for the arthropod *Folsomia candida*. On the basis that the data consists of long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported long-term NOEC of 1,000 mg/kg soil dry weight. The $PNEC_{soil}$ is 100 mg/kg soil dry weight.

PBT Assessment

Methanol is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on an experimental BCF of <10 in fish, methanol does not meet the criteria for bioaccumulation.

There are no adequate chronic toxicity studies on methanol. The acute $E(L)C_{50}$ values of methanol in fish, invertebrates and algae is >1 mg/L; thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that methanol is not a PBT substance.

Environmental Assessment

N-benzyl-alkylpyridium chloride
(CAS No. 68909-18-2)

N-benzyl-alkylpyridium chloride is a UVCB substance.

Biodegradation

No data are available.

Bioaccumulation

No bioconcentration studies have been conducted on N-benzyl alkylpyridium chloride. N-benzyl alkylpyridium chloride is not expected to bioaccumulate based on the experimental log K_{ow} of 3 (ECHA) [Kl. score = 1].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on salts of N-benzyl-alkylpyridium chloride.

Table 1: Acute Aquatic Toxicity Studies on N-benzylalkylpyridium chloride

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Daphnia magna	48-hr EC_{50}	3.1	1	ECHA
Pseudokirchneriella subcapitata	72-hr EC_{50} NOEC	0.47 0.02	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for *Daphnia* (3.1 mg/L), and algae (0.47 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 0.47 mg/L for algae. The $PNEC_{water}$ is 0.005 mg/L.

PBT Assessment

No data are available on the persistence of N-benzyl alkylpyridium chloride.

No bioconcentration studies are available for N-benzyl alkylpyridium chloride. The measured log K_{ow} for N-benzyl alkylpyridium chloride is 3; thus, N-benzyl alkylpyridium chloride does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for N-benzyl alkylpyridium chloride in algae is <1 mg/L. Thus, N-benzyl alkylpyridium chloride meets the screening criteria for toxicity.

The overall conclusion is that N-benzyl alkylpyridium chloride is not a PBT substance.

References

ECHA. ECHA REACH database: http://echa.europa.eu/information-on-chemicals/registered-substances.

Environmental Assessment

Pine Oil
(CAS No. 8002-09-3)

Biodegradation

Pine oil is a UVCB substance. Based on data on its components, pine oil is expected to be readily biodegradable.

Bioaccumulation

No bioconcentration studies have been conducted on pine oil. Based on data on its components, bioaccumulation or bioconcentration (BCF values >2,000) in aquatic organisms is possible (EPA, 2006).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on pine oil.

Table 1: Acute Aquatic Toxicity Studies on Pine Oil

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	LC_{50}	18.4	-	EPA, 2006
Lepomis macrochirus	LC_{50}	54.8	-	EPA, 2006
Daphnia magna	EC_{50}	24.1	-	EPA, 2006

Terrestrial Toxicity

The acute LD_{50} to Bobwhite quail is >2,250 mg/kg (EPA, 2006). The LC_{50} to mallard ducks in a subacute dietary study is >5,620 ppm (EPA, 2006).

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (18.4 mg/L) and *Daphnia* (24.1 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 18.4 mg/L for fish. The $PNEC_{water}$ is 0.02 mg/L.

PBT Assessment

Pine oil is expected to be readily biodegradable based on data of its components. Thus, it does not meet the criteria for persistence.

No bioconcentration studies are available for pine oil. The estimated BCF values of some of its components suggest that bioaccumulation in aquatic organisms is possible. Thus, pine oil may meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for pine oil in fish and invertebrates are >1 mg/L. Thus, pine oil does not meet the screening criteria for toxicity.

The overall conclusion is that pine oil is not a PBT substance.

Environmental Assessment

Polyoxyethylene Nonylphenol Ether
[Nonylphenol, ethoxylated]
(CAS No. 9016-45-9)

Biodegradation

Nonylphenol ethoxylates (NPE) are readily biodegradable. There was 96% degradation of NPEs after 30 days, indicating substantial primary biodegradation. The biodegradation process generated degradants nonylphenol mono- and di-ethoxylates, nonylphenoxy acetate and nonylphenol mono-ethoxyacetate, some of which remained at the end of 30 days (Ying et al., 2002, NICNAS). These degradants are expected to be ultimately biodegraded in the environment (Hayashi et al., 2005; Lu et al., 2009; NICNAS).

Bioaccumulation

Nonylphenol ethoxylates (CAS No. 9016-45-9) are expected to have low bioaccumulation potential in aquatic organisms (NICNAS). The BCF in the fish *Cyprinus carprio* of nonylphenol ethoxylates (CAS No. 9016-45-9) was reported to be <0.2 L/kg at 2 mg/L and <1.4 L/kg at 0.2 mg/L (NITE, 2014; NICNAS).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on nonylphenol ethoxylates (CAS No. 9016-45-9).

Table 1: Acute Aquatic Toxicity Studies on Nonylphenol Ethoxylates (CAS No. 9016-45-9)

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Lepomis macrochirus	96-hr LC_{50}	1.3	-	NICNAS
Scenedesmus opoliensis	120-hr EC_{50}	37.4	-	NICNAS

The 7-d NOEC from a chronic study on *Ceriodaphnia dubia* is 0.285 mg/L. The data was conducted on a chemical with an average ethylene oxide chain (EO) of 1.5 and read-across to nonylphenol ethoxylates (CAS No. 9016-45-9).

The 96-hr NOEC from an algal (Pseudokirchneriella subcapitata) on a nonylphenol ethoxylate (CAS No. 9016-45-9) is 8 mg/L (NICNAS).

Both nonylphenols and short-chain NPEs have been reported to have endocrine activity, with NPEs having less activity than nonylphenols (NICNAS).

Terrestrial Toxicity

The 48-hr LC_{50} to the Gallery worm (*Capitella capitata*) is 3.26 mg/L (NICNAS).

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (1.3 mg/L) and *Daphnia* (37.4 mg/L). Results are available from chronic studies on two trophic levels, with NOEC values for invertebrate (0.285 mg/L) and algae (8 mg/L). On the basis that the data consists of short-term results from two trophic levels and long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported NOEC value of 0.285 mg/L for invertebrates. The $PNEC_{water}$ is 0.006 mg/L.

PBT Assessment

Nonylphenol ethoxylates are readily biodegradable and thus do not meet the screening criteria for persistence.

The measured BCF values in fish for nonylphenol ethoxylates are <1.4; thus, nonylphenol ethoxylates do not meet the screening criteria for bioaccumulation.

The lowest chronic NOEC value for nonylphenol ethoxylates is <1 mg/L. Thus, nonylphenol ethoxylates meet the screening criteria for toxicity.

The overall conclusion is that nonylphenol ethoxylates are not PBT substances.

Environmental Assessment

Potassium carbonate
(CAS No.584-08-7)

Environmental Fate

Potassium carbonate is partially soluble in water, dissociating into potassium (K^+) and carbonate (CO_3^{2-}) ions. Both ions are ubiquitous in the environment.

The addition of potassium carbonate to an aquatic ecosystem could result in a shift towards in alkalinity and a tendency to increase the pH. The carbonate ions will react with water, forming bicarbonate (HCO_3^-) and hydroxide (OH^-) ions, until an equilibrium is reached. A re-equilibration takes place when carbonate (CO_3^{2-}) is dissolved in water according to the following equations:

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ $pK_a = 10.33$
$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ $pK_a = 6.35$

Only a small fraction of the dissolved CO_2 is present as H_2CO_3 (carbonic acid); the major part is present as CO_2. The amount of CO_2 in water is in equilibrium with the partial pressure of CO_2 in the atmosphere. The CO_2/ HCO_3^-/ CO_3^{2-} equilibria are the major buffer of the pH of freshwater.

Based on these equations, CO_2 is the predominant species at a pH smaller than 6.35, while HCO_3^- is the predominant species at a pH in the range of 6.35-10.33 and CO_3^{2-} is the predominant species at a pH higher than 10.33.

K^+ and CO_3^{2-} ions are not expected to adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on potassium carbonate.

Table 1: Acute Aquatic Toxicity Studies on Potassium Carbonate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LC_{50}	68	2	ECHA
Lepomis macrochirus	96-hr LC_{50}	230	2	ECHA
Daphnia pulex	48-hr EC_{50}	200	2	ECHA
Daphnia magna	48-hr EC_{50}	430	2	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

The natural pH, bicarbonate and the potassium concentration (and their fluctuations in time) vary significantly between aquatic ecosystems; so deriving generic PNEC values from aquatic toxicity results on potassium carbonate determined in an experimental system with a defined pH, buffered media and/or media composition to real world conditions is not useful. Therefore, PNEC values for freshwater, sediment, and soil were not derived for potassium carbonate.

PBT Assessment

Potassium carbonate is an organic salt that dissociates completely to potassium and carbonate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and carbonate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Potassium and carbonate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, potassium carbonate is not expected to bioaccumulate.

No chronic aquatic toxicity data exist on potassium carbonate; however, the acute $E(L)C_{50}$ values are >1 mg/L in fish, invertebrates and algae. Thus, potassium carbonate does not meet the screening criteria for toxicity.

The overall conclusion is that potassium carbonate is not a PBT substance.

References

ECHA. ECHA REACH database: http://echa.europa.eu/information-on-chemicals/registered-substances.

Environmental Assessment

Potassium chloride
(CAS No. 7447-40-7)

Environmental Fate

Potassium chloride (KCl) dissociates completely in aqueous solutions to potassium (K^+) and chloride (Cl^-) ions. Potassium chloride and its dissociated ions are ubiquitous in the environment.

The transport and/or leaching of potassium (K^+) and chloride (Cl^-) ions is affected by clay minerals (type and content), pH, and organic matter. Potassium ions are less mobile and less prone to leaching than anions in soil, such as chloride and nitrate (NO_3^-). Chloride binds only weakly to soil particles, and therefore follows water movement (OECD, 2001).

Potassium (K^+) and chloride (Cl^-) ions are essential to all living organisms, and their intracellular and extracellular concentrations are actively regulated (OECD, 2001; Ganong, 1995). Neither potassium chloride or its dissociated ions are expected to bioaccumulate.

Aquatic Toxicity

The results of the acute toxicity studies conducted on potassium chloride are presented in Table 1.

Table 1: Acute Aquatic Toxicity Studies on Potassium Chloride

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-h LC_{50}	880	2	Mount et al., 1997; ECHA
Daphnia magna	48-h EC_{50}	660	2	Mount et al., 1997; ECHA
Ceriodaphnia dubia	48-h EC_{50}	630	2	Mount et al., 1997; ECHA
Scenedesmus subspicatus	72-h EC_{50}	>100* (growth rate)	1	ECHA

*NOEC = >100 mg/L

In a fish early-life-stage test with the fathead minnow (*Pimephales promelas*), the 7-day NOEC was 500 mg/L (ECHA).

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (720 mg/L), *Daphnia* (177 mg/L), and algae (>100 mg/L). Although a chronic study was conducted on fish that fulfils the requirements in the OECD TG 210, it is not considered adequate for deriving a PNEC because of the short duration of the test. On the basis of the short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{water}$ is 0.1 mg/L.

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Potassium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as potassium chloride. Therefore, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sed}$. Based on its properties, no adsorption of potassium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of potassium chloride is dominated by its water solubility. Sorption of potassium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as potassium chloride. Therefore, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on its properties, potassium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Potassium chloride is an inorganic salt that dissociates completely to potassium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and chloride ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Potassium and chloride ions are essential to all living organisms, and their intracellular, and extracellular concentrations are actively regulated. Therefore, potassium chloride is not expected to bioaccumulate.

There are no adequate chronic aquatic toxicity studies available on potassium chloride. The acute $E(L)C_{50}$ values for postassium chloride are >1 mg/L in fish, invertebrates and algae. Therefore, potassium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that potassium chloride is not a PBT substance.

OECD. (2001). Screening Information Assessment Report (SIAR) for Potassium chloride (CAS No. 7447-40-7), UNEP Publications. Available at: http://webnet.oecd.org/Hpv/UI/SIDS_Details.aspx?id=68BF142A-D550-432C-8C48-13883944BA1D.

Environmental Assessment

Potassium hydroxide
(CAS No. 1310-58-3)

Environmental Fate

Due to its high water solubility and low vapour pressure, potassium hydroxide will be found predominantly in the aquatic environment where it dissociates completely to potassium (K^+) and hydroxyl (OH^-) ions. Both ions are ubiquitous in the environment (UNEP, 1995).

Addition of potassium hydroxide to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general, the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

A release of potassium hydroxide into the aquatic environment from the use of KOH could potentially increase the potassium concentration and the pH in the aquatic environment. Table 1 shows the concentration of potassium hydroxide needed to increase the pH to values of 9.0, 10.0, 11.0, and 12.0.

Table 1: Potassium Hydroxide Concentration (mg/L) Needed to Increase pH (DeGroot et al., 2002; taken from OECD, 2002).

Buffer capacity	[KOH] (mg/L)	[K] (mg/L)	[KOH] (mg/L)
0 mg/L HCO_3 (distilled water)	0.56	0.39	0.010
20 mg/L HCO_3 (10^{th} percentile of 77 rivers)	0.86	0.60	0.015
106 mg/L HCO_3^- (mean value of 77 rivers)	4.51	3.14	0.080
195 mg/L HCO_3^- (90^{th} percentile of 77 rivers)	8.30	5.78	0.148

K^+ and OH^- ions will not adsorb on particulate matter or surfaces and will not accumulate in living tissues (OECD, 2002).

Aquatic Toxicity

The OECD-SIDS SIAR on KOH states the following regarding the aquatic toxicity studies on KOH (OECD, 2002):

> At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of potassium is too low to explain the effects. However, it should be realised that the results of toxicity tests with KOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralised, and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the

direct effects (pH change) KOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity e.g., NH_3 is more toxic than NH_4^+.

Acute Fish

The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 80 mg/L. At 56 mg/L, no effects on the fish were observed. The pH was 10.3 at 100 mg/L (OECD, 2002). [Kl. score = 3]

Acute Invertebrate

No studies are available.

Acute Algae

No studies are available.

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

The OECD-SIDS SIAR on KOH states the following regarding the aquatic toxicity studies on KOH (OECD, 2002):

> In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with KOH. The observed variation in LC50 values can be explained by the buffer capacity of the testing water, which was used.
>
> Although valid acute ecotoxicity tests and chronic ecotoxicity tests with KOH or NaOH are not available there is no need for additional testing with KOH. Aquatic ecosystems are characterized by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with pH of 6 to very hard waters with pH values up to 9."
>
> Furthermore, acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterised by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.
>
> Based on the available data it is not considered useful to derive a PNEC or a PNEC added for KOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,
- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems.
- The change in pH due to an anthropogenic KOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for KOH there is a need to assess the environmental effect of KOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

Based on the information above, PNEC values for freshwater, sediment, and soil were not derived for potassium hydroxide.

PBT Assessment

Potassium hydroxide is an inorganic salt that dissociates completely to potassium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Potassium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, potassium hydroxide is not expected to bioaccumulate.

There are no chronic toxicity data available on potassium hydroxide. The acute $E(L)C_{50}$ values for potassium hydroxide are >1 mg/L in fish. Thus, potassium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that potassium hydroxide is not a PBT substance.

Environmental Assessment

Potassium persulfate
(CAS No. 7727-21-1)

Environmental Fate

Potassium persulfate dissociates in aqueous media to the potassium cation (K^+) and persulfate anion ($S_2O_8^{2-}$) (OECD 2005; ECHA). The persulfate anion will readily hydrolyse (decompose) into sulfate ions.

The rates of hydrolysis are expected to be similar for sodium persulfate, potassium persulfate, and ammonium persulfate. The rates of decomposition (hydrolysis) was measured at 50°C at various pHs. The half-lives increased from 20 hours at pH 1 to 210 hours at pH 10 (Koltoff and Miller, 1951).

Biodegradation is not applicable to inorganic compounds. Potassium persulfate is not expected to bioaccumulate; it will dissociate (and decompose) to ions that are ubiquitous in the environment. Potassium persulfate is not expected to absorb to soil or sediment because of its dissociation properties, instability (hydrolysis), and high water solubility.

Aquatic Toxicity

There are no aquatic toxicity studies on potassium persulfate. Table 1 lists the results of acute aquatic toxicity studies on other similar persulfate compounds.

Table 1: Acute Aquatic Toxicity Studies on Sodium Persulfate and Ammonium Persulfate

Substance	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Ammonium persulfate	*Oncorhynchus mykiss*	96-h LC_{50}	76.3	1	ECHA
Sodium persulfate	*Oncorhynchus mykiss*	96-h LC_{50}	163	1	ECHA
Ammonium persulfate	*Daphnia magna*	48-h EC_{50}	120	1	ECHA
Sodium persulfate	*Daphnia magna*	48-h EC_{50}	133	1	ECHA
Ammonium persulfate	*Selenastrum capricornutum*	72-h EC_{50}	83.7	1	ECHA
Sodium persulfate	*Selenastrum capricornutum*	72-h EC_{50}	116	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (76.3 mg/L), *Daphnia* (120 mg/L), and algae (83.7 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 76.3 mg/L for fish. The $PNEC_{water}$ is 0.8 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Potassium persulfate dissociates completely in water; its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as potassium persulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of potassium persulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of potassium persulfate is dominated by its water solubility. Sorption of potassium persulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{oc} and K_{ow} parameters do not readily apply to inorganics, such as potassium persulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, potassium persulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Potassium persulfate is an inorganic compound that dissociates completely to potassium and persulfate ions in aqueous solutions. Persulfate ions are further hydrolysed to sulphate ions. Biodegradation is not applicable to these compounds. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to potassium persulfate or its dissociated compounds.

Potassium persulfate is an inorganic compound that dissociates completely in water to ionic compounds that are ubiquitous in the environment. Thus, potassium persulfate is not expected to bioaccumulate.

There are no chronic aquatic toxicity data on potassium persulfate. The acute $E(L)C_{50}$ values for fish, invertebrates, and algae are >1 mg/L. Thus, potassium persulfate does not meet the criteria for toxicity.

The overall conclusion is that potassium persulfate is not a PBT substance.

Environmental Assessment

Potassium sorbate
(CAS No. 24634-61-5)

Biodegradation

In an OECD 301 D test on sorbic acid, degradation was 74.9% after 28 days. Thus, potassium sorbate is expected to be readily biodegradable (ECHA) [Kl. score = 1].

Bioaccumulation

No bioconcentration studies have been conducted on potassium sorbate. Potassium sorbate is not expected to bioaccumulate based on the experimental log K_{ow} of -1.72 at pH 6.5 for sorbic acid (ECHA) [Kl. score = 1].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on potassium sorbate.

Table 1: Acute Aquatic Toxicity Studies on Potassium Sorbate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rerio	96-hr LC_{50}	500	2	ECHA
Daphnia magna	48-hr EC_{50}	982	1	ECHA
Desmodesmus subspicatus	72-hr EC_{50} NOEC	>85* 8.46*	3	ECHA

*Read-across from sorbic acid.

The 21-d NOEC from a chronic *Daphnia* study on sorbic acid is 50 mg/L (ECHA) [Kl. score = 1].

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (500 mg/L), *Daphnia* (982 mg/L), and algae (>85 mg/L). Results from chronic studies are available for invertebrates (50 mg/L) and algae (8.46 mg/L). On the basis that the data consists of short-term results from three trophic levels and long-term results from two trophic levels, an assessment factor of 50 has been applied to the lowest reported NOEC of 8.46 mg/L for *Daphnia*. The $PNEC_{water}$ is 0.17 mg/L.

PBT Assessment

Potassium sorbate is readily biodegradable and thus does not meet the screening criteria for persistence.

No bioconcentration studies are available for potassium sorbate. The measured log K_{ow} for sorbic acid is -1.72 at pH 6.5; thus, potassium sorbate does not meet the screening criteria for bioaccumulation.

The acute $E(L)C_{50}$ values for potassium sorbate in fish, invertebrates, and algae are >1 mg/L. Thus, potassium sorbate does not meet the screening criteria for toxicity.

The overall conclusion is that potassium sorbate is not a PBT substance.

Environmental Assessment

Quaternary Ammonium Compounds, bis(Hydrogenated Tallow Alkyl) Dimethyl, Salts with Bentonite
[Quaternium-18 Bentonite]
(CAS No. 68953-58-2)

Quaternary ammonium compounds, bis (hydrogenated tallow alkyl) dimethyl, salts with bentonite, also known as quaternium-18 bentonite, will be designated "2M(2Alk) bentonite".

2M(2Alk) bentonite is one of a group of organoclays composed of quaternary ammonium compounds (cations) that have the following general formula:

N+R1, R2, R3, R4

Where R1, R2, R3, and R4 are substitutions on the N (nitrogen atom) of the quaternary compound (salt) as follows:

Methyl – 1 or 2 substitutions
Benzyl – 0 or 1 substitutions
Alkyl (C14-22) – 1, 2 or 3 substitutions

The organoclays discussed in this dossier are hydrogenated tallowalkonium bentonites and are the product of the reaction of hydrogenated tallowalkonium chloride and bentonite. Bentonite is a widely distributed natural material consisting predominantly of the clay montmorillonite, a smectite clay. Bentonite is formed of highly colloidal and plastic clays and is produced by in-situ devitrification of volcanic ash (CIR, 2016).

Biodegradation

No biodegradation studies were located for 2M(2Alk) bentonite. Biodegradation studies are available for quaternary ammonium compounds, benzylbis(hydrogenated tallow alkyl)methyl, chlorides, compounds with bentonite: B(2Alk)M bentonite.

In three separate OECD TG 306 biodegradation tests using B(2Alk)M bentonite, biodegradation ranged from 4.7 to 33.4% in 28 days (OECD, 2007). Based on these data as well as the structural and chemical properties of these compounds, it is assumed that other organoclay category members will also show limited biodegradation. It should be noted that biodegradation relates only to the organic component of the organoclays (*i.e.*, the alkyl quaternary ammonium salts).

Bioaccumulation

Bioaccumulation is not expected due to the insolubility of 2M(2Alk) bentonite.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on 2M(2Alk) bentonite and similar organoclays.

Table 1: Acute Aquatic Toxicity Studies on B(Alk)2M Bentonite or similar organoclays

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Rainbow trout	96-h LC_{50}	> ca. 500*	4	OECD, 2007
Daphnia magna	96-h EC_{50}	>100	4	OECD, 2007
Daphnia magna	96-h EC_{50}	300*	4	OECD, 2007
Daphnia magna	96-h EC_{50}	300**	4	OECD, 2007
Skeletonema costatum	72-h EC_{50}	>1,000** (growth rate)	4	OECD, 2007

***B(Alk)2M Bentonite:** Quaternary ammonium compounds, benzyl(hydrogenated tallow alkyl)dimethyl, chlorides, compounds with bentonite.

****B(2Alk)M hectorite:** Quaternary ammonium compounds, benzylbis(hydrogenated tallow alkyl)methyl, salts with hectorite

There are no chronic aquatic toxicity studies on 2M(2Alk) bentonite. The 21-d NOEC in a *Daphnia* reproduction test on B(2Alk)M hectorite was 3.2 mg/L (OECD, 2007). The mortality of *Daphnia* seen at the LOEC of 32 mg/L was considered to be due, in part, to physical effects of the test material.

Terrestrial Toxicity

The 14-day NOEC of B(Alk)2M bentonite to earthworms is 1,000 mg/kg. Since 1,000 mg/kg is the limit dose, it is assumed that the LC_{50} is >1,000 mg/kg (OECD, 2007).

Terrestrial plant toxicity are available for B(2Alk)M hectorite. The EC_{50} values of B(2Alk)M hectorite for the emergence and early growth stages of wheat and radish seedlings (*Tritium aestivum* and *Raphanus sativus*, respectively) are >100 mg/kg; the NOEC are 100 mg/kg, the highest dose tested (OECD, 2007). The LC_{50} of B(2Alk)M hectorite was 9 mg/kg for the emergence and early growth stages of cress seedling (*Lepidum sativum*); the LOEC was 1 mg/kg and a NOEC was not established (OECD, 2007).

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>500 mg/L), *Daphnia* (>100 mg/L), and algae (>1,000 mg/L). Results from chronic studies are also available for two trophic levels, with the lowest NOEC being 3.2 mg/L for invertebrates. On the basis that the data consists of short-term results from three trophic levels and long-term results from two trophic levels, an assessment factor of 50 has

been applied to the lowest reported long-term NOEC of 3.2 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 0.06 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The K_{ow} of 2M(2Alk) bentonite cannot be calculated because it is essentially insoluble in water. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{sediment}$.

$PNEC_{soil}$: Experimental results are available for two trophic levels. An acute LC_{50} value is available for earthworms (>1,000 mg/kg). Results from the long-term studies are only available for terrestrial plants, which give widely divergent results. On the basis that the data consist of one short-term result from one trophic level, an assessment factor of 1,000 has been applied to the acute LC_{50} value of 1,000 mg/kg for earthworms. The $PNEC_{soil}$ is 1.0 mg/kg soil dry weight.

PBT Assessment

The clay component of 2M(2Alk) bentonite is not biodegradable, and the organic component is not readily biodegradable. Thus, it meets the criteria for persistence.

2M(2Alk) bentonite is insoluble in water and is not bioavailable. Thus, it is not expected to meet the screening criteria for bioaccumulation.

There are no chronic aquatic toxicity studies available on 2M(2Alk) bentonite; however, the NOEC from a chronic *Daphnia* study on a similar organoclay is >0.1 mg/L. The acute $E(L)C_{50}$ values for 2M(2Alk) bentonite and similar organoclays are >1 mg/L in fish, invertebrates, and algae. Thus, it does not meet the criteria for toxicity.

The overall conclusion is that 2M(2Alk) bentonite is not a PBT substance.

Environmental Assessment

Sodium benzoate
(CAS No. 532-32-1)

Biodegradation

In a biotic degradation: closed bottle test, degradation was 111% of ThOD after 330 days with a medium containing high ammonium content. In medium containing low ammonium content, degradation was 92% of ThOD. There was slightly lower degradation (75%) with medium with no nitrification. It can be concluded that sodium benzoate is readily biodegradable but failing the 10-day window (ECHA) [Kl. score = 2].

In an OECD 301 CO_2 evolution test, degradation ranged from 85 to 94% after 28 days (ECHA) [Kl. score = 2].

Bioaccumulation

No bioconcentration studies have been conducted on sodium benzoate. Sodium benzoate is not expected to bioaccumulate based on a calculated log K_{ow} of -2.269 (ECHA) [Kl. score = 2].

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on sodium benzoate.

Table 1: Acute Aquatic Toxicity Studies on Sodium Benzoate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-hr LC_{50}	484	2	ECHA
Pimephales promelas	96-hr LC_{50}	>100	2	ECHA
Daphnia magna	48-hr EC_{50}	>100	2	ECHA
Pseudokirchneriella subcapitata	72-hr EC_{50} EC_{10}	>30.5 6.5	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), *Daphnia* (>100 mg/L), and algae (>30.5 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 30.5 mg/L for algae. The $PNEC_{water}$ is 0.3 mg/L.

PBT Assessment

Sodium benzoate is readily biodegradable and thus does not meet the screening criteria for persistence.

No bioconcentration studies are available for sodium benzoate. The measured log K_{ow} for benzoate is -2.269; thus, sodium benzoate does not meet the screening criteria for bioaccumulation.

The acute $E(L)C_{50}$ values for sodium benzoate in algae is >1 mg/L. Thus, sodium benzoate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium benzoate is not a PBT substance.

Environmental Assessment

Sodium bisulfite
(CAS No. 7631-90-5)

Environmental Fate

At environmental pHs, sodium bisulfite dissociates in water to form sodium (Na^+) ions, bisulfite ions (HSO_3^-), sulfite (SO_2^{3-}) ions, and sulfur dioxide (SO_2) which is a gas (OECD, 2001).

Sodium bisulfite is not expected to bioaccumulate in the environment because of its dissociation to ionic species and a gas. Furthermore, sulfite will oxidize to sulfate, which is ubiquitous in the environment (OECD, 2001).

Sodium bisulfite and its dissociated species are expected to have a low potential to adsorb to soil and sediment.

Aquatic Toxicity

No acute aquatic studies are available on sodium bisulfite; however, studies are available on other inorganic sulfite compounds. The studies on these inorganic sulfite compounds can used to read-across to sodium bisulfite since sulfite ions are formed in water upon dissociation of sodium bisulfite. Table 1 lists the results of acute aquatic toxicity studies on the structural analogues of sodium bisulfite.

Table 1: Acute Aquatic Toxicity Studies on the Structural Analogues of Sodium Bisulfite

Test Species	Test Substance	Endpoint	Results (mg/L)	Klimisch score	Reference
Leuciscus idus	Potassium sulfite	96-hr LC_{50}	316	2	ECHA
Salmo gairdneri	Sodium pyrosulfite	96-hr LC_{50}	147-215 (177.8*)	2	ECHA
Brachydanio rerio	Potassium metabisulfite	96-hr LC_{50}	464-1,000 (681.2*)	1	ECHA
Daphnia magna	Sodium disulfite	48-hr EC_{50}	88.8	2	ECHA
S. subspicatus	Sodium disulfite	96-hr EC_{50} 72-hr EC_{10}	43.9 33.3	2	ECHA

*Geometric mean.

No chronic studies are available on sodium bisulfite; however, studies are available on sodium sulfite. Table 2 lists the results of chronic aquatic toxicity studies conducted on sodium sulfite.

Table 2: Chronic Aquatic Toxicity Studies on Sodium Sulfite (CAS No. 7757-83-7)

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rerio	34-d NOEC	>316	1	ECHA
Daphnia magna	21-d NOEC	>10	2	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: No studies have been conducted on sodium bisulfite; however, the results from studies conducted on other inorganic sulphite compounds can be used to read-across to sodium bisulfite. Hence, experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (177.8 mg/L for sodium pyrosulfite), invertebrates (88.8 mg/L for sodium sulfite), and algae (43.9 mg/L for sodium disulfite). Results from chronic studies on sodium sulfite are also available for all three trophic levels, with the lowest NOEC being 10 mg/L for invertebrates. Using the molecular weights of sodium sulfite (126 g/mol) and sodium bisulfite (104.1 g/mol), the NOEC of 10 mg/L for sodium sulfite is converted to 8.3 mg/L. On the basis that the data consist of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 8.3 mg/L for invertebrates. The $PNEC_{water}$ is 0.8 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium bisulfite dissociates completely in water; its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium bisulfite. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sed}$. Based on its properties, no adsorption of sodium bisulfite to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. Sodium bisulfite dissociates completely in water; its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium bisulfite. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on its properties, no adsorption of sodium bisulfite to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium bisulfite is an inorganic compound that dissociates completely to ionic species and sulfur dioxide gas. Biodegradation is not applicable to these compounds. For the purposes of this PBT assessment, the persistent criterion is not considered applicable to sodium bisulfite or its dissociated compounds.

Sodium bisulfite is not expected to bioaccumulate because its dissociated species are inorganic ions and a gas.

There are no aquatic toxicity data on sodium bisulfite. The lowest NOEC from chronic aquatic toxicity studies on sodium sulfite, a structural analogue of sodium bisulfite, is >0.1 mg/L. Thus, sodium bisulfite is not expected to meet the criteria for toxicity.

The overall conclusion is that sodium bisulfite is not a PBT substance.

Environmental Assessment

Sodium erythrobate
(CAS No. 6381-77-7)

Biodegradation

In an OECD 301E test, biodegradation was 56% after 28 days, indicating that sodium erythrobate is not readily biodegradable (ECHA) [Kl. score = 2].

Bioaccumulation

No bioconcentration studies have been conducted on sodium erythrobate. Sodium erythrobate is not expected to bioaccumulate based on the experimental log K_{ow} of -3.29 (ECHA).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on sodium erythrobate.

Table 1: Acute Aquatic Toxicity Studies on Sodium Erythrobate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LC_{50}	>100	1	ECHA
Daphnia magna	48-hr EC_{50}	>100	1	ECHA
Pseudokirchneriella subcapitata	72-hr EC_{50}	>100	1	ECHA

Terrestrial Toxicity

No studies are available.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), *Daphnia* (>100 mg/L), and algae (>100 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 100 mg/L for fish, invertebrates, and algae. The $PNEC_{aquatic}$ is 1.0 mg/L.

PBT Assessment

Sodium erythrobate is not readily biodegradable; thus, it meets the screening criteria for persistence.

No bioconcentration studies are available for sodium erythrobate. The measured log K_{ow} for sodium erythrobate is -3.29; thus, sodium erythrobate does not meet the screening criteria for bioaccumulation.

The acute E(L)C_{50} values for sodium erythrobate in fish, invertebrates, and algae are >1 mg/L. Thus, sodium erythrobate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium erythrobate is not a PBT substance.

ECHA. ECHA REACH database: http://echa.europa.eu/information-on-chemicals/registered-substances.

Environmental Assessment

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) is a strong alkaline substance that dissociates completely in water to sodium (Na^+) and hydroxyl (OH^-) ions.

Environmental Fate

Due to its high water solubility and low vapour pressure, sodium hydroxide will be found predominantly in the aquatic environment where it dissociates completely to sodium (Na^+) and hydroxyl (OH^-) ions. Both ions are ubiquitous in the environment (UNEP, 1995).

The addition of sodium hydroxide to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general, the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

A release of sodium hydroxide into the aquatic environment from the use of NaOH could potentially increase the sodium concentration and the pH in the aquatic environment. Table 1 shows the concentration of sodium hydroxide needed to increase the pH to values of 9.0, 10.0, 11.0, and 12.0.

Table 1: Sodium Hydroxide Concentration (mg/L) Needed to Increase pH (DeGroot et al., 2002; taken from OECD, 2002b).

Buffer capacity*	Final pH			
	9.0	**10.0**	**11.0**	**12.0**
0 mg/L HCO_3 (distilled water)	0.4	4.0	40	400
20 mg/L HCO_3 (10^{th} percentile of 77 rivers)	1.0	8.2	51	413
106 mg/L HCO_3^- (mean value of 77 rivers)	3.5	26	97	468
195 mg/L HCO_3^- (90^{th} percentile of 77 rivers)	6.1	45	145	525

*The initial pH of a bicarbonate solution with a concentration of 20-195 mg/L was 8.25 to 8.35.

Na^+ and OH^- ions will not adsorb on the particulate matter or surfaces and will not accumulate in living tissues (OECD, 2002b).

Aquatic Toxicity

The OECD-SIDS SIAR on NaOH states the following regarding the aquatic toxicity studies on NaOH (OECD, 2002b):

> "At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realised that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium, the hydroxyl ion will be neutralised, and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity, e.g.; NH_3 is more toxic than NH_4^+."

There are no guideline studies on NaOH; the studies summarised below have Klimisch scores of 3 or 4.

Acute Fish

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L. At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L.

Acute Invertebrate

The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia cf. dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

Acute Algae

No studies were identified.

<u>Terrestrial Toxicity</u>

No studies are available.

<u>Derivation of PNECs</u>

The OECD-SIDS SIAR on NaOH states the following regarding the aquatic toxicity studies on NaOH (OECD, 2002b):

> "In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available, there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available, and the results of the tests are more or less consistent. Altogether they give a sufficient indication of acute toxicity levels of sodium hydroxide."

> "Furthermore, acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterised by an alkalinity/pH, and

the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks."

"Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,
- Also, the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and
- The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water."

"Although a PNEC or a PNEC added was not calculated for NaOH, there is a need to assess the environmental effect of a NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course, the pH change can also be measured very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable."

Based on the information above, PNEC values for freshwater, sediment, and soil were not derived for sodium hydroxide.

PBT Assessment

Sodium hydroxide is an inorganic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms, and their intracellular, and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $E(L)C_{50}$ values are >1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

Environmental Assessment

Sodium Polyacrylate
(CAS No. 9003-04-7)

Sodium polyacrylates are polymers that range in molecular weight (MW) from 1,000 to 78,000 (HERA, 2014). The sodium polyacrylates mostly used in detergents have a typical molecular weight of approximately 4,500 (HERA, 2014).

Biodegradation

Sodium polyacrylates are not readily biodegradable but are partly accessible to ultimate biodegradation particularly under long incubation conditions. Sodium polyacrylates with MW of <2,000 are partly biodegradable under the conditions of soil and sediment inoculation. Test results with activated sludge inoculum indicate different elimination degrees, apparently due to adsorption and precipitation processes. The removal degrees of different sodium polyacrylates show no clear relationship between elimination extent and molecular weight (HERA, 2014).

Bioaccumulation

No experimental studies are available on sodium polyacrylates. Estimated bioconcentration factors based on octanol-water coefficients are not appropriate since the molecular weights of these polymers are higher than the molecular weight range for the QSAR models. Due to their high molecular weights, sodium polyacrylates are not expected to bioaccumulate. In addition, these water-soluble polymers can form insoluble calcium salts in natural waters, suggesting that bioaccumulation is unlikely.

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on sodium polyacrylates.

Table 1: Acute Aquatic Toxicity Studies on Sodium Polyacrylates

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
1,000	*Brachydanio rerio*	96-hr LC_{50}	>200	1	HERA, 2014
1,000	*Salmo gairdneri*	96-hr LC_{50}	>1,000	1	HERA, 2014
1,200	*Leuciscus idus*	96-hr LC_{50}	>500	1	HERA, 2014
2,000	*Brachydanio rerio*	96-hr LC_{50}	>200	1	HERA, 2014
2,500	*Leuciscus idus*	96-hr LC_{50}	>500	1	HERA, 2014
4,500	*Lepomis macrochirus*	96-hr LC_{50}	>1,000	1	HERA, 2014
4,500	*Lepomis macrochirus*	96-hr LC_{50}	>1,000	1	HERA, 2014
8,000	*Leuciscus idus*	96-hr LC_{50}	>500	1	HERA, 2014
10,000	*Lepomis macrochirus*	96-hr LC_{50}	>1,000	1	HERA, 2014

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
15,000	*Leuciscus idus*	96-hr LC_{50}	>10,000	1	HERA, 2014
78,000	*Brachydanio rerio*	96-hr LC_{50}	>400	2	HERA, 2014
1,000	*Daphnia magna*	48-hr EC_{50}	>200	1	HERA, 2014
1,000	*Daphnia magna*	48-hr EC_{50}	>1,000	1	HERA, 2014
2,000	*Daphnia magna*	48-hr EC_{50}	>200	1	HERA, 2014
4,500	*Daphnia magna*	48-hr EC_{50}	>200	1	HERA, 2014
4,500	*Daphnia magna*	48-hr EC_{50}	>1,000	1	HERA, 2014
78,000	*Daphnia magna*	24-hr EC_{50}	276	2	HERA, 2014
8,000	*Selenastrum capricornutum*	72-hr EC_{50}	40	1	HERA, 2014
78,000	*Scenedesmus subspicatus*	96-hr EC_{50}	44	2	HERA, 2014

Table 2 lists the results of chronic aquatic toxicity studies on sodium polyacrylates.

Table 2: Chronic Aquatic Toxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
4,500	*Pimephales promelas*	32-d NOEC	56	2	HERA, 2014
4,500	*Brachydanio rerio*	28-d NOEC	>450	1	HERA, 2014
78,000	*Brachydanio rerio*	14-d NOEC	>400	2	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	450	1	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	58	1	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	12	2	HERA, 2014
78,000	*Daphnia magna*	21-d NOEC	100	2	HERA, 2014
4,500	*Scenedesmus subspicatus*	96-hr NOEC	180	2	HERA, 2014
78,000	*Scenedesmus subspicatus*	96-hr NOEC	32.8	2	HERA, 2014

There is considerable variability in the chronic aquatic toxicity results for *Daphnia magna* for sodium polyacrylates with the same molecular weight of 4,500. This was discussed in HERA (2014) and was explained by the solubility of sodium polyacrylates in water. In distilled water, the solubility of sodium polyacrylates with the molecular weight of 4,500 is >400 mg/L;

however, under test conditions water solubility will decrease due to the presence of Ca^{++} and Mg^{++} (as measured by water hardness). In a study by BASF (reviewed in HERA, 2014), the water solubility of sodium polyacrylate (MW 4,500) was determined with radiolabelled compounds in a test system with a calcium concentration of 70 mg/L, which corresponds to the mean water hardness to the media used in an OECD TG 202 test. Under these conditions, the water solubility of sodium polyacrylate was 1.3 mg/L after 24 hours. So, one explanation for the variability of the chronic *Daphnia* studies may be due to differences in water hardness.

Toxicity to Sediment Organisms

The 96-hr EC_0 to *Chironomus riparius* (larvae) is >4,500 mg/kg sediment dry weight (HERA, 2014).

Terrestrial Toxicity

The results of terrestrial toxicity studies on sodium polyacrylate polymers are listed below in Table 3.

Table 3: Terrestrial Toxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
4,500	*Eisenia foetida foetida*	14-d EC_0	1,000	1	HERA, 2014
78,000	*Eisenia foetida andrei*	14-d EC_0	1,000	2	HERA, 2014
78,000	*Brassica rapa*	21-d NOEC	1,000	2	HERA, 2014
4,500	Nitrogen transformation*	28-d EC_{10}	>2,500	1	HERA, 2014
4,500	Carbon transformation*	28-d EC_{10}	>2,500	1	HERA, 2014

*Soil organisms.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>200 mg/L), invertebrates (>200 mg/L), and plants (40 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 12 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 12 mg/L for invertebrates. The $PNEC_{water}$ is 1.2 mg/L.

$PNEC_{sediment}$: Experimental results are available for one trophic level. There were no visual signs of toxicity to *Chironomus riparius* (larvae) at the highest concentration tested (>4,500 mg/kg sediment dry weight) (HERA, 2014). The EC_0 is considered to be above 4,500 mg/kg and an assessment factor cannot apply. Thus, the equilibrium partitioning method will be used

to determine the $PNEC_{sed}$. The HERA (2014) risk assessment calculated a $PNEC_{sed}$ of 130 mg/kg sediment wet weight using the default of 0.05 as the weight fraction of organic carbon in sediment according to the EU Technical Guidance Document (TGD) (EC, 2003).

$PNEC_{soil}$: Experimental results are available for three trophic levels. An acute LC_{50} value is available for earthworms (1,000 mg/kg soil dry weight). A 21-day NOEC for *Brassica rapa* was reported to be 1,000 mg/kg soil dry weight. Results from two long-term studies are available for soil microorganisms, with the NOECs for nitrogen and carbon transformation being >2,500 mg/kg soil dry weight. On the basis that the data consists of short-term tests, as well as one long-term test from one trophic level, an assessment factor of 100 has been applied to the lowest reported long-term NOEC of >2,500 mg/kg soil dry weight. The $PNEC_{soil}$ is 25 mg/kg soil dry weight.

PBT Assessment

The sodium polyacrylates are not readily biodegradable; thus, they meet the screening criteria for persistence.

The sodium polyacrylates are expected to have high molecular weights and are not expected to be bioavailable. Thus, these polymers do not meet the criteria for bioaccumulation.

Chronic NOECs for fish, daphnia and algae are available for sodium polyacrylates, and the NOEC values are >0.1 mg/L. Thus, sodium polyacrylates do not meet the screening criteria for toxicity.

The overall conclusion is that sodium polyacrylates are not PBT substances.

Environmental Assessment

Sodium tetraborate decahydrate
[Disodium tetraborate decahydrate; Borax]
(CAS No. 1303-96-4)

Environmental Fate

Many minerals contain boron, which is present as the sodium or calcium borate salt. Thus, boron is ubiquitous and widely distributed in the environment. It is present in rocks, soil and water and is released into the environment primarily from the weathering of rock and soil, volatilization of sea water, and anthropogenic activity.

Sodium tetraborate tetrahydrate ($Na_2B_4O \bullet 10H_2O$) is very soluble in water, with the main species in freshwater being the borate ion $[B(OH)_4]^-$ and boric acid $B(OH)_3$, depending on the pH. The relative proportion of boric acid and borate ions is controlled by pH: $B(OH)_3 + 2H_2O \Leftrightarrow [B(OH)_4]^- + H_3O^-$. In dilute aqueous solutions, boric acid does not dissociate at pH <7; at pH values between 7 and 11, both boric acid and borate ions are present. In dilute aqueous solutions and physiological conditions, the predominant species present is un-dissociated boric acid. So, the consideration of boric acid addresses the relevant environmental stability properties for borates.

In natural waters, boron forms stable species and exists primarily as un-dissociated boric acid $[B(OH)_3]$ and complex polyanions (*e.g.,* $[B(OH)_4]^-$). These forms of boron are highly soluble and not easily removed from solution by natural mechanisms. Borate and boric acid are in equilibrium depending on the pH of the water. At an acidic pH, boron exists in solution mainly as un-dissociated boric acid, whereas at alkaline pH it is present as borate ions.

Degradation is not applicable to inorganic borates, such as sodium tetraborate decahydrate. It is not subject to hydrolysis, photodegradation, or biodegradation (ECHA). Inorganic borates are subject to chemical transformation processes (adsorption, complexation, precipitation, fixation) once released into the environment (ECHA).

The WHO review of boron (WHO, 1998) noted that "highly water soluble materials are unlikely to bioaccumulate to any significant degree and that borate species are all present essentially as un-dissociated and highly soluble boric acid at neutral pH". A BCF of <0.1 was reported in Chinook salmon fed boron-supplemented diets for 60 to 90 days (Hamilton and Wiedmeyer, 1990).

Exposure to borates are often expressed in terms of boron (B) equivalents based on the fraction of boron in the source substance on a molecular weight basis. The B equivalents used are a generic designation rather than a designation of the element boron. The factor for converting sodium tetraborate decahydrate to B-equivalents is 0.1134.

Aquatic Toxicity

The summary of the data used by ANZECC to develop a water quality guideline for boron is as follows:

Freshwater Fish

The chronic values for four species ranged from 40 µg/L (32-day LOEC in *O. mykiss*) to 27,600 µg/L (32-day LOEC in *O. mykiss*). Other *O. mykiss* data were order of magnitude higher than 40 µg/L, including those from the same paper (2,100 µg/L for an 87-day NOEC and 27,600 µg/L for a 32-day LC_{50}). All other geometric means were >4,000 µg/L.

Freshwater Crustaceans

The chronic data ranged from a 21-day MATC value of 4,665 µg/L for *Daphnia magna* based on growth to an LC_{50} value of 54,200 µg/L from a 21-day *Daphnia* study. A measured NOEC of 6,000 µg/L based on reproduction was also reported.

Freshwater Algae

The data ranged from a 14-day NOEC of 400 µg/L for *Chlorella pyrenoidosa* to a NOEC of 5,200 µg/L for *Chlorella vulgaris*. Both values are based on population growth.

Terrestrial Toxicity

There are considerable number of terrestrial toxicity studies on borates. See the ECHA REACH database (ECHA) for summaries of the relevant studies.

Derivation of PNECs

$PNEC_{water}$: The ANZECC water quality guideline (2000) used a "freshwater high reliability trigger value for boron of 370 µg/L was calculated using the statistical distribution method at 95% protection."

"Although the 95% protection level is higher than the 32-day LOEC of 100 µg/L for *O. mykiss*, this figure appeared anomalous and other data on this species showed much less toxicity. The low figure may need to be checked. The 95% figure is considered sufficiently protective for slightly-moderate disturbed ecosystems" (ANZECC, 2000).

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium tetraborate, anhydrous dissociates completely in water and its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium tetraborate, anhydrous. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sed}$. Based on the its properties, no adsorption of sodium tetraborate, anhydrous to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: In the ECHA REACH database (ECHA), a $PNEC_{soil}$ was derived for boron using the species sensitivity distribution method and an assessment factor of 2. The $PNEC_{soil}$ was determined to be 5.7 mg/kg soil dry weight.

PBT Assessment

Sodium tetraborate decahydrate is an inorganic compound that dissociates completely to boric acid and the borate anion in aqueous media. Biodegradation is not applicable to these inorganic compounds; both boric acid and borate are also ubiquitous and are present in most water, soil

and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to sodium tetraborate decahydrate.

Sodium tetraborate decahydrate is a water-soluble substance that is not expected to bioaccumulate. Limited data indicate that bioaccumulation (BCF values are low) is not significant in aquatic and terrestrial food chains. Thus, it does not meet the criteria for bioaccumulation.

Boric acid and inorganic borates are reproductive toxicants and have been classified under GHS as known or presumed human reproductive toxicants (Category 1B). Thus, sodium tetraborate decahydrate meets the PBT criteria of toxicity.

The overall conclusion is that sodium tetraborate decahydrate is not a PBT substance.

APPENDIX G.11 HALLIBURTON HYBOR-DELTA HYDRAULIC FRACTURING FLUID SYSTEMS

ACETIC ACID

This dossier on acetic acid does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of acetic acid in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Acetic acid

CAS RN: 64-19-7

Molecular formula: $C_2H_4O_2$

Molecular weight: 60.1

Synonyms: Acetic acid, ethanoic acid, ethylic acid, methane carboxylic acid, vinegar acid

SMILES: CC(=O)O

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Acetic Acid

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Colorless liquid with a pungent odor.	2	ECHA
Melting Point	16.64°C	2	ECHA
Boiling Point	117.9°C	2	ECHA
Density	1.04 g/cm^3	2	ECHA
Vapor Pressure	20.79 hPa @ 25°C	2	ECHA
Partition Coefficient (log K_{ow})	-0.17	2	ECHA

Water Solubility	602.9 g/L	2	ECHA
Flash Point	39ºC @ 101.3 kPa	2	ECHA
Auto flammability	463ºC	2	ECHA
Viscosity	1.056 mPa s @ 25ºC	2	ECHA
Dissociation constant	4.756 @ 25ºC	2	ECHA

Acetic acid readily dissociates in aqueous media to the acetate ($H_3C2O_2^-$) and hydrogen (H^+) ions.

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

The acetate ion of acetic acid is readily biodegradable, is not expected to bioaccumulate, and has a low potential to adsorb to soil.

B. Biodegradation

Acetic acid was readily biodegradable a non-acclimated freshwater study. Degradation was 96% after 20 days (Price et al., 1974; ECHA) [Kl. score = 2]. Acetic acid is also readily biodegradable under anaerobic conditions (Kameya et al., 1995) [Kl. score = 2].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for acetic acid. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} values from log K_{ow} and the molecular connectivity index (MCI) are 1.153 and 1.0 L/kg ,respectively.

D. Bioaccumulation

There are no bioaccumulation studies on acetic acid. Bioaccumulation of acetic acid is not expected to occur because acetic acid dissociates completely in aqueous solution to acetate and its hydrogen ion. Both ions are ubiquitous in the environment. Acetate is naturally found in eukaryotic and prokaryotic cells and is involved in their biochemical pathways.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Acetic acid is a corrosive liquid. Depending on the concentration, aqueous solutions of acetic acid are either corrosive, irritating, or non-irritating to the skin, eyes, and gastrointestinal tract. Vapours from aqueous solutions of acetic acid can cause respiratory irritation. There are no adequate repeated dose toxicity studies on acetic acid. Acetic acid is not genotoxic. Positive findings have been reported in some *in vitro* genotoxicity studies, and are considered to be the result of the pH change in the test system. Animals studies have shown no developmental toxicity from ingestion of acetic acid.

B. Acute Toxicity

The oral LD_{50} of the sodium salt of acetic acid in rats is 3,310 mg/kg (Woodard et al., 1941; ECHA) [Kl. score =2]. The oral LD_{50} of the acetic acid in unfasted rats is 3,530 mg/kg (ECHA) [Kl. score =4]. The oral LD_{50} of the sodium salt of acetic acid in mice is 4,960 mg/kg (Smyth et al., 1951; ECHA) [Kl. score =2].

The 4-hour inhalation LC_{50} in rats for acetic acid vapor is 11.4 mg/L. There were clinical signs that were indicative of corrosion (ECHA) [Kl. score = 2].

C. Irritation

Application of a 3.3% or a 10% aqueous solution of acetic acid to the skin of rabbits for 4 hours was slightly irritating. The Primary Dermal Irritation Index scores were 0.5 and 1.1, respectively (Nixon et al., 1990; ECHA) [Kl. score = 2]. Application of a 10% solution of acetic acid to the skin of rabbits for 4 hours under semi-occlusive conditions was slightly irritating (ECHA) [Kl. score = 2].

Instillation of 0.1 mL of a 10% solution of acetic acid to the eyes of rabbits was considered irritating. The mean of the 24, 48, and 72 hours scores were: 2.67 for erythema; 1.67 for chemosis; 1.72 for corneal opacity; and a mean of 87% corneal swelling (Jacobs and Martens, 1989; ECHA) [Kl. score = 2]

D. Sensitization

No studies are available.

E. Repeated Dose Toxicity

<u>Oral</u>

No adequate studies for human health risk assessment are available.

Inhalation

No studies are available.

Dermal

No adequate studies for human health risk assessment are available.

F. Genotoxicity

In Vitro Studies

The *in vitro* genotoxicity studies on acetic acid are presented below in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Acetic Acid

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* strains)	NC	-	2	Ishidate et al. (1984); ECHA
Bacterial reverse mutation (*S. typhimurium* strains)	-	-	2	Zeiger et al. (1992); ECHA
Chromosomal aberrations (CHO cells)	-**	-**	2	Morita et al. (1990); ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-***	-***	2	Seifried et al. (2006); ECHA

*+, positive; -, negative; NC, not conducted.
**A dose-dependent increase in chromosomal aberrations was observed with 10 mM acetic acid (-S9) and 8 mM acetic acid (+S9). These concentrations were close to the cytotoxic limit at which the cells could no longer be evaluated. These effects were abolished by neutralizing the test medium or increasing the buffer capacity. These results suggest that the positive findings are due to the acidic pH of the incubation medium rather than a consequence of an intrinsic clastogenic potential of acetic acid.
***Acetic anhydride (hydrolyzes to acetic acid in aqueous media).

In vivo Studies

No studies are available on acetic acid.

A bone marrow micronucleus study has been conducted on acetic anhydride (which hydrolyses to acetic acid). Male and female SD rats were exposed by inhalation to 0, 1, 5, or 20 ppm acetic anhydride, 6 hours/day, 5 days/week for 13 weeks. The incidence of micronucleated immature erythrocytes was not increased at any exposure concentration (ECHA) [Kl. score = 1]

G. Carcinogenicity

No oral or inhalation studies are available.

No deaths and no skin tumors were seen when acetic acid was applied dermally once a week to CD-1 mice for 32 weeks (Slaga et al., 1975; ECHA) [Kl. score = 4].

H. Reproductive Toxicity

No studies are available.

I. Developmental Toxicity

Pregnant female Wistar rats were dosed by oral gavage with 0 or various concentrations up to 1,600 mg/kg apple cider vinegar (5% acetic acid) on gestational days 6 to 15. There were no maternal or developmental toxicity at any dose level. The NOAEL for maternal and developmental toxicity is 1,600 mg/kg-day (ECHA). [Kl. score = 2]

Pregnant female CD-1 mice were dosed by oral gavage with 0, 16, 74.3, 345, or 1,600 mg/kg apple cider vinegar (5% acetic acid) on gestational days 6 to 15. There were no treatment-related effects on maternal or fetal survival, or on soft or skeletal tissues. There was no effect on the fetal development in the presence of slight maternal toxicity (reduced body weight gain) at 345 mg/kg. At 1,600 mg/kg, there was an increase in the number of litters containing a dead fetus and some reductions in ossification. The NOAELs for maternal and developmental toxicity are 74.3 and 345 mg/kg-day, respectively (ECHA). [Kl. score = 2]

Pregnant female Dutch-belted rabbits were dosed by oral gavage with 0, 16, 74.3, 345, or 1,600 mg/kg apple cider vinegar (5% acetic acid) on gestational days 6 to 18. There were no treatment-related effects on maternal or fetal survival, or on soft or skeletal tissues. There was a reduction in the pregnancy rate in the high-dose group; and a dose-dependent decrease in maternal body weights at $\geq$74.3 mg/kg. Some deaths or abortions occurred in all treated groups and some litter losses were reported at $\geq$345 mg/kg. Maternal effects were much more noticeable than the effects on fetal development. These findings have been considered a consequence of the bactericidal properties of orally administered acetic

acid within the gastrointestinal tract of female rabbits, and not a direct effect on embryonic implantation and development of acetic acid (EU, 2008). It is likely that this accounts for the apparent increased sensitivity of this species to oral administration of acetic acid. The NOAEL for developmental toxicity is 1,600 mg/kg-day; a NOAEL for maternal toxicity was not identified (ECHA). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for acetic acid follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

There are no repeated dose toxicity studies that were considered adequate for human health risk assessment.

The Joint FAO/WHO Expert Committee on Food Additives (JECFA) has maintained a group ADI of "not limited" for acetic acid and its potassium and sodium salts (JECFA).

The Australian drinking water guidance value for pH may apply to acetic acid.

B. Cancer

There are no carcinogenicity studies by the oral or inhalation route. A dermal carcinogenicity study in mice showed no carcinogenic activity when acetic acid was applied to the skin for 32 weeks. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Acetic acid is a flammable liquid.

Acetic acid does not exhibit the following physico-chemical properties:

- Explosivity
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Acetic acid is of moderate acute toxicity concern to aquatic organisms, in part because of the effect of pH changes from the dissociated hydrogen ion. The acetate ion is of low acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 presents the results of acute aquatic toxicity studies on acetic acid and potassium acetate.

Table 3: Acute Aquatic Toxicity Studies on Acetic acid and Potassium Acetate

Test Substance	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Potassium acetate	*Oncorhynchus mykiss*	96-h LC_{50}	>300.82*	2	ECHA
Potassium acetate	*Danio rerio*	96-h LC_{50}	>300.82*	2	ECHA
Acetic acid	*Oncorhynchus mykiss*	96-h LC_{50}	64.8 (measured)	4	ECHA
Acetic acid	*Oncorhynchus mykiss*	96-h LC_{50}	31.3 – 67.6	4	ECHA
Potassium acetate	*Daphnia magna*	48-h EC_{50}	>300.82*	2	ECHA
Acetic acid	*Daphnia magna*	48-h EC_{50}	79.5 (measured)	4	ECHA
Acetic acid	*Daphnia magna*	48-h EC_{50}	18.9 (measured)	4	ECHA
Acetic acid	*Desmodesmus subspicatus*	72-h EC_{50}	486.5	4	ECHA

*As the acetate ion.

Chronic Studies

In a 21-day fish (*Oncorhynchus mykiss*) chronic study, the measured NOEC values for 60% and 100% acetic acid were 57.2 and 34.3 mg/L, respectively (ECHA). [Kl. score = 4]

In a 21-day *Daphnia* reproduction study, the measured NOEC for 60% and 100% acetic acid were 80 and 31.4 mg/L, respectively (ECHA). [Kl. score = 4]

In a 21-day *Daphnia* reproduction study, the measured NOEC for 100% acetic acid was 22.7 mg/L (ECHA). [Kl. score = 4]

C. Terrestrial Toxicity

No data are available.

D. Calculation of PNEC

The PNEC calculations for acetic acid follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. For the acute toxicity studies, data are available on both acetic acid and potassium acetate; both substances dissociate completely in aqueous media to the acetate anion and the corresponding cations (H^+ and K^+). The toxicity of these substances is expected to be driven by the acetate ion, with the cations having a minor role. The toxicity data on potassium acetate are preferred because of the absence of a potential pH change from the dissociated H^+ ion of acetic acid. For the chronic toxicity studies, only acetic acid has been tested for two trophic levels: fish and invertebrates. These studies will not be used to derive the PNEC value; however, an assessment factor of 100 will be applied to the lowest acute $E(L)C_{50}$ values.

From the potassium acetate studies, acute $E(L)C_{50}$ values (adjusted for acetic acid) are available for fish (300.82 mg/L) and *Daphnia* (300.82 mg/L). By applying an assessment factor of 100 to the $E(L)C_{50}$ value of 300.82 mg/L from either fish or *Daphnia*, the $PNEC_{aquatic}$ for acetic acid is 3.0 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 1.9 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.82/1280) \times 1000 \times 3.0$
$= 1.9$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [(0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [(0.2 \times 0.04/1000 \times 2400]$
$= 0.82$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 1.0 \times 0.04$
$= 0.04$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for acetic acid calculated from EPISUITE™ using the MCI is 1.0 L/kg .
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.04 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.02/1500) \times 1000 \times 3.0$
$= 0.04$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$

= 1.0 x 0.02
= 0.02

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for aceti acid calculated from EPISUITE™ using the MCI is 1.0 L/kg .
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Acetic acid is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Bioaccumulation of acetic acid is not expected to occur because acetic acid dissociates completely in aqueous media to acetate and its hydrogen ion. Both ions are ubiquitous in the environment. Acetate is naturally found in eukaryotic and prokaryotic cells and is involved in their biochemical pathways. The log K_{ow} for acetic acid is -0.17. Thus, acetic acid does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity studies on acetic acid are >0.1 mg/L. The $E(L)C_{50}$ values for potassium acetate are > 1 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Flammable Liquid Category 3
Skin Corrosion Category 1A

EU:
≥90%: Skin Corrosion 1A
≥25% to <90%: Skin Corrosion 1B
≥10% to <25%: Skin irritant Category 2; Eye irritant Category 2

In addition to the hazard statements corresponding the GHS classifications (if Skin Corrosion 1A or 1B is included), the following non-GHS hazard statement is to be added to the SDS: AUH071: Corrosive to the Respiratory Tract.

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. Get medical attention immediately, preferably a physician for an ophthalmologic examination.

Skin Contact
For minor skin contact, avoid spreading material on unaffected skin. Remove and isolate contaminated clothing. Wash the contaminated area of body with soap and fresh water. Get medical attention immediately.

Inhalation
Move person to fresh air. Administer oxygen if breathing is difficult. Do not use mouth-to-mouth method if victim inhaled the substance; give artificial respiration with the air of a pocket mask equipped with a one-way valve or other proper respiratory medical device. Give artificial respiration if victim is not breathing. Get medical attention immediately.

Ingestion
Rinse mouth and lips with plenty of water if person is conscious. Do not induce vomiting. Do not use mouth-to-mouth method if victim had ingested the substance. Obtain medical attention immediately if ingested.

Notes to Physician
Treat as a corrosive due to pH of the material. All treatments should be based on observed signs and symptoms of distress in the patient.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Use water spray or fog, foam, dry chemical or carbon dioxide. Do not use straight streams of water.

Specific Exposure Hazards
Flammable liquid and vapor. Vapors are flammable and heavier than air. Vapors may travel across the ground and reach remote ignition sources causing a flashback fire danger. Emits toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon dioxide, carbon monoxide.

Special Protective Equipment for Firefighters
Structural firefighter's protective clothing provides limited protection in fire situations only; it is not effective in spill situations where direct contact with the substance is possible. Wear chemical protective clothing that is specifically recommended by the manufacturer. It may provide little or no thermal protection. Wear positive pressure self-contained breathing apparatus (SCBA). Move containers from fire area if you can do it without risk.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Isolate area. Keep unnecessary and unprotected personnel from entering the area. Use personal protective clothing. Ensure adequate ventilation. Wear respiratory protection if ventilation is inadequate. Do not breath mist, vapors, or spray Avoid contact with skin, eye, and clothing. Eliminate all sources of ignition.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Eliminate all sources of ignition. All equipment used when handling the material must be grounded. A vapor suppressing foam may be used to reduce vapors. Use clean non-sparking tools to collect absorbed material. Pick up with suitable absorbent material and transfer to a container for chemical waste. For large amounts: dike spillage and pump off product into container for chemical waste. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling

Prevent exposure to ignition sources (i.e., use non-sparking tools and explosion-proof equipment). Avoid contact with eyes, skin, and clothing. Avoid breathing vapor. Wash thoroughly after handling. Keep container closed. Use with adequate ventilation. Use proper bonding and/or ground procedures. However, bonding and grounds may not eliminate the hazard from static accumulation. Peroxides may form upon prolonged storage. Exposure to light, heat or air significantly increases peroxide formation. If evaporated to a residue, the mixture of peroxides residue and material vapor may explode when exposed to heat or shock.

Storage

Keep container tightly closed. Store in a cool, well-ventilated area away from heat and light. Storage containers should be grounded and bonded. Fixed storage containers, transfer containers and associated equipment should be grounded and bonded to prevent accumulation of static charge.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

The workplace exposure standard for acetic acid in Australia is 10 ppm (25 mg/m^3) as a 8-hr TWA and 15 ppm (37 mg/m^3) as a 15-min STEL.

Engineering Controls

Good general ventilation should be used. Ventilation rates should be matched to conditions. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits. If exposure limits have not been established, maintain airborne levels to an acceptable level.

Personal Protection Equipment

Respiratory Protection:

If workers are exposed to concentrations above the exposure limit, they must use appropriate, certified respirators. If there are no applicable exposure limit requirements or guidelines, use an approved respirator. Selection of air-purifying or positive pressure supplied-air will depend on the specific operation and the potential airborne concentration of the product. For emergency conditions, use an approved positive-pressure self-contained breathing apparatus.

Hand Protection:

Use gloves chemically resistant to this material. Consult the SDS for appropriate glove barrier materials.

Skin Protection:

Use protective clothing chemically resistant to the this material. Selection of specific items such as face shield, boots, apron, or full body suit will depend on the task.

Eye protection*:*
Use chemical goggles.

Other Precautions:
Wash hands, forearms, and face thoroughly after handling chemical products, before eating, smoking, and using the lavatory and at the end of the working period. Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

For glacial acetic acid or >80% acetic acid solutions:

UN 2789 (ACETIC ACID, GLACIAL or ACETIC ACID SOLUTION)
Class: 8
Packing Group: II

For ≥50% to 80% acetic acid solutions:

UN 2790 (ACETIC ACID SOLUTION)
Class: 8
Packing Group: II

For >10% to <50% acetic acid solutions:

UN 2790 (ACETIC ACID SOLUTION)
Class: 8
Packing Group: III

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

ALCOHOLS, C12-15, ETHOXYLATED

This dossier on alcohols, C12-15, ethoxylated does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of alcohols, C12-15, ethoxylated in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained primarily from the Human & Environmental Risk Assessment on Ingredients of European Household Cleaning Products: Alcohol Ethoxylates (HERA, 2009), and from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA).. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Alcohols, C12-15, ethoxylated

CAS RN: 68131-39-5

Molecular formula: Not available (UVCB substance)

Molecular weight: Not available (UVCB substance)

Synonyms: Alcohols, C12-15, ethoxylated

SMILES: Not available (UVCB substance)

Alcohol ethoxylates (AE) are a class of non-ionic surfactants that have the basic structure $C_{x-y}AE_n$. The subscript (x-y) following the 'C' indicates the range of carbon chain units. The hydrocarbon chain can be either linear or branched. AEs also contain an ethylene oxide (E) chain attached to the alcohol. The degree of ethylene oxide polymerization is indicated by the subscript (n) which indicates the average number of ethylene oxide units. Alcohols, C12-15, ethoxylated (CAS No. 68131-39-5) has an average number of 1 to 2.5 moles of ethylene oxide units.

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Alcohols, C12-15, Ethoxylated (1 to 2.5 moles ethoxylated)

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Clear liquid with a rancy odor*	2	ECHA
Melting Point	7.22°C	2	ECHA
Boiling Point	ca. 287°C	1	ECHA
Density	0.926 g/cm^3 @ 15.56°C	1	ECHA

Vapor Pressure	Negligible	-	ECHA
Partition coefficient (log K_{ow})	5.06* @ 25°C	2	ECHA
Water Solubility	7 – 63 mg/L @ 25°C	2	ECHA
Flash Point	165.56°C	2	ECHA
Auto flammability	235°C	2	ECHA
Viscosity	28.1 mPA s (dynamic) @ 20°C	2	ECHA

*Based on alcohols, C12-14, ethoxylated (1 to 2.5 EO) [CAS No. 68439-50-9]
**Weight-averaged log K_{oc} of whole substance based on normalized composition

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Alcohols, C12-15, ethoxylated is readily biodegradable. It has a low potential for bioaccumulation and a moderate potential for absorption to soil and sediment.

B. Biodegradation

Alcohols, C12-15, ethoxylated is readily biodegradable. In an OECD 301B test, degradation was 72% in 28 days, but failed the 10-day window (ECHA) [Kl. score = 1].

An alcohol, C12-15, ethoxylated (7 EO) degraded 80 to 88% in 28 days when tested using a shake-flask CO_2-evolution test method (ECHA) [Kl. score = 2].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for alcohols, C12-15, ethoxylated. Using KOCWIN in EPISUITE™ (EPA, 2019), the estimated K_{oc} values for surrogates of alcohols, C12-15, ethoxylated are:

C12 linear alcohol, ethoxylated (2 EO): 279.5 L/kg (MCI) and 464.2 L/kg (K_{ow})

C15 linear alcohol, ethoxylated (2 EO): 1,691 L/kg (MCI) and 3,018 L/kg (K_{ow})

E. Bioaccumulation

The BCF values for alcohol ethoxylates in fathead minnows have been reported to range from <5 to 387.5 (Toll et al., 2000). The uptake rates varied from 330 to 1660 (L x kg/d) and elimination rates varied from 3.3 to 59 per day (Toll et al., 2000). The high concentrations in fish is thought

to be prevented by an efficient biotransformation of the alcohol ethoxylates, leading to a high elimination rate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The acute toxicity of alcohols, C12-15, ethoxylated is low by the oral and dermal routes. The skin irritation rabbit studies on alcohols, C12-15, ethoxylated have shown mixed results, but human patch studies on these alcohol ethoxylates do not support a skin irritant classification. Alcohols, C12-15, ethoxylated is expected to be irritating to the eyes of rabbits. Alcohols, C12-15, ethoxylated is not a skin sensitizer. Repeated dose toxicity studies on alcohol ethoxylates similar to alcohols, C12-15, ethoxylated in rats do not indicate any target organ effects. These alcohol ethoxylates are not genotoxic, carcinogenic, and have a low potential for reproductive and developmental toxicity.

B. Acute Toxicity

No acute toxicity studies are available on alcohols, C12-15, ethoxylated.

The oral LD_{50} in rats for $C_{12\text{-}15}AE_3$ is >5,000 mg/kg (ECHA) [Kl. score = 2]. The oral LD_{50} in rats for $C_{12\text{-}15}AE_7$ is 1,700 mg/kg (HERA, 2009) [Kl. score = 2]. The oral LD_{50} value in rats for $C_{12\text{-}13}AE_{6.5}$ is 2,100 mg/kg (HERA, 2009) [Kl. score = 2]. The oral LD_{50} value in rats for $C_{12\text{-}15}AE_{11}$ is >2,000 mg/kg in males and between 1,000 and 2,000 mg/kg in females (HERA, 2009) [Kl. score = 2]. The oral LD_{50} values in rats for $C_{14\text{-}15}AE_{13}$ in two separate studies are 1,100 and 1,000 mg/kg (HERA, 2009) [Kl. score = 2]. The relative number of EO units, but not the carbon chain length, appears to influence acute oral toxicity (HERA, 2009).

An acute dermal LD_{50} values of >2,000 mg/kg were determined for $C_{12\text{-}14}AE_3$ and $C_{12\text{-}14}AE_6$ in two separate studies (HERA, 2009) [Kl. score = 2]. The acute dermal LD_{50} of $C_{12\text{-}15}AE_7$ is >2,000 mg/kg (HERA, 2009) [Kl. score = 2].

C. Irritation

Skin
Application of 0.5 mL isotridecanol, ethoxylated (3 EO) to the skin of rabbits for 4 hours under occlusive conditions was considered irritating (ECHA) [Kl. score = 2].

Application of 0.5 mL isotridecanol, ethoxylated (3 EO) to the skin of rabbits for 4 hours under semi-occlusive conditions was not considered irritating (ECHA) [Kl. score = 2].

In a 24-hour human patch test, there was some short-lived redness in some individuals from the application of $C_{12\text{-}14}AE_3$, but there was no scaling or edema in any subjects (HERA, 2009) [Kl. score = 2].

In a standard 4-hour human patch test, the irritation potential of $C_{12\text{-}15}AE_5$ and $C_{12\text{-}15}AE_5$ were compared to 20% sodium dodecyl sulfate (which is classified a skin irritant under GHS). The results showed that neither alcohol ethoxylate should be classified as a skin irritant (Basketter et al., 2004) [Kl. score = 2].

Eye

Most alcohol ethoxylates tested as the undiluted neat test material are moderately to severely irritating to the eyes of rabbits, with an eye irritation index (EII) ranging from >25 to 50 (HERA, 2009). The alcohol ethoxylates $C_{12\text{-}14}AE_3$, $C_{12\text{-}14}AE_6$, $C_{13}AE_6$, and $C_{12\text{-}14}AE_{10}$ were found to be moderately to severely irritating to the eyes of rabbits (HERA, 2009). In another study, $C_{12\text{-}15}AE_{11}$ was considered moderately to severely irritating to the eyes of rabbits (HERA, 2009).

Some alcohol ethoxylates were reported to be practically or minimally irritating to the eyes of rabbits with EII scores of 0.5 to 15. These alcohol ethoxylates include: $C_{12\text{-}15}AE_3$, $C_{14\text{-}15}AE_7$, $C_{12\text{-}14}AE_{15}$, $C_{14\text{-}15}AE_{18}$, and $C_{13}AE_{20}$ (HERA, 2009).

D. Sensitization

No sensitization studies are available on alcohols, C12-15, ethoxylated.

In a guinea pig maximization test, $C_{12\text{-}13}AE_{<2.5}$ (CAS No. 66455-14-9) was not considered a skin sensitizer (ECHA) [Kl. score = 2].

In a guinea pig maximization tests, $C_{12\text{-}15}AE_3$, $C_{12\text{-}15}AE_7$, and $C_{14\text{-}15}AE_7$ were not considered skin sensitizers (HERA, 2009) [Kl. scores = 2].

E. Repeated Dose Toxicity

Oral

Rats were given in their diet 0%, 0.0313%, 0.0625%, 0.125, 0.25, 0.5 or 1.0% $C_{12\text{-}15}AE_7$ for 90 days. The animals in the $\geq$0.25% groups showed significantly reduced body weight gain, which was associated with marked decreases in food and water consumption. Relative liver weights were significantly increased in the $\geq$0.5% male rats and $\geq$0.25% females. Histopathologic examination showed hepatocytic enlargement in the $\geq$0.125% groups, suggesting increased liver metabolism on the basis of increased alkaline phosphatase activity at the higher dose levels. The NOAEL was established at 0.0625% in the diet or 102 mg/kg-day (HERA, 2009) [Kl. score = 2].

Rats were fed $C_{12\text{-}14}AE_7$ in the diet at concentrations of 0%, 0.0313%, 0.0625%, 0.125%, 0.25%, 0.5% and 1.0% for 90 days. The animals in the $\geq$0.25% groups showed significantly reduced body weight gain, which was associated with marked decreases in food and water consumption. Relative liver weights were significantly increased in the $\geq$0.5% male rats and $\geq$0.25% females. Histopathologic examination showed hepatocytic enlargement in the $\geq$0.125% groups, suggesting increased liver metabolism on the basis of increased alkaline phosphatase activity at the higher dose levels. The NOAEL was established at 0.0625% in the diet or 110 mg/kg-day (HERA, 2009) [Kl. score = 2].

Male and female Wistar rats given in their diet 0, 300, 1,000, 3,000, and 10,000 ppm $C_{14\text{-}15}AE_7$ for 90 days. There were no deaths during the study. Mean body weights and feed were lower in 10,000 ppm males and the 3,000 ppm females. Feed consumption was lower in the 10,000 ppm animals and the 3,000 ppm females. Relative liver weights were increased in the $\geq$3,000 ppm

animals, and relative spleen weights were increased in the 10,000 ppm males. Clinical chemistry changes were noted in the 10,000 ppm group and consisted of significantly higher urea, chloride and potassium levels in males; significantly higher urea, chloride and cholesterol in females. Increased total leucocytes and lymphocytes were seen in the 10,000 ppm animals and in the 3,000 ppm males. The 10,000 ppm females showed lower numbers of neutrophils; mean cell volume and mean cell hemoglobin were identified in one or both sexes fed in the ≥3,000 ppm dose groups. In the 1,000 ppm females, there were minor, but statistically significant changes in the liver and kidney weights and plasma urea concentration; these effects were considered to be of no toxicological significance. Histopathologic examination showed no treatment-related effects at any dose level. The NOAEL for this study is 1,000 ppm in the diet, which corresponded to 50 mg/kg-day (HERA, 2009) [Kl. score = 2].

Rats were given in their diet 0, 0.1, 0.5, or 1% $C_{14\text{-}15}AE_7$ for 90 days. Body weights, food intake, organ weights, and hematology and clinical chemistry parameters were similar across groups. The NOAEL for this study is 1% in the diet, which corresponded to 700 and 785 mg/kg-day for males and females, respectively (HERA, 2009) [Kl. score = 2].

Rats were given in their diet 0, 0.1, 0.5 or 1% $C_{12\text{-}13}AE_{6.5}$ or $C_{14\text{-}15}AE_7$ for two years. Body weight gain was reduced in the 1% males and ≥0.5% females, which was likely due to the reduced food consumption in these animals. At study termination, organ to body weight ratios were increased in the ≥0.5% females (liver, kidney and brain), 1% females (heart), and 1% males (liver). A dose-related focal myocarditis was observed in males. While focal myocarditis is commonly observed in non-treated aging rats, the incidence in the treated animals were higher than in the controls. The NOAEL was established at 0.1% or 50 mg/kg-day (HERA, 2009) [Kl. score = 2].

Male and female CR rats were given in their diet $C_{14\text{-}15}AE_7$ at 0.1, 0.5 and 1% for two years. A treatment-related body weight depression was observed in females at the two highest treatment levels and in males at the 1% dose level, probably due to the poor palatability of the diet. Relative liver, kidney, heart, and thyroid/parathyroid gland weights were increased in the 1% dietary group at study termination. Histopathological examination showed a dose-related increase in the incidence of focal myocarditis at the 12-month time point, but not at the end of the study at two years. The NOAEL for this study was considered to be 0.5% in the diet, which corresponded to 162 and 190 mg/kg-day for males and females, respectively (HERA, 2009) [Kl. score = 2].

Inhalation

No studies are available.

Dermal

No adequate studies are available.

F. Genotoxicity

In Vitro Studies

The genotoxicity studies conducted on alcohol ethoxylates are reviewed in HERA (2009). The results of few of the *in vitro* studies on similar alcohol ethoxylates to alcohols, C12-15,

ethoxylated are presented below in Table 2.

Table 2: *In Vitro* Genotoxicity Studies on Selected Alcohol Ethoxylates

Test Substance	Test System	Results*		Klimisch Score	References
		-S9	+S9		
$C_{14-15}AE_7$	Bacterial reverse mutation (*S. typhimurium* strains)	-	-	2	HERA, 2009
$C_{14-15}AE_7$	Bacterial reverse mutation (*S. typhimurium* strains)	-	-	2	HERA, 2009
$C_{14}AE_{12}$	Chromosomal aberrations (CHO cells)	-	-	2	HERA, 2009

*+, positive; -, negative

In Vivo Studies

In two separate studies, CD-1 mice were given an intraperitoneal dose of 0, 50, or 100 mg/kg $C_{12-15}AE_3$ or $C_{12-14}AE_9$. There were no increases in the frequency of micronuclei in the bone marrow cells (Talmage, 1994) [Kl. score = 2].

Male and female Tunstall rats were given a single oral gavage dose of 0, 250, 500, or 1,000 mg/kg $C_{14-15}AE_7$. There were no increases in chromosomal aberrations in the bone marrow cells (HERA, 2009 [Kl. score = 2].

G. Carcinogenicity

No studies are available on alcohols, C12-15, ethoxylated.

Male and female Sprague-Dawley rats were given in their diet $C_{12-13}AE_{6.5}$ in the diet at doses up to 1% (500 mg/kg-day). Reduced food consumption was noted at the higher dose levels (*i.e.*, 0.5 and 1% for females and 1% for males), resulting in a lower body weight gain compared to the control group. No treatment-related histopathology was found and no increase in tumor incidence was observed (HERA, 2009) [Kl. score = 2].

Male and female Charles River rats were given in their diet 0, 0.1, 0.5 or 1% $C_{14-15}AE_7$ for two years. There were no treatment-related changes in general behavior and appearance. The survival rate of the test animals was comparable if not better than the controls. Body weights of the 0.5% females and the 1% males and females had significantly lower weight gains than the control. There were no treatment-related effects on organ weights and tumor incidence (HERA, 2009) [Kl. score = 2].

Male and female Sprague-Dawley rats were given in their diet $C_{14-15}AE_7$ at 0.1, 0.5 and 1% for two years. A treatment-related body weight depression was observed in females at the two highest treatment levels and in males at the 1% dose level, probably due to the poor palatability of the diet. There was no evidence for any carcinogenic activity (HERA, 2009) [Kl. score = 2].

H. Reproductive Toxicity

No studies are available on alcohols, C12-15, ethoxylated.

CD rats were given in their diet 0, 0.05, 0.1 or 0.5% (approximately 0, 25, 50 or 250 mg/kg-day) $C_{12}AE_6$ in a two-generation reproductive toxicity study. There were no treatment related effects in the parents or pups on general behavior, appearance or survival. At 0.5%, there was reduced weight gain in both the parental animals and the pups compared to the controls. Fertility was unaffected by treatment. The NOAEL for reproductive toxicity is 0.5% in the diet, which corresponds to 250 mg/kg-day (HERA, 2009) [Kl. score = 2].

In a two-generation developmental and teratogenicity study, CD rats were given in their diet 0, 0.05, 0.1 or 0.5% $C_{14\text{-}15}AE_7$ (approximately 0, 25, 50 or 250 mg/kg-day). Three of the treated groups were given the test substance continuously throughout the study; in the other three groups the females received the test substance on GD 6-15 and the males were untreated. None of the deaths of parental rats during the study was considered to be compound-related. There were no treatment-related changes in behavior or appearance in the parental rats or pups. Slightly lower body weight gain was noted in the 0.5% continuously treated females. Food consumption was similar for control and treated rats. Fertility, gestation and viability indices were similar across groups. The average 21-day body weights for the 0.5% continuous treated pups were significantly lower than that of the control. Relative liver weights of the 0.5% continuously treated F_1 parental animals were increased at the 91-day sacrifice; relative liver weights of the 0.5% continuously treated males were also increased at the 60-day and caesarean section sacrifices. There were no treatment-related histopathological lesions in any of the tissues from the F_0 and F_1 generations. The NOAEL for reproductive toxicity is 0.5% in the diet or 250 mg/kg-day (HERA, 2009) [Kl. score = 2].

I. Developmental Toxicity

No studies are available on alcohols, C12-15, ethoxylated.

In a two-generation reproductive toxicity study, Charles River rats were given in their diet 0, 0.05, 0.1 or 0.5% (about 0, 25, 50 or 250 mg/kg-day) $C_{12}AE_6$. General behavior, appearance and survival were unaffected by treatment. At the 0.5% dose level, adults and pups gained less weight than the control rats. In the 0.5% dose group, there was a statistical increase in embryo lethality and soft tissue anomalies and at the 0.1% there was a statistical decrease in mean fetal liver weight. Neither of these effects was considered to be treatment-related by the authors as they showed no dose response characteristics. The NOAEL for maternal toxicity is 50 mg/kg-day. The NOAEL for developmental and teratogenicity is 0.1% in the diet or 50 mg/kg-day (HERA, 2009) [Kl. score = 2].

Pregnant rabbits were given by oral gavage 0, 50, 100 or 200 mg/kg $C_{12}AE$ from gestational days 2 to 16. Nine control rabbits and 31 treated rabbits died during the study. Surviving rabbits at the 200 mg/kg dose group generally showed slight losses of body weight. At 100 and 200 mg/kg, ataxia and a slight decrease in body weight was observed in the pregnant animals. In seven treated and two control rabbits, early deliveries were recorded. There were no treatment-related effects on corpora lutea, implantations, number of live fetuses and spontaneous abortions. The NOAEL for maternal toxicity is 50 mg/kg-day; the NOAEL for developmental toxicity is 200 mg/kg-day (HERA, 2009) [Kl. score = 2].

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for alcohols, C12-15, ethoxylated follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

Two-year dietary studies in rats have been conducted on alcohol ethoxylates $C_{12\text{-}13}AE_{6.5}$ and $C_{14\text{-}15}AE_{7}$ (HERA, 2009). The lowest NOAEL from these studies is 50 mg/kg-day based on increased organ weights. The NOAEL of 50 mg/kg-day will be used to derive an oral reference dose and drinking water guidance value for alcohols, C12-15, ethoxylated.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 50/(10 x 10 x 1 x 1 x 1) = 50/100 = 0.5 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.5 x 70 x 0.1)/2 = 1.8 mg/L

B. Cancer

Several alcohol ethoxylates similar to alcohols, C12-16, ethoxylated were not carcinogenic to rats in a two-year dietary study. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Alcohols, C12-15, ethoxylated does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Alcohol, C12-15, ethoxylated has moderate chronic toxicity concern to aquatic life.

B. Aquatic Toxicity

In developing a water quality guideline for alcohol ethoxylates (ANZECC, 2000), the toxicity data was normalized for a specific alkyl chain length or a specific number of ethoxylate (EO) groups. The NOECs listed below were normalized to an alkyl chain length of C13.3 and EO of 8.2.

Freshwater fish: 2 species, 720 to 1,500 μg/L.

Freshwater crustaceans: 2 species, 590 to 860 μg/L.

Freshwater rotifers: 1 species, *Brachionus calyciflorus*, 1,300 μg/L

Freshwater algae, diatoms and blue-green algae: 6 species, 200 to 8,700 μg/L.

Freshwater mesocosms: 4 NOEC data for multiple species tests were 80, 80, 320, and 330 μg/L, although replication was insufficient to meet OECD (1992) requirements. Normalized data were 380, 380, 320, and 1,520 μg/L.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

$PNEC_{water}$: The ANZECC water quality guideline (2000) for freshwater is: **"A high reliability trigger value of 140 μg/L was derived for AE (normalized data) using the statistical distribution method with 95% protection."**

For the purposes of calculating the PNEC values for sediment and soil, the $PNEC_{water}$ will be 0.14 mg/L.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ values are 0.9 to 5.6 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (9.28/1500) \times 1000 \times 0.14$
$= 0.87$

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (60.36/1500) \times 1000 \times 0.14$
$= 5.63$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 464 \times 0.02$
$= 9.28$

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 3{,}018 \times 0.02$
$= 60.36$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} values for alcohols, C12-15, ethoxylated based on K_{ow} values range from 464 to 3,018 L/kg (see section III.C)
.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Alcohols, C12-15, ethoxylated is readily biodegradable and thus does not meet the screening criteria for persistence.

The bioconcentration factors (BCF) in fish for ethoxylated alcohols (which includes alcohols, C12-15, ethoxylated) have been reported to range from <5 to 387.5. Thus, alcohols, C12-15, ethoxylated does not meet the screening criteria for bioaccumulation.

The chronic NOEC values for alcohols ethoxylates are >0.1 mg/L. Thus, alcohols, C12-15, ethoxylated do not meet the criteria for toxicity.

The overall conclusion is that alcohols, C12-15, ethoxylated is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Acute Toxicity Category 4 [Oral]
Eye Irritant Category 2
Aquatic Chronic Toxicity Category 3

B. Labelling

Warning

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Rinse immediately with plenty of running water. If easy to do, remove contact lenses. Get medical attention.

Skin Contact
Wash with soap and water. Get medical attention if symptoms occur.

Inhalation
Treat symptomatically. Move to fresh air. Get medical attention.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. Seek medical attention.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, dry chemical, foam. Do not use water jet.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon oxides.

Special Protective Equipment for Firefighters
Self-contained breathing apparatus and full protective clothing must be worn in case of fire.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Wear appropriate personal protective equipment. Do not breath mist or aerosol.

Environmental Precautions
Prevent from entering sewers, waterways, or low area

Steps to be Taken if Material is Released or Spilled
Absorb spill with inert absorbent material, then place in a container for chemical waste.

D. STORAGE AND HANDLING

General Handling
Protect against moisture. Shut containers immediately after taking product because product takes up the humidity of air. No special precautions are necessary beyond normal good hygiene practices.

Other Handling Precautions
Wash hands thoroughly after handling. Avoid breathing mists or aerosols.

Storage
Keep container closed.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure standard for isotridecanol, ethoxylated.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Wear respiratory protection if ventilation is inadequate.

Hand Protection:
Chemical resistant protective gloves.

Skin Protection:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Chemical safety goggles.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Isotridecanol, ethoxylated is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

AMIDES, TALL OILS FATTY, N,N-BIS(HYDROXYETHYL)

This dossier on amides, tall oils fatty, N,N-bis(hydroxyethyl) does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of amides, tall oils fatty, N,N-bis(hydroxyethyl) in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997; Kl).

I. SUBTANCE IDENTIFICATION

Chemical Name: Amides, tall oils fatty, N,N-bis(hydroxyethyl)

CAS RN: 68155-20-4

Synonyms:

Synonyms for oleamide DEA listed below.

While no specific composition data are available on amides, tall oils fatty, N,N-bis(hydroxyethyl), it is expected to be a mixture of diethanolamides of the fatty acids that constitute tall oil, which is composed of predominantly C18 unsaturated fatty acids: 48% oleic acid, 35% linoleic acid, 7% conjugated linoleic acid (REF).

This dossier is based on information on Amides, C18-unsatd, N,N-bis(hydroxyethyl) [CAS No. 93-83-4]. This is justified because amides, tall oils fatty, N,N-bis(hydroxyethyl) is predominantly diethanolamides of unsaturated C18 fatty acids and there are no available studies on this substance.

AMIDES, C18-UNSATD., N,N-BIS(HYDROXYETHYL)

Chemical Name: Oleamide DEA

CAS RN: 93-83-4

Molecular formula: UVCB substance

Molecular weight: UVCB substance

Synonyms for oleamide DEA:
Oleyl diethanolamide;(9Z)-N,N-Bis(2-hydroxyethyl)-9-octadecenamide; (z)-n,n-bis(2-hydroxyethyl)-9-octadecenamide; 9-Octadecenamide, N,N-bis(2-hydroxyethyl)-, (Z)-; Alkamide DO-280;

N,N-Bis(2-hydroxyethyl)-9-octadecenamide; Alrosol O; Amisol ode; Clindrol 2000; Clindrol 2020, Comperlan OD; Diethanololeamide; EMID 6545; Emulsifier WHC; Lauridit OD; Mackamide O, Marlamid D 1885, N,N-Diethanololeamide, Nitrene NO, Oleamide, N,N-bis(2-hydroxyethyl)-, Oleic acid diethanolamide, Oleic acid diethanolamine condensate, Oleic diethanolamide, Schercomid ODA, Stafoam DO, Steinamid DO 280SE, Witcamide 511C

SMILES: Not applicable.

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Amides, C18-unsatd, N,N-bis(hydroxyethyl) [CAS No. 93-83-4]

Property	Value	Klimisch score	Reference
Physical state at 20ºC and 101.3 kPa	Liquid	2	ECHA
Melting point	ca. -80ºC	1	ECHA
Boiling point	>300ºC	1	ECHA
Density	0.967 g/cm^3@ 20ºC	1	ECHA
Vapor pressure	0 Pa @ 25ºC	1	ECHA
Partition coefficient (log K_{ow})	>6 (experimental)	1	ECHA
Water solubility	<1 mg/L @ 20ºC	1	ECHA
Flash point	218ºC	1	ECHA
Auto flammability	350ºC	1	ECHA
Viscosity	805.87 mPa s @ 20ºC	1	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

According to ECHA, hydrolysis studies were not conducted; “the study does not need to be conducted because the substance is readily biodegradable.” (ECHA)

B. Biodegradation

Amides, C18-unsatd, N,N-bis(hydroxyethyl) is readily biodegradable. In an OECD 301 D test, degradation was 70% after 28 days (ECHA) [Kl. score = 1]. In an OECD 301 B test, degradation was 79% after 14 days and 86% after 28 days (ECHA) [Kl. score = 1].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for amides, C18-unsatd, N,N-bis(hydroxyethyl). Using KOCWIN v2.00, the estimated K_{oc} values for the individual components were calculated using the molecular connectivity index (MCI) approach. The final K_{oc} value was calculated on a weighted-average basis using the mole fractions of the individual components. The final K_{oc} value is 1,717 L/kg.

D. Bioaccumulation

There are no bioaccumulation studies on amides, C18-unsatd, N,N-bis(hydroxyethyl). The bioaccumulation potential of amides, C18-unsatd, N,N-bis(hydroxyethyl) was estimated using BCFBAF v3.01. The final BCF was calculated on a weighted-average basis using the mole fractions of all individual components. The calculated BCF was 112.53 L/kg, indicating a low potential for bioaccumulation (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

Human health toxicity data were obtained from ECHA, unless another source is explicitly cited.

A. Summary

Amides, C18-unsatd, N,N-bis(hydroxyethyl) are considered acutely toxic and an skin and eye irritant. It is not considered a skin sensitizer or toxic via repeated doses, and has no reported reproductive or developmental effects. It is not considered genotoxic or carcinogenic.

B. Acute Toxicity

Amides, C18-unsatd, N,N-bis(hydroxyethyl) is considered acutely toxic via oral route of exposure, with an LD50 of 10,000 mg/kg in male Sprague-Dawley rats (Kl = 2).

C. Irritation

Based on the available data, the test substance is considered irritating to both the skin and eyes. The available in vivo studies demonstrate:

- Clear irritation response following semi-occlusive exposure to the test substance for 24 h. The data support a classification as Skin Irrit. 2 - H315 (causes skin irritation) according to CLP (EC 1272/2008) criteria (Kl =1).

- Undiluted test substance showed irritation to rabbit eyes and supports classification as Eye Irrit. 2 – H319 (causes serious eye irritation) according to CLP (EC 1272/2008) criteria (Kl = 1).

D. Sensitization

The test substance is not expected to be a skin sensitiser based on a negative in vivo skin sensitisation study conducted on a structurally similar substance (Kl=1). Therefore no classification is required for sensitisation according to CLP (EC 1272/2008) criteria. There are no data on the respiratory sensitization potential of the substance.

E. Repeated Dose Toxicity

Based on the NOAEL derived from an oral subacute study in rat (>750 mg/kg bw/day) in which no treatment-related effects were observed, and observed effects in a chronic dermal study in rat (NOAEL of 50 mg/kg bw/day for systemic effects and LOAEL of 50 mg/kg bw/day for local effects), the test substance is not considered to meet the requirements for repeated dose toxicity classification according to CLP (EC 1272/2008) criteria. There are no data to evaluate the repeated dose toxicity classification for the inhalation exposure route.

F. Genotoxicity

The test substance and read across substance (amides, C8-18 (even numbered) and C18-unsatd. N,N bis(hydroxyethyl) were negative in short-term in vitro and in vivo genotoxicity tests. Therefore no classification is required for this endpoint according to CLP (EC 1272/2008) criteria.

In Vitro Studies

The *in vitro* studies conducted for this substance are described in Table 2. The referenced studies indicate that the substance is not mutagenic or genotoxic *in vitro.*

Table 2: *In vitro* Genotoxicity Studies

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
In vitro gene mutation study in bacteria (*S. typhimurium* TA97, TA98, TA100 and TA1535)	-	-	2	Irwin, 1999**
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-	-	1	Irwin, 1999**
Bacterial reverse mutation (S. typhimurium and E. coli strains)	-	-	1	Verspeek-Rip, 2014**

*+, positive; -, negative. ** As cited in ECHA.

In Vivo Studies

A study was conducted to evaluate the potential of the test material to induce micronuclei in B6C3F1 mice. Under the conditions of the study, the test substance did not increase the frequencies of micronucleated normochromatic erythrocytes (NCEs) in peripheral blood of both male and female mice at the end of 13 weeks (Kl =1).

G. Carcinogenicity

No studies are available for assessing the carcinogenicity of this substance via the oral or inhalation routes of exposure.

Rodent tests indicate that the substance is not carcinogenic by the dermal route. A study was conducted to evaluate the effects of chronic exposure to the test substance in B6C3F1 mice. Under the test conditions, no evidence of carcinogenic activity was observed with the test substance at any tested dose levels in mice (Kl =1). A study was conducted to evaluate the effects of chronic exposure to the test substance in F344/N rats. Under the test conditions, no evidence of carcinogenic activity was observed with the test substance at any tested dose levels in rats (Kl =1).

H. Reproductive and Developmental Toxicity

No studies were available to assess the effects of the substance on reproduction. No adverse developmental effects were observed following administration of 1,000 mg/kg bw day to pregnant Sprague-Dawley rats (Kl = 2).

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The lowest NOAEL from these studies is a 750 mg/kg bw/day based on bodyweight, hematology, clinical chemistry, urinalysis, gross and microscopic pathology in male and female rats from a 28-day oral gavage study (Potokar, 1983). The NOAEL of 750 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10

UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 750/(10 x 10 x 1 x 10 x 1) = 750/1000 = 7.5 mg/kg-day

Drinking water guidance value

The drinking water guidance value is calculated as:

(animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD, the drinking water guidance value is calculated as:

(oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:

Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (7.5 x 70 x 0.1)/2 = 26.3 mg/L

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on amides, C18-unsatd, N,N-bis(hydroxyethyl).

Table 3: Acute Aquatic Toxicity Studies on Amides, C18-unsatd, N,N-bis(hydroxyethyl)

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rerio	96-hr LC_{50}	5.1	1	ECHA
Daphnia magna	48-hr EC_{50}	3.2	2	ECHA
Desmodesmus subspicatus	72-hr EC_{50}	18.6	2	ECHA

Chronic Studies

The 28-day NOEC to *Oncorhynchus mykiss* in a fish chronic toxicity study is 0.32 mg/L [nominal] and 0.26 mg/L [measured] (ECHA) [Kl. score = 2].

The 21-d NOEC in a *Daphnia* reproduction test is 0.1 mg/L [nominal] and 0.07 mg/L [measured] (ECHA) [Kl. score = 2].

The 72-hr EC_{10} to *Desmodesmus subspicatus* is 1.4 mg/L (ECHA) [Kl. score = 2].

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for amides, C18-unsatd, N,N-bis(hydroxyethyl) follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (5.1 mg/L), invertebrates (3.2 mg/L), and algae (18.6 mg/L). Results from chronic studies are available for fish (0.26 mg/L), invertebrates (0.07 mg/L), and algae (1.4 mg/L). On the basis that the data consists of short-term and long-term results for three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC or EC_{10} value of 0.07 mg/L for invertebrates. The $PNEC_{water}$ is 0.007 mg/L.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.16 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (34.34/1500) \times 1000 \times 0.007$
$= 0.16$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 1717 \times 0.02$
$= 34.34$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for Amides, C18-unsatd, N,N-bis(hydroxyethyl) based on the molecular connectivity index (MCI) is 1,717 L/kg (ECHA).
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Amides, C18-unsatd, N,N-bis(hydroxyethyl) is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Based on an estimated BCF value of 113 L/kg, amides, C18-unsatd, N,N-bis(hydroxyethyl) does not meet the criteria for bioaccumulation.

The lowest chronic NOEC or EC_{10} value for amides, C18-unsatd, N,N-bis(hydroxyethyl) is <0.1 mg/L. Thus, amides, C18-unsatd, N,N-bis(hydroxyethyl) meets the criteria for toxicity.

The overall conclusion is that amides, C18-unsatd, N,N-bis(hydroxyethyl) is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Skin Irritant Category 2
Eye Irritant Category 2
Aquatic Chronic Toxicity Category 2

May cause respiratory tract irritation.

B. Labelling

Warning

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Rinse thoroughly for at least 15 minutes and consult a physician.

Skin Contact
Remove contaminated clothing. Wash with soap and plenty of water. Consult a physician immediately.

Inhalation
Move the person to fresh air.

Ingestion
Rinse mouth with water; consult a physician immediately. Do not induce vomiting.

Notes to Physician
No data available

Medical Conditions Aggravated by Exposure

No data available

Emergency Personnel Protection
No additional notes

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, alcohol-resistant foam, dry chemical, or carbon dioxide.

Specific Exposure Hazards
May be combustible at high temperatures; container explosion may occur under fire conditions or if heated. Hazardous combustion products include carbon oxides and nitrogen oxides.

Special Protective Equipment for Firefighters
As in any fire, wear self-contained breathing apparatus and full protective gear.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Remove all sources of ignition. Ensure adequate ventilation. Use personal protective equipment. Avoid dust formation. Avoid breathing vapours, mist, or gas. Evacuate unprotected persons.

Environmental Precautions
Stop the spill if possible and safe. Prevent from reaching drains, sewers, or waterways.

Steps to be Taken if Material is Released or Spilled
Contain spill material by diking or using inert absorbent such as vermiculite, dry sand, or earth. Transfer to a disposal or recovery container.

D. STORAGE AND HANDLING

General Handling
Avoid contact with skin and eyes. Avoid formation of dust and aerosols.

Other Handling Precautions
Provide appropriate exhaust ventilation at places where dust is formed. Do not eat or drink while working with chemical substances.

Storage

Store in a cool, dry, well-ventilated place. Keep container tightly closed.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
No data available.

Engineering Controls
Provide ventilation.

Personal Protection Equipment

Respiratory Protection:
Wear dust mask when handling large quantities

Hand Protection:
Wear impervious gloves, inspect gloves before use.

Skin Protection:
Wear impervious clothing; PPE is to be selected according to the concentration and amount of the substance to be handled.

Eye protection*:*
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN 166(EU).

Other Precautions:
No data available

F. TRANSPORT INFORMATION

UN Number: Not regulated

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

BUTYL ALCOHOL (1-BUTANOL)

This dossier on butyl alcohol (1-butanol) does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of 1-butanol in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997; Kl).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Butan-1-ol

CAS RN: 71-36-3

Molecular formula: C4H10O

Molecular weight: 74.123

Synonyms: 1-Butanol, 1-Butyl alcohol, 1-hydroxybutane, Butan-1-ol, butyl alcohol, Butyl hydroxide, Butylalcohol, CCS 203, ET5740PTB, Hemostyp, Methylolpropane, n-Butanol, n-Butyl alcohol, N300PTB, Nacol 4, PP100, Propylcarbinol

SMILES: CCCCO

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of 1-Butanol

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Clear, colorless liquid with an alcoholic odor	2	ECHA
Melting point	<-90°C	2	ECHA
Boiling point	119°C	2	ECHA
Density	0.81 g/cm^3 @ 20°C	2	ECHA
Vapor pressure	< 10 hPa @20°C	2	ECHA
Partition coefficient (log K_{ow})	1 @ 25°C	1	ECHA

Property	Value	Klimisch score	Reference
Water solubility	66 g/L @ 20°C	1	ECHA
Flash point	35°C	2	ECHA
Auto flammability	355°C	1	ECHA
Viscosity	2.947 mPa s @ 20°C	2	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

1-Butanol is readily biodegradable and not expected to bioaccumulate. No experimental data are available for adsorption/desorption; the estimated Koc value is 3.471 L/kg.

A calculated logKoc of 0.54 is available, suggesting a high mobility of 1-butanol in soil.

B. Biodegradation

1-Butanol is readily biodegradable. In a BOD test, degradation was 87% after 10 days and 92% after 20 day, meeting the 10-day window (ECHA) [Kl. score = 2].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for 1-butanol. Using KOCWIN in EPISUITE™ (EPA, 2019), the estimated K_{oc} value from log K_{ow} is 10.01 L/kg. The estimated K_{oc} value from the molecular connectivity index (MCI) is 3.471 L/kg.

D. Bioaccumulation

There are no bioaccumulation studies on 1-butanol. 1-Butanol is not expected to bioaccumulate based on a log K_{ow} of 1.0 (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Butyl alcohol is slightly acutely toxic to experimental animals via the oral and dermal routes of exposure; a low acute toxicity was observed after inhalative exposure. The chemical is classified in Australia as respiratory system and skin irritant but is not

considered a skin sensitiser. Butyl alcohol is not expected to be genotoxic; although there are no data on the carcinogenicity of butyl alcohol, based on the lack of genotoxicity, it is not expected to be. Few studies have evaluated reproductive or developmental toxicity but the available studies do not indicate reproductive or developmental effects. Any developmental toxicity is expected to be secondary to maternal toxicity.

B. Acute Toxicity

Butyl alcohol is slightly acutely toxic to experimental animals via the oral and dermal routes of exposure; a low acute toxicity was observed after inhalative exposure.

Oral

The most sensitive LD50 value was provided by a study comparable to OECD TG 401 (Union Carbide Corporation 1967). Here, 60 -day-old female Harlan Wistar rats were dosed with butan-1 -ol at various dose levels per gavage. The acute LD50 value was 2.83 mL/kg bw in female rats, corresponding to 2290 mg/kg bw (calculated with a density of 0.81 g/mL). No further data were available.

A comparable LD50 level was observed in a study following the standard acute method with acceptable restrictions (Jenner et al.1967). In this study, 5 young adult Osborne-Mendel rats per sex were dosed with butan-1-ol at different, but unspecified doses. The rats were observed for 14 days and the LD50 values were calculated. After 14 d observation period, the LD50 was 2510 mg/kg bw in rats. Mortality occurred within 4 -18 h after dosing, and depression and coma were reported as clinical signs. Weighing and performance of necropsy was not reported.

In another oral acute study, groups of 10 female rats were orally gavaged with 3160, 3980, 5000 or 6300 mg/kg and observed for 14 days after dosing. Here, 0, 3, 8 and 10 rats died at dose levels of 3160, 3980, 5000 or 6300 mg/kg, respectively. Deaths following oral doses occurred in many cases within 4 hours and in all but one instance within 24 hours. The LD50 was 4360 mg/kg/bw for female rats (Union Carbide Corporation 1951).

For other common test species oral LD50 values were reported with limited details: 2680 mg/kg bw for mice (Rumyanstev et al., 1979, Val. 4), 3500 mg/kg bw for rabbits (Munch, 1972; Munch and Schwarze, 1925, Val. 4), 1200 mg/kg bw for Golden hamsters (Dubina and Maksimov, 1976, Val. 4), and a minimum lethal dose of 1782 mg/kg bw for dogs (Von Oettingen, 1943, Val. 4). In the ECETOC JACC (2003) document also one publication with an oral LD50 in rats below 2000 mg/kg (790 mg/kg) is reported.

Dermal

The most reliable data were provided by a study comparable to OECD TG 402 (Union Carbide Corporation 1951). Here, butan-1 -ol was applied to the shaved skin of rabbits for 24 hours under occlusive conditions. Four doses of 1.26 to 10 ml/kg were applied to groups of four male rabbits and a LD50 value of 4.24 ml/kg bw (corresponding to ca. 3434 mg/kg bw; calculated with a density of 0.81 g/mL) was determined after an observation period of 14 days. Three rabbits of the 5 mL/kg bw group and all rabbits of

the 10 ml/kg bw group died; all deaths occurred on the day of application. Body weight gain during the observation period was highly variable in the sublethal dose groups and negative in the survivor of the 5 mL/kg bw group. No information regarding clinical signs or local effects was available. In the ECETOC JACC (2003) document further dermal LD50 values in rabbits of 7600, 5300 and 4200 mg/kg are reported.

Inhalation

In a study similar to OECD TG 403, 10 Sprague-Dawley rats per sex per dose were whole-body exposed to vapour atmospheres of butan-1-ol for 4 h and observed for 14 d. The LC0 is >17.76 mg/L; no mortality or clinical signs were observed at 17.76 mg/L; only slightly reduced body weight gain was observed. Therefore, the LD50 level is considered to be > 20 mg/L (BASF 1979).

In another study, which was similar to the inhalation hazard test of OECD TG 403, 12 Sprague-Dawley rats of both sexes were exposed to a vapour saturated butan-1-ol atmosphere for 7 h. None of the animals died (BASF 1980).

Additionally, in a further study comparable to OECD TG 403 no mortalities were observed after exposure to a substantially saturated vapour for 8 hours in male rats and after exposure to 8000 ppm (ca. 24 mg/L) for 4 h in female rats, respectively. Poor coordination or prostration was observed in both trials (Union Carbide Corporation 1951).

C. Irritation

Respiratory Irritation

The chemical is classified in Australia as hazardous with the risk phrase ‘Irritating to respiratory system’ (Xi; R37) in HSIS (Safe Work Australia). The available data from observations in animals and humans support this classification.

Based on an inhalation study in mice, it was reported that 1268 ppm (3909 mg/ m^3) of the chemical was predicted to be intolerable in humans, 127 ppm (390.9 mg/ m^3) would be uncomfortable in humans and 13 ppm (40 mg/ m^3) was expected to have no effect on humans (OECD 2001).

Skin Irritation

The chemical is classified in Australia as hazardous with the risk phrase ‘Irritating to skin’ (Xi; R38) in HSIS (Safe Work Australia). The available data from observations in animals and humans support this classification.

Moderate irritation was reported in a 24 hour patch test (non-guideline study) where 405 or 500 mg of the chemical was applied to the skin of the rabbits. It was reported that these effects may be due to the chemical's defatting (chemical dissolving of dermal lipids from the skin) and drying characteristics (OECD 2001).

Another non-guideline study reported the chemical was a skin irritant in several Vienna white rabbits exposed to 0.5 mL of the chemical for five minutes, one hour or two hours under occlusive conditions. The animals were observed for eight days. The authors concluded that exposure for two hours under occlusive conditions resulted in higher Draize scores and observed superficial necrosis (death of tissue). However, there was no full thickness destruction of the skin (REACH).

Eye Irritation

The chemical is classified in Australia as hazardous with the risk phrase 'Risk of serious damage to the eyes' (Xi; R41) in HSIS (Safe Work Australia). The available data from observations in animals and humans support this classification.

The chemical was reported to be a severe eye irritant when tested according to OECD Test Guideline (TG) 405 using 0.1 mL of the chemical applied to three New Zealand white rabbits. Severe ocular lesions were present at the end of the seven-day observation period, indicating severe eye damage and irreversible effects on the eye (REACH).

The chemical was reported to be a severe eye irritant in rabbits in non-guideline studies where 1.62 or 20 mg of the chemical was applied into rabbit eyes over a 24 or 72 hour period (OECD 2001). An additional non-guideline study reported severe corneal irritation when 0.005 mL of the chemical was applied into rabbit eyes.

D. Sensitization

Based on available repeat dose dermal studies, the chemical is not expected to be a skin sensitiser. OECD (2001) reported that human studies and experience show that the chemical is not likely to be a skin sensitiser.

E. Repeated Dose Toxicity

Oral

A no observed adverse effect level (NOAEL) of 125 mg/kg bw/day and a lowest observed adverse effect level (LOAEL) of 500 mg/kg bw/day in male and female CD rats was reported based on results from a repeat dose oral study (Kl = 1) using the chemical (OECD 2001). Groups of male and female rats (30/sex/group) were administered the chemical via gavage at 0, 30, 125 or 500 mg/kg/day for 13 weeks. It was reported that ataxia (impaired muscle coordination) and hypoactivity were observed at the highest dose during the final six weeks of the study. No treatment related effects were reported in the 30 and 125 mg/kg/ bw/day dose groups (OECD 2001).

Inhalation

In a non-guideline study, the chemical was applied to the skin of rabbits under occlusive conditions over a period of 21 days. Local effects were reported such as drying of the skin, cracking, wrinkling and exfoliation of the epidermis. However, no systemic toxicity was reported (REACH). In another non-guideline repeat dose dermal study on rabbits, 42 to 55 mL/kg of the chemical applied to the skin of rabbits over four consecutive days

resulted in 100 % mortality. However, the same study reported that 30 applications of 20 mL/kg of the chemical over six weeks did not produce any deaths (OECD 2001).

Dermal
No data are available.

F. Genotoxicity
The chemical is not expected to be genotoxic.

The chemical tested negative in a number of tests for genotoxicity. These included several in vitro tests (OECD Guideline 473: mammalian chromosome aberration test on Chinese hamster lung fibroblasts V79; OECD Guideline 471: bacterial reverse mutation assay on *S. typhimurium* TA 98, TA 100, TA 98, TA 1535 and TA 1537; OECD Guideline 476: mammalian cell gene mutation test on Chinese hamster lung fibroblasts V79) and in vivo tests (OECD Guideline 474: mouse micronucleus) (OECD 2001, REACH).

In Vitro Studies

Table 2: *In vitro* Genotoxicity Studies on

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (S. typhimurium strain TA 98, TA 100, TA 98, TA 1535 and TA 1537)	-	-	2	Jung et al., 1992
Mammalian cell gene mutation (Chinese hamster lung fibroblasts (V79))	-	-	1	REACH

*+, positive; -, negative

In Vivo Studies
Fewer studies are available for in vivo testing but are also negative for genotoxicity. According to the results of a reliable mouse study conducted according to OECD Guideline 474 (Mammalian Erythrocyte Micronucleus Test) (Kl =1), the single oral administration of butan-1-ol did not lead to any increase in the number of polychromatic erythrocytes containing either small or large micronuclei. The rate of micronuclei was always in the same range as that of the negative control in all dose groups and at all sacrifice intervals. No inhibition of erythropoiesis determined from the ratio of polychromatic to normochromatic erythrocytes was detected.

G. Carcinogenicity
OECD (2001) reported that based on the number of negative mutagenicity and clastogenicity findings, the chemical is not expected to be a carcinogen. A weight of

evidence study reported that the chemical is not expected to have carcinogenic potential as it does not contain structural components to support carcinogenicity (REACH, HSDB).

H. Reproductive and Developmental Toxicity

The chemical is not expected to be toxic to reproduction (OECD 2001). In a non-guideline study, male and female Sprague Dawley (SD) rats were exposed to the chemical via inhalation at 0, 3000 or 6000 ppm for seven hours/day. Female rats were exposed to the chemical throughout gestation, while males were exposed to the chemical for six weeks prior to mating. No harmful effects on fertility or pregnancy rate were reported at any of the dose levels. In another non-guideline study, no testicular toxicity (effect on testes weight or histopathology) was reported in SD male rats that were administered the chemical via oral intubation at 533 mg/kg bw/day over six days (OECD 2001).

Any developmental effects were only reported to be observed secondary to maternal toxicity, so the chemical is not expected to be a developmental toxin. OECD (2001) reported that the chemical showed mild foetotoxicity and developmental variations in offspring only at or near the maternally toxic and, in some cases, lethal dose of 8000 ppm. Offspring of female SD rats exposed via inhalation to 0, 3500, 6000 or 8000 ppm of the chemical on gestations days 1 to 19, reported a reduction of foetal weights at 6000 and 8000 ppm and a slight increase in skeletal malformations at 8000 ppm but not at the lower dosage levels. At a maternally toxic dose of 8000 ppm, decreased weight gain, food consumption and dam deaths were reported. The NOAEL for offspring and dams was 3500 ppm as there was a slight decrease in foetal weight at the 6000 ppm dose level.

In another 20 day study in male and female SD rats exposed to 0, 3000 or 6000 ppm of the chemical via inhalation, a small number of behavioural and neurochemical variations in offspring at 6000 ppm were reported. No maternal toxicity was reported throughout gestation for females or for six weeks prior to mating for males as a result of maternal or paternal exposure. However, the effects observed in offspring were not regarded as biologically significant by the authors due to inconsistences between dose-response patterns.

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for butyl alcohol follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

<u>Oral</u>

The lowest NOAEL from these studies is 125 mg/kg-day based on CNS effects in rats from a 90-day oral gavage study (Kl = 1; REACH). The NOAEL of 125 mg/kg-day will

be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 3
UF_D (database uncertainty) = 1

Oral RfD = 125/(10 x 10 x 1 x 3 x 1) = 125/300 = 0.4 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:

Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.4 x 70 x 0.1)/2 = 1.4 mg/L

B. Cancer

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

1-Butanol is a flammable liquid.

1-Butanol does not exhibit the following physico-chemical properties:

- Explosivity
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on 1-butanol.

Table 3: Acute Aquatic Toxicity Studies on 1-Butanol.

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephelas promelas	96-hr LC_{50}	1,376	1	ECHA
Daphnia magna	48-hr EC_{50}	1,328	1	ECHA
Pseudokirchneriella subcapitata	72-hr EC_{50}	225	1	ECHA

Chronic Studies

The 21-d NOEC from a *Daphnia* reproduction test is 4.1 mg/L (ECHA) [Kl. score = 2].

96-hr EC_{10} to *Pseudokirchneriella subcapitata* is 134 mg/L (ECHA) [Kl. score = 1].

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for 1-butanol follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (1,376 mg/L), invertebrates (1,328 mg/L), and algae (225 mg/L). Results from chronic studies are available for invertebrates (4.1 mg/L) and algae (124 mg/L). On the basis that the data consists of short-term studies for three trophic levels and long-term studies for two trophic levels, an assessment factor of 50 has been applied to the lowest reported EC_{10} value of 4.1 mg/L for fish. The $PNEC_{water}$ is 0.08 mg/L.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.004 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.07/1500) \times 1000 \times 0.08$
$= 0.004$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 3.471 \times 0.02$
$= 0.07$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for 1-butanol based on the molecular connectivity index (MCI) is 3.471 L/kg (EPA, 2019).
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

1-Butanol is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Based on a measured log K_{ow} of 1.0, 1-butanol does not meet the screening criteria for bioaccumulation.

The lowest chronic EC_{10} or NOEC value for 1-butanol is >0.1 mg/L. The acute $E(L)C_{50}$ values are >1 mg/L. Thus, 1-butanol does not meet the criteria for toxicity.

The overall conclusion is that 1-butanol is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification
Flammable liquid Category 3

Acute toxicity Category 4
Specific target organ toxicity Category 3
Skin irritation Category 2
Eye damage Category 1

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Rinse continuously with water for several minutes. Remove contact lenses if present and easy to do so. Continue rinsing. Call physician or poison center.

Skin Contact
Remove/Take off immediately all contaminated clothing. Rinse skin with water/shower.

Inhalation
Remove victim to fresh air and keep at rest in a position comfortable for breathing.

Ingestion
Call physician or poison center.

Notes to Physician
May cause drowsiness or dizziness

Irritating to eyes, respiratory system and skin. Central nervous system effects. Hearing impairment Treat symptomatically.

Medical Conditions Aggravated by Exposure
No data available

Emergency Personnel Protection

First-Aid Providers: Avoid exposure to blood or body fluids. Wear gloves and other necessary protective clothing. Dispose of contaminated clothing and equipment as bio-hazardous waste.

B. FIRE FIGHTING INFORMATION

Extinguishing Media

Use foam, dry chemical, CO2 or water spray for extinction. Alcohol-resistant Foam; butanol is an alcohol. Do not use a solid (straight) water stream as it may scatter and spread fire.

Specific Exposure Hazards

Combustion products include carbon monoxide and carbon dioxide. Flammable. May be ignited by heat, sparks or flames. Material can burn with invisible flame. Vapor may travel considerable distance to source of ignition and flash back.
Vapors may form explosive mixtures with air. Most vapors are heavier than air. They will spread along the ground and collect in low or confined areas (sewers, basements, tanks). Container explosion may occur under fire conditions or when heated. Fire may produce irritating, corrosive and/or toxic gases.

Special Protective Equipment for Firefighters

Wear SCBA and fully encapsulating, gas-tight suit when handling these substances. Structural firefighter's uniform is NOT effective for these materials.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Ensure adequate ventilation. Keep people away from and upwind of spill/leak. Avoid contact with skin, eyes and clothing. Use personal protective equipment. Remove all sources of ignition. Pay attention to flashback. Take precautionary measures against static discharges. All equipment used when handling the product must be grounded. Use spark-proof tools and explosion-proof equipment. In case of large spill, water spray or vapor-suppressing foam may be used to reduce vapors, but may not prevent ignition in closed spaces.

Environmental Precautions

Prevent further leakage or spillage if safe to do so. Prevent product from entering drains. Prevent entry into waterways, sewers, basements or confined areas. In case of large spill, dike if needed. Dike far ahead of liquid spill for later disposal.

Steps to be Taken if Material is Released or Spilled

Stop leak if you can do it without risk. Absorb spill with inert material (e.g. vermiculite, dry sand or earth).
Use appropriate tools to put the spilled material in a suitable chemical waste disposal container. Use clean non-sparking tools to collect absorbed material.
Clean contaminated surface thoroughly.

D. STORAGE AND HANDLING

General Handling
Wear personal protective equipment. Use only in well-ventilated areas. Avoid contact with skin, eyes and clothing.
Keep away from heat and sources of ignition. Do not breathe vapors or spray mist. Do not ingest. When using do not smoke. Handle in accordance with good industrial hygiene and safety practice.

Other Handling Precautions
Remove all sources of ignition. To avoid ignition of vapors by static electricity discharge, all metal parts of the equipment must be grounded. Keep away from incompatible materials.

Storage
Keep container tightly closed in a dry and well-ventilated place. Store at room temperature in the original container. Keep away from heat and sources of ignition. Store in a segregated and approved area. Store away from incompatible materials.
Incompatible Materials: Oxidizing agents, Acids, Alkali Metals, Halogens, Aluminum, Caustics, isocyanates

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
The workplace exposure standard for butanol in Australia is 152 mg/m3 as an 8-hr TWA. No STEL is listed.

Engineering Controls
Ensure adequate ventilation. Provide exhaust ventilation or other engineering controls to keep the airborne concentrations of vapors and mist below their respective threshold limit value.

Personal Protection Equipment

Respiratory Protection:
Where ventilation is not adequate, respiratory protection may be required. Avoid breathing vapours or mists. Select and use respirators appropriately. When mists or vapours exceed the exposure standards then the use of the following is recommended: Approved respirator with organic vapour and dust/mist filters. Filter capacity and respirator type depends on exposure levels.

Hand Protection: Use appropriate, impervious gloves. Inspect gloves before use.

Skin Protection:
Chemical resistant apron, long sleeved clothing

Eye protection*:*
Use face shield, chemical goggles or safety glasses with side shield protection as appropriate.

Other Precautions:
No additional notes available.

F. TRANSPORT INFORMATION

UN Number 1120
Hazard class 3

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

AICS: Listed

CHLOROUS ACID, SODIUM SALT

This dossier on chlorous acid, sodium salt does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of chlorous acid, sodium salt in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Sodium chlorite

CAS RN: 7758-19-2

Molecular formula: $ClHO_2.Na$

Molecular weight: 90.44

Synonyms: Chlorous acid, sodium salt; sodium chlorite

SMILES: [O-]Cl=O.[Na+]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Chlorous Acid, Sodium Salt

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White solid, slightly hydroscopic crystals or flakes. Aqueous solutions are colorless to greenish yellow with a slight chlorine-like odor	2	ECHA
Melting Point	180 – 200°C; decomposes at 200°C	2	ECHA
Density	2.432 g/mL	1	ECHA
Vapor Pressure	1.1×10^{-7} Pa @ 25°C	1	ECHA

Partition Coefficient (log K_{ow})	<-2.7	1	ECHA
Water Solubility	Very soluble (572 g/L @ 20°C)	1	ECHA
Oxidizing Properties	25.6% aq. solution – not an oxidizing liquid	1	ECHA

Chlorous acid, sodium salt in its dry form is a strong oxidizer.

Chlorous acid, sodium salt readily dissociates in aqueous solutions to the sodium (Na^+) and chlorite (ClO_2^-) ion. The chlorite (ClO_2^-) ion is in equilibrium with chlorous acid ($HClO_2$) in water. The chemical reaction is as follows:

$ClO_2^- + H^+ \rightleftharpoons HClO_2$

At pH values found in environmental media or physiological fluids, the chlorite ion will be the predominant form (pK_a of chlorous acid is 1.94).

Under acidic conditions, chlorous acid ($HClO_2$) will predominate and will disintegrate to chlorine dioxide (ClO_2). Chlorine dioxide (ClO_2) will degrade further to chlorite (ClO_2^-), and, ultimately, the chloride ion (Cl^-) is formed. The proportion of each oxy-chlorine species depends in part on the pH of the solution.

III. ENVIRONMENTAL FATE PROPERTIES

Chlorous acid, sodium salt readily dissociates in aqueous solutions to the sodium (Na^+) and chlorite (ClO_2^-) ion. The chlorite ion will ultimately degrade to chloride ions. Both sodium and chloride ions are ubiquitous in the environment. Biodegradation is not applicable to sodium chlorite. Neither sodium chlorite nor its dissociated ions are expected to adsorb to soil or sediment, or bioaccumulate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Chlorous acid, sodium salt (sodium chlorite) in solution is moderately-to-highly toxic by the oral route, but has low acute toxicity by the dermal route. It is corrosive the skin and eyes. It is not a skin sensitizer. The critical effect seen in rodents given repeated oral administration of sodium chlorite is hemolytic anemia. Sodium chlorite was not mutagenic in a bacterial reverse mutation (Ames) test; however, chlorine dioxide (which breaks down to chlorite) was mutagenic in the mouse lymphoma assay in the absence and presence of metabolic activation. *In vivo* genotoxicity studies on sodium chlorite were generally negative. No reproductive toxicity was seen in male or female rats given sodium chlorite

in drinking water. There was, however, an effect on post-natal development in pups from the first generation; the effect was not seen in the pups from the second generation. There was no developmental toxicity in pregnant female rabbits given sodium chlorite in drinking water.

B. Acute Toxicity

The oral LD_{50} in rats is 284 mg/kg (ECHA) [Kl. score = 1]. The oral LD_{50} in rats of a 31% aqueous solution of chlorous acid, sodium salt is 390 mg/kg (ECHA) [Kl. score = 2).

There are no acute inhalation toxicity studies.

The dermal LD_{50} in rabbits is 134 mg/kg (ECHA) [Kl. score = 1]. The dermal LD_{50} in rabbits of a 31% aqueous solution of chlorous acid, sodium salt is >2,000 mg/kg (ECHA) [Kl. score = 2).

C. Irritation

Application of 0.5 mL of undiluted chlorous acid, sodium salt to the skin of rabbits for 4 hours under occlusive conditions was corrosive (ECHA) [Kl. score = 2]. Application of 0.5 mL of a 34.5% solution of chlorous acid, sodium salt to the skin of rabbits for four hours under semi-occlusive conditions was essentially non-irritating (ECHA) [Kl. score = 1].

Instillation of 0.1 mL of a 31% aqueous solution of chlorous acid, sodium salt to the eyes of rabbits was severely irritating (ECHA) [Kl. score = 2].

D. Sensitization

Chlorous acid, sodium salt was not considered to be a skin sensitizer when tested in a mouse local lymph node assay (ECHA). [Kl. score = 1]

E. Repeated Dose Toxicity

<u>Oral</u>

Male and female Crj:CD(SD) rats were dosed by oral gavage with 0, 10, 25, or 80 mg/kg chlorous acid, sodium salt for 13 weeks. Five animals died during the study: one in the 25 mg/kg group and five in the 80 mg/kg group subsequent to blood sampling. The deaths in the 80 mg/kg group were likely treatment-related; the animals were anemic and blood sampling may have exacerbated this problem, contributing to their death. Clinical signs were noted in the 25 and 80 mg/kg animals, the most notable being salivation. Body weights and feed consumption were similar across all groups. Hematological effects were

noted in the 80 mg/kg animals. The group mean erythrocyte count was significantly lower (both sexes). In males, hematocrit and hemoglobin levels were significantly lower, and methemoglobin levels and neutrophils counts were significantly higher than controls. The reticulocyte count was increased, but was not statistically significant. Two of the 80 mg/kg rats that prematurely died had marked changes in these hematological parameters. Morphological changes were also seen in the blood smears of three 80 mg/kg females: these were polychromasia, poikilocytosis, macrocytosis, and neutrophilia. Lymphocyte counts were significantly lower than controls in the 80 mg/kg males, and was likely due to the increased neutrophil count. Where the primary red blood cell parameters (mean erythrocyte count, hemoglobin, and hematocrit) were affected, there were also associated changes in mean cell volume, mean cell hemoglobin, and mean cell hemoglobin concentration. In the 25 mg/kg animals (both sexes) and the 10 mg/kg males, statistical trends highlighted a dose-dependent downward trend for erythrocyte counts. Statistical significance was not confirmed by direct comparison with the control group, and group mean values were within background range. Urine volume was unusually high in four 80 mg/kg females, and urinary specific gravity was reduced. There were no histopathologic changes seen in the kidneys of these animals. Absolute and relative spleen weights were increased in the 80 mg/kg males. Absolute spleen weights were increased in the 10 and 80 mg/kg females; relative spleen weights were increased in the 25 and 80 mg/kg females. Relative adrenal weights were increased in the 80 mg/kg males. Absolute adrenal weights were increased in the 80 mg/kg females; relative adrenal weights were increased in the 25 and 80 mg/kg females. Histopathologic changes indicative of chronic irritation were seen in the stomachs of many of the 80 mg/kg animals and a few of the 25 mg/kg males. Extramedullary hematopoiesis was seen in the spleen of a few 80 mg/kg animals and one animal each in the lower two dose groups. The NOAEL for this study is 10 mg/kg-day (ECHA). [Kl. score = 1]

Male C/J and C57L/L mice were given in their drinking water 0, 0.75, 7.5, or 75 mg/L chlorous acid, sodium salt (0, 0.19, 1.9, or 19 mg/kg-day chlorite ion) for 30 days. There were slight signs of oxidative stress of red blood cells at the high-dose. Glucose-6-phosphate dehydrogenase (G6PD) activity and osmotic fragility were slightly increased. Erythrocytes with irregular shapes were also observed. It was suggested that the primary effect of chlorous acid, sodium salt was a disruption of the erythrocyte cell membrane. However, the glutathione level in the erythrocyte was not affected and there were no associated signs of hemolytic anemia, suggesting that the slight increase in G6PD activity acted as a sufficient compensatory mechanism to limit the oxidative stress. The NOAEL for this study is considered to be 7.5 mg/L chlorous acid, sodium salt or 1.9 mg/kg-day chlorite (Moore and Calabrese, 1980). [Kl. score = 2]

Male C57L/J mice were given chlorous acid, sodium salt in their drinking water for 30, 90, or 180 days. The doses were 0, 3, 15, or 75 mg/L expressed as chlorite ion. The average daily doses were estimated to be: 0, 0.74, 3.57, and 17.23 mg/kg-day for the 30-day period; 0, 0.64, 3.15, and 16.2 mg/kg-day for the 90-day period; and 0, 0.69, 3.71, and 17.11 mg/kg-day for the 180-day period. There were no significant changes in body weight gain, absolute or relative kidney weights, water consumption, or histopathologic changes in the

kidney. The NOAELs for this study are: 17.23, 16.20, and 17.11 mg/kg-day for the 30-, 90-, and 180-day exposure periods, respectively (Connor et al., 1985). [Kl. score = 2]

Inhalation

No studies are available.

Dermal

No adequate studies are available.

F. Genotoxicity

In Vitro Studies

Table 2 lists the results of the *in vitro* genotoxicity studies on chlorous acid, sodium salt.

Table 2: *In vitro* Genotoxicity Studies on Chlorous Acid, Sodium Salt

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* TA97, TA102 strains)	-	-	4	ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	+**	+**	2	ECHA

*+, positive; -, negative
**Test material: chlorine dioxide (chlorite is a breakdown product)

In Vivo Studies

Male and female CD-1 mice were given by oral gavage a single dose of 0, 0.2, 0.5, or 1 mg/day (0, 10, 25, or 59 mg/kg-day) chlorous acid, sodium salt. Chromosomal aberrations were not increased in bone marrow cells of treated mice compared to those in the controls (Meier et al., 1985; ECHA).

Male and female CD-1 mice were given by oral gavage 0, 0.2, 0.5, or 1 mg/day (0, 10, 25, or 59 mg/kg-day) chlorous acid, sodium salt for five consecutive days. There were no significant differences between treated and control mice in the frequency of micronuclei or chromosomal aberrations in bone marrow cells (Meier et al., 1985; ECHA).

Male ddY mice were given a single intraperitoneal injection of 0, 7.5, 15, 30, or 60 mg/kg chlorous acid, sodium salt. Micronucleated polychromatic erythrocytes were statistically significantly increased at all dose levels. The increase was dose-dependent, but the frequency of micronucleated polychromatic erythrocytes decreased at the highest dose level (Hiyashi et al., 1988; ECHA). [Kl. score = 2]

Male ddY mice were given a single intraperitoneal injection of 0 or 15 mg/kg chlorous acid, sodium salt for four consecutive days. The frequency of micronucleated polychromatic erythrocytes were similar between treated and control mice (Hiyashi et al., 1988; ECHA). [Kl. score = 2]

Male ddY mice were given a single oral dose of 0, 37.5, 75, 150, or 300 mg/kg chlorous acid, sodium salt. There was no significant increases in the frequency of micronucleated polychromatic erythrocytes in the bone marrow of the treated mice compared to the controls (Hiyashi et al., 1988; ECHA). [Kl. score = 2]

G. Carcinogenicity

No studies are available.

H. Reproductive Toxicity

A two-generation reproductive toxicity study has been conducted on chlorous acid, sodium salt. Male and female SD rats were given in their drinking water 0, 35, 70, or 300 ppm chlorous acid, sodium salt. The average daily intakes are: 0, 4, 8, and 30 mg/kg-day for males ; and 0, 5, 10, and 39 mg/kg-day for females. The average daily intakes for chlorite are: 0, 2.9, 6, and 22 mg/kg-day for males; and 0, 4, 7.5, and 29 mg/kg-day for females. During lactation, the drinking water levels were reduced 50% to 17.5, 35, and 150 ppm chlorous acid, sodium salt. Water consumption was reduced in all treated groups. Body weights and feed consumption were reduced in the 70 and 300 ppm groups. There was no evidence of reproductive toxicity at any dose level. In the 300 ppm group, pup weights were reduced at birth and on PND 11 (-14%) compared to the controls. There was a decrease in the percent of the 300 ppm F_{2a} pups with eyes open on PND15 compared to the control group; this effects was not observed for the F_1 or F_{2b} pups. There was a small, but statistically significant, increase in the average time to preputial separation for the 70 and 300 ppm F_1 pups and in the vaginal opening for the 300 ppm F_1 pups. Similar changes were not observed for the F_2-generation pups. All of the high-dose animals exhibited mild methemoglobinemia. Thyroid levels were unaffected by treatment. There was a small decrease in the amplitude of auditory startle responses in the 70 and 300 ppm pups on PND 25; the toxicological significance of this effect is questionable. The NOAEL for reproductive toxicity is 300 ppm chlorous acid, sodium salt, the highest dose tested. The NOAEL for developmental toxicity is 35 ppm (4 and 5 mg/kg-day chlorous acid, sodium salt for males and females, respectively) based on the increase in the average time to preputial separation in the $\geq$70 ppm F_1 pups. The NOAELs for hematological effects is 70

ppm (8 and 10 mg/kg-day chlorous acid, sodium salt for males and female, respectively). The NOAEL for neurotoxicity is 300 ppm (30 and 39 mg/kg-day chlorous acid, sodium salt for males and females, respectively) (ECHA) [Kl. = 2].

I. Developmental Toxicity

Pregnant New Zealand White rabbits were given 0, 200, 600, or 1,200 mg/L (0, 12.2, 36.6, or 58.8 mg/kg-day) chlorous acid, sodium salt in their drinking water during GD 7 to PND 19. The animals in the mid- and high-dose groups showed reduced water consumption, along with reduced feed consumption, production of fecal pellets, and body weight gain. There was no evidence of embryotoxicity or teratogenicity at any dose level. The NOAELs for maternal and developmental toxicity are 12.2 and 58.8 mg/kg-day, respectively (ECHA). [Kl. score = 1]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for chlorous acid, sodium salt follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The lowest NOAEL values from key toxicity studies on chlorous acid, sodium salt are listed below in Table 3.

Table 3: Lowest NOAEL Values from Key Toxicity Studies on Chlorous Acid, Sodium Salt by the Oral Route

Species/sex	Study Duration	mg/kg-day	Endpoint	Reference
Male/female rats	13 weeks	10	Clinical signs, stomach irritation	ECHA
Male pups	2-generation reproductive	4	↑ average time to preputial separation	ECHA
Male parental rats	2-generation reproductive	8	Hematological effects	ECHA

Female pregnant rabbits	Developmental (GD 6 to PND 17)	12.2	↓ Body weight gain, feed consumption	ECHA

The lowest NOAEL is 4 mg/kg-day based on increased average time to preputial separation in F_2 male pups from a two-generation reproductive toxicity study (ECHA). The NOAEL of 4 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Derivation of an Oral Reference Dose

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 4/(10 x 10 x 1 x 10 x 1) = 4/1000 = <u>0.004 mg/kg-day</u>

Derivation of a drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.004 x 70 x 0.1)/2 = <u>0.014 mg/L</u>

Australian Drinking Water Guidelines

The Australian drinking water guideline value for chlorite is 0.3 mg/L (ADWG, 2011).

The Australian drinking water guideline value for sodium is 180 mg/L based on aesthetics (ADWG, 2011).

B. Cancer

No carcinogenicity studies were found on chlorous acid, sodium salt. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Chlorous acid, sodium salt in solution does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing Potential

[It should be noted that chlorous acid, sodium salt as a solid is a strong oxidizer.]

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Chlorous acid, sodium salt has a high acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on chlorous acid, sodium salt.

Table 3: Acute Aquatic Toxicity Studies on Chlorous Acid, Sodium Salt

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-h LC_{50}	149	2	ECHA
Daphnia magna	48-h EC_{50}	<1	2	ECHA

Peudokirchneriella subcapitata	96-h EC_{50}	1	1	ECHA

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for chlorous acid, sodium salt follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (149 mg/L), invertebrates (<1 mg/L), and plants (1 mg/L). On the basis that the data consists of short-term studies from three trophic levels, an assessment factor of 1,000 has been applied to the EC_{50} value of 1 mg/L for algae. The $PNEC_{aquatic}$ is 0.001 mg/L.

PNEC sediment

No reliable experimental toxicity data on sediment organisms are available. Chlorous acid, sodium salt dissociates completely in water with its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as chlorous acid, sodium salt. Therefore, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sed}$. Based on its properties, no adsorption of chlorous acid, sodium salt to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PNEC soil

No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of chlorous acid, sodium salt is dominated by its water solubility. Sorption of chlorous acid, sodium salt should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{oc} and K_{ow}

parameters do not readily apply to inorganics, such as chlorous acid, sodium salt. Therefore, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on its properties, chlorous acid, sodium salt is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Chlorous acid, sodium salt is an inorganic salt that dissociates completely in water to sodium (Na^+) and chlorite (ClO_2^-) ions. Chlorite will ultimately degrade to chloride (Cl^-) ions. Biodegradation is not applicable to these inorganic ions. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

As an inorganic compound, neither chlorous acid, sodium salt nor its dissociated ions are expected to accumulate. Thus, chlorous acid, sodium salt does not meet the criteria for bioaccumulation.

There are no chronic toxicity studies on chlorous acid, sodium salt. The acute $E(L)C_{50}$ values for chlorous acid, sodium salt are $\leq$1 mg/L in invertebrates and algae. Thus, chlorous acid, sodium salt meets the criteria for toxicity.

The overall conclusion is that chlorous acid, sodium salt is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification (Chlorous acid, sodium salt solutions)

Acute Toxicity Category 3 [Oral]
Skin Corrosive Category 1B
STOT RE Category 2 [Target organ: blood]
Aquatic Acute Category 1
Aquatic Chronic Category 3

B. Labelling

Danger

C. Pictogram

In addition to the hazard statements corresponding to the GHS classifications, the following non-GHS hazard statement is to be added to the SDS: AUH031: Contact with acids liberates toxic gas.

X. SAFETY AND HANDLING

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. Get medical attention immediately, preferably a physician for an ophthalmologic examination.

Skin Contact
Remove and isolate contaminated clothing. Rinse skin immediately with water for at least 15 min. Get medical attention immediately.

Inhalation
Move person to fresh air. Administer oxygen if breathing is difficult. Do not use mouth-to-mouth method if victim inhaled the substance; give artificial respiration with the air of a pocket mask equipped with a one-way valve or other proper respiratory medical device. Give artificial respiration if victim is not breathing. Get medical attention immediately.

Ingestion
Rinse mouth with water and then drink plenty of water. Get medical attention. Do not induce vomiting. Never give anything by mouth to an unconscious person.

Notes to Physician
Chlorine dioxide vapors are emitted when this product contacts acids or chlorine. If these vapors are inhaled, monitor patient closely for delayed development of pulmonary edema which may occur up to 48-72 hours post-inhalation Following ingestion, neutralization and use of activated charcoal is not indicated (OxyChem, 2015).

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Use dry chemical, carbon dioxide, water spray or fog, or foam.

Specific Exposure Hazards

Dried material can ignite upon contact wit combustibles. This product may represent an explosion hazard if it contacts acids, chlorine, or organic materials. Emits toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: chlorine and sodium oxides.

Special Protective Equipment for Firefighters

Structural firefighter's protective clothing provides limited protection in fire situations only; it is not effective in spill situations where direct contact with the substance is possible. Wear chemical protective clothing that is specifically recommended by the manufacturer. It may provide little or no thermal protection. Wear positive pressure self-contained breathing apparatus (SCBA). Move containers from fire area if it can be done without risk.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Ventilate enclosed areas. Do not walk through spilled material. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Wear appropriate personal protective equipment, avoid direct contact. Do not breath mist, vapors, or spray. Do not get in eyes, on skin, or on clothing.

Environmental Precautions

Prevent entry into waterways, sewers, basements or confined areas.

Steps to be Taken if Material is Released or Spilled

As an immediate precautionary measure, isolate spill or leak area for at least 50 meters in all directions. Keep unauthorized personnel away. Remove all sources of ignition. Absorb or cover with dry earth, sand, or other non-combustible material and transfer to containers. Dike to collect large liquid spills. Every attempt should be made to avoid mixing spilled material with other chemicals or debris when cleaning up. Dried material can ignite upon contact with combustibles. Dispose immediately.

D. STORAGE AND HANDLING

General Handling

Do not get in eyes, on skin, or on clothing. Do not ingest or taste. Wear appropriate personal protective equipment, avoid direct contact. Do not breath mist, vapours, or spray. Use caution when combining with water. DO NOT add water to corrosive liquid, ALWAYS add corrosive liquid to water while stirring to prevent release of heat, steam, and fumes. This product becomes a fire hazard if allowed to dry. Remove and wash contaminated clothing to avoid fire.

Storage

Keep contain tightly closed. Store in a cool, dry, well-ventilated place. Keep from direct

sunlight. Avoid exposure to sunlight or ultraviolet light. Keep separated from acids, reducing agents, combustible material, oxidizing agents, hypochlorite, organic solvents and compounds, garbage, dirt, organic materials, household products, chemicals, soap products, paint products, vinegar, oils, pine oil, dirty rags, sulfur-containing rubber, or any other foreign matter.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure standard for chlorous acid, sodium salt.

Engineering Controls

Good general ventilation should be used. Localized ventilation should be used where vapours, mist, or aerosols may be generated.

Personal Protection Equipment

Respiratory Protection:

Wear an approved acid gas respirator with dust/mist pre-filters if any exposure to dust of mist is possible.

Hand Protection:

Wear appropriate chemical-resistant gloves.

Skin Protection:

Wear protective clothing to minimize skin contact.

Eye protection*:*

Wear chemical splash goggles and face shield.

Other Precautions:

Wash hands, forearms, and face thoroughly after handling chemical products, before eating, smoking, and using the lavatory and at the end of the working period. Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Sodium chlorite (dry)

UN1496 (SODIUM CHLORITE)
Class: 5.1
Packing Group: II

Environmentally Hazardous Substance

Sodium chlorite (liquid)
UN1908 (CHLORITE SOLUTION)
Class: 8
Packing Group: II
Contains Sodium chlorite

Environmentally Hazardous Substance

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

CHOLINE CHLORIDE

This dossier on choline chloride does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of choline chloride in its use in hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the OECD-SIDS documents on choline chloride (OECD, 2004), and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): 2-Hydroxy-N,N,N-trimethylethanaminium chloride

CAS RN: 67-48-1

Molecular formula: $C_5H_{14}NO.Cl$
$C_5H_{14}NO^+$ (choline)

Molecular weight: 139.6
104.2 (choline)

Synonyms: Choline chloride; 2-hydroxy-N,N,N-trimethylethanaminium chloride; trimethyl(2-hydroxyethyl)ammonium chloride; cholinium chloride; 2-hydroxyethyl(trimethyl)azanium chloride

SMILES: C[N+](C)(C)CCO.[Cl-]
C[N+](C)(C)CCO (choline)
OCCN(C)(C)C (choline)

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Choline Chloride

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa*	White crystalline solid*	2	OECD (2004)
Melting Point	ca. 200°C	1	ECHA
Boiling Point	Decomposition at 305°C prior to boiling.	2	ECHA
Density	70% aq. solution: 1.10 g/cm^3	4	OECD (2004)

Partition Coefficient (log K_{ow})	75% aq. solution: -3.77	1	ECHA
Water Solubility	Powder containing 50% choline chloride: 650 g/L	4	OECD (2004)
Auto flammability	330°C	2	ECHA
Viscosity	75% aq. solution: 26.2 mPa.s @ 20°C; 14.1 mPa.s @ 40°C	1	ECHA
Henry's Law Constant	2.06 x 10^{-11} Pa.m^3/mole @ 25°C (estimated using HENRYWIN v3.10)	-	OECD (2004)

*Choline chloride is a white crystalline solid; it is marketed as an aqueous solution (70-75% w/w in water), which is colorless with an amine-like odor.

Choline chloride is a quaternary amine salt that will dissociate in water into choline ($C_5H_{14}NO^+$) and chloride (Cl^-) ions.

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Choline chloride is readily biodegradable. Distribution modeling using Mackay Level 1 shows choline to be distributed completely into water. Choline chloride will not adsorb on soil and sediments. It is not expected to bioaccumulate.

B. Biodegradation

Choline chloride is readily biodegradable (93% within 14 days) in a MITI-I test (MITI, 1992; OECD, 2004). In another MITI-I test, biodegradation was $\geq$60%, indicating ready biodegradation (Tunkel *et al.*, 2000; OECD, 2004). A $BOD_5/ThOD_5$ ratio of 75% was obtained in a BOD_5 test performed according to DIN 38409 part 43 (BASF AG, 1984; OECD, 2004).

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for choline. Choline is a quaternary ammonium compound (QAC); these compounds are not included in the training set for the K_{oc} estimation of the QSAR model KOCWIN v. 2.00 in EPISUITE™ (EPA, 2016), and therefore outside the program's prediction domain. A K_{oc} value of 2.3 had been estimated using the older QSAR model PCKOCWIN v. 1.66 (OECD, 2004).

Distribution Modeling

Results from Mackay Level I modeling indicate that choline chloride will be distributed completely into water (OECD, 2004).

D. Bioaccumulation

No measured data on bioaccumulation of choline chloride are available. An experimental log K_{ow} is -3.77 (OECD, 2004). Bioaccumulation is not expected in aquatic organisms.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Choline is a vitamin-like essential nutrient. It has low acute toxicity by the oral route, and is slightly irritating to the skin and eyes. Repeated high intake of choline in humans has been reported to cause a slight hypotensive effect. No adverse effects (including tumors) were seen in rats given choline in the diet for 72 weeks. Choline is not genotoxic. High dietary doses of choline to pregnant mice resulted in developmental toxicity (but no teratogenic effects) at levels that were maternally toxic.

B. Metabolism

Choline is a vitamin-like essential nutrient. Although the body can synthesize choline in small amounts, it is insufficient to maintain health and must be consumed in the diet. Choline is required for the synthesis of phospholipids in cell membranes, methyl group metabolism and acetylcholine synthesis (neurotransmitter) (Zeisel and Blusztajn, 1994).

Dietary choline is taken up into the body by transporter proteins present in the cells lining the small intestine (IOM, 2000). In the small intestine, prior to uptake into the small intestinal cells, some choline is metabolized by bacteria to betaine and methylamines (Zeisel et al., 1983). Dietary choline can be present as free choline or in esterified forms (i.e., phosphocholine, glycerophosphocholine, sphingomyelin, and phosphatidylcholine) (Zeisel and Blusztain, 1994). Free choline is formed from these esterified choline compounds by pancreatic enzymes.

Choline is involved in a number of biochemical pathways in eukaryotic and prokaryotic cells. It is a precursor for acetylcholine (a neurotransmitter); phospholipids (structural integrity and signaling roles for cell membranes); and a major source for methyl groups (IOM, 2000).

C. Acute Toxicity

The oral LD_{50} values of choline in rats are approximately 3,500 and 5,500 mg/kg (ECHA). [Kl. scores = 2]

No acute inhalation or dermal toxicity studies are available.

D. Irritation

Application of a 70% aqueous solution to the skin of rabbits for 20 hours under occlusive conditions resulted in ambiguous skin irritation (BASF AG, 1963a; OECD, 2004). [Kl. score = 2].

Slight eye irritation was seen in the eyes of rabbits after instillation of a 70% aqueous solution of choline chloride; no effects were seen 24 hours after exposure (BASF AG, 1963b; OECD, 2004). [Kl. score = 2].

E. Sensitization

No data are available in animals. In a Human Repeated Insult Patch Test (HRIPT), there was no evidence of dermal sensitization in two hundred subjects given 0.5% (w/v) aqueous solution of choline chloride during the induction phase and 0.2% (w/v) aqueous solution during the challenge phase (Colgate-Palmolive, 2003; OECD, 2004).

F. Repeated Dose Toxicity

Oral

A 72-week feeding study was conducted to investigate the impact of choline chloride on the liver tumor promoting activity of phenobarbital and DDT in diethylnitroamine-initiated Fischer 344 rats. Animals received approximately 500 mg/kg-day choline chloride. Following the end of the exposure period, the animals were kept on the same untreated diet as the control group until study termination at week 103. Histopathology was limited to the liver and organs that developed gross abnormalities. There were no significant differences between treated and control animals on survival rates, body weights, and relative liver weights. There were no increased number of neoplastic liver nodules, hepatocellular carcinomas, lung tumors, leukemia or other tumors between treated and control animals. The NOAEL for choline chloride in this study is 500 mg/kg-day (Shivapurkar *et al.*, 1986). [Kl. score = 3]

In humans, oral administration of 10,000 mg/day choline chloride in a pilot study treating a small number of patients with Alzheimer's disease resulted in a slight hypotensive effect (Boyd *et al.*, 1977). This dose was regarded as a LOAEL by the U.S. Institute of Medicine (IOM) Standing Committee on the Scientific Evaluation of Dietary Reference Intake (2000).

Inhalation

No studies are available.

Dermal

No studies are available.

G. Genotoxicity

In Vitro Studies

Choline chloride was not mutagenic to bacteria in reverse mutation assays (Haworth *et al.*, 1984; JETOC, 1997; Litton Bionetics, 1977).

A small, but statistically significant, and dose-related increase in chromosomal aberrations was reported in Chinese Hamster Ovary (CHO) cells at doses of 50 and 500 μg/ml choline chloride in the absence of S9 only (Bloom *et al.*, 1982). No higher concentrations were examined. These results could not be confirmed in two studies using CHO cells at concentrations of choline chloride up to 5,000 μg/ml (Galloway *et al.*,1985).

In sister chromatid exchange (SCE) assays, ambiguous results were obtained in two parallel studies (at two different laboratories) in CHO cells at concentrations up to 50 and 500 μg/ml choline chloride, respectively. Cytotoxicity was observed at 5,000 μg/ml. In laboratory 2, the increase in SCEs, which was sporadic and not dose-related, that was observed with metabolic activation was not reproduced in laboratory 1. Laboratory 1 showed a weak positive at the top dose without metabolic activation, but a comparison with laboratory 2 was not possible due to insufficient number of cells analyzed (Bloom *et al.*, 1982; Galloway *et al.*, 1985).

Choline chloride was negative in a gene conversion assay with *Saccharomyces cerevisiae* strain D4 in the presence or absence of metabolic activation (Litton Bionetics, 1977; OECD, 2004).

In Vivo Studies

No studies are available.

G. Carcinogenicity

No studies are available.

H. Reproductive Toxicity

No reliable studies have been conducted that address female fertility or reproductive toxicity by a relevant route of exposure.

I. Developmental Toxicity

Pregnant female mice were given in their feed 0, 1, 2.5, 5, or 10% choline chloride (0 or approximately 1,250, 4,160, 10,800, or 20,000 mg/kg choline chloride) on gestational days 1 to 18. Maternal body weight gain was reduced in all treated groups except for the 1,250 mg/kg group. Maternal weight gain of dams with embryonic/fetal absorptions showed no net weight gain at ≥4,160 mg/kg, but there was net weight loss in the 20,000 mg/kg group. All fetuses were resorbed in the 20,000 mg/kg group. Embryonic/fetal lethality of 35% and 69% were seen in the 4,160 and 10,800 mg/kg groups, respectively. No resorptions occurred in the 1,250 mg/kg group. Developmental toxicity was seen at ≥4,160 mg/kg group. There were no statistically significant increases in malformations in any dose group. The NOAEL for maternal and developmental toxicity is 1,250 mg/kg-day (BASF AG 1966; OECD 2004). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The Standing Committee on the Scientific Evaluation of Dietary Reference Intakes selected hypotension as the critical effect from the study by Boyd *et al.* (1977) when deriving a Tolerable Upper Intake Level. Boyd *et al.* (1977) reported a LOAEL of 10,000 mg/day choline chloride (7,500 mg/day choline). An uncertainty factor of 2 was chosen because of the limited data regarding hypotension and the inter-individual variation in response to cholinergic effects. Thus, the value for the Tolerable Upper Intake Value for repeated exposure of adults to choline is 3,500 mg/day choline.

Note that the Australian National Health and Medical Research Council (2014) concluded that there are no data to suggest that there is increased susceptibility to choline during pregnancy or lactation; thus the upper level of intake choline is the same for women during pregnancy or lactation as it is for adults (3,500 mg/day choline).

Oral Reference Dose (oral RfD)

An oral RfD for choline is derived as follows: the LOAEL of 7,500 mg/day from the Boyd *et al.* (1977) study is divided by an uncertainty factor of 2 to obtain a value of 3,500 mg choline/day or 50 mg choline/kg-day for a 70 kg person.

Oral RfD = 50 mg/kg-day [choline]

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (50 x 70 x 0.1)/2 = 175 mg/L [choline]

The Australian drinking water guideline value for chloride ions is 250 mg/L based on aesthetics (ADWG, 2011).

B. Cancer

There are no carcinogenicity studies on choline chloride. Thus a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Choline chloride does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Choline chloride is of low toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 2 lists the results of acute aquatic toxicity studies conducted on choline chloride.

Table 2: Acute Aquatic Toxicity Studies on Choline Chloride

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oryzias latipes	96-hr LC_{50}	>100 (nominal and measured)	1	MOE Japan (1999a); OECD (2004)
Leuciscus idus	96-hr LC_{50}	>10,000*	2	OECD (2004); ECHA
Daphnia magna	48-hr EC_{50}	349 (nominal and measured)	2	MOE Japan (1999a); OECD (2004)
Daphnia magna	48-hr EC_{50}	>500*	2	OECD (2004)
Pseudokirchneriella subcapitata	72-hr EC_{50}	>1,000 (nominal and measured)	1	MOE Japan (1999a); OECD (2004)

*78% aqueous solution of choline chloride.

Chronic Studies

In a 21-day *Daphnia magna* reproduction test, the nominal and measured NOEC was reported to be 30.2 mg/L (MOE Japan, 1999d) [Kl. score = 1].

The NOEC from a 72-hr algae *Pseudokirchneriella subcapitata* study is 30.2 mg/L (MOE Japan, 1999c; OECD, 2004) [Kl. score = 1].

C. Terrestrial Toxicity

No data are available.

Choline is present in all plant and animal cells, mostly in the form of phospholipids (phosphotidylcholine or lecithin, lysophosphatidylcholine, choline plasmalogens and sphingomyelin), which are essential components of membranes (IOM, 2000).

D. Calculation of PNEC

The PNEC calculations for choline chloride follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>100 mg/L), invertebrates (349 mg/L), and algae (>1,000 mg/L). Results from chronic studies are available for invertebrates (21-day NOEC = 30.2 mg/L) and algae (72-hour NOEC = 32 mg/L). On the basis that the data consists of chronic studies on two trophic level (albeit not on the species with the lowest $E(L)C_{50}$), an assessment factor of 100 has been applied to the lowest reported NOEC of 30 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 0.3 mg/L (0.22 mg/L for choline).

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.15 mg/kg sediment wet weight.

The calculations are as follows:

$$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$$
$$= (0.844/1280) \times 1000 \times 0.22$$
$$= 0.15$$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{solid}]$$
$$= 0.8 + [0.2 \times 0.092/1000 \times 2400]$$
$$= 0.844$$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$$Kp_{sed} = K_{oc} \times f_{oc}$$

= 2.3 x 0.04
= 0.092

Where:

K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for choline is estimated to be 2.3 L/kg (OECD, 2004).
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ for choline is 0.007 mg/kg soil dry weight (choline).

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
= (0.05/1500) x 1000 x 0.22
= 0.007

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
= 2.3 x 0.02
= 0.05

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for choline is estimated to be 2.3 L/kg (OECD, 2004).
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. LIVESTOCK HAZARD ASSESSMENT

Although choline is present in the diet of livestock (as a component of plant cell membranes), it is also given in significant volumes as an feed additive. Unlike humans, dietary choline in ruminants is rapidly and extensively degraded in the rumen of sheep (Neill et al., 1979) and cattle (Atkins *et al.*, 1988; Sharma and Erdman, 1988). Sharma and Erdman (1988) reported that increasing dietary choline intake in cows from 23.5 g/day in the controls to 326 g/day in the choline-supplemented diet group increased duodenal choline flow from 1.2 to 2.5 g/day, indicating intestinal uptake of only 0.8% to 5%.

No toxicity data are available on livestock.

A livestock oral reference dose (RfD) was derived for choline using the value determined for humans and taking into account the low oral uptake (≤5%) of choline in ruminants.

Oral RfD [livestock] = oral RfD [humans]/oral uptake fraction [livestock]
= 50/0.05
= 1,000 mg/kg-day [choline]

IX. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Choline chloride is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on a measured log Kow of -3.77, choline chloride does not meet the criteria for bioaccumulation.

The NOEC values from chronic toxicity studies on choline chloride are >0.1 mg/L. Thus, choline chloride does not meet the criteria for toxicity.

The overall conclusion is that choline chloride is not a PBT substance.

X. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None

XI. SAFETY AND HANDLING (Aqueous Solutions of Choline Chloride)

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes.

Skin Contact
Wash thoroughly with soap and water.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Keep product and empty container away from heat and sources of ignition. May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon dioxide, nitrogen oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and protective suit.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Soak up with inert absorbent material.

D. STORAGE AND HANDLING

General Handling
Keep product and empty container away from heat and sources of ignition. Ensure adequate ventilation, especially in confined areas.

Storage

Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard for choline chloride.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Respiratory protection is not required.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Choline chloride is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XII. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XIII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

CITRIC ACID

This dossier on citric acid does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of citric acid in its use in drilling muds and water treatment. The information presented in this dossier was obtained primarily from the OECD-SIDS documents on citric acid (OECD 2001a,b) and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): 2-Hydroxy-1,2,3-propanetricarboxylic acid

CAS RN: 77-92-9

Molecular formula: $C_6H_8O_7$

Molecular weight: 192.122

Synonyms: citric acid; 1,2,3-propanetricarboxylic acid, 2-hydroxy-; 2-hydroxy-1,2,3-propanetricarboxylic acid

SMILES: C(C(=O)O)C(CC(=O)O)(C(=O)O)O

Citric acid is an ubiquitous natural substance that is an intermediate in the basic physiological tricarboxylic acid (TCA) cycle in every eukaryote cell.

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Citric Acid

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White crystalline solid; odourless.	2	ECHA
Melting Point	153°C	2	ECHA
Boiling Point	Not available; decomposition	-	ECHA
Density	1.67 @ 20°C	2	ECHA
Vapor Pressure	2.21 x 10^{-6} Pa @ 25°C	2	ECHA
Partition Coefficient (log K_{ow})	-1.61 to -1.80	2	ECHA
Water Solubility	Very soluble	4	ECHA
Flash Point	345°C	4	ECHA
Auto flammability	1010°C	4	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Citric acid is readily biodegradable. It is not expected to bioaccumulate. Due to its high water solubility, citric acid is unlikely to adsorb to soil or sediment.

B. Biodegradation

Citric acid can be considered readily biodegradable based on the results of the ready and inherent aerobic biodegradation studies listed in Table 2.

Table 2: Biodegradation Studies on Citric Acid (OECD 2001a,b)

Test System	Results*	Notes	Klimisch Score
Modified Sturm	97% (CO_2 evolution); 100% (DOC removal)	Readily biodegradable; exposure period not stated	2
Closed Bottle Test	BOD_{30}/COD Ratio = 90%	Readily biodegradable	2
BOD_5/COD Ratio	BOD_5 = 526 mg; COD = 728 mg; BOD_5/COD Ratio = 0.72	Readily biodegradable; concentration of test substance and activated sludge not stated	2
BOD_1/ThOD Ratio	BOD_1/ThOD Ratio = 13%	-	2
BOD_{20}/ThOD Ratio	BOD_{20}/COD Ratio = 98%	Readily biodegradable; initial test substance concentration 720 mg/L	2
Zahn-Wallen Test	85%, 1 day (DOC removal)	Inherently biodegradable	2
Zahn-Wallen Test	98%, 7 days (DOC removal)	Inherently biodegradable	
Coupled Units Test	93% (COD removal)	Ultimately biodegradable; exposure period not stated.	2

C. Environmental Distribution

Absorption/desorption

No experimental data are available for citric acid. Using KOCWIN program in EPISuite™ (EPA, 2016), the estimated K_{oc} value from the K_{ow} value of -1.08 is 0.3617 L/kg.

D. Bioaccumulation

The log K_{ow} for citric acid is -1.61 to -1.80. Thus, citric acid is not expected to bioaccumulate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Citric acid exhibits low toxicity by the oral and dermal routes. It is an eye irritant, but slightly to non-irritating to the skin. No adequate studies were found to evaluate the sensitization potential of citric acid. Minimal toxicity and no carcinogenic effects were observed in rats given oral doses of citric acid for up to two years. Citric acid was not mutagenic to bacteria, but *in vitro* studies using human lymphocytes showed genotoxic effects. *In vivo* genotoxicity studies were negative. There were no reproductive or developmental effects in rats given oral doses of citric acid.

B. Acute Toxicity

The acute oral LD_{50} in male rats was reported to be 11,700 mg/kg (ECHA) [Kl. score = 2]. The acute oral LD_{50} values in mice are 5,400 and 5,790 mg/kg (ECHA) [Kl. score = 2]. The acute dermal LD_{50} value in rats is >2,000 mg/kg (ECHA) [Kl. score = 1].

C. Irritation

Application of 0.5 g citric acid powder to the skin of rabbits for 4 hours under semi-occlusive conditions was slightly irritating. The mean of the 24, 48, and 72-hour scores were: 0.3 for erythema and 0.0 for edema (ECHA) [Kl. score = 1]. Application of a 50% aqueous solution of citric acid to the skin of rabbits for 4 hours under occlusive conditions was non-irritating (ECHA) [Kl. score = 2].

Instillation of a 30% aqueous solution of citric acid into the eyes of rabbits produced well defined to moderate conjunctival irritation that did not fully resolve after the 14-day observation period. A 10% solution was associated with weak to moderate conjunctival effects, which resolved after 7 days (ECHA) [Kl. score = 2].

D. Sensitization

No adequate studies were found to evaluate the sensitization potential of citric acid.

E. Repeated Dose Toxicity

Oral

Male rats were given 0, 1.2, 2.4, or 4.8% citric acid in their feed for 6 weeks. The daily intakes were reported to be 1,150, 2,260, or 4,670 mg/kg-day. The high-dose animals had mild blood and urine parameter changes and slight degeneration of the thymus gland and spleen. The NOAEL is 2.4% in the diet or 2,260 mg/kg-day (OECD, 2001a,b). [Kl. score = 4]

Rats were given 3% or 5% citric acid in their diet for two years. The estimated daily intakes were 1,200 and 2,000 mg/kg-day, respectively. A slight decrease in growth was reported in the 2% group, but no tissue abnormalities in the major organs. The NOAEL is 1,200 mg/kg-day (OECD, 2001a,b). [Kl. score = 4]

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

Citric acid was not mutagenic in bacterial reverse mutation assays with strains of *S. typhimurium* or *E. coli* with and without metabolic activation (OECD, 2001a,b; ECHA). [Kl. score = 2]

Peripheral human lymphocytes were treated with 50 to 3,000 µg/ml citric acid. A statistically significant dose-dependent increase in the micronuclei was observed. In another set of studies by the same laboratory, there was a statistically significant and dose-related increase in the number of cells with aberrations, including sister chromatid unions. The study authors reported that the pH of the medium was unchanged (ECHA). [Kl. score = 2]

In Vivo Studies

Citric acid was not mutagenic in a dominant lethal assay when male rats were given either a single oral dose of citric acid (1.2 to 120 mg/kg) or a single oral dose on five consecutive days (300 to 3,500 mg/kg) (OECD 2001a,b) [Kl. score = 2]. There were no increases in chromosomal aberrations in the bone marrow of rats given either a single oral dose of citric acid (1.2 to 120 mg/kg) or a single oral dose on five consecutive days (300 to 3,500 mg/kg) (ECHA) [Kl. score = 2].

G. Carcinogenicity

Oral

There was no evidence of carcinogenicity in rats given 3% or 5% citric acid in feed (1,200 or 2,000 mg/kg/day, respectively) for two years (OECD, 2001a,b). [Kl. score = 4]

H. Reproductive Toxicity

In a non-standard repeat dose dietary study (duration and frequency not specified), 5% citric acid in feed did not affect either the number of young born to mice or rats or their subsequent survival up to the point of weaning (ECHA). [Kl. score = 4]

I. Developmental Toxicity

Pregnant female rats were dosed by oral gavage with 0, 2.95, 13.7, 63.6, or 295 mg/kg citric acid on GD 6-15. No maternal or developmental effects were noted. The NOAEL for maternal and developmental toxicity is 295 mg/kg-day, the highest dose tested (OECD, 2001a,b; ECHA). [Kl. score = 2]

Pregnant female rats were dosed by oral gavage with 0, 2.41, 11.2, 52, or 241 mg/kg citric acid on GD 6-15. No maternal or developmental effects were noted. The NOAEL for maternal and developmental toxicity is 241 mg/kg-day, the highest dose tested (OECD, 2001a,b; ECHA). [Kl. score = 2]

Pregnant female rabbits were dosed by oral gavage with 0, 4.25, 19.75, 91.70, or 425 mg/kg citric acid on GD 6-18. No maternal or developmental effects were noted. The NOAEL for maternal and developmental toxicity is 425 mg/kg-day, the highest dose tested (OECD, 2001a,b; ECHA). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for citric acid follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

In a two-year dietary study, the only effect seen in rats fed either 3 or 5% citric acid (approx. 1,200 or 2,000 mg/kg-day) was a slight decrease in growth in the 5% dose group. In the absence of statistical analysis of the body weight gain data, a conservative approach was taken, and the 5% dose group was considered an LOAEL. The NOAEL of 3% citric acid in the diet (1,200 mg/kg-day) will be used for determining the oral reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
- UF_A (interspecies variability) = 10
- UF_H (intraspecies variability) = 10
- UF_L (LOAEL to NOAEL) = 1
- UF_{Sub} (subchronic to chronic) = 1
- UF_D (database uncertainty) = 1

Oral RfD = 1,200/(10 x 10 x 1 x 1 x 1) = 1,200/100 = 12 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,

Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

Where:
- Human weight = 70 kg (ADWG, 2011)
- Proportion of water consumed = 10% (ADWG, 2011)
- Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (12 x 70 x 0.1)/2 = 42 mg/L

B. Cancer

Citric acid was not carcinogenic to rats in a chronic dietary study. Thus, no cancer reference value was derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Citric acid does not exhibit the following physico-chemical properties:
- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Citric acid is of low toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

The 48-hour LC_{50} values in *Leuciscus idus melanotus* (golden orfe) from two separate laboratories were 440 mg/L and 760 mg/L (ECHA) [Kl. scores = 2]. The 96-hour LC_{50} in *Lepomis macrochirus* (fathead minnow) is >100 mg/L (ECHA) [Kl. score = 2).

The 24-hour EC_{50} in *Daphnia* is 85 mg/L in un-neutralized test solution and 1,535 mg/L in a neutralized solution (OECD, 2001a,b; ECHA). [Kl. score = 2]

The 8-day toxicity threshold value (EC_0) in *Scenedesmus quadricauda* is 640 mg/L (ECHA; OECD, 2001a,b). [Kl. score = 2]

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for citric acid follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for only fish (440 mg/L) and *Daphnia* (1,535 mg/L, neutralized). On the basis that the data consist of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 440 mg/L for fish. The $PNEC_{water}$ is 0.44 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.277 mg/kg wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.807/1280) \times 1000 \times 0.44$
$= 0.277$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{soilid}]$
$= 0.8 + [0.2 \times 0.014/1000 \times 2400]$
$= 0.807$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).

BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
= 0.3617 x 0.04
= 0.014

Where:

K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for citric acid is estimated to be 0.3617 L/kg.
F_{oc} = fraction of organic carbon suspended sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.002 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
= (0.007/1500) x 1000 x 0.44
= 0.002

Where:

Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
= 0.3617 x 0.02
= 0.007

Where:

K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for citric acid is estimated to be 0.3617 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009, ECHA, 2008).

Citric acid is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The log K_{ow} values for citric acid are -1.61 to -1.80. Thus, citric acid does not meet the screening criteria for bioaccumulation.

There are no adequate chronic aquatic toxicity studies on citric acid. The acute $E(L)C_{50}$ values for citric acid are >1 mg/L in fish and invertebrates. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that citric acid is not a PBT substance.

IX. CLASSIFICATION AND LABELING

The information in this section is for a citric acid solution.

A. Classification

Eye Irritant Category 2

B. Labelling

Warning

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact

In the case of contact, immediately flush eyes with plenty of water for at least 15 minutes. If symptoms persist, seek medical advice.

Skin Contact

Wash thoroughly with soap and water.

Inhalation

If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion

Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. If symptoms develop, seek medical advice.

B. FIRE FIGHTING INFORMATION

Extinguishing Media

Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards

No data are available.

Special Protective Equipment for Firefighters

Wear self-contained breathing apparatus.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Use appropriate protective equipment.

Environmental Precautions

Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilt

Pick up with absorbent material. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling

No special measures necessarily provided product is used correctly.

Other Handling Precautions

Avoid eye and skin contact.

Storage

Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure standard for citric acid.

Engineering Controls

None

Personal Protection Equipment

Respiratory Protection: Respiratory protection is not required.

Hand Protection: Chemical resistant protective gloves.

Skin Protection: Body protection must be chosen depending on activity and possible exposure.

Eye protection: Safety glasses with side-shields.

Other Precautions: Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Citric acid is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods Code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

COFFEE EXTRACT

This dossier on coffee extract does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of coffee extract in its use in hydraulic fracturing fluids. The information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Coffee, bean, roasted, extract

CAS RN: 68916-18-7

Molecular formula: UVCB substance

Molecular weight: UVCB substance

Synonyms: Coffee extract; coffee, bean, roasted, extract

Table 1 shows all of the constituents found in roasted arabica and robusta coffees.

Table 1: Composition of Medium-Roasted Coffee (Clarke, 1987; IARC, 1991)

Components	**Typical average content (dry basis, %)**		**% extractable with water, 100°C[a]**
	Arabica	**Robusta**	
Alkaloids (caffeine)	1.3	2.4	75 - 100
Trigonelline (including roasted by-products)	1.0	0.7	85 - 100
Minerals (as oxide ash)	4.5	4.7	90
Acids			
Residual chlorogenic	2.5	3.8	100
Aquinic	0.8	1.0	100
Aliphatic	1.6	1.6	100
Sugars			
Sucrose	0.0	0.0	-
Reducing	0.3	0.3	100

Flash point	No flash to boiling.	1	ECHA
Auto flammability	>600°C	1	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Coffee extract is inherently biodegradable and is expected to have a low potential for bioaccumulation. The potential for adsorption is unknown; however, the low octanol water partition coefficient for coffee extract suggests that it is low. The acute toxicity by the oral and dermal routes is low.

B. Biodegradation

Coffee extract is inherently biodegradable. In an OECD 301D test, degradation was 50.2% after 28 days (ECHA) [Kl. score = 1].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for coffee extract. Coffee extract is an UVCB substance containing a wide range of different constituents (see Table 1); thus, a K_{oc} value cannot be calculated.

D. Bioaccumulation

No bioconcentration studies have been conducted on coffee extract. Coffee extract is not expected to bioaccumulate based on the experimental log K_{ow} of <0.36 (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The information on the human health hazard for coffee extract includes primarily data on caffeine, the pharmacologically active constituent of coffee extract, as well as the extract itself. Coffee extract is not irritating to the skin or eyes. Caffeine consumption up to 400 mg caffeine/day in healthy adults is not associated with overt, adverse cardiovascular effects, behavioral effects, reproductive and developmental effects, acute effects, or bone status. Also, consumption up to 300 mg caffeine/day in healthy pregnant women is generally not associated with adverse reproductive and developmental effects.

B. Pharmacokinetics

Caffeine is rapidly and completely adsorbed in humans, with approximately 99% absorbed within 45 minutes of consumption (Carillo and Benitez, 2000). Plasma caffeine levels may be influenced by the diet or route of exposure, but peak plasma levels occur approximately 15 to 120 minutes after consumption (Mandel, 2002; Beach *et al.*, 1984; Bonati *et al.*, 1984; Collomp *et al.*,

1991). Caffeine is water soluble and is rapidly distributed throughout the body, detected in all bodily fluids, including saliva, breast milk, urine and semen (Beach *et al.*, 1984). Caffeine elimination follows first-order kinetics (Newton *et al.*, 1981), with the plasma half-life of caffeine at approximately 3 to 6 hours in healthy adults and does not accumulate in body fat or other tissues (Kaplan *et al.*, 1997; Nawrot *et al.*, 2003). Caffeine is rapidly metabolized and excreted (1-3 mg/kg/minute) in the urine (Kaplan *et al.*, 1997), and varies between species, with a slightly different metabolic route noted in rats (Nawrot *et al.*, 2003).

C. Acute Toxicity

Animal Studies

The oral LD_{50} value of an aqueous extract of roasted and ground beans of *Coffea canephora robusta* containing 7.5% caffeine was between 2,000 and 5,000 mg/kg (ECHA) [Kl. score = 1].

No acute inhalation studies are available on coffee extract. The 4-hour LC_{50} value of a caffeine aerosol in rats is 4.94 mg/L (ECHA) [Kl. score = 2].

No acute dermal studies are available on coffee extract. The dermal LD_{50} value of an aqueous solution of caffeine in rats is >2,000 mg/kg (ECHA) [Kl. score = 2].

Human Studies

Studies in human have focused on caffeine, the pharmacologically active component in coffee. The fatal acute oral dose is estimated at 10 and 14 g (approximately 160 to 230 mg/kg for a 60 kg person) (Hodgman, 1998). The serum caffeine concentration is the most reliable indicator of potential caffeine toxicity, with a serum caffeine concentration >100 μg/ml considered lethal in humans (Mrvos *et al.*, 1989). Human caffeine consumption at up to 10 g has caused convulsions and vomiting, with recovery in six hours (Dreisbach, 1974). An acute dose of one gram caffeine can cause adverse effects, progressing from restlessness, nervousness, and irritability to delirium, emesis, neuromuscular tremors and convulsions (IOM, 2004). However, caffeine consumption through the day at up to 900 mg has been reported without adverse effects (Nawrot *et al.*, 2003).

D. Irritation

Coffee silverskin extracts was not considered a skin irritant when tested in an *in vitro* reconstructed human epidermis test (ECHA) [Kl. score = 1].

Coffee, bean, roasted, extract was not considered an eye irritant when tested in a bovine corneal opacity and permeability test (ECHA) [Kl. score = 1].

E. Sensitization

No studies are available.

F. Repeated Dose Toxicity

<u>Oral</u>

Male and female rats were given in their drinking water 0, 25, 50, or 100% with either instant or brewed coffee for 91 days. The average daily intakes of caffeine were 0, 20, 40, or 80 mg/kg-day for the brewed coffee and slightly lower intakes for the instant coffee. At study termination, the kidneys of the 100% male coffee groups had enlarged kidneys based on both absolute and relative weights. In the females, liver and kidneys were enlarged in all rats given brewed coffee, although the relative weights were significantly higher only in the 100% group. In the ≥50% instant coffee groups, both absolute and relative liver and kidney weights were increased, although there was no clear dose-response pattern. Histopathologic examination showed no treatment-related effects. In the absence of corresponding histopathologic changes, the liver and kidney weight changes were considered to be adaptive changes and not adverse. The NOAEL for this study is 100% coffee in drinking water, which corresponds to 80 mg/kg-day (Nolen, 1981; ECHA) [Kl. score = 2].

In an NTP study, male and female F344 rats were dosed by oral gavage with 0, 188, 375, 750, 1,500, or 3,000 ppm caffeine for 90 days. The average daily intakes were: 0, 19.7, 42, 85.4, 151, or 272 mg/kg-day for males; and 0, 23, 51, 104, 174, or 287 mg/kg-day for females). Body weight gain was reduced in all treated groups but was only significant in the 3,000 ppm animals (26% and 20% for males and females, respectively). Water consumption was decreased in the 3,000 ppm animals; it was increased in the 375 and 750 ppm groups. The only treatment-related effects observed was cellular enlargement in the salivary gland, which was dose-dependent. This effect in the salivary gland was considered an adaptive response as a result of the pharmacological effect of caffeine (sympathomimetic) and not an adverse effect. The NOAEL for this study is 1,500 ppm, which corresponds to 151 and 174 mg/kg-day for males and females, respectively (ECHA) [Kl. score = 2].

Inhalation

No studies are available.

Dermal

No studies are available.

G. Genotoxicity

In Vitro Studies

Instant and home brew coffees (caffeinated and decaffeinated) were evaluated for genotoxicity in an in vitro chromosomal aberration test using human lymphocytes with or without metabolic activation (S9 mix). Chromosomal aberrations were increased with all coffee samples with or without S9, although there was less of an increase with S9. Pure caffeine tested with or without S9 at doses equivalent to the levels in the caffeine-containing coffees did not induce a statistically significant increase in chromosomal aberrations (Aeschbacher et al., 1985; ECHA) [Kl. score 2].

Instant and home brew coffees (caffeinated and decaffeinated) were evaluated for mutagenicity in an in vitro bacterial reverse mutation assay with or without metabolic activation (S9 mix). The *S. typhimurium* strains were TA 98, TA 100, TA1535, TA 1537, and TA 1538. A mutagenic response was observed with TA 100 in the absence of S9, but not with S9. None of the other

strains showed a mutagenic response with or without S9 (Aeschbacher and Würzner, 1980; ECHA) [Kl. score = 2].

Five Americano coffees from selected coffee chains were evaluated for mutagenicity in an in vitro bacterial reverse mutation assay with or without metabolic activation (S9 mix). The *S. typhimurium* strains were TA 98, TA 100, and TA 1535. There were no mutagenic responses with or without metabolic activation (Liu et al., 2017; ECHA) [Kl. score = 2].

In Vivo Studies

Male Swiss OF-1 mice were dosed by oral gavage with 0, 500, 1,000, 2,000, or 3,000 mg/kg instant coffee for five consecutive days. There was no treatment-related increase in the frequency of micronuclei in bone marrow cells (Aeschbacher et. al., 1984 ECHA) [Kl. score = 2].

H. Carcinogenicity

No carcinogenicity studies are available.

I. Reproductive/Developmental Toxicity

Animal Studies

A one-generation reproductive toxicity study was conducted in rats. Male and female rats were given in their drinking water 0, 25, 50, or 100% with either instant or brewed coffee. The average daily intakes were 0, 20, 40, or 8 mg/kg-day for the brewed coffee and slightly lower intakes for the instant coffee. Exposure of parental animals were for 91 days and during mating. Exposure continued through the first gestation period and through weaning. Ten days later, the females were mated the second time and were sacrificed on GD 13 or 21. There were no indications of reproductive or developmental toxicity (Nolen, 1981; ECHA) [Kl. score = 2].

Human Studies

Studies in human have focused on caffeine, the pharmacologically active component in coffee. Studies that evaluated the potential teratogenicity of caffeine have been discussed in a review (Christian and Brent, 2001). In animal studies, caffeine administration to pregnant animals has been found to induce teratogenicity and toxic effects on the development of the fetuses only at doses that also caused toxic effects in the dams (Christian and Brent, 2001). Christian and Brent (2001) concluded that studies reporting positive teratogenic effects were administering large doses of caffeine that were far greater than human consumption and were providing the caffeine via gavage, which results in much higher peak serum caffeine levels and therefore overstates toxicity potential. Neither rodents nor humans could attain such peak exposures by consuming solutions of caffeine over several hours, the usual mode of human caffeine consumption.

There have been questions raised on whether high intake of coffee or caffeine may increase the risk of miscarriage. Caffeine crosses the placenta and increases maternal catecholamine levels (Goldstein and Warren, 1962). The American College of Obstetricians and Gynecologists (2010) have concluded the following: “Moderate caffeine consumption (less than 200 mg per day) does not appear to be a major contributing factor in miscarriage or preterm birth. The relationship of

caffeine to growth restriction remains undetermined. A final conclusion cannot be made at this time as to whether there is a correlation between high caffeine intake and miscarriage."

The American College of Obstetricians and Gynecologists (2010) have concluded that moderate caffeine consumption (<200 mg/day) does not appear to be a major contributing factor in miscarriage or preterm birth.

A recent systematic review of the potential adverse effects of caffeine consumptions in humans concluded that consumption up to 400 mg caffeine/day in healthy adults is not associated with reproductive and developmental effects. Also, consumption up to 300 mg caffeine/day in healthy pregnant women is generally not associated with adverse reproductive and developmental effects (Wikoff et al., 2017).

J. Human Studies

Caffeine is a stimulant and has been studied for its physiological and behavioral effects. Caffeine increases heart rate and blood pressure, increases diuresis, increases locomotion and alertness, and decreases sleepiness. Clinical studies indicate that doses <450 mg do not increase the risk or severity of cardiac arrhythmia, while acute doses of 150 mg caffeine may decrease heart rate (James, 1991; Green *et al.*, 1996; Myer, 1998). Studies evaluating effects of caffeine on cardiovascular health or serum cholesterol levels have not provided a consistent adverse effect with caffeine consumption (Nawrot *et al.*, 2003).

Nawrot *et al.* (2003) concluded in their review of the effects of caffeine on human health that "for the healthy adult population, moderate daily caffeine intake at a dose level up to 400 mg/day (equivalent to 6 mg/kg body weight/day in a 65-kg person) is not associated with adverse effects such as general toxicity, cardiovascular effects, effects on bone status and calcium balance (with consumption of adequate calcium), changes in adult behavior, increased incidence of cancer and effects on male fertility." It was indicated that habitual daily use of caffeine at greater than 500-600 mg/day (8.3 - 10 mg/kg) (4-7 cups of coffee or 7-9 cups of tea) could be considered a health risk. For women, caffeine intake greater than 400 mg/day (6.7 mg/kg) "may increase the risk of detrusor instability (unstable bladder) development in women" (Nawrot *et al.*, 2003).

A recent systematic review of the potential adverse effects of caffeine consumptions in humans also concluded that consumption up to 400 mg caffeine/day in healthy adults is not associated with overt, adverse cardiovascular effects, behavioral effects, acute effects or bone status (Wikoff et al., 2017).

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for coffee extract follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

<u>Oral</u>

A 90-day drinking water study on brewed and instant coffee reported no adverse effects up to 80 mg/kg-day (Nolen, 1982). A NTP 90-day oral gavage toxicity study in rats showed no adverse effects up to 174 mg/kg-day (NTP).

In two separate reviews (Nawrot et al., 2003; Wikoff et al., 2017) with the most recent one conducted using a systematic review approach (Wikoff et al., 2003), caffeine consumption in healthy adults up to 400 mg/day is not associated with any adverse health effects. Based on the acceptable daily intake of caffeine in coffee extract, the acceptable daily intake of caffeine of 400 mg/day will be used to derive the oral reference dose and drinking water guidance value for coffee extract.

Oral Reference Dose (oral RfD)

For a 70 kg person, the oral reference dose is 400/70 = 6 mg/kg-day.

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (5.7 x 70 x 0.1)/2 = <u>20 mg/L</u>

B. Cancer

No studies are available. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Coffee extract does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Coffee extract has a low acute toxicity concern for aquatic life.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on coffee extract.

Table 3: Acute Aquatic Toxicity Studies on Coffee Extract

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LL_{50}	>100 WAF	1	ECHA
Daphnia magna	48-hr EL_{50}	>100 WAF	1	ECHA
Pseudokirchneriella subcapitata	72-hr EL_{50}	>100 WAF (growth)	1	ECHA

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for coffee extract follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)L_{50}$ values are available for fish (>100 mg/L WAF), invertebrates (>100 mg/L WAF), and algae (>100 mg/L WAF). On the basis that the data consist of short-term results from three trophic levels, an assessment factor of 100 has been applied to the acute $E(L)L_{50}$ value of 100 mg/L WAF from fish, invertebrates, and algae. The $PNEC_{water}$ is 1 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. The $PNEC_{sed}$ was not calculated using the equilibrium partitioning method because the K_{oc} value cannot be determined.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. The $PNEC_{soil}$ was not calculated using the equilibrium partitioning method because the K_{oc} value cannot be determined.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008). Coffee extract is not readily biodegradable, but it does appear to be inherently biodegradable; thus, it is not expected to meet the screening criteria for persistence.

Based on a measured log K_{ow} of <0.36, coffee extract does not meet the screening criteria for bioaccumulation.

There are no chronic aquatic toxicity studies on coffee extract. The acute $E(L)L_{50}$ values for coffee extract are >1 mg/L for fish, invertebrates, and algae. Thus, coffee extract does not meet the screening criteria for toxicity.

The overall conclusion is that coffee extract is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water. If easy to do, remove contact lenses.

Skin Contact
Take off contaminated clothing immediately. Wash thoroughly with soap and water. Get medical attention if irritation develops and persists.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention.

Ingestion
Rinse mouth with water and then drink a glass of water. Get medical attention. Do not induce vomiting. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon oxides, nitrogen oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use personal protective clothing.

Environmental Precautions
Do not empty into drains.

Steps to be Taken if Material is Released or Spilled
For small amounts: Pick up with absorbent material. Dispose of contaminated material. For large amounts: pump off product.

D. STORAGE AND HANDLING

General Handling
No special measures necessary provided product is used correctly.

Storage
Keep container tightly closed and dry. Store in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure limit for coffee extract.

Engineering Controls
None

Personal Protection Equipment

Respiratory Protection: Respiratory protection not required.

Hand Protection: Wear chemical resistant protective gloves.

Skin Protection: Body protection must be chosen depending on activity and possible exposure.

Eye protection*:* Wear safety goggles with side shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Coffee extract is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

DIETHANOLAMINE

This dossier on diethanolamine (DEA) does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of diethanolamine in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): 2,2'-iminodiethanol

CAS RN: 111-42-2

Molecular formula: $C_4H_{11}NO_2$

Molecular weight: 105.14

Synonyms: Diethanolamine; 2,2'-iminodiethanol; 2,2'-dihydroxydiethylamine; 2-[(2-hydroxyethyl)amino]ethanol; bis(2-hydroxyethyl)amine; DEA; di(2-hydroxyethyl)amine; ethanol, 2,2'-iminobis-(9Cl); ethanol, 2,2'iminodi-(8Cl)

SMILES: C(CO)NCCO

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Diethanolamine

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Crystals (prisms) or syrupy liquid (>82°F)	2	ECHA
Melting Point	27°C	1	ECHA
Boiling Point	268.9°C (decomposition occurs ≥200°C)	1	ECHA
Density	1.095.3 kg/m^3	2	ECHA
Vapor Pressure	1 hPa @ 108°C (measured); 0 hPa at 25°C	2	ECHA

Partition Coefficient (log K_{ow})	-2.46 @ 25°C	2	ECHA
Water Solubility	Miscible	2	ECHA
Flash Point	176°C @ 1,013 hPa	2	ECHA
Auto flammability	375°C @ 1,013 hPa	1	ECHA
Flammable	Not flammable	1	ECHA
Viscosity	390.9 mPa s @ 30°C; 102.7 mPa s @ 50°C	2	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Diethanolamine is readily biodegradable. It is not expected to bioaccumulate, and it has low potential to adsorb to soil.

B. Biodegradation

Diethanolamine is readily biodegradable. In an OECD 301F test, there was 50% degradation after 7 days, 80% after 14 days, and 93% after 28 days (OECD 2007; ECHA) [Kl. score = 1]. In a "Ready" Biodegradability – Dissolved Organic Carbon (DOC) Die-Away test, there was 86% degradation after 7 days and 96% degradation after 10 days (ECHA) [Kl. score = 2]. In modified OECD 301E screening tests using river or pond water, there was 93% and 97% degradation (measured as DOC removal) after 28 days (OECD 2007; ECHA) [Kl. score = 2].

C. Environmental Distribution

Distribution Modeling

No experimental data are available for diethanolamine. The K_{oc} for diethanolamine (as the charged molecule) was calculated to be 10 at pH values between 5 and 8 (Franco and Trapp, 2008; Franco et al., 2009; ECHA). [Kl. score = 2]

E. Bioaccumulation

There are no bioaccumulation studies on diethanolamine. The BCF was estimated to be 2.3 based on calculations from OASIS Catalogic v.5.11.15 [BCF base-line model v.0208] (Dimitrov et al., 2005; ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Diethanolamine exhibits moderate acute toxicity by the oral route, but low acute toxicity by the inhalation and dermal routes. It is a skin irritant and a severe eye irritant. Diethanolamine is not a skin sensitizer. Repeated oral exposure to rats (in drinking water) resulted in anemia, kidney toxicity, demyelinization of the brain/spinal cord, and damage to the testes in males, which included adverse effects on the sperm. Repeated oral exposure to mice (in drinking water) resulted in adverse effects to the kidney, liver, and heart. Repeated dermal exposure to rats and mice resulted in systemic toxicity, which included kidney toxicity, anemia (rats only), and liver toxicity (mice only). Rats exposed nose-only to an aerosol of diethanolamine developed anemia, adaptive liver and kidney effects, damage to the male reproductive organs, and upper respiratory tract irritation. There was no evidence of neurotoxicity. In short-term oral studies, rats and mice exposed to diethanolamine showed some immune-modulating effects at dose levels that resulted in overt signs of systemic toxicity. Diethanolamine was not genotoxic in a variety of *in vitro* and *in vivo* genotoxicity tests. Diethanolamine was not carcinogenic to rats in a two-year NTP dermal bioassay; but, in mice, there was an increased incidence of liver tumors in males and females and kidney tumors in males. Studies by the oral and dermal routes showed testicular damage in male rats, but no adverse effects in female reproductive organs. Developmental toxicity occurred in rats when exposures by the oral, dermal, or inhalation routes also caused maternal toxicity. There was no developmental toxicity in rabbits even at doses that caused maternal toxicity.

B. Pharmacokinetics/Metabolism

Following oral administration of [^{14}C]-diethanolamine, 57% of the dose was absorbed (Matthews et al., 1997). Absorption was lower through the skin than from oral administration. Diethanolamine may also facilitate its own absorption in rats, as 3% and 16% of the dermally applied doses (in 95% ethanol) of 2 and 27 mg/kg, respectively, were absorbed through the skin in a 48-hour period. Dermal absorption of diethanolamine is higher in the mouse than the rat: absorption was 25 to 60% from dermal doses of 8 to 80 mg/kg (Matthews et al., 1997).

The distribution of diethanolamine is similar across all routes of exposure (Matthews et al., 1997; Mendrala et al., 2001). The highest concentrations were found in the liver and kidney. The half-life of diethanolamine from tissues is about 6-7 days (Mendrala et al., 2001).

Following an oral dose of [^{14}C]diethanolamine to male F344 rats, the livers showed levels of un-metabolized diethanolamine, N-methyl-diethanolamine, N,N-dimethyl-diethanolamine, and phosphates of diethanolamine. In addition, the organic extract of the liver had radioactivity co-eluting with phosphatidyl ethanolamine and phosphatidyl choline. When the organic extract was digested with sphingomyelinase, 30% of the phospholipids were identified as ceramides and the remaining 70% as phosphoglycerides. Incubation of human liver slices with [^{14}C]-diethanolamine showed similar incorporation of diethanolamine into ceramides, followed by methylation (Matthews et al., 1995).

Diethanolamine is excreted primarily in urine as the parent compound (25-36%), with lesser amounts of O-phosphorylated and N-methylated metabolites (Matthews et al., 1997).

C. Acute Toxicity

The oral LD_{50} value for male and female rats combined was determined to be 1,600 mg/kg (ECHA) [Kl. score = 2]. The oral LD_{50} in female Wistar rats is 1,820 mg/kg (ECHA) [Kl. score = 2].

There were no deaths in rats following an 8-hour inhalation exposure to an atmosphere enriched with diethanolamine vapor. The technically highest attainable concentration is 1.9 mg/m^3 or 0.44 ppm (ECHA) [Kl. score = 2]. There were no deaths in rats following an 8-hour exposure to 0.2 mg/L diethanolamine vapor (ECHA) [Kl. score = 2].

There are no reliable acute dermal toxicity studies on diethanolamine.

D. Irritation

Application of 2 mL of diethanolamine to the skin of rabbits for 20 hours was irritating. The mean of the 24, 48, and 72 hours scores were 2.00 for erythema and 1.33 for edema (ECHA) [Kl. score = 2].

Instillation of diethanolamine into the eyes of rabbits was irritating. The mean of the 24, 48, and 72 hour scores were 1.67 for corneal opacity; 0.00 for iridial lesions; 1.50 for conjunctival redness; and 0.83 for chemosis. Corneal lesions still persisted in one of two animals at the end of the 8-day observation period (ECHA) [Kl. score = 2]. Instillation of 100 mg diethanolamine into the eyes of rabbits produced a mean irritation score based on Kay and Calandra of 50.75, indicating severe irritation (ECHA) [Kl. score = 2].

E. Sensitization

Diethanolamine was not considered a skin sensitizer in a mouse local lymph node assay (ECHA). [Kl. score = 1]

F. Repeated Dose Toxicity

Oral

Male and female F344 rats were given diethanolamine in their drinking water for 13 weeks at concentrations of 0, 320, 630, 1,250, 2,500, or 5,000 ppm for males; and 0, 160, 320, 630, 1,250, or 2,500 ppm for females. The average daily intakes were estimated to be: 0, 25, 48, 97, 2,202, or 436 mg/kg-day for males; and 0, 14, 32, 57, 124, or 242 mg/kg-day for females. In the top dose group, 2/10 males died during the study. Weight gain was reduced in the ≥630 ppm males and the ≥320 ppm females. Decreased water consumption among the higher dose groups may have contributed in part to the decreased body weight gain. Clinical signs of toxicity included tremors, emaciation, abnormal posture, and rough hair coat in the two highest dose groups. A dose-dependent microcytic, normochromic anemia was seen in all dose groups for both sexes. Hematologic effects included decreases in erythrocyte and reticulocyte counts, hemoglobin concentration, hematocrit, MCV, and MCH. MCV was reduced in rats at all dose levels. Hematologic effects were not associated with microscopic changes in the femoral bone marrow. Relative kidney weights were increased in a dose-dependent manner in the ≥320 ppm males and ≥160 ppm females, accompanied by increases in the incidence and/or severity of nephropathy, renal tubular cell necrosis, or tubular mineralization. Nephropathy consisted of tubules lined by epithelial cells with more basophilic staining of the cytoplasm and a higher nuclear/cytoplasmic ratio; occasionally, thickened basement membranes were seen around these tubules. This lesion was present to a minimal degree in controls, particularly in male rats, but was increased in incidence and severity in the 5,000 ppm males and in most of the groups of treated females. Increased nephropathy was considered a regenerative change and was supported by the observation of tubular necrosis at the higher dose groups. Relative liver weights were increased in the ≥630 ppm males and ≥320 ppm females, with no corresponding histopathological changes in the liver. There was, however, mild to moderate increases in serum levels of total bile acids in the ≥160 ppm females and in the ≥630 ppm males. Decreases in testis and epididymis weights (≥1,250 ppm) were associated microscopically with degeneration of seminiferous epithelium and with hypospermia (≥2,500 ppm). Testicular degeneration was diagnosed in all high-dose males and in 3/10 of the 2,500 ppm males. Intraluminal cellular debris and reduced numbers of sperm cells were present in the epididymis. These findings correlated with decreases in sperm motility and sperm count per gram caudal tissue. There was also atrophy of the seminal vesicle and prostate glands in the higher dose group males. In females, the estrous cycle length was similar across all groups. Minimal to mild demyelination of the brain and spinal cord was noted in the ≥2,500 ppm males and the ≥1,250 ppm females; there were no neurological clinical signs that could be attributed to these lesions. Cytoplasmic vacuolization of the zona glomerulosa of the adrenal cortex was seen in the 5,000 ppm males and in the ≥1,250 ppm females. This was a minimal change consisting of small clear vacuoles in the cytoplasm of these cells and may have been related to increased mineralocorticoid production secondary to kidney damage and/or dehydration. The most

sensitive endpoints were the microcytic anemia in both sexes and kidney effects in females (weight, nephrotoxicity) and males (weights). The LOAELs are 320 ppm (25 mg/kg-day) for males and 160 ppm (14 mg/kg-day) for females (NTP 1992; Melnick et al., 1994a). [Kl. score = 1]

Male and female B6C3F1 mice were given diethanolamine in their drinking water at concentrations of 0, 630, 1,250, 2,500, 5,000 or 10,000 ppm for 13 weeks. The average daily intakes were estimated to be: 0, 104, 178, 442, 807, or 1,674 mg/kg-day for males; and 0, 142, 347, 884, 1,154, or 1,128 mg/kg-day for females. All of the ≥5,000 ppm animals and 3/10 of the 2,500 ppm females died during the study. Body weight gains were lower in the 2,500 ppm males and in the 1,250 and 2,500 ppm females. Animals that survived to the end of the study had similar water consumption compared to the controls. Clinical signs in the animals that died early in the 2,500 ppm group were tremors, ruffled fur, emaciated appearance, abnormal posture, and hypoactivity. There was no significant gross findings at necropsy in the mice that died early or survived to study termination. Absolute and relative liver weights were increased in a dose-dependent manner in male and female mice and was associated with increases in serum alanine aminotransferase and sorbital hydrogenase activities and, in addition, microscopic changes diagnosed as hepatocellular cytologic alteration and necrosis. Cytologic alteration consisted of multiple hepatocyte changes including hypertrophy with increased eosinophilia and disruption of hepatic cords. These lesions were observed in mice that died early and those that survived to the end of the study. There was also increased nuclear pleomorphism and the frequent presence of large, multinucleated hepatocytes. These giant cells often contained 10 or more nuclei. Hepatocyte necrosis was randomly distributed and involved single cells or small foci. Absolute and relative kidney weights were increased in males and were associated with a dose-dependent increase in the incidence of nephropathy among those mice that survived to the end of the study. Nephropathy was minimal; there were renal tubules lined by basophilic cells with high nuclear/cytoplasmic ratio. This was considered to be a regenerative response, although active tubular necrosis was observed only in a few early-death mice at ≥5,000 ppm. Increased heart weight was seen in the 2,500 ppm females, and relative heart weight was seen in the 2,500 ppm males and the 1,250 and 2,500 ppm females. There was also minimal-to-marked degeneration and necrosis of cardiac myocytes in both sexes exposed to ≥2,500 ppm. Myocardial degeneration was generally more severe in mice that died early than in those that survived to study termination. The most sensitive endpoint was the increase in liver weights with corresponding histopathological changes. The LOAEL was 630 ppm (104 and 142 mg/kg-day in males and females, respectively) (NTP, 1992; Melnick *et al.*, 1992b). [Kl. score = 1]

Inhalation

Male and female Wistar rats were exposed nose-only to 0, 15, 150, or 450 mg/m^3 diethanolamine aerosol, 6 hours/day, 5 days/week for 90 days. The MMAD values were 1.1 – 1.9 μm, 1.0 μm, and 0.6 – 0.9 μm for the 15, 150, and 450 mg/m^3 exposure groups, respectively. The percent aerosol ranged among the exposure groups,, from 92 to 95%.

There were no deaths during the study. The 400 mg/m^3 males had slightly decreased body weights. The neurotoxicity endpoints (functional observation battery, sensorimotor test/reflexes, and motor activity) and ophthalmoscopy examination showed no treatment-related effects. At 400 mg/m^3, there was a significant decrease in red blood cells, hemoglobin, hematocrit, and mean corpuscular volume in both sexes. A marginal increase in anisocytosis was seen in the 400 mg/m^3 males; and no treatment-related effects were seen in white or differential blood counts. ALP serum activity was increase in the $\geq$150 mg/m^3 animals, and reduced ALT in the $\geq$150 mg/m^3 males. Blood chemistry changes included increased calcium, total protein, albumin, globulin in the $\geq$150 mg/m^3 females; and increased total protein and albumin in the $\geq$150 mg/m^3 males as a trend. Absolute and relative liver and kidney weights were increased in the $\geq$150 mg/m^3 animals. Histopathologic examination showed diffuse testicular atrophy accompanied by oligozoospermia in the epididymides, and slight prostate atrophy in the some of the 400 mg/m^3 males. There was also minimal or slight tubular hyperplasia of the kidney in some females as well as intratubular lithiasis in increased number (also in the 400 mg/m^3 males). There was also indications of local irritation of the respiratory tract. The larynx appeared to be the most sensitive area where some epithelia damage was observed at all concentrations. Focal inflammation at the tracheal bifurcation occurred in the $\geq$150 mg/m^3 animals. No treatment-related effects were seen in the neuropathologic examination. The NOAEC for systemic toxicity is 15 mg/m^3. The LOAEC for localized effects (irritation) is 15 mg/m^3; a NOAEC was not established (Garner et al., 2008). [Kl. score = 1]

Male and female Wistar rats were exposed nose-only to 0, 1.5, 3, or 8 mg/m^3 diethanolamine aerosol, 6 hours/day, 5 days/week for 90 days. Additional group of female rats were exposed for 90 days followed by a 3-month recovery period. The MMAD values were 0.6 μm, 0.6 μm, and 0.7 μm for the 1.5, 3, and 8 mg/m^3 exposure groups, respectively. At 8 mg/m^3, the animals showed upper respiratory tract irritation in the form of squamous metaplasia of the laryngeal epithelium at the base of the epiglottis; this was accompanied by some inflammatory cell infiltration. These effects were reversible following the 3-month recovery period. The NOAEC for localized effects (irritation) is 3 mg/m^3 (ECHA). [Kl. score = 1]

Dermal

Male and female F344 rats were given daily dermal applications of 0, 32, 63, 125, 250, or 500 mg/kg diethanolamine, 5 days/week for 13 weeks. The animals that died during the study are as follows: one 500 mg/kg male during week 9 and 2 500 mg/kg females that were killed in a moribund condition during week 10. Final mean body weights were lower in the $\geq$250 mg/kg male and the $\geq$125 mg/kg females. The primary clinical signs of toxicity in the $\geq$125 mg/kg animals were irritation and crusting of the skin at the application site. In all dosed groups, there was a moderate, poorly regenerative, microcytic, normochromic anemia in both sexes. Red blood cell variables were decreased in the $\geq$32 mg/kg dose groups. There were no histologic changes in the femoral bone marrow in any dose group. Serum biochemical changes in males were

increased UN and albumin in the 63 and 250 mg/kg groups, respectively, and mild increases in ALT in the ≥125 mg/kg animals. In females, UN, albumin, and total protein increased in the ≥32 mg/kg groups (≥63 mg/kg for total protein), and total bile acids increased in the ≥250 mg/kg groups. A mild increase was seen in ALT in the 500 mg/kg females. The kidney was a target organ. Absolute and relative kidney weights in male and female rats; these were associated with increased severity or increased incidences of nephropathy, renal tubular cell necrosis, or tubular mineralization. The incidence and severity of nephropathy was increased in a dose-dependent manner at the lower dose levels in females, but there was no clear treatment effect on this lesion in males. Tubular necrosis was observed in the ≥250 mg/kg females, but no active necrosis was found in the corresponding male groups. Tubular mineralization, consistent with previous necrosis, was present in the 500 mg/kg males, as well as being increased in incidence and severity in most treated female groups. The absolute and relative liver weights were increased in a dose-dependent manner in both sexes; there were no corresponding histopathologic changes even though there were some mild serum biochemical changes. There were no adverse effects on the testes or epididymides; sperm morphology and vaginal cytology was unaffected by treatment. The skin lesions were dose-related in incidence and severity, and consisted of ulcers, chronic active inflammation, acanthosis, and hyperkeratosis. Demyelination in the medulla oblongata was observed in the 500 mg/kg animals, and in seven 250 mg/kg females; the lesions were characterized by intramyelinic vacuoles arranged symmetrically around the medial medulla oblongata in the region of the tectospinal tract. The lesions were minimal in severity and there was no spinal cord involvement. The LOAEL for this study is 32 mg/kg-day; a NOAEL was not established (NTP, 1992; Melnick et al., 1994a). [Kl. score = 1]

Male and female $B6C3F_1$ mice were given daily dermal applications of 0, 80, 160, 320, 630, and 1,250 mg/kg diethanolamine, 5 days/week for 13 weeks. At 1,250 mg/kg, there were early deaths and reduced body weight gain. Skin lesions were seen in the ≥80 mg/kg groups, there was acanthosis at 80 mg/kg and with a dose-dependent increased incidence up to ulcerations, inflammation, and hyperkeratosis at the higher levels. Liver weights were increased in a dose-dependent manner in the ≥32 mg/kg groups and were associated with morphological alterations in the liver in the ≥32 mg/kg groups. Kidney weights were increased in a dose-dependent manner in the ≥32 mg/kg groups with an increased incidence of tubular necrosis only in the 1,250 mg/kg group. There was also degeneration in the heart and cytologic alterations in the salivary gland in the 1,250 mg/kg group only. The LOAEL for this study is 80 mg/kg-day; a NOAEL was not established (NTP, 1992;Melnick et al., 1994b) [Kl. score = 1]

G. Genotoxicity

In Vitro Studies

Table 2 presents the results of the *in vitro* genotoxicity studies on diethanolamine.

Table 2: *In vitro* Genotoxicity Studies on Diethanolamine

Test System	Results*	Klimisch	Reference

*+, positive; -, negative; NA, not applicable

In vivo Studies

Male and female B6C3F$_1$ mice were given daily dermal applications of 0, 80, 160, 320, 630, or 1,250 mg/kg diethanolamine for 13 weeks. There was no induction of micronuclei in the peripheral blood erythrocytes at any dose level (NTP, 1992; Witt et al., 2000) [Kl. score = 1].

H. Carcinogenicity

Oral

No studies are available.

Inhalation

No studies are available.

Dermal

Male and female F344/N rats were given dermal application of diethanolamine for 104 weeks. For males, the doses were 0, 16, 32 or 64 mg/kg-day; and for females, the doses were 0, 8, 16 or 32 mg/kg-day. There was no difference in survival rates between treated and control animals. Mean body weights were lower in the 64 mg/kg-day males from

week 8 to 89 and in the 32 mg/kg-day females from week 97 compared to the control animals. The incidences of tumors was not increased in the treated groups compared to the controls. (NTP, 1999). [Kl. score = 1]

Male and female B6C3F$_1$ mice were given dermal applications of 0, 40, 80 or 160 mg/kg-day diethanolamine by dermal application for 104 weeks. There was reduced survival in the treated female mice (88, 66, 66, and 46% for the 0, 40, 80 and 160 mg/kg-day groups, respectively). This was attributed to liver tumors. No differences were seen in survival rates in the treated male mice compared to the controls. Mean body weights in the 80 and 160 mg/kg-day males were lower than those in the control animals after week 88. Mean body weights in the treated female mice were lower than those of the controls from week 73 (40 and 80 mg/kg-day) and week 53 (160 mg/kg-day).

The incidence of hepatocellular adenomas and of hepatocellular adenomas and carcinomas (combined) were significantly increased in all male and female dose groups, while the incidences of hepatoblastoma was increased in the mid- and high-dose groups. In the female mice, the incidences of hepatocellular neoplasms were significantly higher in all dosed groups compared to the control. Non-neoplastic lesions were seen only in the liver of all male and female dose groups and consisted of cytoplasmic alteration, characterized by mild to moderate enlargement of centrilobular hepatocytes, and syncytial alteration, characterized by scattered hepatocytes with three or more small nuclei.

The incidence of renal tubule adenomas was also increased in males with a positive trend, but the incidences of carcinoma and hyperplasia did not follow this pattern. A step section evaluation found additional adenomas and hyperplasias in all treated male groups. The combined analysis of single and step sections indicated a dose-related increase in the incidence of renal hyperplasia and renal tubule adenoma or carcinoma (combined), and increase in the incidences of renal tubule adenoma in male mice (NTP, 1999). [Kl. score = 1]

<u>Mode-of-Action for Mouse Liver Tumors in DEA-exposed Mice</u>

Effects of DEA on choline homeostasis

Dietary choline deficiency or deprivation induces liver tumors in rodents (Newberne *et al.*, 1982). In contrast, dietary supplementation of choline with or without methionine reduces the incidence of liver tumors in carcinogen-treated mice (Fullerton *et al.* 1990; Newberne *et al.*, 1990). DEA is structurally similar to ethanolamine and choline, important endogenous precursors for normal membrane structure and function. Choline is also oxidized to betaine, an essential methyl group donor in 1-carbon metabolism. The mechanisms by which choline deficiency is thought to be carcinogenic include enhanced cell proliferation, altered methylation status, and altered signal transduction (Rogers, 1995; Zeisel, 1996; Zeisel and Blustjazn, 1994). The development of intracellular

choline deficiency as the mode of action by which DEA cause the mouse liver tumors observed in the NTP bioassay is supported by the following experimental evidence:

1. $B6C3F_1$ mice dosed dermally with 160 mg/kg DEA, 5 days/week for 2 weeks showed a marked decrease in choline metabolites and S-adenosylmethionine (SAM) levels in their livers similar to animals kept on a choline-devoid diet, indicating the development of choline deficiency. These effects were reversed following a 2-week recovery period (Lehman-MeKeeman *et al.*, 2002). A significant reduction in the hepatic levels of choline metabolites, including choline, phosphocholine, and glycerophospho-choline, and SAM levels was also reported by Stott *et al.* (2000) with $B6C3F_1$ mice dosed in a similar regimen with DEA via dermal and/or oral routes.

2. $B6C3F_1$ mice have a much lower ability than C57Bl/6 mice to maintain nascent methylation capacity, a characteristic that is believed to contribute to a higher spontaneous liver tumor incidence in $B6C3F_1$ mice (Counts *et al.*, 1996). In a study by Lehman-McKeeman *et al.*, (2002), choline deficiency, as evidenced by changes in phosphocholine concentrations, was produced in both strains of mice. However, unlike the $B6C3F_1$ mouse, DEA did not alter SAM concentrations in the C57Bl/6 strain.

3. DEA is incorporated into rat liver phospholipids (Barbee and Hartung, 1979; Mathews *et al.*, 1995) and can alter the biosynthesis of hepatic phosphatidylethanolamine and phosphatidylcholine (PC). In cultured cells, DEA inhibited cellular uptake of choline, decreased PC synthesis, and became incorporated into phospholipid fractions. These *in vitro* effects were prevented by culturing cells in the presence of excess choline (Lehman-McKeeman and Gamsky, 1999).

4. DEA caused morphological transformation in Syrian hamster embryo (SHE) cell transformation assay. However, this response was prevented when SHE cells were cultured in a medium containing excess choline (Lehman-McKeeman and Gamsky, 2000).

5. DNA synthesis was increased in mouse and rat, but not human, hepatocytes incubated with DEA. Incubation of mouse and rat, but not human, hepatocytes in medium containing reduced choline increased DNA synthesis. Mouse and rat hepatocytes incubated in medium with excess choline reduced DEA-induced DNA synthesis to control levels or below (Kamendulis and Klaunig, 2005).

6. DNA hypomethylation in GC-rich promotor regions observed in primary mouse hepatocytes which have been treated with DEA are similar to those caused by choline-deficient medium (Bachman *et al.*, 2005).

In situ formation of N-nitrosodiethanolamine

DEA is a secondary amine and may react with a nitrosating agent under certain conditions to form N-nitrosodiethanolamine. This nitrosoamine has been shown to be mutagenic *in vitro* and cause liver tumors in rats and doses of 2 mg/kg-day and higher (ECETOC, 1990). Rats given high, often toxic, oral bolus doses of DEA and nitrite have

shown or inferred to produce N-nitrosodiethanolamine (Preussman *et al.*, 1981; Yamamoto *et al.*, 1995). Studies by Stott *et al.* (2000) showed, however, that mimicking the dosing conditions in the NTP study (160 mg/kg DEA dermally) and drinking water supplemented with 170 ppm sodium nitrite to favor nitrosation did not result in N-nitrosodiethanolamine formation in the gastric contents, blood or urine of mice. The findings of Stott *et al.* (2000) suggest that the mouse liver tumors observed in the NTP bioassay were unlikely due to *in situ* nitrosamine formation.

Relevance to Humans

There are marked species differences in susceptibility to choline deficiency, with rats and mice being far more susceptible than other species including humans (Zeisel and Blusztajn, 1994). Rats and mice have a higher dietary choline requirement than humans in large part because rodents oxidize choline more rapidly than humans (Sidransky and Farber 1960). DEA was carcinogenic in mice, but not in rats, in the NTP dermal carcinogenicity studies. The fact that DEA was not carcinogenic to rats, a species highly susceptible to choline deficiency, should be an important consideration in the overall evaluation of human cancer risk. DEA is less readily absorbed across rat skin than mouse skin, and the resulting blood and tissue concentrations of DEA are at least three-times lower in rats than in mice at similar dosages (Mathews *et al.*, 1997). Lehman-McKeeman *et al.*, (2002) determined the NOAEL for DEA-induced choline deficiency in mice (based on phosphocholine concentrations) to be 10 mg/kg-day. Thus, there is a critical concentration of DEA that must be reached in order to affect choline homeostatis. In the rats, the lack of a carcinogenic response suggests that it is unlikely that exposure to DEA reached this concentration or that rats are not as susceptible as mice to the effects of DEA on hepatic choline metabolism. Overall, the results suggest that the hepatocarcinogenic effects of DEA in mice are not predictive of similar susceptibility in other laboratory animals or humans.

I. Reproductive Toxicity

No specific reproductive toxicity studies have been conducted on diethanolamine by any route of exposure.

In the NTP 13-week drinking water study, F344 rats were given 0, 160 (females only), 320, 630, 1,250, 2,500 or 5,000 ppm (males only) diethanolamine. All high-dose males and 3/10 of the 2,500 ppm males showed testicular degeneration; male rats in the higher dose groups also had atrophy of the seminal vesicles and prostate glands. Testis and epididymal weights in the $\geq$1,250 ppm males were decreased and were associated microscopically with degeneration of seminiferous epithelium, as well as hypospermia and reduced sperm motility in the $\geq$2,500 ppm males. The NOAEL for reproductive effects in males was 630 ppm (corresponding to 48 mg/kg-day). There were no effects noted in the female reproductive organs (NTP 1992; Melnick *et al.* 1994b).

In a 90-day inhalation study, some of the male Wistar rats exposed whole-body to 400 mg/m^3 showed diffuse testicular atrophy accompanied by oligozoospermia in the epididymides, and slight prostate atrophy (ECHA).

J. Developmental Toxicity

Oral

A Chernoff-Kavlok screen was conducted on diethanolamine. Initially, four female CD-1 mice were given by oral gavage 0, 200, 380, 720, 1,370, 2,605, and 2,605 mg/kg diethanolamine during GD 6-15; a subsequent study was conducted which consisted of dosing 50 female CD-1 mice with 450 mg/kg during GD 6-15. Mortality was seen at ≥720 mg/kg, with 100% mortality in the ≥1,370 mg/kg groups. Dams dosed with ≥200 mg/kg showed clinical signs of intoxication. There was no mortality in the 450 mg/kg dams; nor was there any effect on litter size and pup birth weight, but the number of viable litters, the percent of pup survival, and pup weight gain were reduced (York *et al.* 1988). Kl. score = 2]

Female SD rats were dosed by oral gavage with 0, 50, 125, 200, 250, or 300 mg/kg diethanolamine from GD 6-19. All dams in the 300 mg/kg group had to be killed early due to excessive toxicity. At 200 and 250 mg/kg, the dams exhibited either morbidity or died. Water intake was affected early in the gestation period in the 125 and 250 mg/kg dams; it was comparable to controls after GD 12. Reduced maternal body weight and weight change, as well as food intake, were seen in the ≥200 mg/kg dose groups. The ≥125 mg/kg dams had increased absolute kidney weights on postnatal day (PND) 21. There were no maternal effects in the 50 mg/kg dams. There was postimplantation deaths at ≥200 mg/kg on PND 0 and increased early postnatal mortality (PND 0-4) in the ≥125 mg/kg dose groups. Pup body weight was reduced at ≥200 mg/kg, with females affected more than males. Pup body weight gain was predominantly reduced during the early postnatal period. There were statistically significant differences at the end of the lactational period, which were flawed by the low number of animals. The NOAEL for maternal and postnatal developmental (screening) toxicity was 50 mg/kg-day (Price *et al.* 2005). [Kl. score = 2]

Inhalation

Pregnant female Wistar rats were exposed by inhalation to 0, 10, 50, or 200 mg/m^3 diethanolamine 6 hours/day on GD 6 to 15. Maternal toxicity was seen at 200 mg/m^3; there were vaginal hemorrhages in 8/21 pregnant rats on GD 14. There was also a markedly increased number of fetuses with skeletal variations (mainly cervical ribs) in the 200 mg/m^3 exposed group. The NOAEC for maternal and developmental toxicity is 200 mg/m^3 (ECHA). [Kl. score = 1]

Dermal

Pregnant female SD rats were given dermal applications of 0, 150, 500, or 1,500 mg/kg diethanolamine from GD 6 to 15. There was a dosing discrepancy and mid-dose was adjusted from 500 to 380 mg/kg. There was moderate skin irritation in the 380 mg/kg group, and severe skin irritation in the 1,500 mg/kg group. Body weight gain was lower in the 1,500 mg/kg group, and absolute and relative kidney weights were increased in the $\geq$380 mg/kg group All treated groups exhibited hematological effects that included anemia, abnormal red cell morphology (poikilocytosis, anisocytosis, polychromasia), and decreased platelet count. The 1,500 mg/kg group also had increased lymphocytes and total leukocytes. There were no treatment-related effects on body weight or incidences of malformations/abnormalities. In the 1,500 mg/kg litters, there were increased incidences of six skeletal variations involving the axial skeleton and distal appendages. The skeletal variations included poor ossification in the parietal bones; cervical centrum #5 and thoracic centrum #10; lack of ossification in all proximal hindlimb phalanges and some forelimb metacarpals; and callused ribs. The NOAELs for maternal and developmental toxicity are 150 and 380 mg/kg-day (Marty et al., 1999). [Kl. score = 2]

Pregnant female New Zealand rabbits were given dermal applications of 0, 35, 100, or 350 mg/kg diethanolamine on GD 6 to 18. At 350 mg/kg, maternal toxicity consisted of marked skin irritation, reduced feed consumption, and color changes in the kidneys. There were no hematologic changes. Body weight gain was reduced in the 100 mg/kg group. There was no evidence of developmental toxicity at any dose level. The NOAELs for maternal and developmental toxicity are 35 and 350 mg/kg-day (Marty et al., 1999). [Kl. score = 2]

K. Immunotoxicity

Female F344 rats were given oral gavage doses of 0, 50, 100, or 200 mg/kg diethanolamine for 14 days. Body weights and/or body weight changes were significantly decreased in the $\geq$100 mg/kg dose groups; liver and kidney weights were increased in a dose-dependent manner. A dose-dependent increase in urea nitrogen was seen in all dose groups. Erythrocytes, hematocrit, hemoglobin and reticulocytes were dose-dependently decreased. The reticulocytes were the most sensitive erythroid parameter, which was decreased at all dose levels. Besides an increase in the proliferative response to allogenic cells (MLR), several immune functional assays were decreased including the natural killer cell response and the cytotoxicity of resident macrophages. Conversely, the cytotoxicity of peptone-elicited macrophages was increased. The LOAEL was 50 mg/kg-day based on a significant decrease in reticulocyte number and increase in urea nitrogen (Munson *et al.* 1992a). [Kl. score = 2]

Female B6C3F$_1$ mice were given oral gavage doses of 0, 100, 300, or 600 mg/kg diethanolamine for 14 days. There was no effect of body weights. The liver weights were increased and red blood cell count parameter were dose-dependently decreased at all dose levels. Diethanolamine treatment increased the number of B-cells, decreased the number of CD4+CD8- (18%) T-cell subsets. A dose-dependent decrease in the antibody-

forming cell response to sheep erythrocytes at the high-dose was seen, as well as a decreae in the cytotoxic T-cell response at the highest effector/target ratio. The cytotoxicity of resident macrophages was decreased, but the cytotoxicity of resident macrophages stimulated with gamma interferon was not affected nor the cytotoxicity of peptone-elicited macrophages with or without stimulation. Among the three host resistance studies, a decrease in host resistance was observed to *Streptococcus pneumonia* and in the B16F10 melanoma tumor model. The LOAEL for this study was considered to be 100 mg/kg-day based on significantly reduced cytotoxic T lymphocytes (CTL) activity, an increase in tumor burden following challenge with the B16F10 melanoma tumor and a clear decrease in red blood cell parameter at the lowest dose (Munson *et al.* 1992b). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for diethanolamine follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

In a 13-week study conducted by the National Toxicology Program, F344 rats were given diethanolamine in their drinking water for 13 weeks. The doses were 0, 25, 48, 97, 2,202, or 436 mg/kg-day for males; and 0, 14, 32, 57, 124, or 242 mg/kg-day for females. The most sensitive endpoints were the microcytic anemia in both sexes and kidney effects in females (weight, nephrotoxicity) and males (weight). The LOAELs were 25 and 14 mg/kg-day) for males and females, respectively (NTP 1992; Melnick et al., 1994a).

In a 13-week study conducted by the National Toxicology Program, $B6C3F_1$ mice were given diethanolamine in their drinking water for 13 weeks. The doses were 0, 104, 178, 442, 807, or 1,674 mg/kg-day for males; and 0, 142, 347, 884, 1,154, or 1,128 mg/kg-day for females. The most sensitive endpoint was the increase in liver weights with the corresponding histopathological changes. The LOAELs were 104 and 142 mg/kg-day in males and females, respectively (NTP, 1992; Melnick *et al.*, 1992b).

The lowest NOAEL of 14 mg/kg-day from the rat 13-week drinking water study will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 10
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

[maximum UF = 3,000]

Oral RfD = 14/3,000 = <u>0.005 mg/kg-day</u>

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.005 x 70 x 0.1)/2 = <u>0.02 mg/L</u>

B. Cancer

Diethanolamine was not carcinogenic to rats in the two-year NTP dermal bioassay; but, in the mice, there was an increased incidence of liver tumors in males and females and kidney tumors in males (NTP, 1999). As discussed above, the mouse liver tumors from DEA exposure are unlikely to be predictive of the carcinogenic risk to humans based on choline deficiency as a mechanism of carcinogenesis. No mode-of-action has been proposed for the kidney tumors in male mice.

NICNAS conducted a human health tier III assessment on diethanolamine (NICNAS). Regarding the classification for carcinogenicity, NICNAS concluded that "[t]he data on the mode of action are insufficient to conclude that diethanolamine-induced tumours in mice are relevant for humans and, therefore, based on the available information, diethanolamine is not classified for carcinogenicity."

Thus, a cancer reference value for diethanolamine was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Diethanolamine does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Diethanolamine exhibits moderate acute toxicity to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies on diethanolamine.

Table 3: Acute Aquatic Toxicity Studies on Diethanolamine

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-h LC_{50}	460	2	ECHA
Pimephales promelas	96-h LC_{50}	1,460*	2	Mayes et al. (1983)
Pimephales promelas	96-h LC_{50}	1,664	2	ECHA
Lepomis macrochirus	48-h LC_{50}	1,850	2	Turnbull et al. (1954)
Carassius auratus	24-h LC_{50}	>5,000 (neutralised) 800 (non-neutralised)	2	Bridlé et al. (1979)

Ceriodaphnia dubia	48-h EC_{50}	30.1 (24°C) 89.9 (20°C)	2	Cowgill et al. (1985)
Daphnia magna	48-h EC_{50}	55	2	LeBlanc (1980)
Daphnia magna	48-h EC_{50}	171	2	Zurita et al. (2005)
Pseudokirchneriella subcapitata	72-h EC_{50} (growth rate)	9.5 (Test 1) 19 (Test 2)	2	ECHA
Desmodesmus subspicatus	72-h EC_{50}	14.9 (growth rate) 6.2 (biomass)	2	ECHA
Desmodesmus subspicatus	72-h EC_{50}	107.3 (growth rate) 74.5 (biomass)	2	ECHA
Chorella vulgaris	72-h EC_{50}	778 (growth rate)	2	ECHA

*Geometric mean of 96-h LC_{50} values of fry, juvenile, and subadult fish. Not neutralized.

Chronic Studies

Table 4 lists the results of chronic aquatic toxicity studies on diethanolamine.

Table 4: Chronic Aquatic Toxicity Studies on Diethanolamine

Test Species	**Endpoint**	**Results (mg/L)**	**Klimisch score**	**Reference**
Daphnia magna	EC_{10} NOEC	1.05 0.76	1	ECHA
Pseudokirchneriella subcapitata	EC_{10} (growth rate)	1.4 (Test 1) 1.1 (Test 2)	2	ECHA
Desmodesmus subspicatus	EC_{10} (neutralized)	2.4 (growth rate) 2.0 (biomass)	2	ECHA
Desmodesmus subspicatus	EC_{10} (non-	85.7 (growth rate)	2	ECHA

	neutralized)	41.3 (biomass)		
Pseudokirchneriella subcapitata	7-d NOEC	10	2	ECHA

C. Terrestrial Toxicity

In an earthworm (*Eisenia Andrei, Eisenia fetida*, or *Lumbricus terrestris*) study, the 35-day LC_{50} was 4,141 mg/kg soil dry weight (mortality); the 63-day EC_{50} was 776 mg/kg soil dry weight (reproduction); and the 63-day EC_{25} was 171 mg/kg soil dry weight (reproduction) (ECHA). [Kl. score = 2]

In a springtails (*Folsomia candida*) study, the 28-day LC_{50} was 8,301 mg/kg soil dry weight (mortality); the 28-day EC_{50} was 4,205 mg/kg soil dry weight (reproduction); and the 28-day EC_{25} was 2,102 mg/kg soil dry weight (reproduction) (ECHA). [Kl. score = 2]

D. Calculation of PNEC

The PNEC calculations for diethanolamine follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (460 mg/L), *Daphnia* (30.1 mg/L), and algae (9.5 mg/L). Results from chronic studies are also available for two trophic levels, with the lowest EC_{10} value being 1.1 mg/L for *Daphnia* and algae. On the basis that the data consists of short-term results from three trophic levels and long-term results from three trophic levels, an assessment factor of 50 has been applied to the lowest reported EC_{10} of 1.1 mg/L for algae. The $PNEC_{water}$ is 0.02 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.016 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.99/1280) \times 1000 \times 0.02$
$= 0.016$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [(0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [(0.2 \times 0.4/1000 \times 2400]$
$= 0.99$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 10 \times 0.04$
$= 0.4$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for diethanolamine (as the charged molecule) was calculated to be 10 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

Experimental results are available for chronic toxicity on two trophic levels. Although $E(L)C_{50}$ values are available from these studies, there are no EC_{10} or NOEC values. Therefore, the PNECsoil was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.027 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.2/1500) \times 1000 \times 0.02$
$= 0.027$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 10 \times 0.02$
$= 0.2$

Where:

K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for diethanolamine (as the charged molecule) was calculated to be 10 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Diethanolamine is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The estimated BCF value for diethanolamine calculated from a QSAR model is 2.3; thus, it does not meet the criteria for bioaccumulation.

The EC_{10} or NOEC values from the chronic aquatic toxicity studies on diethanolamine are >0.1 mg/L. Thus, diethanolamine does not meet the screening criteria for toxicity. In a mouse dermal carcinogenicity study, there was an increased incidence of liver tumors in males and females and kidney tumors in males. NICNAS has concluded that "[t]he data on the mode of action are insufficient to conclude that diethanolamine-induced tumours in mice are relevant for humans and, therefore, based on the available information, diethanolamine is not classified for carcinogenicity." Thus, diethanolamine does not meet the criteria for toxicity.

The overall conclusion is that diethanolamine is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Acute Toxicity Category 4 [Oral]
Skin Irritant Category 2
Eye Damage Category 1
STOT RE Category 2 [Target organs: liver, blood, kidney]

[Aquatic Acute Category 2]

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. Get medical attention immediately, preferably a physician for an ophthalmologic examination.

Skin Contact
Remove contaminated clothing. Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Give artificial respiration if victim is not breathing. Get medical attention.

Ingestion
Rinse mouth with water and then drink plenty of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Keep product and empty container away from heat and sources of ignition. May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: nitrogen oxides, carbon monoxide, carbon dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment. Handle in accordance with good industrial hygiene and safety practice. Avoid contact with skin, eyes, and clothing.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
For large amounts: dike spillage and pump off product. For residues: pick up with suitable absorbent material. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling
Keep product and empty container away from heat and sources of ignition. Ensure adequate ventilation, especially in confined areas.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard for diethanolamine.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection in case of vapor or aerosol release.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Diethanolamine is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

DISODIUM OCTABORATE TETRAHYDRATE

This dossier on disodium octaborate tetrahydrate does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of disodium octaborate tetrahydrate in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC) [Disodium octaborate]: disodium;(9,11-dioxido-5-oxoboranyloxy-2,4,6,8,10,12,13-heptaoxa-1,3,5,7,9,11-hexaborabicyclo[5.5.1]tridecan-3-yl)oxy-oxovorane

CAS RN: 12280-03-4

Molecular formula: $Na_2B_8O_{13}\bullet 4H_2O$

Molecular weight: 412.4

Synonyms: Disodium octaborate tetrahydrate; disodium octaborate

SMILES (disodium octaborate): B(=O)OB1OB2OB(OB(OB(O2)OB(O1)OB=O)[O-])[O-].[Na+].[Na+]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Disodium Octaborate Tetrahydrate

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White, odorless, crystalline powder	1	ECHA
Melting Point	>1,000°C	1	ECHA
Density	1.874 g/cm^3	1	ECHA
Vapor Pressure	9.9 x 10^{-17} Pa @ 25°C	1	ECHA
Water Solubility	223.65 g/L @ 20°C	1	ECHA
Auto flammability	Not a self-heating substance	1	ECHA

Exposure to borates are often expressed in terms of boron (B) equivalents based on the fraction of boron in the source substance on a molecular weight basis. The B equivalents used are a generic designation rather than a designation of the element boron. The factor for converting disodium octaborate tetrahydrate to B-equivalents is 0.2096.

III. ENVIRONMENTAL FATE PROPERTIES

Many minerals contain boron, which is present as the sodium or calcium borate salt. Thus, boron is ubiquitous and widely distributed in the environment. It is present in rocks, soil and water and is released into the environment primarily from the weathering of rock and soil, volatilization of sea water, and anthropogenic activity.

Disodium octaborate tetrahydrate ($Na_2B_8O_{13} \bullet 4H_2O$) is very soluble in water, with the main species in freshwater being the borate ion $[B(OH)_4]^-$ and boric acid $B(OH)_3$, depending on the pH. The relative proportion of boric acid and borate ions is controlled by pH: $B(OH)_3 + 2H_2O \Leftrightarrow [B(OH)_4]^- + H_3O^-$. In dilute aqueous solutions, boric acid does not dissociate at pH <7; at pH values between 7 and 11, both boric acid and borate ions are present. In dilute aqueous solutions and physiological conditions, the predominant species present is un-dissociated boric acid. So, the consideration of boric acid addresses the relevant environmental stability properties for borates.

In natural waters, boron forms stable species and exists primarily as un-dissociated boric acid [$B(OH)_3$] and complex polyanions (*e.g.*, $[B(OH)_4]^-$). These forms of boron are highly soluble and not easily removed from solution by natural mechanisms. Borate and boric acid are in equilibrium depending on the pH of the water. At an acidic pH, boron exists in solution mainly as un-dissociated boric acid, whereas at alkaline pH it is present as borate ions.

Degradation is not applicable to inorganic borates, such as disodium octaborate tetrahydrate. It is not subject to hydrolysis, photodegradation, or biodegradation (ECHA). Inorganic borates are subject to chemical transformation processes (adsorption, complexation, precipitation, fixation) once released into the environment (ECHA).

The WHO review of boron (WHO, 1998) noted that “highly water soluble materials are unlikely to bioaccumulate to any significant degree and that borate species are all present essentially as un-dissociated and highly soluble boric acid at neutral pH”. A BCF of <0.1 was reported in Chinook salmon fed boron-supplemented diets for 60 to 90 days (Hamilton and Wiedmeyer, 1990).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Disodium octaborate tetrahydrate exhibits low acute toxicity by the oral and dermal routes. It is not a skin or eye irritant, or a skin sensitizer. Toxicity studies on boric acid, borax (disodium tetraborate decahydrate), and boron oxide have been used to read-across to disodium octaborate tetrahydrate. This is justified because, in aqueous media at physiological pH, all of these inorganic borate compounds will predominantly exist as un-dissociated boric acid. The developing fetus and the testes are the two most sensitive targets of boron toxicity in multiple species. The testicular effects include reduced organ weight and organ to body weight ratio, atrophy, degeneration of the spermatogenic epithelium, impaired spermatogenesis, reduced fertility, and sterility. The developmental effects from boron exposure include high prenatal mortality; reduced fetal body weight; and malformations and variations. Repeated inhalation exposure to boron oxide resulted in slight irritation to the respiratory tract, but no systemic toxicity. Boric acid was not genotoxic; and boric acid and borax was not carcinogenic to rodents.

B. Acute Toxicity

The oral LD_{50} of disodium octaborate tetrahydrate in rats is 2,550 mg/kg (ECHA) [Kl. score = 1]. The oral LD_{50} of boric acid in rats is 3,450 mg/kg (ECHA) [Kl. score = 1]. The oral LD_{50} of anhydrous boric acid in rats is >2,500 mg/kg. [Kl. score = 1].

There are no acute inhalation studies on disodium octaborate tetrahydrate. The 4-hour inhalation LC_{50} value for boric acid in rats is >2.01 mg/L. The mass median aerodynamic diameter (MMAD) was 2.8 μm (ECHA) [Kl. score = 1]. In another study, the 4-hour inhalation LC_{50} value for boric acid in rats was >2.03 mg/L (ECHA) [Kl. score = 1]. The 4-hour inhalation LC_{50} value for disodium tetraborate pentahydrate in rats is >2.04 mg/L (ECHA) [Kl. score = 1].

The dermal LD_{50} of disodium octaborate tetrahydrate in rabbits is >2,000 mg/kg (ECHA) [Kl. score = 1]. The dermal LD_{50} of boric acid in rabbits is >2,000 mg/kg (ECHA) [Kl. score = 1]. The dermal LD_{50} of sodium tetraborate pentahydrate in rabbits is >2,000 mg/kg (ECHA) [Kl. score = 1].

C. Irritation

Application of 0.5 g. of disodium octaborate tetrahydrate to the skin of rabbits for 4 hours under occlusive conditions was not irritating. The mean of the 24, 48, and 72 hour scores were: 0.22 for erythema and 0.00 for edema (ECHA) [Kl. scores = 1].

Application of 0.5 g. of boric acid to the skin of rabbits for 24 hours under occlusive conditions was not irritating. The mean of the 24 and 72 hour scores were: 0.13 for erythema and 0.00 for edema (ECHA) [Kl. scores = 1]. Application of 0.5 g. of sodium tetraborate pentahydrate to the skin of rabbits for 4 hours under occlusive conditions was not irritating. The mean erythema and edema scores were 0.00 (ECHA) [Kl. scores = 2].

Disodium octaborate tetrahydrate was not considered to be an eye irritant when 0.053 or 0.049 g. was instilled into the eyes of rabbits (ECHA) [Kl. scores = 1]. Instillation of 0.08 mL boric acid into the eyes of rabbits was slightly irritating. The mean of 24, 48, and 72 hours scores were: 0.22 for corneal opacity; 0.22 for iridial lesions; 2.8 for conjunctival redness; and 1.89 for chemosis (ECHA) [Kl. score = 1].

D. Sensitization

Disodium octaborate tetrahydrate was not a skin sensitizer to guinea pigs in a Buehler test (ECHA) [Kl. score = 1].

Boric acid was not a skin sensitizer to guinea pigs in a Buehler test (ECHA) [Kl. score = 1]. Sodium tetraborate pentahydrate was not a skin sensitizer to guinea pigs in a Buehler test (ECHA) [Kl. score = 1]. Sodium tetraborate decahydrate was not a skin sensitizer to guinea pigs in a Buehler test (ECHA) [Kl. score = 1].

E. Repeated Dose Toxicity

Oral

Male and female SD rats were given in their feed boric acid at doses of 0, 52.5, 175, 525, 1,750 or 5,250 ppm B equivalents for 90 days. The average intake has been estimated to be approximately 0, 2.6, 8.8, 26, 87.5 or 262.5 mg B/kg-day, respectively (EPA, 2004). By week 6, all of the animals in the highest dose died. Clinical signs in the top two dose levels were rapid respiration, inflamed eyes, swollen paws, and desquamated skin on the paws and tails. There was also reduced food consumption and body weight gain. The 1,750 ppm females showed reduced liver, spleen ovary, and adrenal weights; the 1,750 ppm males showed reduced liver, spleen, kidney, testes, and adrenal weights. The adrenals of 4 of the 1,750 ppm males showed minor increases in lipid content and size of the cells in the zona reticularis. Atropied testis (complete atrophy of the spermatogenic epithelium and decreased in the size of the seminiferous tubules) was seen in all of the 1,750 ppm males. One 525 ppm male had partial testicular atrophy. The NOAEL for this study is 175 ppm boron or 8.8 mg B/kg-day (Weir and Fisher, 1972). [Kl. score = 2]

Male and female SD rats were given in their diet borax at doses of 0, 52.5, 175, 525, 1,750 or 5,250 ppm B equivalents for 90 days. The average intake has been estimated to be approximately 0, 2.6, 8.8, 26, 87.5 or 262.5 mg B/kg-day, respectively (EPA, 2004). By week 6, all of the animals in the highest dose died. Clinical signs in the top two dose levels were rapid respiration, inflamed eyes, swollen paws, and desquamated skin on the paws and tails. There was also reduced food consumption and body weight gain. The 1,750 ppm females showed reduced liver, spleen and ovary weights; the 1,750 ppm males showed reduced liver, spleen, kidney, testes, and brain weights. The adrenals of the majority of the 1,750 ppm males and females showed slight to moderate increases in lipid content and size of the cells in the zona reticularis. Atropied testis (complete atrophy of the spermatogenic epithelium and decreased in the size of the seminiferous tubules) was

seen in all of the 1,750 ppm males. Four 525 ppm males had partial testicular atrophy. Spermatogenic arrest was found in one 525 ppm male. The NOAEL for this study is 175 ppm boron or 8.8 mg B/kg-day (Weir and Fisher, 1972). [Kl. score = 2]

Male and female B6CF1$_1$ mice were given in the diet 0, 1,200, 2,500, 5,000, 10,000 or 20,000 ppm boric acid for 13 weeks (control and highest dose group) or 16 weeks (remaining dose groups). These dietary levels correspond to approximately 0, 34, 70, 141, 281 and 563 mg B/kg-day for males, respectively; and 0, 47, 97, 194, 388 and 776 mg B/kg-day for females, respectively (EPA, 2004). There was mortality (8/10 males; 6/10, females) in the 20,000 ppm, as well as hyperkeratosis and acanthosis. One male also died in 10,000 ppm group. Degeneration or atrophy of the seminiferous tubules occurred in the $\geq$5,000 ppm males. Minimal to mild extramedullary hematopoiesis of the spleen was observed in all dose groups. The LOAEL for this study is 1,200 ppm, corresponding to 34 and 47 mg B/kg-day for males and females, respectively (NTP 1987). [Kl. score = 2]

Male and female SD rats were given in their diet 0, 117, 350 or 1,170 ppm boric acid for two years. The average intake has been estimated to be approximately 0, 5.9, 17.5 or 58.5 mg B/kg-day, respectively (EPA, 2004). The 1,170 ppm rats had decreased food consumption during the first 13 weeks of the study and suppressed growth throughout the study. Signs of toxicity in the 1,170 ppm animals included swelling and desquamation of the paws, scaly tails, inflammation of the eyelids, and bloody discharge from the eyes. All of the 1,170 ppm males had testicular atrophy at the 6, 12 and 24 month time points. The seminiferous epithelium was atrophied, and the tubular size in the testes was decreased. There were significant decreases in the absolute and relative testes weights. Brain and relative thyroid weights were increased. The NOAEL for this study is 350 ppm B equivalents or 17.5 mg B/kg-day (Weir and Fisher, 1972). [Kl. score = 2]

Male and female B6C3F$_1$ mice were given 0, 2,500 or 5,000 ppm boric acid in their feed for 103 weeks (NTP, 1987). These dose levels were equivalent to 0, 275 or 550 mg/kg-day boric acid or 0, 48 or 96 mg B/kg-day (EPA, 2004). There was reduced survival in the male mice, which was significantly different from the controls in the 2,500 ppm mice after week 63 and in the 5,000 ppm mice after week 84. The survival rates by the end of the study were 82, 60 and 44% in the 0, 2,500, and 5,000 ppm males, respectively; and 66, 66 and 74% in the 0, 2,500, and 5,000 ppm females, respectively. Mean body weights were 10-17% lower in the 5,000 ppm animals after 32 (males) or 52 (females) weeks compared to the controls There was testicular atrophy and interstitial cell hyperplasia in the testes of the 5,000 ppm males. A dose-related increase in the incidences of splenic lymphoid depletion in male mice was also observed. NTP considered this lesion to be associated with stress and debilitation, and it is reflected in the increased mortality in these groups of male mice. The NOAEL for this study is (NTP, 1987). [Kl. score = 2]

Inhalation

Male and female rats were exposed by inhalation to 0, 77, 175, or 470 mg/m^3 boron oxide. The exposures were 6 hours/day, 5 days/week for 24, 12, and 10 weeks for the 77, 175, and 470 mg/m^3 concentrations groups, respectively. The MMAD were 2.5, 1.9, and 2.4 μm for the 77, 175, and 479 mg/m^3 concentrations groups, respectively. There was no evidence of systemic toxicity. Some of the 470 mg/m^3 had reddish exudate from the nose. As these animals were covered with dust, this effect may have been local irritation of the nose and from the animals scratching the nose. The NOAEL for systemic toxicity is 470 mg/m^3, the highest exposure concentration tested. The NOAEL for localized effects (irritation) is 175 mg/m^3 (ECHA). [Kl. score = 2]

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

There are no *in vitro* genotoxicity studies on disodium octaborate tetrahydrate. Table 2 presents the results of the *in vitro* genotoxicity studies on boric acid.

Table 2: *In vitro* Genotoxicity Studies on Boric Acid

Test System	**Results***		**Klimisch Score**	**Reference**
	-S9	**+S9**		
Bacterial reverse mutation (*S. typhimurium* strains)	-	-	1	ECHA
Bacterial reverse mutation (*S. typhimurium* strains)	-	-	2	ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-	-	1	ECHA

Chromosomal aberrations (Chinese Hamster Ovary cells)	-	-	1	ECHA
Chromosomal aberrations (Human peripheral lymphocytes)	NS	+	2	ECHA

Unscheduled DNA synthesis (rat liver cells)	NA	-	1	ECHA

*+, positive; -, negative; NA, not applicable; NS, not specified.

In Vivo Studies

No studies are available on disodium octaborate tetrahydrate.

Male and female Swiss Webster mice were given two daily doses of 0, 225, 450, 900, 1,800, or 3,500 mg/kg boric acid. The frequency of micronucleated polychromatic erythrocytes were not increased at any dose level (ECHA) [Kl. score = 1].

G. Carcinogenicity

Oral

No studies have been conducted on disodium octaborate tetrahydrate.

Male and female SD rats were given in their diet disodium tetraborate decahydrate (Borax) or boric acid at doses of 0, 117, 350, or 1,170 ppm as B equivalents (approximately 0, 5.9, 17.5, or 58.5 mg B/kg-day) for two years. There was no mention of tumors in the report. Nevertheless, NTP (1987) concluded that this study provided adequate data on the lack of carcinogenic effects of boric acid in rats (Weir and Fisher, 1972; EPA, 2004).

Male and female $B6C3F_1$ mice were given in their diet 0, 2,500, or 5,000 ppm boric acid for 103 weeks. The dietary levels are equivalent to 0, 446, or 1,150 mg/kg-day boric acid or 0, 78.1, or 201.3 mg B/kg-day. There was no evidence of carcinogenicity (NTP, 1987). [Kl. score = 2]

H. Reproductive Toxicity

A three-generation reproductive toxicity study was conducted in albino rats (strain not specified) with boric acid. Male and female rats were fed a diet containing 0, 117, 350 or 1,170 ppm boron (approximately 0, 5.9, 17.5 or 58.5 mg B/kg-day, respectively). In the lower two dose groups, there were no treatment-related effects on reproduction. Litter size, progeny weights, fertility, live birth indices, lactation, appearance were similar to the controls. No gross abnormalities were noted in these two dose groups. The 1,170 ppm dose group were found to be sterile, and there were no litters from mating the treated females with control males. Lack of viable sperm was found in the atrophied testes of all 1,170 ppm males. Decreased ovulation was also seen in the majority of the ovaries of the 1,170 ppm females. The NOAEL for this study is 350 ppm boron or approximately 17.5 mg B/kg-day (Weir and Fisher, 1972). [Kl. score = 2]

A three-generation reproductive toxicity study was conducted in albino rats (strain not specified) with disodium tetraborate decahydrate. Male and female rats were fed a diet containing 0, 117, 350 or 1,170 ppm boron (approximately 0, 5.9, 17.5 or 58.5 mg B/kg-day, respectively). In the lower two dose groups, there were no treatment-related effects on reproduction. Litter size, progeny weights, fertility, live birth indices, lactation, appearance were similar to the controls. No gross abnormalities were noted in these two dose groups. The 1,170 ppm dose group were found to be sterile, and there were no litters from mating the treated females with control males. Lack of viable sperm was found in the atrophied testes of all 1,170 ppm males. Decreased ovulation was also seen in the majority of the ovaries of the 1,170 ppm females. The NOAEL for this study is 350 ppm boron or approximately 17.5 mg B/kg-day (Weir and Fisher, 1972). [Kl. score = 2]

In a continuous breeding protocol, male and female CD-1 mice were given in their diet 0, 1,000, 4,500 or 9,000 ppm boric acid in their feed. The authors estimated that the average daily intakes were: 0, 26.6, 111, and 220 mg B/kg-day to males; and 0, 31.8, 152, 257 mg B/kg-day to females. Boric acid consumption did not differ among the groups. There were no litters in the 9,000 ppm breeding pairs. At 4,500 ppm, there was a successful first litter, after which there was a progressive decrease in fertility; only one pair produced a fourth and fifth litter. All fertility indices were affected in the 4,500 ppm group. A complete crossover mating trial was conducted using control mice and the 4,500 ppm mice. The results showed that the probable cause of the reduced fertility was a decrement in male fertility. A dose-related decrease in body, testicular and epididymal weights was observed in the 4,500 and 9,000 ppm F_0 males. Sperm count was significantly decreased in these two dose groups, and percent motile sperm was decreased in all dose groups. Testicular histopathology showed seminiferous tubular atrophy in the 9,000 ppm males and partial atrophy of the seminiferous tubules in the 4,500 ppm males. There were no histopathologic changes in the 4,500 ppm females. No statistically significant decreases in mating index, fertility index, or live pups/litter in the 4,500 ppm females, but the number of days to litter in this dose group was increased. Estrous cyclicity was unaffected. Reproductive organ weights were unaffected, but relative maternal liver and kidney/adrenal weights were reduced. An F_1 fertility trial was performed using offspring from the 1,000 ppm groups. There was no decreases in mating, fertility or reproductive performance. The F_2 adjusted live pup weight was slightly, but significantly, reduced from controls. A clear NOAEL for reproductive toxicity in males was not seen in this study. The 1,000 ppm males had decreased sperm motility in the F_0 generation and decreased sperm concentration in the F_1 generation. Decreased F_2 pup relative body weight was statistically significant from controls. The NOAEL in this study for females is 1,000 ppm boric acid or 32 mg B/kg-day). The LOAEL in this study for males is 1,000 ppm or 27 mg B/kg-day; a NOAEL was not established (Fail *et al.* 1991). [Kl. score = 2]

I. Developmental Toxicity

Pregnant female SD rats were given 0, 0.1, 0.2 or 0.4% boric acid in their feed on gestational days (GD) 0 to 20 or 0.8% boric acid on GD 6 to 15. The average amounts of boric acid ingested were estimated to be 0, 78, 163, 330 or 539 mg/kg-day (0, 13.6, 28.5 or 57.7 mg B/kg-day), respectively. Effects on the pregnant rats were altered food and/or water intake at ≥0.2% boric acid, increased liver and kidney weights relative to body weights at ≥0.2%, reduced weight gain at ≥0.4%, and increased corrected weight gain at 0.4% boric acid. There was a reduction in fetal body weights in all treated groups (94, 87, 63, and 47% of control weight, respectively). Increased malformations occurred at ≥0.2%, and prenatal mortality was increased at 0.8%. There was a dose-response for altered skeletal morphology in rats (≥0.1%), and specific findings were significantly elevated above controls at ≥0.2%. Specifically, there was an increased incidence of short rib XIII (a malformation) and a decreased incidence or rudimentary or full rib(s) at lumbar I (an anatomical variation) (Heindel *et al.* 1992). [Kl. score = 2]

Pregnant female SD rats were given in their feed 0, 0.025, 0.005, 0.075, 0.1 or 0.2% boric acid on GD 0 to 20. Approximately half of the dams were terminated on GD 20, and the remaining dams delivered their litters. Pup growth and viability were monitored until postnatal day (PND) 21. The average amounts of boron ingested on GD 20 were: 0, 3.3, 6.3, 9.6, 13.3, and 25 mg B/kg-day], respectively. The average amounts of boron ingested on PND 21 were : 0, 3.2, 6.5, 9.7, 12.9, and 25.3 mg B/kg-day, respectively. There were no maternal deaths and no treatment-related clinical signs. Maternal body weights were similar across all groups during gestation. However, decreased maternal body weights (GD 19 and 20 at sacrifice) and decreased maternal body weight gain (GD 15-18 and GD 0-20) were statistically significant in trend tests. There was a 10% reduction in gravid uterine weight (statistically significant) in the 0.2% group. Corrected maternal weight (maternal gestational weight minus reduced gravid uterine weight) was unaffected by treatment. Feed intake in the 1,000 ppm dams was minimally affected and only during the first three days of dosing. Water consumption was higher in the treated groups after GD 15. The number of corpora lutea and uterine implantation sites, and the percentage of preimplantation loss were similar across all groups. Increased relative kidney weights were increased in the 0.2% group. There were no differences in the viability of the offspring between treated and controls. On GD 20, fetal body weight was 94% and 88% of controls in the 0.1% and 0.2% groups, respectively; recovery was complete at birth (~GD 22). The incidence of short rib XIII was increased on GD 20 in the ≥0.1% groups, but only in the 0.2% group at PND 21. The incidence of wavy rib was increased on GD 20 in the ≥0.1% group; the reversibility of this effect was confirmed on PND 21. There was a slight decrease in extra lumbar ribs in the 0.2% group on GD 20, and extra lumbar ribs were seen in the 0.2% group on PND 21. The developmental NOAEL was considered to be 0.075% boric acid or 9.6 mg B/kg-day on GD 20; and 0.1% boric acid or 12.9 mg B/kg-day on PND 21 (Price *et al.* 1996a). [Kl. score = 1]

Pregnant Swiss mice were given in their diet 0, 0.1, 0.2 or 0.4% boric acid on gestational days (GD) 0 to 17. The average amounts of boric acid ingested were estimated to be 248, 452 or 1,003 mg/kg-day (0, 43.4, 79.0 or 175.3 mg/B/kg-day), respectively. Maternal toxicity consisted of mild kidney lesions (≥0.1%), increased water intake and relative kidney weights (0.4%), and decreased water intake during treatment. Fetal body weights

were reduced in the ≥0.2% groups, and there were increased incidences of resorptions and malformed fetuses per litter in the 0.4% group. The LOAEL for maternal toxicity is 248 mg/kg-day boric acid or 43.4 mg B/kg-day; a NOAEL was not established. The NOAEL for developmental toxicity is 248 mg/kg-day boric acid or 43.4 mg B/kg-day (Heindel *et al.* 1992). [Kl. score = 2]

Pregnant female New Zealand rabbits were dosed by oral gavage with 0, 62.5, 125 or 250 mg/kg boric acid (0, 10.9, 21.9 or 43.7 mg B/kg) during GD 6-19. Feed intake was in the 250 mg/kg maternal animals during the exposure period, but it was increased in the ≥125 mg/kg dose groups. In the 250 mg/kg group, maternal body weights during GD 9-30, weight gain during GD 6-19, gravid uterine weight, and number of corpora lutea per dam were significantly reduced. In the ≥125 mg/kg groups, maternal corrected gestational weight gain was increased compared to controls. Maternal liver weights were unaffected by treatment. In the 250 mg/kg group, relative, but not absolute, kidney weights were increased, although no effects in the kidney were noted in the histopathological examination. Prenatal mortality was increased in the 250 mg/kg group (90% resorptions/litter versus 6% for controls); the proportion of pregnant females with no live fetuses was increased (73% versus 0%), and live litter size was reduced (2.3 fetuses versus 8.8). Thus, there were only 14 live fetuses (6 live litters) available for evaluation in the 250 mg/kg group. The percentage malformed fetuses/litter was increased in the 250 mg/kg group, primarily due to cardiovascular defects (72% versus 3% of controls). There was no definitive maternal or developmental toxicity in the 62.5 or 125 mg/kg dose groups. The NOAEL for maternal and developmental toxicity is 125 mg/kg-day boric acid or 21.9 mg B/kg-day (Price *et al.* 1996b). [Kl. score = 1]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for disodium octaborate tetrahydrate follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The developing fetus and the testes are the two most sensitive targets of boron toxicity in multiple species (EPA, 2004; ECHA, 2010). The testicular effects include reduced organ weight and organ to body weight ratio, atrophy, degeneration of the spermatogenic epithelium, impaired spermatogenesis, reduced fertility, and sterility (EPA, 2004). The developmental effects from boron exposure include high prenatal mortality; reduced fetal body weight; and malformations and variations (EPA, 2004).

The U.S. Environmental Protection Agency (U.S. EPA) derived an Oral Reference Dose

(RfD) for boron of 0.2 mg B/kg-day (U.S. EPA 2004) based on developmental effects in rats from two studies (Price *et al.* 1996a; Heindel *et al.* 1992).

The RfD was derived using the benchmark dose (BMD) method ($BMDL_{05}$ from Allen *et al.* 1996) using a data derived uncertainty factor of 66. Decreased fetal body weight ($BMDL_{50}$ = 59 mg boric acid/kg-day or 10.3 mg B/kg-day) was considered by Allen *et al.* (1996) as the most suitable endpoint for developing a point of departure, because the benchmark doses calculated for the other endpoints (incidence of total malformations, enlarged lateral ventricles in the brain, shortening of rib XIII, and variations of the first lumbar rib) were higher.

Derivation of an Oral Reference Dose

Oral RfD = $BMDL_{05}$ / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 7.9 [3.16, toxicodynamics; 3.3, toxicokinetics]
UF_H (intraspecies variability) = 6.2 [3.16, toxicodynamics; 2.0, toxicokinetics]
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 10.3/(7.9 x 6.3 x 1 x 1 x 1) = 10.3/66 = <u>0.2 mg B/kg-day</u>

Derivation of a drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.2 x 70 x 0.1)/2 = <u>0.7 mg/L</u>

Australian drinking water guideline

The Australian drinking water guideline for boron is 4 mg/L (ADWG, 2011).

B. Cancer

There was no evidence of carcinogenicity in rat and mouse chronic studies conducted on disodium tetraborate decahydrate and/or boric acid. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Disodium octaborate tetrahydrate does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Aquatic Toxicity

The summary of the data used by ANZECC to develop a water quality guideline for boron is as follows:

Freshwater Fish
The chronic values for four species ranged from 40 μg/L (32-day LOEC in *O. mykiss*) to 27,600 μg/L (32-day LOEC in *O. mykiss*). Other *O. mykiss* data were order of magnitude higher than 40 μg/L, including those from the same paper (2,100 μg/L for a 87-day NOEC and 27,600 μg/L for a 32-day LC_{50}). All other geometric means were >4,000 μg/L.

Freshwater Crustaceans
The chronic data ranged from a 21-day MATC value of 4,665 μg/L for *Daphnia magna* based on growth to an LC_{50} value of 54,200 μg/L from a 21-day *Daphnia* study. A measured NOEC of 6,000 μg/L based on reproduction was also reported.

Freshwater Algae
The data ranged from a 14-day NOEC of 400 μg/L for *Chlorella pyrenoidosa* to a NOEC of 5,200 μg/L for *Chlorella vulgaris*. Both values are based on population growth.

C. Terrestrial Toxicity

There are considerable number of terrestrial toxicity studies on borates. See the ECHA REACH database (ECHA) for summaries of the relevant studies.

D. Calculation of PNEC

PNEC water

The ANZECC water quality guideline (2000) used a "freshwater high reliability trigger value for boron of 370 μg/L was calculated using the statistical distribution method at 95% protection."

"Although the 95% protection level is higher than the 32-day LOEC of 100 μg/L for O. mykiss, this figure appeared anomalous and other data on this species showed much less toxicity. The low figure may need to be checked. The 95% figure is considered sufficiently protective for slightly-moderate disturbed ecosystems" (ANZECC, 2000).

PNEC sediment

No experimental toxicity data on sediment organisms are available. Disodium octaborate tetrahydrate dissociates completely in water and its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as disodium octaborate tetrahydrate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sed}$. Based on the its properties, no adsorption of disodium octaborate tetrahydrate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PNEC Soil

In the ECHA REACH database (ECHA), a $PNEC_{soil}$ was derived for boron using the species sensitivity distribution method and an assessment factor of 2. The $PNEC_{soil}$ was determined to be 5.7 mg/kg soil dry weight.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Disodium octaborate tetrahydrate is an inorganic compound that dissociates completely to boric acid and the borate anion in aqueous media. Biodegradation is not applicable to these inorganic compounds; both boric acid and borate are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to disodium octaborate tetrahydrate.

Disodium octaborate tetrahydrate is a water-soluble substance that is not expected to bioaccumulate. Limited data indicate that bioaccumulation (BCF values are low) is not significant in aquatic and terrestrial food chains. Thus, it does not meet the criteria for bioaccumulation.

Boric acid and inorganic borates are reproductive toxicants and have been classified under GHS as known or presumed human reproductive toxicants (Category 1B). Thus, disodium octaborate tetrahydrate meets the PBT criteria of toxicity.

The overall conclusion is that disodium octaborate tetrahydrate is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Reproductive Toxicant Category 1B

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. First Aid

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. Get medical attention.

Skin Contact
Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Swallowing small quantities (one teaspoon) will not cause any harm to adults. If larger amounts are swallowed, give two glasses of water to drink and seek medical attention. Never give anything by mouth to an unconscious person.

Notes to Physician
Observation only is required for adult ingestion of <5 grams. For ingestion of >5 grams, maintain adequate kidney function and force fluids.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Disodium octaborate tetrahydrate is a flame retardant. It is not flammable, combustible, or explosive.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use personal protective clothing. Avoid dust formation. Ensure adequate ventilation. Do not breathe dust. Wear respiratory protection if ventilation is inadequate. Avoid contact with skin, eye, and clothing.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Scoop up and remove.

D. STORAGE AND HANDLING

General Handling
No special measures necessary provided product is used correctly.

Other Handling Precautions
Avoid eye and skin contact. Avoid creating or inhaling dust.

Storage

Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard for disodium octaborate tetrahydrate.

[The workplace exposure standard for disodium tetraborate decahydrate (borax) in Australia is 5 mg/m^3 as an 8-hour TWA. The workplace exposure standard for disodium tetraborate pentahydrate in Australia is 1 mg/m^3 as an 8-hour TWA.]

Engineering Controls
Ensure adequate ventilation. Localized ventilation should be used to control dust levels below permissible exposure limits.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection when airborne concentrations are expected to exceed exposure limits.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Disodium octaborate tetrahydrate is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

ETHANOL

This dossier on ethanol does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of ethanol in its use in drilling muds and hydraulic fracturing fluids. Ethanol consumption in alcoholic beverages is out of the scope of this dossier. The information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Ethanol

CAS RN: 64-17-5

Molecular formula: C_2H_6O

Molecular weight: 46.069

Synonyms: Ethyl alcohol, grain alcohol, alcohol, methylcarbinol, ethyl hydroxide, ethyl hydrate, algrain, alkohol, anhydrol, tecsol

SMILES: CCO

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Ethanol

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Colorless liquid with a mild odor.	2	ECHA
Melting point	-114°C	2	ECHA
Boiling point	78.2°C	2	ECHA
Density	0.789 g/cm^3 @ 20°C	2	ECHA
Vapor pressure	57.26 hPA @ 19.6°C	2	ECHA
Partition coefficient (log K_{ow})	-0.35 @ 24°C	2	ECHA
Water solubility	789 g/L @ 20°C	2	ECHA
Flash point	13°C	2	ECHA

Property	Value	Klimisch score	Reference
Auto flammability	>363 and <425ºC	2	ECHA
Viscosity	1.17 mPa s @ 20ºC	2	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Ethanol is readily biodegradable and not expected to bioaccumulate.

B. Biodegradation

Ethanol is readily biodegradable. The degradation of ethanol was approximately 74% and 84% (O_2 consumption) within 10 and 20 days, respectively, in a biodegradation test using a non-adapted domestic inoculum in a freshwater medium (ECHA) [Kl. score = 2].

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for ethanol. Using KOCWIN in EPISUITE™ (EPA, 2019), the estimated K_{oc} value from log K_{ow} is 2.199 L/kg. The estimated K_{oc} value from the molecular connectivity index (MCI) is 1.045 L/kg.

D. Bioaccumulation

There are no bioaccumulation studies on ethanol. Ethanol is not expected to bioaccumulate based on a log K_{ow} of -0.35 (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

Human health toxicological information was obtained from Inventory Multi-Tiered Assessment and Prioritisation (IMAP), which is an assessment framework conducted via Australia's National Industrial Chemicals Notification and Assessment Scheme (NICNAS), unless otherwise cited. Statements regarding toxicity are based solely on the determination of applicable regulatory agency.

A. Summary

Ethanol has a low acute toxicity by the oral, dermal, and inhalation routes of exposure, as measured by lethality. Sublethal doses, however, have been shown to produce central nervous system depression, respiratory depression, and coma. Deaths were reported in rodent studies due to cardiorespiratory failure. Ethanol is not irritating to the skin, but it is slightly irritating to the eyes. Repeated exposures by the oral route have not resulted in any systemic toxicity to rodents, except from exposure to high doses. Evidence of the carcinogenicity of ethanol is confined to epidemiological studies assessing the impact of alcoholic beverage consumption. These do not indicate any such hazard exists from potential exposure to ethanol in the workplace or from the use of ethanol in consumer products (OECD, 2004). Ethanol is not genotoxic or mutagenic. Ethanol does not show specific reproductive or developmental toxicity. Any reproductive and developmental effects were only observed secondary to maternal toxicity.

B. Acute Toxicity

Oral

The chemical has low acute toxicity by oral exposure in animal tests. The median lethal dose (LD50) in rats is >2000 mg/kg bw. Observed sub-lethal effects included central nervous system depression, e.g. inebriation, disturbances of gait, dose-related decreases in responses to painful stimuli, respiratory depression, and coma. Deaths were reported due to cardiorespiratory failure (OECD, 2005; HSDB; REACH).

Dermal

Few studies are available on the dermal toxicity of the chemical. A poorly documented rabbit study reported death in one of four animals following a dose of 20000 mg/kg bw. Although limited data are available, the apparent low dermal toxicity from this study is regarded as consistent with low uptake of ethanol through intact skin. The median lethal dose (LD50) in rats is greater than 2000 mg/kg bw. Observed sub-lethal effects were not reported for the study (OECD, 2005; REACH).

Inhalation

The chemical has low acute toxicity by inhalation exposure in animal tests. The lowest reported median lethal concentration (LC50) is 124.7 mg/L/four hours in rats. Observed sub-lethal effects included attempts to escape, reddish-watery eyes, nasal secretions, closing of eyelids, snout wiping, intermittent respiration, loss of pain reflex, abdominal position, and apathy (OECD, 2005; REACH).

C. Irritation

The chemical is not regarded as irritating to skin. The chemical is frequently applied to skin as a biocidal surgical wipe (70–80 % concentration) and as a component of cosmetics, personal care, and household cleaning products. There appear to be few documented concerns regarding skin irritation arising from these uses. Direct contact of the eye with the liquid chemical causes immediate discomfort accompanied by reflexive closure of the eye. Even though the acute effect subsides rapidly and the recovery is complete, foreign body type discomfort may persist for a day or two. Although inhaling the chemical at 5000 ppm (9600 mg/m^3) has been reported as irritating in humans;

lacrimation and coughing are only induced at a much higher concentrations (OECD, 2005).

Concentrations of the chemical attained in humans in the upper gastrointestinal tract after consumption of alcoholic beverages can cause local irritation.

The chemical produced irritant effects in several eye irritation studies in rabbits. While the severity of these effects was not consistent across all the studies, these were sufficiently severe in some studies to support classification, particularly under the Globally Harmonised System of Classification and Labelling of Chemicals.

D. Sensitization

The available data indicate that the chemical does not induce skin sensitisation in animals. An ear swelling study was used to examine the skin sensitising potential of ethanol. Ethanol was applied twice on the right ear after an induction procedure involving two scapular subcutaneous injection of adjuvant and multiple topical ethanol applications to the abdomen over a period of 14 days. The degree of contact hypersensitivity is deduced from ear swelling measured 24 and 48 hours after application. Ethanol was found not to cause any statistical increase in ear swelling, in contrast to 3 positive controls which all caused a statistically significant increase.

Data is also available from studies using ethanol as a vehicle. In a guinea pig maximisation study that used ethanol as a carrier solvent for the substance being tested (polyakylene glycol block copolymers) no positive reactions were obtained. It can be concluded that ethanol cannot have any significant skin sensitising properties since it was used as a solvent in this study at levels of up to 75%. A study was carried out to evaluate the effect of vehicles (e.g. ethanol) for use in the mouse local lymph node assay (LLNA), and their influence on the skin sensitization potential of fragrance materials. Groups of mice were treated with each test fragrance in ethanol (1:3 or 3:1 mixtures of the two), or with ethanol alone. Although there were no true control data for comparison with the ethanol-alone treated animals, the level of induced T-lymphocyte proliferation was low for ethanol when compared with that for fragrance materials known to be mild to moderate skin sensitizers, and comparable to other inert vehicles tested.

E. Repeated Dose Toxicity

<u>Oral</u>

Many repeated dose studies of chemical have been conducted in many species, predominantly with the aim of assessing adverse effects associated with the consumption of alcoholic beverages. Consequently, these are mostly conducted through oral exposure and with doses well in excess of those that might be encountered in occupational exposure or consumer products (OECD, 2005), or unintentional public exposures from environmental contamination.

In a 90-day study, SD rats were fed a mixture containing 16.25% USP ethanol at 3 dose levels (Kl =2). A single dose of 4 ml/kg of pure ethanol and water were used as controls. No significant differences were noted in body weight, haematology, opthamology, clinical chemistry or urine chemistry. Dose-related increases in liver to body weight ratios of female rats were seen at final sacrifice although the absolute liver weights of the high dose ethanol treated group, while significantly increased relative to the 100% ethanol treated group, was not different from the water control group. In addition, increased liver weights were observed in the male rats. Significant increases in kidney weights were observed in the mid and high dose groups. No histopathologic findings were attributed to ethanol treatment with exception of increased minimal focal to multifocal renal tubular epithelial hyperplasia in the high dose 20 ml/kg mixture containing 16.25% ethanol and the 100% USP ethanol control treated rats versus the water treated controls. It should be noted however that renal tubular epithelial hyperplasia is a common incidental finding in laboratory rats and it is uncertain whether the higher incidence of this lesion in the ethanol dosed rats compared with water controls is due to a random variation or to ethanol. Gonadal tissues were examined for both gross pathology and histopathology and no treatment-related effects were detected. The NOAEL for the study was determined at 10 ml/Kg for a mixture containing 16.25% ethanol for increased kidney weight and renal tubular epithelial hyperplasia in males (equivalent to 1.73g/kg). The LOAEL for this study was determined at 4 ml/kg for 100% USP ethanol (3.16g/kg) for increased kidney weight and renal tubular epithelial hyperplasia in males.

Inhalation

As properly conducted studies in animals are not available, there are no valid data on the effects of repeated inhalation exposure to the chemical. However, limited information is presented below to indicate that the chemical is likely to be of low toxicity following repeated inhalation exposure.

Dermal

No data are available.

F. Genotoxicity

Overall, ethanol is not considered to be mutagenic or genotoxic (OECD, 2005; REACH).

In Vitro Studies

Table 2: *In vitro* Genotoxicity Studies on Ethanol

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	1	Zeiger et al., 1992
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-	-	2	Wangenheim and Bolcsfoldi, 1988

*+, positive; -, negative;

In Vivo Studies

Several in vivo micronucleus assays have assessed the potential for the chemical to induce damage to chromosomes of erythroblasts. No effect was reported in rats when administered 5 % of the chemical (approximately 4 g/kg bw/day) in drinking water, or in mice at up to 40 % (approximately 31 g/kg bw/day). Chemical-related mortality was observed in the latter study. Marginally statistically significant increases in the incidence of micronucleated bone marrow erythrocytes were reported in rats fed for six weeks with a diet containing ethanol at 12–16 g/kg/day. Although there is very limited evidence that the chemical induces micronuclei in the bone marrow of rodents, the chemical has the potential to induce micronuclei in bone marrow erythrocytes at very high doses. KI scores were not listed for these studies (IMAP, 2014).

G. Carcinogenicity

Oral

A significant number of carcinogenicity studies have been identified, but the majority of these are only partial studies designed to look at aspects of the carcinogenic hazard resulting from drinking ethanol containing beverages and are judged unreliable for assessing the cancer hazard of ethanol as a chemical substance. Only two studies were identified as reliable.

In a study to assess the carcinogenic potential of ethanol, groups of rats were exposed to ethanol at concentrations of 1% and 3% in a liquid semi-synthetic diet for a period of 2 years, approximately equivalent to 1 and 3g/kg respectively. Each dose group used a control matched for caloric content using glucose. From the data it was possible to conclude that ethanol did not cause any treatment related increase in tumours and the no effect level was identified as > 3g/kg.

In a study designed and conducted to determine the long-term toxicity and carcinogenicity of urethane in ethanol, groups of mice were exposed to ethanol at concentrations up to 5% in drinking water for a period of 2 years, with control groups consuming drinking water alone. The only significant cancer finding was a dose related increase in the rate of hepatocellular adenomas for male mice in comparison with the concurrent controls. The species of mouse used in this study is known to have a high spontaneous incidence of these tumours. In comparison to historic controls, the incidence rate in the ethanol dosed animals was not high and the controls were significantly lower (although it should be noted that no historic control information was available for animals on the study diet used.) Analysis of the data using the Benchmark dose approach showed a BMDL10 of 1400mg/kg for liver adenomas in males. There was no significant increase in tumour rates (including mammary tumours) in females.

The International Agency for Research on Cancer (IARC) has concluded that there is sufficient evidence in humans and experimental animals to establish carcinogenicity of alcohol consumption and ethanol, respectively. It was also concluded that there is sufficient evidence in experimental animals to establish carcinogenicity of acetaldehyde (major metabolite of ethanol). Consequently, IARC has classified that ‘alcohol

consumption is carcinogenic to humans (Group 1)' and that 'ethanol in alcoholic beverages is carcinogenic to humans (Group 1)'. This conclusion was supported by an analysis of the expanded human dataset that carcinogenic effects appeared independent of the type of alcoholic beverage (IARC, 2010; IARC, 2012). As the use of the chemical in alcoholic beverages is not considered in this report, the above assessment of carcinogenicity of alcohol beverages may not be relevant to occupational exposure to the chemical or from using the chemical in consumer products (OECD, 2005). Furthermore, studies in animals conducted mostly through oral exposure at very high doses, exceeding the 'maximum tolerated dose', may be of little relevance when assessing risks associated with occupational exposure or using consumer products containing the chemical (OECD, 2005). Thus, classification is not considered appropriate (IMAP).

Inhalation
No information available (IMAP, REACH).

H. Reproductive and Developmental Toxicity

The chemical does not show specific reproductive or developmental toxicity. Any reproductive and developmental effects were only observed secondary to maternal toxicity. As results of inhalation studies showed no developmental toxicity from chemical exposures even at maternally toxic doses, it can be concluded that deliberate oral consumption of alcoholic beverages is required for any reproductive or developmental toxicity (OECD, 2005).

The most reliable study (Kl = 1) performed to the most appropriate protocol and the one given the greatest weight as well as the key study is a two-generation study investigated the effects of 5%, 10% and 15% ethanol in drinking water in reproduction and fertility. Male and female CD-1 mice were continuously treated for 1 week prior to mating and for a 14-week breeding period followed by a 21-day holding period when they were separated and housed individually. The F1 offspring of the 15% ethanol pairs had fewer live pups per litter but ethanol treatment had no effect on the proportion of breeding pairs producing at least 1 litter during the continuous breeding phase or the number of litters per pair. The F1 offspring from the 15% group had decreased bodyweight at weaning and mating, and a decreased weight of testis, epididymides and seminal vesicles which was no longer evident when these were adjusted for body weight. There was also a significantly decreased percentage motile sperm but no changes in sperm concentration, and percentage of abnormal sperm or tailless sperm. When reproductive performance of F1 control and 15% ethanol-treated breeding pairs was assessed at 74 days of age, there was no significant difference in mating and fertility between the groups. However, adjusted live pup weight for the ethanol group was significantly reduced compared to controls which was likely due to generalized maternal toxicity.

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for ethanol follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The lowest NOAEL from these studies is 1,730 mg/kg-day based on increased relative and absolute liver weight and absolute heart, liver, kidney and lung weight in male mice from a 90-day dietary study (1996). The NOAEL of 1,730 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD):

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 3
UF_D (database uncertainty) = 1

Oral RfD = 1730/(10 x 10 x 1 x 3 x 1) = 1730/300 = 6 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:

Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (6 x 70 x 0.1)/2 = 21 mg/L

B. Cancer

Evidence of the carcinogenicity of ethanol is confined to epidemiological studies assessing the impact of alcoholic beverage consumption. These do not indicate any such hazard exists from potential exposure to ethanol in the workplace or from the use of

ethanol in consumer products (OECD, 2004). Therefore, no cancer reference value was derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Ethanol is a flammable liquid.

Ethanol does not exhibit the following physico-chemical properties:
- Explosivity
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on ethanol.

Table 3: Acute Aquatic Toxicity Studies on Ethanol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-hr LC_{50}	15,300	2	ECHA
Pimephales promelas	96-hr LC_{50}	14,200	2	ECHA
Ceriodaphnia dubai	48-hr EC_{50}	5012	2	ECHA
Chlorella vulgaris	72-hr EC_{50}	275	2	ECHA

Chronic Studies

The 5-d NOEC to *Brachydanio rerio* in an OECD 212 embryo and sac-fry stage test is 250 mg/L (ECHA) [Kl. score = 2].

The 10-d NOEC to *Ceriodaphnia dubia* in a *Daphnia* reproduction test is 9.6 mg/L (ECHA) [Kl. score = 2].

The 72-hr EC_{10} to algae *Chlorella vulgaris* is 11.5 mg/L (ECHA) [Kl. score = 2].

C. Terrestrial Toxicity

No data are available.

D. Calculation of PNEC

The PNEC calculations for ethanol follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (14,200 mg/L), invertebrates (5,012 mg/L), and algae (275 mg/L). Results from chronic studies are available for fish (250 mg/L), invertebrates (9.6 mg/L), and algae (11.5 mg/L). On the basis that the data consists of short- and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC or EC_{10} value of 9.6 mg/L for invertebrates. The $PNEC_{aquatic}$ is 0.96 mg/L.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the PNECsoil was calculated using the equilibrium partitioning method. The PNECsoil is 0.013 mg/kg soil dry weight.

The calculations are as follows:

$$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$$
$$= (0.02/1500) \times 1000 \times 0.96$$
$$= 0.013$$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$$Kp_{soil} = K_{oc} \times f_{oc}$$
$$= 1.05 \times 0.02$$
$$= 0.02$$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for ethanol based on the molecular connectivity index (MCI) is 1.05 L/kg (EPA, 2019).
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Ethanol is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Based on a measured log K_{ow} of -0.35, ethanol does not meet the screening criteria for bioaccumulation.

No chronic aquatic toxicity studies are available on ethanol. The acute $E(L)C_{50}$ values for ethanol are >1 mg/L. Thus, ethanol does not meet the criteria for toxicity.

The overall conclusion is that ethanol is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Flammable liquid, Category 2
Eye irritation, Category 2B
Acute Toxicity, Category 3
Reproductive toxicity, Category 2
Specific target organ toxicity – Repeated exposure, Category 2
Specific target organ toxicity – Single exposure, Category 3

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact

Protect unexposed eye. Rinse/ flush exposed eye(s)s gently using water for 15-20 minutes. Remove contact lens(es) if able to do so during rinsing. Seek medical attention if irritation persists or if concerned.

Skin Contact
Wash affected area with soap and water. Rinse thoroughly. Seek medical attention if irritation, discomfort, or vomiting persists.

Inhalation
Move exposed individual to fresh air. Loosen clothing as necessary and position individual in a comfortable position. Seek medical advice if irritation persists.

Ingestion
Rinse mouth thoroughly. Do not induce vomiting. Have exposed individual drink sips of water. Seek medical attention if irritation, discomfort, or vomiting persists.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
For small fires, use dry chemicals, CO_2, water spray or alcohol-resistant foam. For large fire, use water fog or alcohol-resistant foam. Use appropriate fire suppression agents for adjacent combustible materials or sources of ignition.

Specific Exposure Hazards
Combustion products may include carbon oxides or other toxic vapors. Dangerous fire hazard when exposed to hear, sparks, and open flames.

Special Protective Equipment for Firefighters
Wear protective equipment. Use NIOSH-approved respiratory protection/ breathing apparatus. Use spark-proof tools and explosion-proof equipment. Move product containers away from fire or keep cool with water spray as a protective measure, where feasible.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Beware of vapors accumulating to form explosive concentrations. Vapors can accumulate in low areas. Keep unprotected persons away.
Wear protective equipment. Use respiratory protective device against the effects of fumes/ dust/ aerosol. Ensure adequate ventilation. Keep away from ignition sources. Protect from heat.
For large spills, wear splash goggles, full suit, respirator, boots and gloves and use self-contained breathing apparatus.

Environmental Precautions

Prevent from reaching drains, sewer, or waterway. Collect contaminated soil for characterisation. Collect spilled liquid for recovery, treatment, or disposal.

Steps to be Taken if Material is Released or Spilled
Eliminate sources of ignition. Stop the spill, if possible. Contain spill material by diking or using inert absorbent. Spill may also be contained by using electrically protected vacuum cleaner or by wet-brushing. Transfer to a disposal or recovery container.

D. STORAGE AND HANDLING

General Handling
Prevent formation of aerosols. Use only in well ventilated areas. Avoid splashes or spray in enclosed areas. Prevent exposure to ignition sources; use non-sparking tools and explosion-proof equipment.

Other Handling Precautions
Avoid contact with eyes, skin, and clothing. Avoid breathing vapor. Follow good hygiene procedures when handling chemical materials. Do not eat, drink, smoke, or use personal products when handling substances. Wash hands before breaks and at the end of work.

Storage
Store in a cool location. Provide ventilation for containers. Avoid storage near extreme heat, ignition sources, or open flame. Store away from foodstuffs. Store away from oxidizing agents. Store in cool, dry conditions in well-sealed containers. Keep containers tightly sealed. Store in secure flammable storage area away from sources of ignition. Protect from freezing and physical damage.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
The workplace exposure standard for ethanol in Australia is 1000 ppm (1880 mg/m^3) as an 8-hr TWA. No STEL is listed.

Engineering Controls
Good general ventilation should be used. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits. Avoid storage near extreme heat, ignition sources, or open flame. Use non-sparking tools and explosion-proof equipment.

Personal Protection Equipment

Respiratory Protection: Not required under normal conditions of use. Use suitable respiratory protective device when high concentrations are present. Use suitable respiratory protective devise when aerosol mist is formed. For spills, respiratory protection may be advisable.

Hand Protection: Gloves that are impermeable and resistant to the substance

Skin Protection: Wear chemical resistant gloves (rubber, neoprene or vinyl). Use personal protection equipment that is chemical resistant and prevents skin contact.

Eye protection: Goggles or safety glasses with side shields

Other Precautions:

- Use other PPE as required by the situation.
- Ethanol is a flammable liquid; keep away from ignition sources. Wash hands, forearms, and face thoroughly after handling chemical products, before eating, smoking, and using the lavatory and at the end of the working period.
- Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing.
- Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

UN Number: 1170
UN proper shipping name: Ethanol (mixture)

Transport hazard class: 3 Flammable liquids
Packing group: II

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

ETHYLENE GLYCOL

This dossier on ethylene glycol does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of ethylene glycol in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Ethane-1,2-diol

CAS RN: 107-21-1

Molecular formula: $C_2H_6O_2$ ($HOCH_2CH_2OH$)

Molecular weight: 62.07

Synonyms: Ethylene glycol; ethane-1,2-diol; 1,2-ethanediol, 2-hydroxyethanol; monoethylene glycol; MEG; glycol alcohol; EG

SMILES: C(CO)O

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Ethylene Glycol

Property	**Value**	**Klimisch score**	**Reference**
Physical state at 20°C and 101.3 kPa	Colourless and odourless syrupy liquid	2	ECHA
Melting Point	-13°C	2	ECHA
Boiling Point	197.4°C	2	ECHA
Density	1.11 g/cm^3	2	ECHA
Vapor Pressure	0.123 hPa	2	ECHA
Partition Coefficient (log K_{ow})	-1.36 (calculated)	2	ECHA
Water Solubility	1,000 g/L @ 20°C	2	ECHA

Flash Point	111°C	2	ECHA
Auto flammability	398°C	2	ECHA
Viscosity	16.1 mPa s @ 25°C	2	ECHA
Henry's Law Constant	0.133 @ 25°C (QSAR)	2	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Ethylene glycol is readily biodegradable, and it is not expected to bioaccumulate. Ethylene glycol has low potential to adsorb to soil and sediment.

B. Biodegradation

Ethylene glycol was readily biodegradable in an OECD 301A test. After 10 days, degradation was 90-100% (ECHA) [Kl. score = 1]. There was 97% degradation after 20 days in a BOD test; and 96% degradation after 28 days in an OECD 301D test (Waggy et al., 1994; OECD, 2004a,b) [Kl. score = 2].

The aerobic degradation of ethylene glycol was measured from grab river water samples at 4, 8, and 20°C. At 20°C, ethylene glycol was completely degraded in three days in all river waters tested; at 8°C, degradation was complete within 14 days. Degradation at 4°C was substantially slower, with degradation of <20% after 14 days in river samples with limited suspended matter and a starting concentration of 10 mg/L (Evans and David, 1974).

C. Environmental Distribution

<u>Adsorption/desorption</u>

No experimental data are available for ethylene glycol. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} values from the molecular connectivity index (MCI) and from the log K_{ow} are 1 and 0.2239 L/kg, respectively.

D. Bioaccumulation

The calculated log K_{ow} for ethylene glycol is -1.36 (ECHA). The BCF for ethylene glycol in golden ide (*Leuciscus idus melanotus*) after three days of exposure was determined to be 10 (Freitag *et al.*, 1985).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Following acute ingestion of ethylene glycol, the critical effects in humans in three subsequent stages are central nervous system toxicity, metabolic acidosis, and kidney toxicity. The lethal effects of ethylene glycol in human adults occur at oral doses of ≥1,600 mg/kg. Ethylene glycol is not a skin irritant or a skin sensitizer in laboratory animals. In humans, ethylene glycol may cause skin irritation; there is also a low potential for skin sensitization. It is not an eye irritant. The kidney is the primary target organ from repeated exposures. The proposed mode-of-action (MOA) for the kidney damage involves the formation of a precipitate or crystals from the ethylene glycol metabolite oxalic acid with calcium in the urine. Ethylene glycol is not genotoxic or carcinogenic to rodents. Ethylene glycol did not affect fertility in animal studies, but it did cause developmental effects. In rodents, the developmental effects caused by oral doses of ethylene glycol include teratogenic effects (craniofacial and axial-skeletal malformations and variations). In contrast, no developmental toxicity was seen in rabbit studies. The relevant metabolite for the developmental toxicity seen in rodent, but not rabbit, studies appears to be glycolic acid. This metabolite can be reached at higher concentrations in rats than in rabbits. Based on a physiologically-based pharmacokinetic (PBPK) model for ethylene glycol, humans are unlikely to achieve blood levels of glycolic acid necessary for developmental toxicity.

B. Metabolism

Ethylene glycol is almost completely absorbed in laboratory animals by the oral route (OECD, 2004; Frantz et al., 1996a). A range of 1-51% of ethylene glycol is absorbed by the dermal route based on *in vivo* studies in rodents (Frantz *et al.*, 1996a,b).

The main metabolic pathway for metabolism of ethylene glycol is oxidation via alcohol dehydrogenases and aldehyde dehydrogenases. The main metabolites of ethylene glycol are carbon dioxide, oxalic acid and glycolic acid (OECD, 2004a).

The relevant metabolite for the repeated dose toxicity studies is oxalic acid, which is slowly transported from the liver to the kidneys, where is forms calcium-oxalate crystals (Corley *et al.*, 2005a).

The relevant metabolite for the developmental toxicity seen in rodent, but not rabbit, studies appears to be glycolic acid. This metabolite can be reached at higher concentrations in rats than in rabbits (Carney *et al.*, 1998).

A physiologically-based pharmacokinetic (PBPK) model has been developed for ethylene glycol. When internal dose surrogates were compared in rats and humans over a wide range of exposures, it has been concluded that humans are unlikely to achieve blood levels of glycolic acid necessary for developmental toxicity (Corley *et al.*, 2005b).

C. Acute Toxicity

The oral LD_{50} in rats was reported to be 7,712 mg/kg (ECHA) [Kl. score = 2]. The 6-hour inhalation LC_{50} value for male and female rats was >2.5 mg/L (Tyl *et al.*, 1995a) [Kl. score = 2]. The dermal LD_{50} for male and female mice is >3,500 mg/kg (Tyl *et al.*, 1995b) [Kl. score = 2].

Following acute ingestion of ethylene glycol, the critical effects in humans in three subsequent stages are central nervous system toxicity, metabolic acidosis, and kidney toxicity (ECHA). The lethal effects of ethylene glycol in human adults occur at oral doses of $\geq$1,600 mg/kg (Hess et al., 2004).

D. Irritation

Application of 0.5 mL of ethylene glycol to the skin of rabbits for 23 hours under occlusive conditions was not irritating (Guillot *et al.*, 1982). [Kl. score = 2].

In a Human Repeated Insult Patch Test (HRIPT), ethylene glycol was applied to the skin for 24 hours under occlusive or semi-occlusive conditions for nine times during the induction phase. The induction phase was followed by a rest period of two weeks, followed by a 24-hour challenge on the sixth week of the study. Erythema was seen in a small proportion of the 401 subjects that completed the study. Under the conditions of the study, three subjects had reactions on challenge that were indicative of possible irritation and/or low-level sensitization. These three subjects were re-challenged under occlusive or semi-occlusive conditions one or two weeks later. Re-challenge testing was negative for one subject, but the other two subjects were judged to have irritant reactions to ethylene glycol since their reactions were similar or lesser compared to the skin responses observed during the induction period, and the skin reactions were not greater over time after the challenge or re-challenge (ECHA).

Instillation of 0.05 mL of ethylene glycol into the eyes of rabbits was not irritating (ECHA). [Kl. score = 2]

E. Sensitization

Ethylene glycol was not a skin sensitizer to guinea pigs in a Magnusson and Kligman test (Kurihara *et al.*, 1996) [Kl. score = 2]. In a HRIPT, ethylene glycol was considered to have a low potential for dermal sensitization in humans (ECHA).

F. Repeated Dose Toxicity

<u>Oral</u>

Male and female Fischer 344 rats were given in their feed 0, 0.32, 0.63, 1.25, 2.5, or 5% ethylene glycol for 13 weeks. Mortality was seen in the 5% males, but not in females. Mean weight gain was significantly decreased in the 2.5 and 5% males; there was no significant differences in female rats. Feed consumption was similar across all groups. A significant increase was seen in the left kidney weight in the 2.5 and 5% dose groups (both sexes); this was not seen in the right kidneys. Mean thymus ratio to terminal body weight was significantly decreased in the 5% males. Serum urea nitrogen levels were significantly increased in the 2.5 and 5% males, and significantly increased in the $\geq$0.32% females. Creatinine levels were decreased in the 0.32% groups and significantly increased in the 2.5 and 5% groups. The 2.5% and 5% male rats had kidneys that were rough, granular and/or pitted appearances. The 5% females showed nephrosis, and the 5% males had clusters of crystals in the brain. The NOAEL for this study is 1.25%, which was estimated to be 600 to 1,000 mg/kg-day (Melnick, 1984). [Kl. score = 2]

Male and female Sprague Dawley rats were given in their drinking water ethylene glycol for 90 days. The concentrations for females were 0, 0.5, 1.0, 2.0 or 4.0% (0, 597, 1,145, 3,087 or 5,744 mg/kg-day). The concentrations for males were 0, 0.25, 0.5, 1.0 or 2.0% (0, 205, 407, 947 or 3,134 mg/kg-day). In the 4% groups, there was mortality and decreased body weights (males only). Significant organ weights were noted only in males. Kidney weights were significantly increased in the 1% and 2% males; heart, liver, and lung were significantly decreased in the 2% males. The 4% males also had a significant increase in the brain and gonads relative to body weights. Leukocyte levels were significantly decreased in the 0.5, 2 and 4% females, but not in males. Significant differences were noted in LDH, creatinine, ALT, calcium and glucose in the 1% males; and phosphorus, BUN, and creatinine in the 2% males. There were significant increases in phosphorus in the 1% females and glucose in the 0.5 and 4% females. Kidney lesions were seen in the $\geq$2% females and in the $\geq$1% males, with the lesions more prominent in males than in females. The kidney changes consisted of tubular dilation, tubular degeneration, acute inflammation, birefringent crystals in tubules and pelvic epithelium. The NOAEL for this study is 407 mg/kg-day for males. The LOAEL for females is 597 mg/kg-day; a NOAEL was not established (Robinson *et al.*, 1990). [Kl. score = 2]

Male and female B6C3F$_1$ mice were given in their feed 0, 0.32, 0.63, 1.25, 2.5, or 5.0% ethylene glycol for 13 weeks. There was no mortality and no treatment-related effect on mean weight gain and feed consumption. Organ/body weight ratios were similar across all groups. Serum urea nitrogen and creatinine levels were unaffected. Kidney effects were seen in the male, but not female, mice. Kidney lesions were observed in half of the 5% male mice and one mouse in the 2.5% dose level. Lesions were tubular dilation, cytoplasmic vacuolization, and regenerative hyperplasia of tubular cells. There was no evidence of crystal formation in the tubules. These changes were focal, randomly distributed, and of minimal to mild severity. Hyaline degenerative of the liver was present in the centrilobular hepatocytes in all of the 2.5% and 5% males. These cells showed cytoplasmic accumulations of non bifringent, eosinophilic (hyaline), globular, or crystalline material which resembled erythrocytes in size, shape, and tinctorial properties.

The NOAEL for this study is 1.25%, which was estimated to be 600 to 1,000 mg/kg-day (Melnick, 1984). [Kl. score = 2]

Male Fischer 344 and Wistar rats were given in their feed 0, 150, 500 or 1,000 mg/kg ethylene glycol for 16 weeks. At 1000 mg/kg, the following effects were seen: mortality in Wistar strain (2/10) with prior clinical observations of emaciation and dermal atonia and macroscopic findings of changes in kidneys (pale, calculi) and small seminal vesicles in these animals; mean body weight losses, lower mean body weights and mean cumulative body weight changes in Wistar strain (weeks 2 – 16); lower mean food consumption in Wistar strain; higher mean water consumption in both F344 and Wistar strains; lower mean specific gravity and higher mean total urine volume in both F344 and Wistar strains; macroscopic findings of pale kidneys, presence of calculi, rough surface and dilated pelvis; higher mean absolute and relative kidney weights in both F344 and Wistar strains; renal macroscopic findings of crystal nephropathy in Wistar and F-344 rats, with more severe nephropathy in Wistar strain than in the F344 strain. At 500 mg/kg, the following effects were seen: lower mean body weights (study weeks 3, 6-8, and 10-12) and mean cumulative body weight changes in the Wistar strain throughout the study with slightly lower mean food consumption throughout the study; higher mean water consumption in the Wistar strain; lower mean urine specific gravity and higher mean total urine volume in the Wistar strain; macroscopic findings in the Wistar strain consisting of predominantly pale kidneys, presence of calculi, rough surface, and dilated pelvis; higher mean absolute and relative kidney weight in the Wistar strain; renal macroscopic findings of crystal nephropathy in Wistar and F-344 strains, with more severe nephropathy in the Wistar strain than in the F344 strain. The NOAEL in both the F344 and Wistar rats is 150 mg/kg-day (Cruzan *et al.*, 2004). [Kl. score = 2]

Male Wistar rats were given in their feed 0, 50, 150, 300 or 400 mg/kg ethylene glycol for 12 months. There was mortality in the 300 and 400 mg/kg dose groups (5/20 and 4/20, respectively); the remaining 400 mg/kg animals were euthanized early (day 203) due to excessive weight loss. The 300 mg/kg animals had increased water consumption and urine volume with decreased specific gravity, most likely due to osmotic diuresis. Calculi (calcium oxalate crystals) were found in the bladder and kidney pelvis in the $\geq$300 mg/kg animals. The $\geq$300 mg/kg rats that died prematurely had transitional cell hyperplasia with inflammation and hemorrhage of the bladder wall. Crystal nephropathy (basophilic foci, tubule or pelvic dilatation, birefringent crystals in the pelvic fornix, or transitional cell hyperplasia) was seen in all of the 400 mg/kg and most of the 300 mg/kg rats. These effects were not seen in the 50 or 150 mg/kg rats. Kidney oxalate levels, the metabolite responsible for the kidney toxicity, was not increased in the 50 and 150 mg/kg animals compared to the controls. The NOAEL for this study is 150 mg/kg/day (Corley *et al.*, 2005). [Kl. score = 1]

Male and female Sprague-Dawley rats were given in their feed 0, 0.1, 0.2, 0.5, 1.0 or 4.0% ethylene glycol for two years. There was significant reduction in growth in the 4% males after week 16, and in the 1% males after week 70. The 4% females did not gain any weight past the first year of the study. Water consumption was double that of the controls in the 4% males that initiated soon after the start of the study. The 1% males had

significant increases in water consumption after 6 months and some increase was observed in the 0.5% males. Females only showed increased water consumption in the 4% group. There was 100% mortality in the 1 and 4% males, while mortality of additional dose levels were below that of the controls. There was 100% mortality in the 4% females, while the 1% females were similar to the controls; the 0.1, 0.2 and 0.5% females were increased compared to the controls. Since the 1 and 4% males and the 4% females all died before the study termination date, there are no data for these groups on terminal organ weight. For males, the terminal organ weights were decreased in all dose levels compared to the controls. For females, the organ weights were similar to the controls. The 1 and 4% males and females had kidneys with stones and crystals. The NOAEL for this study is 0.2% (data was insufficient to calculate the dose) (Blood, 1965). [Kl. score = 2]

Male and female Fischer 344 rats were given in their feed 0, 40, 200 or 1,000 mg/kg ethylene glycol for 24 months. There were numerous adverse effects in the 1,000 mg/kg males and, to a lesser degree, in the 1,000 mg/kg females. The most remarkable effect was the production of urinary calculi in the kidneys, ureters, and urinary bladders of the 1,000 mg/kg males, along with the presence of high levels of calcium oxalate in the urine. Increased incidences of tubular cell hyperplasia, tubular dilation, peritubular nephritis, and focal granulomatous nephritis occurred in the 1,000 mg/kg males. Other significant findings in these males were markedly lower body weight gain, increased absolute and relative kidney weights, decreased absolute and relative liver weights, various hematopoietic changes, and increased water consumption (likely a result of impaired kidney function). Histopathological changes in the 1,000 mg/kg males were mineralization of the heart, lungs, stomach, and vas deferens being the most noteworthy. The various adverse effects in these males resulted in reduced survival; there was increased mortality which became apparent by 8 months, with all males in this group died by month 16. Although calcium oxalate crystals were found in the urine of the 1,000 mg/kg females, no urinary calculi were seen. Absolute and relative kidney weights were increased in these rats. The most significant histopathologic finding in the 1,000 mg/kg females was fatty metamorphosis of the liver. There were transient changes in organ weights, erythroid parameters, water consumption rates, and urine specific gravity in the 200 and 40 mg/kg rats; these effects were considered to be statistical artifacts attributable to chance. Focal soft mineralization was observed in certain organs of the 200 and 40 mg/kg rats, which were considered to be the result of altered calcium metabolism associated with ingestion of ethylene glycol. The NOAEL for this study is considered to be 200 mg/kg-day (DePass *et al.*, 1986a; ECHA). [Kl. score = 2]

Male and female B6C3F$_1$ mice were given in their feed 0, 6,250 ppm (males only), 12,500 and 25,000 ppm (males and females) or 50,000 ppm (females only) for 103 weeks. These concentrations are approximately equivalent to 0, 1,500, 3,000, 6,000 or 12,000 mg/kg-day. Survival, mean body weights, and feed consumption was similar across all groups. There were no treatment-related clinical signs of toxicity. Liver lesions (males only) and arterial hyperplasia (females only) were observed at 12,500 ppm, but no adverse effects were observed at 6,250 ppm. The NOAEL for this study is 6,250 ppm in males, which corresponds to 1,500 mg/kg-day (NTP, 1993). [Kl. score = 2]

Inhalation

No studies are available.

Dermal

No studies in rodents or rabbits are available.

G. Genotoxicity

In Vitro Studies

The *in vitro* genotoxicity studies on ethylene glycol are presented in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Ethylene Glycol

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	1	ECHA
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	2	ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	+/-	-	2	McGregor et al. (1991)
Chromosomal aberration (CHO cells)	-	-	2	ECHA

*+, positive; -, negative

In Vivo Studies

A dominant lethal study was conducted in F344 rats given 0, 40, 200, or 1,000 mg/kg-day ethylene glycol in feed. There were slight increases in the dominant lethal mutation index in the high-dose and low-dose groups; these appear to be random occurrences and were not considered to be treatment-related. It was concluded that ethylene glycol was not genotoxic in this study (DePass et al., 1986b). [Kl. score = 2]

H. Carcinogenicity

Oral

Male and female Fischer 344 rats were given in their feed 0, 40, 200 or 1,000 mg/kg ethylene glycol for 24 months. There was increased mortality in the 1,000 mg/kg males, starting at 8 months and resulting in all males in this group dead by 16 months. Survival for the 1,000 mg/kg females and the 200 and 40 mg/kg males and females were similar to the controls. The incidence of mononuclear cell leukemia was statistically significantly higher in the 200 mg/kg males compared to the male controls, but not when compared to the pooled controls (males and females). Evaluation of the data by the method of Thomas et al. (2007), however, showed no treatment-related effect. It was concluded that ethylene glycol was not carcinogenic to rats in this study (DePass et al., 1986). [Kl. score = 2]

Male and female B6C3F_1 mice were given in their feed 0, 6,250 ppm (males only), 12,500 and 25,000 ppm (males and females) or 50,000 ppm (females only) ethylene glycol. These concentrations were approximately equivalent to 0, 1,500, 3,000, 6,000 or 12,000 mg/kg-day. Body weights, survival, and incidence of tumors were similar between treated and control mice (NTP, 1993). [Kl. score = 2]

Inhalation

No studies are available.

Dermal

No studies are available.

I. Reproductive Toxicity

Ethylene glycol was assessed in a Reproductive Assessment by Continuous Breeding (RACB) protocol. The parental mice were administered ethylene glycol via drinking water during pre-mating exposure, cohabitation, pregnancy, and lactation. The F_1 generation received prenatal exposure via maternal exposure during gestation, with the exposure continuing during lactation, weaning, and mating of F_1 animals and production of an F_2 litter. The doses were 0, 0.25, 0.5 or 1% ethylene glycol, which corresponded to approximately 0, 410, 840 or 1,640 mg/kg-day. No adverse effects were noted in the parental animals at doses up to 1%. There was a small, but statistically significant, effects on the numbers of litters per fertile pair, the number of live pups per litter, and live pup weight in the 1% dose group. Neither the 0.25 nor 0.5% dose groups were significantly affected. The number of live pups per litter was lower in the treated groups, but differences were not statistically significant. Unusual facial features (*i.e.*, shorter snout and wide-set eye) and skeletal defects (shortened frontal, nasal, and parietal bones; fused ribs abnormally shaped or missing sternebrae, abnormally shaped vertebrae; and

twisting of the spine) were noted on some of the offspring of the treated mice in the 1% group, but not in the controls. The parental NOAEL is 1% (approximately 1,640 mg/kg-day), and the NOAEL for reproductive toxicity is 0.5% (approximately 840 mg/kg-day (Lamb *et al*., 1985). [Kl. score = 2]

In a three-generation reproductive toxicity study, Fischer 344 rats were given in their diet 0, 40, 200 or 1,000 mg/kg-day ethylene glycol. There were no treatment-related effects on clinical signs of toxicity or survival in the parental animals. There were no significant effects on fertility index, gestation index, gestation survival for all three generations. Mean pup weights in the all three generations were similar between treated and control animals. The NOAEL for parental and reproductive toxicity is 1,000 mg/kg/day (DePass *et al.*, 1986b). [Kl. score = 2]

J. Developmental Toxicity

Pregnant Sprague-Dawley rats were dosed by oral gavage with 0, 50, 150, 500, 1,000 or 2,500 mg/kg ethylene glycol during gestational days (GD) 6-15. Maternal toxicity was observed in the 2,500 mg/kg group and consisted of significantly decreased body weights, increased water consumption, decreased uterine weights, increased kidney weights, and increased relative liver weights. At 500 mg/kg, there were developmental effects, which included reduced fetal body weights, extra or missing ribs, missing arches, and poor ossification in thoracic and lumbar centra. In the 2500 mg/kg group, in addition to skeletal malformations, there was gastroschisis, hydrocephaly, lateral ventricle dilated (tissue depressed), umbilical hernia, and atelectasis. The NOAELs for maternal and developmental toxicity are 1,000 and 500 mg/kg-day, respectively (Neeper-Bradley *et al.*, 1995). [Kl. score = 2]

Pregnant CD rats were dosed by oral gavage with 0, 1,250 2,500 or 5,000 mg/kg ethylene glycol during GD 6-15. In the $\geq$2,500 mg/kg groups, the dams had increased relative kidney weights, decreased gravid uterine weight, and increased water consumption. Maternal body weight gain was significantly decreased in the 1,250 mg/kg group. Live litter size was significantly decreased in the 5,000 mg/kg group, and fetal body weights were decreased in the 1,250 and 5,000 mg/kg groups. Litters with malformed fetuses were observed in the $\geq$1,250 mg/kg groups. The LOAELs for maternal and developmental toxicity are 1,250 mg/kg/day; NOAELs were not established (Price *et al.*, 1985). [Kl. score = 2]

Pregnant Fischer 344 rats were given by oral gavage 0, 40, 200 or 1,000 mg/kg ethylene glycol during GD 6-15. No maternal toxicity was observed at any dose level. There were no significant effects on preimplantation loss, fetal length, fetal weight, total implantations or litter size. There was an increased incidence of skeletal alterations in the 1,000 mg/kg group, which consisted of poorly ossified and unossified vertebral centra. No significant increases in the incidence of major malformations were observed. The NOAELs for maternal and developmental toxicity are 1,000 and 400 mg/kg/day (Maronpot *et al.*, 1983). [Kl. score = 2]

Pregnant CD-1 mice were dosed by oral gavage with 0, 50, 150, 500 or 1,500 mg/kg ethylene glycol during gestational days (GD) 6 to 15. There was no maternal toxicity. At 1,500 mg/kg, there were reduced fetal body weights, fused ribs and arches, poor ossification in thoracic and lumbar centra, and increased occurrence of an extra 14^{th} rib. At 500 mg/kg, there was slight reductions in fetal body weight and increased incidences of extra ribs. The NOAELs for maternal and developmental toxicity were 1,500 and 150 mg/kg/day, respectively (Neeper-Bradley et al., 1995). [Kl. score = 2]

Pregnant CD-1 mice were dosed by oral gavage with 0, 750, 1,500 or 3,000 mg/kg ethylene glycol during GD 6 to 15. There was a significant decrease in maternal gain, gravid uterine weights, and liver weights in the 1,500 mg/kg group. A decreased number of implantation sites per litter was observed in the 1,500 mg/kg group. Significant decrease in liver litter size was observed in the 3,000 mg/kg group and decreased fetal body weights were seen at $\geq$750 mg/kg. Litters with a significant increase in malformed fetuses were observed in the $\geq$750 mg/kg groups. There was a significant dose-related increase in postimplantation loss per litter, though there were no significant pairwise comparisons. The NOAEL for maternal toxicity is 750 mg/kg-day. The LOAEL for developmental toxicity is 750 mg/kg-day; the NOAEL was not established (Price *et al.*, 1985). [Kl. score = 2]

In a short-term reproductive and developmental toxicity screen test, male and female Swiss Crl:CD-1 mice were allowed to mate over a three-day period. The males were dosed by oral gavage from study day 3 to study day 20. The Group A females were exposed throughout the 21-day test period; the Group B females were exposed during GD 8-14. The doses were 0, 250, 700 or 2,500 mg/kg ethylene glycol. The Group A females were sacrificed after 19 days of treatment, and the Group B females were allowed to litter and rear to postnatal day (PND) 4. There was no maternal or paternal toxicity. The 2,500 mg/kg females in Group A had significantly fewer liver implants and more dead implants. The 2,500 mg/kg in Group B had significantly lower total litter weights on PND 1 and 4. The NOAELs for parental and developmental toxicity are 2,500 and 700 mg/kg/day (Harris *et al.*, 1992). [Kl. score = 2]

In a Chernoff/Kavlock assay, pregnant CD-1 mice were dosed by oral gavage with 0 or 11,090 mg/kg ethylene glycol during GD 7-14. The females were allowed to litter and rear to PND 3. Ten percent of the maternal animals died. The number of surviving pups per litter (40% survived), birth weight and pup weight gain were reduced. The LOAELs for maternal and developmental toxicity are 11,090 mg/kg; NOAELs were not established (Schuler *et al.*, 1984; Hardin *et al.*, 1987). [Kl. score = 2]

Pregnant female New Zealand White rabbits were dosed by oral gavage with 0, 100, 500, 1,000, or 2,000 mg/kg ethylene glycol on GD 6 to 19. At 2,000 mg/kg, eight of the 17 does (42.1%) died. Maternal body weights and body weight gain were similar across all groups. There was no developmental toxicity. The NOAEL for maternal toxicity is 1,000 mg/kg-day. The NOAEL for developmental toxicity is 2,000 mg/kg-day, the highest dose tested (ECHA). [Kl. score = 2]

Pregnant female CD rats were dosed by oral gavage with 0, 250, 1,250, or 2,250 mg/kg ethylene glycol on GD 6 to 20. At 2,250 mg/kg, maternal body weight, body weight gain, kidney weight, and postpartum uterine weight were significantly reduced. At 1,250 mg/kg, the gestational period was lengthened and maternal kidney histopathological effects were noted. Developmental toxicity was noted in the 2,250 mg/kg group and included reduced pup weight, reduced viability, and increased malformations (primarily hydrocephaly and abnormalities of the axial skeleton). No developmental toxicity was seen in the 1,250 mg/kg group. The NOAEL for maternal and developmental toxicity is 250 mg/kg-day (ECHA). [Kl. score = 2]

Inhalation

Pregnant female CD rats were exposed by inhalation (whole-body) to 0, 150, 1,000, or 2,500 mg/m^3 ethylene glycol aerosol 6 hours/day on gestational days 6 to 15. There was no treatment-related mortality; a dose-related increased in clinical signs (red fur discoloration on the head and neck) was noted, which was considered to be a non-specific indication of stress. Body weights and body weight gain were unaffected by treatment. There was some evidence of treatment-related reductions in ossification of the fetal skeleton at 1,000 and 2,500 mg/m^3 (considered as fetotoxicity). The NOAECs from inhalation exposure cannot be determined due to confounding oral exposure during whole-body exposure. However, there was no maternal or embryotoxicity at 150 mg/m^3 and no teratogenicity at any aerosol concentration tested (Tyl et al., 1995a). [Kl. score = 2]

Pregnant female CD-1 mice were exposed by inhalation (whole-body) to 0, 150, 1,000, or 2,500 mg/m^3 ethylene glycol aerosol 6 hours/day on gestational days 6 to 15. Reduced maternal body weight was observed in the 2,500 mg/m^3 group on GD 12,15, and 18 and in the 1,000 mg/m^3 group on GD 18. Reduced maternal weight gain was also seen during GD 6-12, 6-15, and GD 6-18 for the $\geq$1000 mg/m^3 groups, and for GD 5-18 for the 2,500 mg/m^3 group. Terminal body weights were reduced in the $\geq$1,000 mg/m^3 groups. Gravid uterine weight was also reduced in the $\geq$1,000 mg/m^3 groups, so that body weight corrected for gravid uterine weight was unaffected. The number of viable implantations per litter was reduced at 2,500 mg/m^3. The number of non-viable implantations per litter was elevated at $\geq$1,000 mg/m^3 because of a significant increase in late resorptions at 1,000 mg/m^3, and a significant increase in late resorptions and in dead fetuses at 2,500 mg/m^3. The number of early resorptions at 2,500 mg/m^3 was also elevated but not statistically. Fetal body weights per litter (male, female, and total) were reduced at $\geq$1,000 mg/m^3. There was a significant increase in the incidence of a number of external, visceral, and skeletal malformation, as well as skeletal variations, at $\geq$1,000 mg/m^3. There was no observable maternal or developmental toxicity at 150 mg/m^3. However, a NOAEC cannot be determined because of the amount of ethylene glycol that may have been ingested from the presence of ethylene glycol on the fur (Tyl et al., 1995a). [Kl. score = 2]

Pregnant female CD-1 mice were exposed by inhalation (nose-only) to 0, 500, 1,000, or 2,500 mg/m^3. The study also included a group exposed to 2,100 mg/m^3 (not discussed

here). Reduced maternal body weight gain were seen in the 2,500 mg/m^3 for GD 9-12, 12-15, 6-15, and 0-18. Absolute kidney weights were increased in the ≥1,000 mg/m^3 groups. Fetal body weights per litter were significantly reduced for the 2,500 mg/m^3. In the 2,500 mg/m^3, there was a significant increase in one skeletal malformation (fusion of the ribs) and an increased incidence of skeletal variations. No other teratogenic effects were observed. The NOECs for maternal and developmental toxicity are 500 and 1,000 mg/m^3, respectively (Tyl et al., 1995c). [Kl. score = 2]

Dermal

Pregnant CD-1 mice were administered by dermal applications of 0, 400, 1,677 or 3,549 mg/kg ethylene glycol 6 hours/day on GD 6-15. There was minimal, if any, treatment-related maternal toxicity. Copora lutea, total implants, percentage of live fetuses per litter, fetal body weights, and incidence of external or visceral malformations were unaffected by treatment. There was, however, a significant increase in two skeletal variations in the 3,549 mg/kg group. The NOAELs for maternal and developmental toxicity were considered to be 3,549 mg/kg-day (Tyl *et al.*, 1995b). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for ethylene glycol follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The NOAEL from a 24-month rat dietary study was reported to be 200 mg/kg-day based on kidney lesions in male F344 rats at 1,000 mg/kg-day (Depass et al., 1986b). A subsequent 12-month rat dietary study using male Wistar rats reported a NOAEL of 150 mg/kg-day also based on kidney toxicity at 300 mg/kg-day and higher (Corley et al., 2008). The Wistar rat strain was shown to be more sensitive (approximately three-fold) to the kidney toxicity of ethylene glycol than F344 rats (Cruzan et al., 2004). The NOAEL of 150 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Snellings et al. (2013) derived an oral reference dose for ethylene glycol using benchmark dose modeling, with toxicokinetic (PBPK modeling) and toxicodynamic data. The human equivalent dose ($[BMDL_{05}]_{HED}$) was calculated to be 150 mg/kg-day.

Oral RfD = $[BMDL_{05}]_{HED}$ / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 1
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 150/(1 x 10 x 1 x 1 x 1) = 150/10 = 15 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (15 x 70 x 0.1)/2 = 53 mg/L

B. Cancer

Ethylene glycol was not carcinogenic to rats and mice in two-year dietary studies. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Ethylene glycol does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Ethylene glycol is of low toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on ethylene glycol.

Table 3: Acute Aquatic Toxicity Studies on Ethylene Glycol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-h LC_{50}	>72,860	1	Pillard (1995)
Oncorhynchus mykiss	96-h LC_{50}	22,810 24,591	2	OECD (2004a,b)
Daphnia magna	48-h EC_{50}	>100	1	ECHA
Daphnia magna	48-h EC_{50}	46,300	2	Gersich et al. (1986)
Ceriodaphnia dubia-affinis	48-h EC_{50}	25,800 (20^oC) 10,000 (24^oC)	2	Cowgill et al. (1985)
Daphnia magna	48-h EC_{50}	46,300 (20^oC) 51,000 (24^oC)	2	Cowgill et al. (1985)
Selenastrum capricornutum	96-h IC_{50} NOEC	10,940 10,000	2	Pillard and DuFrescne (1999)

Chronic Studies

Table 4 lists the results of chronic aquatic toxicity studies conducted on ethylene glycol.

Table 4: Chronic Aquatic Toxicity Studies on Ethylene Glycol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	7-day NOEC	15,380	2	Pillard (1985)
Ceriodaphnia dubia	7-day NOEC (reproduction)	8,590	2	Pillard (1985)

C. Terrestrial Toxicity

No guideline studies have been conducted on ethylene glycol.

D. Calculation of PNEC

The PNEC calculations for ethylene glycol follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute E(L)C_{50} values are available for fish (22,810 mg/L), *Daphnia* (>100 mg/L), and algae (10,940 mg/L). NOEC values from long-term studies are available for fish (15,380 mg/L), invertebrates (8,590 mg/L), and algae (10,000 mg/L). On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported E(L)C_{50} value of 100 mg/L for fish. The E(L)C_{50} value is used because the value for fish is lower than the NOEC values for all three trophic levels. The $PNEC_{aquatic}$ is 10 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 6.4 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.82/1280) \times 1000 \times 10$
$= 6.4$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water}$ = 0.8 + [(0.2 x Kp_{sed})/1000 x BD_{solid}]
= 0.8 + [(0.2 x 0.04/1000 x 2400]
= 0.82

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

Kp_{sed} = K_{oc} x f_{oc}
= 1 x 0.04
= 0.04

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for ethylene glycol calculated from EPISUITE™ using the MCI is 1 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.13 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil}$ = (Kp_{soil}/BD_{soil}) x 1000 x $PNEC_{water}$
= (0.02/1500) x 1000 x 10
= 0.13

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

Kp_{soil} = K_{oc} x f_{oc}
= 1 x 0.02
= 0.02

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for ethylene glycol calculated from EPISUITE™ using the MCI is 1 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Ethylene glycol is readily biodegradable and thus does not meet the screening criteria for persistence.

The measured BCF in fish is 10. Thus, ethylene glycol does not meet the criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity studies on ethylene glycol are >0.1 mg/L. The acute E(L)C_{50} values from the acute aquatic toxicity studies on ethylene glycol are >1 mg/L. Thus, ethylene glycol does not meet the criteria for toxicity.

The overall conclusion is that ethylene glycol is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

STOT RE Category 2 (target organ: kidney)

B. Labelling

Warning

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes.

Skin Contact
Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention.

Ingestion
Rinse mouth with water and then drink a glass of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Keep product and empty container away from heat and sources of ignition. May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment. Handle in accordance with good industrial hygiene and safety practice.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
For large amounts: dike spillage and pump off product. For residues: pick up with suitable absorbent material. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling
Keep product and empty container away from heat and sources of ignition. Ensure adequate ventilation, especially in confined areas.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

The workplace exposure standards for ethylene glycol in Australia is as follows: 10 mg/m^3 as an 8-hour TWA for ethylene glycol (particulate); 20 ppm (52 mg/m^3) as an 8-hour TWA for ethylene glycol (vapour). There is also a skin notation indicating that absorption through the skin may be significant source of exposure.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Respiratory protection is not required.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Ethylene glycol is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

FATTY ACIDS, TALL OIL, ETHOXYLATED

This dossier on fatty acids, tall oil, ethoxylated does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of fatty acids, tall oil, ethoxylated in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Fatty acids, tall oil, ethoxylated

CAS RN: 61791-00-2

Molecular formula: UVCB

Molecular weight: UVCB

SMILES: UVCB

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Fatty Acids, Tall Oil, Ethoxylated (1 – 2.5 Moles Ethoxylated)

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Liquid	1	ECHA
Melting point	-85 to -5°C	1	ECHA
Boiling point	ca. 172°C	1	ECHA
Density	0.958 g/cm^3 @ 20°C	1	ECHA
Vapor pressure	Could not be determined experimentally.	1	ECHA
Partition coefficient (log K_{ow})	Could not be determined experimentally. 5.94 (QSAR)	1 2	ECHA
Water solubility	Could not be determined experimentally.	1	ECHA
Flash point	138°C	1	ECHA

Auto flammability	377°C	1	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Fatty acids, tall oil, ethoxylated is readily biodegradable; will adsorb to soil and sediment; but is not expected to bioaccumulate.

B. Biodegradation

Fatty acids, tall oil, ethoxylated is readily biodegradable. In an OECD 301 B test, degradation was 90 – 100% after 28 days (ECHA) [Kl. score = 1].

C. Environmental Distribution

Adsorption/desorption

Experimental data are available for fatty acids, tall oil, ethoxylated. The test material had different components which differed considerably in adsorption potential. The log K_{oc} values were: <1.8, 2.02, 2.9, 4.39, 5.24, and >5.63. The main constituents peak 4 (log K_{oc} = 4.39) and peak after determination of dead time (DDT) were 49.4% and 43.6% of the test substance.

The log K_{oc} values used to calculate the $PNEC_{soil}$ values are 4.39 and >5.63 (K_{oc} values of 24,547 to 426,580 L/kg, respectively).

D. Bioaccumulation

There are no bioaccumulation studies on fatty acids, tall oil, ethoxylated. Fatty acid, tall oil, ethoxylated contains constituents with log K_{ow} values in the range of 5 to >10 based on QSAR modeling using KOWWIN v1.68 (ECHA), suggesting a potential for bioaccumulation. Bioaccumulation is not expected because the constituents of fatty acids, tall oil, ethoxylated are rapidly biodegraded, metabolized enzymatically, and are sterically hindered from crossing biological membrane (at least for the diester constituents). QSAR modeling using BCFBAF (v. 3.01, Arnot-Gobas, including biotransformation, upper trophic) estimated low BCF values of <100 L/kg for different constituents and including mono- and diester EO1 to EO5 (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The acute toxicity of fatty acids, tall oil, ethoxylated is low by the oral and inhalation routes. It is not an irritant to the skin and eyes; but it is a skin sensitizer. In a combined repeated dose toxicity study with a reproductive/developmental screening toxicity (OECD 422) test, there was no evidence of systemic, reproductive or developmental toxicity in rats at doses up to 1,000 mg/kg-day of fatty acids, tall oil, ethoxylated. In vitro genotoxicity studies on this substance were negative.

B. Acute Toxicity

The oral LD_{50} in rats is >10,000 mg/kg (ECHA) [Kl. score = 2].

The inhalation 8-hour LC_{50} in rats was greater than the saturated vapor concentration at 20°C (approximately 0.28 mg/L) (ECHA) [Kl. score = 2].

There are no acute dermal toxicity studies on fatty acids, tall oil, ethoxylated.

C. Irritation

Fatty acids, tall oil, ethoxylated was not considered an irritant in an in vitro reconstructed human epidermis test (ECHA) [Kl. score = 1].

Fatty acids, tall oil, ethoxylated was not considered an irritant in an in vitro reconstructed human cornea-like epithelium test (ECHA) [Kl. score = 1].

D. Sensitization

Fatty acids, tall oil, ethoxylated was not considered to be a skin sensitizer in a mouse local lymph node assay (ECHA) [Kl. score = 1].

In a guinea pig Buehler test, fatty acids, tall oil, induced a skin sensitizing response (ECHA) [Kl. score = 1].

E. Repeated Dose Toxicity

Oral

Fatty acids, tall oil, ethoxylated was tested in a combined repeated dose toxicity study with a reproductive/developmental screening toxicity (OECD 422) test. Male and female Wistar rats were dosed daily by oral gavage with 0, 100, 300, or 1,000 mg/kg fatty acids, tall oil, ethoxylated for at least 28 days, including 14 days of pre-mating. There was no indication of toxicity at any dose level. The NOAEL for systemic toxicity is 1,000 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 1].

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

The in vitro studies on fatty acids, tall oil, ethoxylated are presented below in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Fatty Acids, Tall Oil, Ethoxylated

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	1	ECHA
Mammalian cell gene mutation (Chinese hamster fibroblast cells)	-	-	1	ECHA
Chromosomal aberration (human lymphocytes)	-	-	1	ECHA

*+, positive; -, negative

In Vivo Studies

No studies are available.

G. Carcinogenicity

No studies are available.

H. Reproductive/Developmental Toxicity

Fatty acids, tall oil, ethoxylated was tested in a combined repeated dose toxicity study with a reproductive/developmental screening toxicity (OECD 422) test. Male and female Wistar rats were dosed daily by oral gavage with 0, 100, 300, or 1,000 mg/kg fatty acids, tall oil, ethoxylated for at least 28 days, including 14 days of pre-mating. There was no indication of parental toxicity, reproductive, or developmental toxicity at any dose level. The NOAEL for reproductive and developmental toxicity is 1,000 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 1].

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for fatty acids, tall oil, ethoxylated follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The NOAEL for systemic, reproductive, and developmental toxicity from an OECD 422 study on fatty acids, tall oil, ethoxylated is 1,000 mg/kg-day, the highest dose tested (ECHA). The NOAEL of 1,000 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 1,000/(10 x 10 x 1 x 10 x 1) = 1,000/1,000 = 1.0 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (1 x 70 x 0.1)/2 = 3.5 mg/L

B. Cancer

There are no carcinogenicity studies on fatty acids, tall oil, ethoxylated. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Fatty acids, tall oil, ethoxylated does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Fatty acids, tall oil, ethoxylated has a moderate concern for acute toxicity to aquatic life.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on fatty acids, tall oil, ethoxylated.

Table 3: Acute Aquatic Toxicity Studies on Fatty Acids, Tall Oil, Ethoxylated

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Brachydanio rerio	96-hr LL_{50}	>100 [WAF]	1	ECHA
Daphnia magna	48-hr EL_{50}	12.41 [WAF]	1	ECHA
Pseudokirchneriella subcapitata	72-hr EL_{50} 72-hr EL_{10}	39.7 [WAF] 7.08 [WAF]	1	ECHA

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for fatty acids, tall oil, ethoxylated follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)L_{50}$ values are available for fish (>100 mg/L WAF), invertebrates (12.41 mg/L WAF), and algae (39.7 mg/L). On the basis that the data consists of short-term studies for three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)L_{50}$ value of 12.41 mg/L [WAF] for *Daphnia*. The $PNEC_{water}$ is 0.12 mg/L.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ values range from 39 to >683 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (491/1500) \times 1000 \times 0.12$
$= 39$

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (8532/1500) \times 1000 \times 0.12$
$= 683$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 24{,}547 \times 0.02$
$= 491$

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 426{,}580 \times 0.02$
$= 8{,}532$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for fatty acids, tall oil, ethoxylated were experimentally determined to range from 24,547 to >426,580 (see Section IIIC).
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Fatty acids, tall oil, ethoxylated is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Based on predicted BCF values of <100 L/kg for constituents, fatty acids, tall oil, ethoxylated does not meet the criteria for bioaccumulation.

There are no chronic aquatic toxicity data on fatty acids, tall oil, ethoxylated. The acute $E(L)L_{50}$ values are >1 mg/L. Thus, fatty acids, tall oil, ethoxylated does not meet the screening criteria for toxicity.

The overall conclusion is that fatty acids, tall oil, ethoxylated is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Skin Sensitizer Category 1
Aquatic Acute Toxicity Category 3

B. Labelling

Warning

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Rinse immediately with plenty of running water. If easy to do, remove contact lenses. Get medical attention if symptoms occur.

Skin Contact
Wash with soap and water. Get medical attention if symptoms persist.

Inhalation
Treat symptomatically. Move to fresh air. Get medical attention if symptoms occur.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. Seek medical attention if symptoms occur.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, dry chemical, foam. Do not use water jet.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon oxides.

Special Protective Equipment for Firefighters

Self-contained breathing apparatus and full protective clothing must be worn in case of fire.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Wear appropriate personal protective equipment. Do not breath mist or aerosol.

Environmental Precautions
Prevent from entering sewers, waterways, or low area

Steps to be Taken if Material is Released or Spilled
Absorb spill with inert absorbent material, then place in a container for chemical waste.

D. STORAGE AND HANDLING

General Handling
Provide adequate ventilation. Wear appropriate personal protective equipment. Observe good hygiene practices.

Other Handling Precautions
Wash hands thoroughly after handling. Avoid breathing mists or aerosols.

Storage
Keep container closed.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure standard for fatty acids, tall oil, ethoxylated.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Wear respiratory protection if ventilation is inadequate.

Hand Protection:
Chemical resistant protective gloves.

Skin Protection:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*

Chemical safety goggles.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Fatty acids, tall oil, ethoxylated is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

GLUTARALDEHYDE

This dossier on glutaraldehyde does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of glutaraldehyde in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from NICNAS (1994) and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): Glutaraldehyde

CAS RN: 111-30-8

Molecular formula: $C_7H_8O_2$

Molecular weight: 100.12

Synonyms: Pentanedial; glutaral; glutaric dialdehyde; 1,3-diformylpropane; 1,5-pentanedial; glutaric aldehyde; glutaric acid dialdehyde; dioxopentane; glutardialdehyde; 1,5-pentanedione; Algicide®C

SMILES: C(CC=O)CC=O

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Physico-Chemical Properties of Glutaraldehyde

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa*	Sweetish smelling, clear water liquid	1	ECHA
Melting Point*	-33°C	1	ECHA
Boiling Point*	101.5°C @ 987.1 hPa	1	ECHA
Density*	1.13 kg/m^3	1	ECHA
Vapour Pressure*	30 hPa @ 26.3°C	1	ECHA
Partition Coefficient (log K_{ow})*	-0.36	1	ECHA
Water Solubility*	miscible	2	ECHA
Flash Point*	Not measurable	1	ECHA
Auto flammability*	395°C @ ~1,000hPa	1	ECHA
Viscosity*	12.75 mm^2/s (static) at 25°C	1	ECHA
Henry's Law Constant	0.011 Pa m^3/mol at 25°C [QSAR]	2	ECHA

*ca. 50% glutaraldehyde solution (in water)
1 ppm = 4.095 mg/m^3
1 mg/m^3 = 0.244 ppm

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Glutaraldehyde is considered readily biodegradable. It is also expected to have a low potential for bioaccumulation. The K_{oc} values for glutaraldehyde indicate that it will have low potential for adsorption to suspended solids and sediment in water and moderate adsorption to soil. Glutaraldehyde

is not expected to undergo hydrolysis in the environment. Overall, glutaraldehyde shows limited persistence in the environment.

B. Abiotic Degradation

Hydrolysis

In an OECD TG 111 test (hydrolysis as a function of pH), glutaraldehyde was hydrolytically stable at pH 4 and pH 7, but decomposed at pH 9 (ECHA). [Kl. score = 2]

Phototransformation in Water

Photolytic degradation of glutaraldehyde occurred in water under sensitised conditions: the half-life was 18 days when equivalent to 36 days of natural sunlight (12 hours/day; sensitised acetone system); and 49 days when equivalent to 34 days of natural sunlight (12 hours/day; sensitised acetonitrile system). There was no photodegradation of glutaraldehyde under darkness or non-sensitised conditions (ECHA). [Kl. score = 2]

C. Biodegradation

Glutaraldehyde was considered readily biodegradable in an OECD 301A (DOC die away test). Degradation was 90-100% in 28 days (ECHA). [Kl. score = 1]

In a simulation test involving aerobic sewage treatment [activated sludge units] (OECD TG 303A), glutaraldehyde degraded 97% after 73 days based on DOC removal (ECHA). [Kl. score = 1]

In an aerobic aquatic metabolism test, [^{14}C]-glutaraldehyde had a half-life of 10.6 hours in the water/sediment system. A minor transformation product was glutaric acid: the maximum yield was 18.9 to 21.5% at 12 hours, which then declined rapidly to 10.1 to 11% by 24 hours; and was not observed at the end of the study period in the aqueous phase (ECHA). [Kl. score = 1]

In an anaerobic aquatic metabolism test, [^{14}C]-glutaraldehyde was rapidly metabolised with the first-order half-life being 7.7 hours. Glutaraldehyde was transformed to 5-hydroxypentanal (ca 37% of applied radioactivity) on day 1; after that, it declined to <10%; it was not detected at all after 30 days. The second stable transformation product was 1,5-pentanediol (35% of radioactivity on Day 1), which accounted for 70% of the radioactivity at the end of the test. A minor transformation product was a compound formed via Aldol condensation, cyclisation and dehydration. This compound accounted for about 10-20% of total radioactivity from day 1 onwards (ECHA). [Kl. score = 1]

In an aerobic soil metabolism test, the half-life of the degradation of [^{14}C]-glutaraldehyde was calculated to be 1.7 days, indicating rapid degradation in soil by microbial biotransformation. Degradation products were measured but not identified. (ECHA). [Kl. score = 1]

D. Environmental Distribution

Adsorption/desorption

The organic carbon/water partition coefficients (K_{oc}) values were determined for sediment and four types of soil. The values are as follows: 120 for sediment; 210 for sandy loam; 500 for silty clay loam; 340 for silt loam; and 460 for loamy sand (ECHA; Leung et al., 2001). [Kl. score = 1]

Distribution Modelling

No fugacity calculations were performed as glutaraldehyde has limited persistence. Its environmental fate is primarily determined by degradation rather than equilibration between compartments (OECD-SIDS, 1995).

E. Bioaccumulation

Glutaraldehyde is not expected to bioaccumulate. The measured log K_{ow} at pH 5, 7 and 9 are -0.41, -0.36 and -0.80, respectively (ECHA).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Glutaraldehyde has moderate-to-high acute toxicity by the oral route, low-to-moderate toxicity by the dermal route, and moderate-to-high toxicity by the inhalation route. Acute inhalation exposure may cause respiratory irritation. Glutaraldehyde is corrosive to the skin and eyes; it is also a skin and respiratory sensitizer. Repeated oral exposures via drinking water to rats have resulted in general systemic toxicity, but no target organ effects. In contrast, the upper respiratory tract, particularly the nasal cavity, is the target organ in rodents from repeated inhalation exposure. Glutaraldehyde may exhibit weak genotoxic effects in some *in vitro* tests, whereas the *in vivo* studies consistently show no genotoxic activity. Glutaraldehyde is not a reproductive toxicant; developmental toxicity can occur at maternally toxic doses, but there is no teratogenicity.

B. Toxicokinetics

Dermal Absorption

[1,5-^{14}C]-glutaraldehyde was applied to the skin of male and female F344 rats. Doses were 0.75% and 7.5%: this corresponds to approximately 6.5 and 63 mg/kg for males; and approximately 8.7 and 102 mg/kg for females. The dermal absorption data are presented below in Table 2. The results indicate that glutaraldehyde has a low rate of absorption by the dermal route (ECHA).

Table 2: Dermal Absorption Data in Rats on Glutaraldehyde (ECHA)

Sex	Absorption rate constant/hr		% of applied dose	
	Low Dose	High Dose	Low Dose	High Dose
Males	1.5	0.7	0.7	1.3
Females	1.8	0.9	0.3	2.1

An *in vitro* percutaneous absorption study was conducted on glutaraldehyde using excised skin from rats, rabbits, mice, guinea pigs, and humans. The skin samples were placed in a flow-through skin penetration chamber, and [^{14}C]-glutaraldehyde was added at doses of 0.75% and 7.5%. The results are presented below in Table 3. Glutaraldehyde did not penetrate any of the skin samples to a significant degree, suggesting that only minimal amounts of glutaraldehyde may be available for systemic uptake and distribution after skin exposure. The results also show that skin absorption was greater for the animal species used in toxicity tests than human skin (ECHA; Frantz et al., 1993).

Table 3: *In vitro* Percutaneous Absorption (mg/cm^2) of Glutaraldehyde (ECHA; Frantz et al., 1993)

Species	Low Dose	High Dose
Animal*	0.006	0.08

Human	0.002	0.02

*Percutaneous absorption in rats, mice, guinea pigs, mice and rabbits were similar to each and were reported as a single value.

C. Acute Toxicity

The oral LD_{50} values are: 123 to 820 mg/kg in rats; 100 to 352 mg/kg in mice; and 50 mg/kg in guinea pigs (NICNAS, 1994).

The dermal LD_{50} values are: 640 to 2,000 mg/kg in rabbits; >2,500 mg/kg in rats; and >4,500 mg/kg in mice (NICNAS, 1994).

The 4-hour inhalation LC_{50} values for glutaraldehyde are listed in the table below:

Table 4: Acute inhalation LC_{50} values for Glutaraldehyde

Test Material	LC_{50} (males) [mg/L]	LC_{50} (females) [mg/L]	LC_{50} (both sexes) [mg/L]	Reference
50% aq. aerosol	0.52	0.45	-	OECD, 1995
25% aq. aerosol	-	-	0.8	OECD, 1995
50% aq. aerosol	0.35	0.28	-	OECD, 1995
5% soln. vapour	0.096	0.164	-	OECD, 1995

During the exposure period, the animals showed signs of eye and respiratory irritation, as indicated by laboured and audible breathing, and wetness and encrustation around the nose and eyes.

D. Irritation

Glutaraldehyde is corrosive to the skin and eyes of rabbits (NICNAS, 1994; ECHA). Signs of irritation occurred at a concentration of 2% for skin and 0.2% for eyes (NICNAS, 1994). In the acute inhalation studies, rats exposed to aerosols or vapours of glutaraldehyde showed signs of eye and respiratory irritation (OECD, 1995).

E. Sensitisation

Glutaraldehyde is a skin sensitiser to guinea pigs and humans. Information on the individual studies can be found in NICNAS (1994) and in the ECHA REACH database (ECHA).

Asthmatic symptoms, such as wheezing, coughing, chest tightness, breathing difficulties and non-specific hyper-responsiveness have been reported to occur in humans occupationally exposed to glutaraldehyde (NICNAS, 1994). It is unclear whether the asthma is an allergic hypersensitivity response or a result of the aggravation of pre-existing asthma due to the irritating properties of glutaraldehyde. Nevertheless, glutaraldehyde should be considered a respiratory sensitiser, although one of low potency.

F. Repeated Dose Toxicity

Oral

Male and female Wistar rats were given in their drinking water 0, 100, 500, or 2,000 ppm glutaraldehyde for 90 days. The approximate daily intakes were 0, 3, 15, or 53 mg/kg-day for males, and 0, 4, 19, or 72 mg/kg-day for females. There were no signs of neurotoxicity at any dose level. There was slight impairment of food consumption in the 2,000 ppm animals, as well as slight

impairment of body weight and body weight gain. Impaired water consumption was seen in the 100 and 500 ppm females. The NOAEL for males is 500 ppm (15 mg/kg-day). The NOAEL for females is 100 ppm (4 mg/kg-day), since the impaired water consumption in the 100 ppm females was considered a palatability problem and not an adverse effect (ECHA). [Kl. score = 1]

Male and female F344 rats were given in their drinking water 0, 50, 250, or 1,000 ppm glutaraldehyde for 13 weeks. Additional groups of animals were given in their drinking water 0 or 1000 ppm glutaraldehyde for 13 weeks followed by a 4-week recovery period. The approximate daily intakes were 0, 5, 25, or 100 mg/kg-day for males; and 0, 7, 35, or 120 mg/kg-day for females. Water consumption was reduced in a dose-dependent manner in the ≥250 ppm males and 1,000 ppm females, which was attributed to an aversion to the taste and/or odour of glutaraldehyde in the water. There was also a reduction in food consumption in the 1,000 ppm animals with a parallel reduction in body weights. It is unclear whether the reduction in food consumption was related to the decreased water consumption. Urine volume was decreased with an increase in specific gravity, along with a slight increase in protein and ketone concentration, in the ≥250 ppm animals, which was probably related to the decreased water consumption. There were no treatment-related changes in the haematology parameters measured. Blood urea nitrogen was increased in a dose-related manner in the ≥250 ppm females at the 6-week time point, but at the 13-week or 17-week time points. Relative kidney weights were increased in a dose-related manner in the ≥250 ppm males and females, and increased absolute kidney weights in the females. Histopathological examination showed no treatment-related effects. The NOAEL is 50 ppm (5 and 7 mg/kg-day for males and females, respectively) based on dose-related increase in kidney weights at ≥250 ppm (ECHA). [Kl. score = 2]

Male and female Wistar rats were given in their drinking water 0, 100, 500, or 2000 ppm glutaraldehyde for 12 months. The approximate daily intakes were: 0, 6.4, 30.5, or 116.6 mg/kg-day for males; and 0. 9.6, 46, or 153 mg/kg-day for females. There was no treatment-related mortality. At 2,000 ppm, treatment-related effects included respiratory sounds (both sexes), decrease in body weight (males), decrease in body weight gain (both sexes), decrease in food consumption (both sexes), reduced water consumption (both sexes), lesions within the glandular stomach (both sexes showed erosion/ulceration of the glandular stomach), increased incidence of clear cell foci in the liver (males), and a single case of slight diffuse squamous metaplasia in the epithelium of the larynx (male). At 500 ppm, water consumption was reduced in males which was considered to be a palatability (bad taste) problem and not an adverse effect. No effects were seen in the 100 ppm animals. The NOAEL for this study is 500 ppm, which corresponds to 30.5 and 46 mg/kg-day for males and females, respectively (ECHA). [Kl. score = 1]

Male and female Fischer 344 rats were given in their drinking water 0, 50, 250, or 1000 ppm glutaraldehyde for 104 weeks. The mean glutaraldehyde consumption was 0, 4, 17, and 64 mg/kg-day for males and 0, 6, 25 ,and 86 mg/kg-day for females. There were no treatment-related mortalities or clinical symptoms of toxicity. In the 250 and 1,000 ppm groups, there was reduction in body weight and body weight gain; reduction in food and water consumption; increased statistically significant incidence of nucleated erythrocytes and of large monocytes; decreases in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and glutamate dehydrogenase; dose-related decrease in urine volume accompanied by a dose-related increase in osmolality; changes in absolute and relative kidney weight; gastric irritation; increases in bone marrow hyperplasia; and increased incidence of renal tubular pigmentation. The decreased water consumption was considered to be due to the bad taste, smell and/or irritancy of the test substance in the drinking water; thus, it is of no toxicological relevance. As a result of reduced water intake, there are renal physiological adaptation, such as decreased urine, increased osmolality and changes in kidney weight. The haematological and clinical chemistry parameter changes were marginal and were considered to be of not toxicological relevance. The main haematological finding seen at the end of the study and which consisted of the appearance of nucleated erythrocytes and large monocytes in all treated groups (statistically significant for the ≥250 ppm males) was related to the incidence of large granular lymphocytic leukaemia (LGLL) in the spleen. The bone marrow hyperplasia and renal tubular pigmentation are related to the

occurrence/incidence of LGLL, and were considered by the authors of the study as being secondary to a low grade haemolytic anaemia in animals with LGLL. The NOAEL for this study is 50 ppm which corresponds to 4 and 6 mg/kg-day for males and females, respectively (Van Miller *et al.* 2002). [Kl. score = 2]

Inhalation

Male and female F344 rats were exposed by inhalation to 0, 0.0625, 0.125, 0.25, 0.5, or 1.0 ppm (0, 0.26, 0.5, 1, 2, or 4.1 mg/m^3) glutaraldehyde for 6.5 hours/day, 5 days/week for 13 weeks. The study focused on the respiratory tract, using histopathology and epithelial cell labelling index as end points. Histopathological lesions in the nasal passages and turbinates were seen at ≥0.25 ppm. Treatment-related effects were primarily the respiratory mucosa (nasal cavity and tips of the turbinates) and the olfactory epithelium (dorsal meatus). Hyperplasia, squamous metaplasia, olfactory degeneration, squamous exfoliation (accumulation of keratin, cell debris and bacteria in the lumen of the nasal vestibule) and focal erosions were reported for both sexes, and the severity and incidence of the findings increased with increasing concentration of glutaraldehyde. The NOAEL for this study is 0.125 ppm (Gross et al., 1994). [Kl. score = 1]

Male and female B6C3F$_1$ mice were exposed by inhalation to 0, 0.0625, 0.125, 0.25, 0.5, or 1.0 ppm (0, 0.26, 0.5, 1, 2, or 4.1 mg/m^3) glutaraldehyde for 6.5 hours/day, 5 days/week for 13 weeks. The study focused on the respiratory tract, using histopathology and epithelial cell labelling index as end points. Histopathologic lesions in the nasal passages and turbinates were seen at all exposure concentrations (≥0.0625 ppm). Treatment-related lesions were primarily the respiratory mucosa (nasal cavity and tips of the turbinates) and the olfactory epithelium (dorsal meatus). Hyperplasia, squamous metaplasia, olfactory degeneration, squamous exfoliation (accumulation of keratin, cell debris and bacteria in the lumen of the nasal vestibule) and focal erosions were reported for both sexes, and the severity and incidence of the findings increased with increasing test concentration. Furthermore, neutrophilic inflammation was seen at ≥0.062 ppm, and squamous metaplasia as well as necrosis were seen in the larynx at 1 ppm). The LOAEL for this study is 0.0625 ppm; a NOAEL was not established (Gross et al., 1994). [Kl. score = 1]

Male and female B6C3F$_1$ mice were exposed by inhalation to 0 or 0.1 ppm (0 or 0.41 mg/m^3) glutaraldehyde for 6 hours/day, 5 days/week for 52 and 78 weeks. Survival was similar between treated and control groups. Hyperplasia of the squamous epithelium lining of the dorsal wall of the nasal passages and the lateral aspect of the atrioturbinate was seen in a greater number of exposed females than in controls. Epidermal erosion and ulceration as well as squamous and inflammatory exfoliation were also seen in the nasal lumens. All of these changes were dependent on the length of glutaraldehyde exposure. The authors concluded that, since the induced lesions occurred in the more anterior part of the nasal passages, that they were likely the result of an irritation mechanism (Zissu et al., 1998). [Kl. score = 2]

Male and female Fischer 344 rats were exposed by inhalation to 0, 0.25, 0.5, or 0.75 ppm (0, 1, 2, or 3.1 mg/m^3) glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival in the mid- and high-dose females was statistically significantly decreased compared to controls. Mean body weights of all exposed males and the mid- and high-dose females were generally less than those of the controls. Non-neoplastic lesions were limited primarily to the most anterior region of the nasal cavity. Effects included hyperplasia and inflammation of the squamous epithelium; hyperplasia, goblet cell hyperplasia, inflammation, and squamous metaplasia of the respiratory epithelium; and hyaline degeneration of the olfactory epithelium. The LOAEL for this study is 0.25 ppm based on hyperplasia and inflammation of the squamous epithelium of the nose in both sexes. A NOAEL was not established (van Birgelen et al., 2000). [Kl. score = 2]

Male and female B6C3F$_1$ mice were exposed by inhalation to 0, 0.0625, 0.125, or 0.25 ppm (0, 0.26, 0.5, or 1 mg/m^3) glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival of the treated

animals was similar to controls. Mean body weights of the high-dose females were generally lower than the controls. Non-neoplastic lesions were limited primarily to the anterior region of the nasal cavity; the effects were qualitatively similar to those seen in the rats (see accompanying summary on the two-year rat study by van Birgelen et al., 2000). Squamous metaplasia of the respiratory epithelium was observed in both sexes of mice while female mice also had inflammation and hyaline degeneration of the respiratory epithelium. The incidence and severity grade (in parentheses) of the hyaline degeneration were: 16/50 (1.4), 35/49 (1.4), 32/50 (1.3), and 30/50 (1.1) for the 0, 0.0625, 0.125, and 0.25 ppm dose groups, respectively. The LOAEL for this study is 0.0625 ppm based on hyaline degeneration of the respiratory epithelium in female mice. A NOAEL was not established (van Birgelen et al., 2000). [Kl. score = 2]

Dermal

Applications of a 50% solution of glutaraldehyde was applied to the skin of male and female SD rats for 13 weeks. The doses were 0, 50, 100, and 150 mg/kg glutaraldehyde. At the application site, there were signs of irritation (scabs, desquamation and very slight or well-defined erythema). There was no treatment-related mortality, clinical signs, body weights, feed consumption, and ophthalmoscopic effects. There were no changes in the haematology and clinical chemistry parameters that were considered to be biologically or toxicologically relevant. Organ weights were similar between treated and control animals. Histopathological examination showed a treatment-related effects in the skin associated with chronic irritation; no other changes were noted that were considered to be treatment-related. The NOAEL for this study is 150 mg/kg, the highest dose tested (ECHA). [Kl. score = 1]

G. Genotoxicity

In Vitro Studies

Glutaraldehyde may exhibit weak genotoxic effects in some *in vitro* tests. The bacterial reverse mutation assays have been the most consistent. Variable results have been reported for the forward gene mutation tests; and for sister chromatid exchange (SCE), chromosomal aberration and Unscheduled DNA Synthesis (UDS) tests (Vergnes and Ballantyne, 2002).

In Vivo Studies

The *in vivo* studies conducted on glutaraldehyde are presented below in Table 5. All of the studies show that glutaraldehyde is not mutagenic or genotoxic.

Table 5: *In Vivo* Genotoxicity Studies on Glutaraldehyde

Test System	Results*	Klimisch Score	Reference
Rat bone marrow (chromosomal aberration)	-	1	ECHA
Rat bone marrow (chromosomal aberration)	-	2	ECHA

H. Carcinogenicity

Oral

Male and female Fischer 344 rats were given in their drinking water 0, 50, 250, or 1,000 ppm glutaraldehyde for 104 weeks. The mean glutaraldehyde consumption was 0, 4, 17, and 64 mg/kg-day for males and 0, 6, 25, and 86 mg/kg-day for females. Mortality rates were 25-30% and 19-23% for males and females, respectively, with no dose-related increase. The major cause of death in all dose groups including the controls was LGLL. There was an increased incidence of LGLL in the liver and spleen in all treated females (≥50 ppm). The incidence of LGLL was not significantly increased in the treated males compared to the controls. No other treatment-related increased incidence of tumours was seen (Van Miller et al., 2002). [Kl. score = 2]

Male and female Wistar rats were given in their drinking water 0, 100, 500, or 2,000 ppm glutaraldehyde for two years. The mean daily intake of glutaraldehyde was as follows: 0, 6.1, 31.9, and 120.7 mg/kg-day for males; and 0, 10.5, 48.5, and 176.4 mg/kg-day for females. In the high-dose animals, there was mortality (2 males and 9 females) from asphyxia, and mean terminal body weights were significantly decreased compared to the controls. There were no treatment-related neoplastic effects (ECHA). [Kl. score = 1]

Inhalation

Male and female $B6C3F_1$ mice were exposed by inhalation to 0 or 0.1 ppm (0 or 0.4 mg/m^3) glutaraldehyde for 6 hours/day, 5 days/week for 52 and 78 weeks. No exposure-related neoplastic lesions were observed in either males or females (Zissu et al., 1998). [Kl. score = 2]

Male and female Fischer 344 rats were exposed by inhalation to 0, 0.25, 0.5, or 0.75 ppm (0, 1, 2, or 3.1 mg/m^3) glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival in the mid- and high-dose females was statistically significantly decreased compared to controls. Survival of the treated males was similar to controls. No exposure-related neoplastic lesions were observed in either males or females (van Birgelen et al., 2000). [Kl. score = 2]

Male and female $B6C3F_1$ mice were exposed by inhalation to 0, 0.0625, 0.125, or 0.25 ppm (0, 0.26, 0.5, or 1 mg/m^3) glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival of the treated animals was similar to controls. No exposure-related neoplastic lesions were observed in either males or females (van Birgelen et al., 2000). [Kl. score = 2]

I. Reproductive Toxicity

A two-generation reproductive toxicity study was conducted in Wistar rats given 0, 100, 500 and 2000 ppm glutaraldehyde in their drinking water. The approximately mean daily intake is 0, 12, 58, and 199 mg/kg-day for the parental males and females of the F_0 and F_1 generation during premating. There were no adverse effects on reproductive performance or fertility. Oestrous cycle data, mating behaviour, conception, gestation, parturition, lactation and weaning as well as sperm parameters, sexual organ weights, gross and histopathological findings of these organs were similar between treated and control groups. In the high-dose animals, there was decreased water and/or food consumption; and decreased body weights and/or reduced body weight gains during the premating periods in the F_0 and F_1 parental females during premating, gestation and/or lactation. The high-dose F_1 parental females also had increased the number of erosions/ulcers with microscopic erosion(s) or inflammatory oedema in the mucosa/submucosa of the glandular stomach. There were no adverse effects in the 500 ppm animals except for slight decreases in water consumption due to a palatability

(bad taste) problem. Treatment-related signs of developmental toxicity were seen in the progeny of the high-dose F_0 and F_1 parental generation, and included impairment in body weight and consequently in organ weights in the respective F_1 and F_2 pups. The NOAEL for reproductive toxicity is 2,000 ppm (199 mg/kg-day), the highest dose tested. The NOAEL for parental systemic toxicity is 500 ppm (58 mg/kg-day). The NOAEL for developmental toxicity is 500 ppm or 58 mg/kg-day (ECHA). [Kl. score = 1]

A two-generation reproductive toxicity study was conducted in Crj: CD(SD) rats given 0, 50, 250 and 1,000 ppm glutaraldehyde in their drinking water. Mean daily intake was not calculated. Parental body weights and body weight gains were significantly reduced at 1,000 ppm at some periods, particularly during pre-mating. Food consumption was significantly reduced at 1,000 ppm for the F_0 and F_1 parental animals during pre-mating and gestation, and F_1 females during lactation. Water consumption was reduced throughout the pre-mating period for the F_0 and F_1 250 and 1,000 ppm parental animals. There was no indication of adverse effects on reproductive performance or fertility at any dose level. For the F_1 1,000 ppm offspring, body weights were reduced from lactation days 21-28. The NOAEL for reproductive toxicity is 1,000 ppm, the highest dose tested. The NOAEL for parental systemic toxicity is 50 ppm. The NOAEL for developmental toxicity is 250 ppm (Neeper-Bradley and Ballantyne, 2000). [Kl. score = 2]

J. Developmental Toxicity

Pregnant Wistar rats were given in their drinking water 0, 50, 250, or 750 ppm (0, 5, 26, or 68 mg/kg) glutaraldehyde from GD 6 to 16. Water consumption was reduced in a dose-related manner in the $\geq$250 ppm dams, and was considered not to be a toxic response, but due to the palatability (bad taste) of the drinking test solution. No other maternal effects were seen in the study. There were no significant differences between treated and controls in the sex distribution, placental weights, fetal weights, malformations or variations. The NOAEL for maternal and developmental toxicity in this study is 68 mg/kg-day, respectively (ECHA). [Kl. score = 1]

Pregnant Wistar rats were dosed by oral gavage with 0, 25, 50, or 100 mg/kg glutaraldehyde on GD 6 to 15. Mortality was significantly increased in the high-dose group (5/26); there were 2/21 deaths in the mid-dose group. Clinical signs (piloerection) occurred in all treated groups in a dose-dependent manner. Maternal body weight gain and feed consumption were significantly reduced in the high-dose dams, but not at the lower doses. The necropsy findings showed evidence of stomach irritation in almost all of the animals that died during the study and in 12/21 of the surviving dams in the high-dose group. The number of implantation per litter, resorptions and dead foetuses per litter, live foetuses per litter, and incidence of post-implantation loss per litter was similar across all groups. The mean foetal body weights for male and female foetuses were significantly reduced in the high-dose group; this was attributed to the reduced food consumption of the dams during gestation rather than a direct effect of treatment. There was no evidence of a treatment-related teratogenic effect. The NOAEL for maternal and developmental toxicity is 50 mg/kg-day, respectively (Ema et al., 1992). [Kl. score = 2]

Pregnant Himalayan rabbits were dosed by oral gavage with 0, 5, 15 or 45 mg/kg glutaraldehyde on GD 7 to 19. In the high-dose group, 5/15 died on GD 9-11. Food consumption and body weight gain were also significantly reduced in the high-dose group. Clinical observations in 12/15 high-dose does included soft faces, diarrhoea, and blood in the bedding. The mean gravid uterus weight was significantly reduced in the high-dose group. Post-implantation loss was greatly increased (94.3%) in the high-dose group: no viable foetuses in 9/15 of the high-dose does, only early resorptions; only one female gave 4 alive foetuses on the scheduled date. There were reduced placental and foetal body weights in the only four foetuses. No significant maternal or developmental effects were seen in the mid- and low-dose groups. The NOAEL for maternal and developmental toxicity in this study is 15 mg/kg-day (ECHA). [Kl. Score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for glutaraldehyde follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The lowest NOAEL values from key toxicity studies on glutaraldehyde are listed below in Table 6.

Table 6: Lowest NOAEL Values from Key Toxicity Studies on Glutaraldehyde by the Oral Route

Species/Sex	Study Duration	mg/kg-day	Endpoint	Reference
Rats, female	90-days	4	Decreased body weights, food and water consumption	ECHA
Rats, male	13-wk (drinking water)	5	Increased kidney weights	ECHA
Rats, male	12-months (drinking water)	30.5	Clinical signs; decreased body weights and food consumption; increased clear cell foci in liver	ECHA
Rats, male	2-yr (drinking water)	4	Reduced body weight, body-weight gain, and food consumption	Van Miller *et al.* (2002)
Rats	2-generation (drinking water)	58	Systemic toxicity	ECHA
Rats	GD 6-16 (drinking water)	68	Developmental toxicity	ECHA
Rats	GD 6-15 (oral gavage)	50	Developmental toxicity	Ema *et al.* (1992)
Rabbits	GD 7-19 (oral gavage)	15	Developmental toxicity	ECHA

The lowest NOAEL from these studies is 4 mg/kg-day based on reduced body weights, body weight gain, and feed consumption in male rats from the two-year drinking water study (Van Miller et al., 2002). The NOAEL of 4 mg/kg-day will be used for determining the oral Reference Dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1

UF_D (database uncertainty) = 1

Oral RfD = 4/(10 x 10 x 1 x 1 x 1) = 4/100 = 0.04 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD: Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

Where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2 L (ADWG, 2011)

Drinking water guidance value = (0.04 x 70 x 0.1)/2 = 0.14 mg/L

B. Cancer

Increased incidence of large granular cell lymphatic leukaemia (LGLL) was observed in all groups of male and female Fischer 344 rats given glutaraldehyde in their drinking water, including the controls (Van Miller *et al.* 2002). For the males, the incidence of LGLL was not statistically significantly increased. However, for the females, the incidence of LGLL was significantly increased in all treated females (≥50 ppm). Inhalation exposure of Fischer 344 rats to glutaraldehyde did not result in an increased incidence of tumours, including LGLL.

LGLL, also known as mononuclear cell leukaemia, is an extremely common spontaneous neoplastic disease of the ageing F344 rat (Stromberg 1985, Ward *et al.* 1990; Thomas et al. 2007). Consistent features are splenomegaly, anaemia, thrombocytopenia and leukemic infiltration of the spleen, liver lung, and in an advanced stage, of several other organs. The incidence is variable but has been increasing progressively with time and can exceed 70% in controls in some studies. This compares with background incidence of less than 1% in other strains of commonly used laboratory rats (Haseman et al., 1998; Thomas et al., 2007). The incidence in F344 rats is modulated by a variety of factors not clearly related to carcinogenicity. Corn oil gavage, for example, has been shown consistently to reduce the incidence of MCL in male, but not female, controls (reviewed in Thomas et al., 2007).

The neoplastic mononuclear cells appear to be derived from large granular lymphocytes (LULs) (reviewed in Thomas et al., 2007). The tumour cell is of the NK type in most, if not all, cases. LGL leukaemia, although uncommon, does occur in humans. There are two types: T-LGL leukaemia which has a chronic course characterised by neutropenia, recurrent infections, splenomegaly and accompanying rheumatoid arthritis, and the much rarer NK-LGL leukaemia which has an acute course, more pronounced splenomegaly, and thrombocytopenia. The latter type appears to resemble more closely the disease in the F344 rat than the former. The aetiology of human LGL leukaemia is unknown. There is some evidence that viral infection may play a role but no evidence that a chemically-related increased of LGLL in the F344 rat is indicative of the potential to induce LGL leukaemia in humans.

To extrapolate results from an animal model that has a clear predisposition (high spontaneous rates) to a tumour type to humans, of which this is not the case, seems inappropriate if the mechanism(s) for LGLL formation in that strain is not understood. Although that rat strain may be useful for understanding the disease process in humans, it does not seem reasonable to use the results from that

rat strain for risk assessment purposes. There should be confirmation of a putative leukemogenic effect in the F344 rat in another strain before any conclusions are made about the use of this tumour type for human health risk assessment purposes.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Glutaraldehyde does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidising potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Glutaraldehyde has a moderate acute toxicity concern to fish and invertebrates, but is highly toxic to algae. It is of low toxicity concern to terrestrial invertebrates and plants. To birds, glutaraldehyde is moderately toxic on an acute basis and slightly toxic on a subacute dietary basis.

B. Aquatic Toxicity

Acute Studies

Table 7 lists the results of acute aquatic toxicity studies conducted on glutaraldehyde.

Table 7: Acute Aquatic Toxicity Studies on Glutaraldehyde

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Bluegill sunfish	96-hr LC_{50}	13	2	ECHA
Oncorhynchus mykiss	96-hr LC_{50}	10	2	ECHA
Daphnia magna	48-hr LC_{50}	14.87	2	ECHA
Daphnia magna	48-hr LC_{50}	14	2	ECHA
Scenedesmus subspicatus	72-hr EC_{50}	0.375 (biomass) 0.6 (growth rate) 0.025 (NOEC)	1	ECHA
Scenedesmus subspicatus	72-hr EC_{50}	0.92 (growth rate) 0.61(biomass) 0.33 (NOEC)	2	ECHA; Leung et al., 2001
Scenedesmus subspicatus	72-hr EC_{50}	0.61 (growth rate)	2	ECHA

Chronic Studies

The chronic aquatic toxicity studies conducted on glutaraldehyde are listed in Table 8.

Table 8: Chronic Aquatic Toxicity Studies on Glutaraldehyde

Test Species	Endpoint	Results (mg/L)	Kl. score	Reference
Oncorhynchus mykiss	97-day (OECD 210)	LOEC = 5 NOEC = 1.6	1	ECHA
Daphnia magna	21-day	NOEC = 5	1	ECHA

C. Terrestrial Toxicity

Table 9 lists the results of toxicity studies conducted on glutaraldehyde with earthworms, soil microorganisms, and birds.

Table 9: Terrestrial Toxicity Studies on Glutaraldehyde

Test Species (method)	Endpoint	Results	Kl. score	Reference
Earthworm *Eisenia fetida* (OECD 207)	14-d LC_{50}	>500 mg/kg soil dw	1	ECHA
Soil microorganisms* (OECD 216)	28-d EC_{50} 28-d EC_{10}	360 mg/kg soil dw 11.5 mg/kg soil dw	1	ECHA
Soil microorganisms* (OECD 217)	28-d EC_{50} 28-d EC_{10}	>593 mg/kg soil dw 1.5 mg/kg soil dw	1	ECHA
Mallard ducks	Single-dose (oral gavage) LC_{50}	206 mg/kg	2	ECHA
Mallard ducks	5-d (dietary) NOEC	>2,500 ppm	1	ECHA

*organic carbon content of soil = 1.34% dry weight

Glutaraldehyde has also been evaluated in a terrestrial plants test: seedling emergence and seedling growth test (OECD TG 208). The test material contained 48.9% glutaraldehyde. The results are as follows:

Avena sativa (oats): 19-day EC_{50} value is >1,000 mg/kg soil dry weight based on emergence rate, dry weight and shoot length. The NOECs for *Avena sativa* (oats) were $\geq$1,000 mg/kg dry weight on all three parameters tested

Brassica napus (rapeseed): 19-day EC_{50} is >1,000 mg/kg soil dry weight based on emergence rate and shoot length and 994 mg/kg soil dry weight based on dry weight. The NOECs were $\geq$1,000, 500, and 250 mg/kg soil dry weight for emergence rate, dry matter, and shoot length, respectively.

Vicia sativa (vetch): 19-day EC_{50} is >1,000 mg/kg soil dry weight based on emergence rate and shoot length, and 901 mg/kg soil dry weight based on dry weight. The NOECs were $\geq$1,000, 125, and 125 mg/kg soil dry weight for emergence rate, dry matter, and shoot length, respectively (ECHA). [Kl. score = 1]

D. Calculation of PNEC

The PNEC calculations for glutaraldehyde follow the methodology discussed in DEWHA (2009).

PNECwater

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (10 mg/L), *Daphnia* (14 mg/L), and algae (0.375 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 0.025 mg/L for algae. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 0.025 mg/L for algae. The $PNEC_{water}$ is 0.0025 mg/L.

PNECsediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.006 mg/kg wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (3.1/1280) \times 1000 \times 0.0025$
$= 0.006$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{solid}]$
$= 0.8 + [(0.2 \times 4.8)/1000 \times 2400]$
$= 3.1$

Where:
Kpsed = solid-water partition coefficient (L/kg).
BDsolid = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{0c} \times f_{oc}$
$= 120 \times 0.04$
$= 4.8$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for glutaraldehyde in sediment is 120.
F_{oc} = fraction of organic carbon suspended sediment = 0.04 [default].

PNECsoil

Experimental results are available for three trophic level. An acute LC_{50} value is available for earthworms (>500 mg/kg). Results from long-term studies are available for two trophic levels, with the lowest NOEC or EC_{10} being 1.5 mg/kg soil dry weight for soil organisms.

The EC_{10} value is corrected for bioavailability of glutaraldehyde in soil by normalising the organic carbon content in the soil using the following equation:

$EC_{10(std)} = EC_{10(exp)} \times Fom_{soil(std)}/Fom_{soil(exp)}$

Where:
$Fom_{soil(std)}$ = 1% (www.scew.gov.au/node/941)
$Fom_{soil(exp)}$ = 1.34% (see Table 9)

$EC_{10(std)}$ = 1.5 mg/kg x 1/1.34 = 1.12 mg/kg

On the basis that the data consists of one short-term from one trophic level and two long-term results from two additional levels, an assessment factor of 50 has been applied to the lowest reported long-

term EC_{10} of 1.12 mg/kg soil dry weight [corrected for organic carbon content] for soil organisms. The $PNEC_{soil}$ is 0.02 mg/kg soil dry weight.

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Glutaraldehyde is readily biodegradable and thus does not meet the screening criteria for persistence.

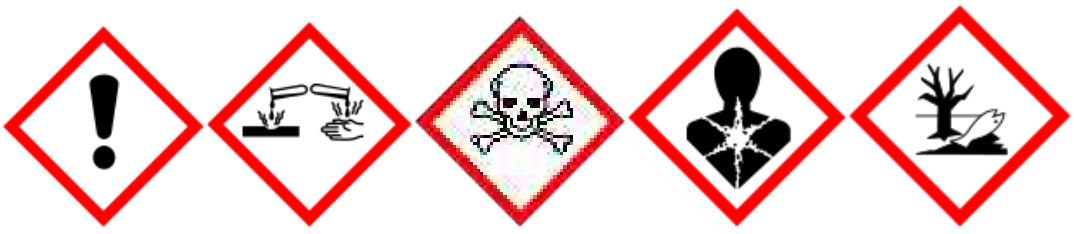
The log K_{ow} for glutaraldehyde at different pH values ranges from -0.36 to -0.80. Thus, glutaraldehyde does not meet the screening criteria for bioaccumulation.

The lowest NOEC value from chronic aquatic toxicity studies is <0.1 mg/L. Thus, glutaraldehyde meets the screening criteria for toxicity.

The overall conclusion is that glutaraldehyde is not a PBT substance.

IX. CLASSIFICATION AND LABELLING

A. Classification



Acute Toxicity Category 3 [oral]
Acute Toxicity Category 2 [inhalation]
Skin Corrosion Category 1B
Eye Damage Category 1
Respiratory Sensitiser 1A
Skin Sensitiser 1A
STOT Single Exposure Category 3 [respiratory irritation]
Aquatic Acute Category 1
Aquatic Chronic Category 2

The appropriate hazard statements corresponding the GHS classifications are to be added to the SDS, including the non-GHS hazard statement “AUH071: Corrosive to the Respiratory Tract”.

B. Labelling

Danger

C. Pictograms

X. SAFETY AND HANDLING

A. First Aid

First aid information was obtained from the ECHA REACH database (ECHA).

Eye Contact

Wash immediately and continuously with flowing water for at least 30 minutes. Remove contact lenses after the first 5 minutes and continue washing. Obtain prompt medical consultation, preferably from an ophthalmologist. Eye wash fountain should be located in immediate work area.

Skin Contact

Take off contaminated clothing. Wash skin with soap and plenty of water for 15-20 minutes. Call a poison control centre or doctor for treatment advice. Wash clothing before reuse. Shoes and other leather items which cannot be decontaminated should be disposed of properly. Safety shower should be located in immediate work area.

Inhalation

Move person to fresh air. If a person is not breathing, call an emergency responder or ambulance, then give artificial respiration; if by mouth to mouth use rescuer protection (pocket mask, etc.). Call a poison control centre or doctor for treatment advice. If breathing is difficult, oxygen should be administered by qualified personnel.

Ingestion

If the person is fully alert and cooperative, have the person rinse mouth with plenty of water. In cases of ingestion have the person drink 4 to 10 ounces (120-300 mL) of water. Do not induce vomiting. Do not attempt mouth rinse if the person has respiratory distress, altered mental status, or nausea and vomiting. Call a physician and/or transport to an emergency facility immediately. See Note to Physician. Seek medical attention immediately.

Notes to Physician

Maintain adequate ventilation and oxygenation of the patient. May cause asthma-like (reactive airways) symptoms. Bronchodilators, expectorants, antitussives and corticosteroids may be of help. Glutaraldehyde may transiently worsen reversible airways obstruction including asthma or reactive airways disease. Chemical eye burns may require extended irrigation. Obtain prompt consultation, preferably from an ophthalmologist. If the burn is present, treat as any thermal burn, after decontamination. Due to irritant properties, swallowing may result in burns/ulceration of mouth, stomach and lower gastrointestinal tract with subsequent stricture. Aspiration of vomitus may cause lung injury. Suggest endotracheal/oesophagal control if lavage is done. Probable mucosal damage may contraindicate the use of gastric lavage. Inhalation of vapours may result in skin sensitization. In sensitised individuals, re-exposure to very small amounts of vapour, mist, or liquid may cause a severe allergic skin reaction. No specific antidote. Treatment of exposure should be directed at the control of symptoms and the clinical condition of the patient. Have the Safety Data Sheet, and if available, the product container or label with you when calling a poison control centre or doctor, or going for treatment.

Medical Conditions Aggravated by Exposure

Excessive exposure may aggravate pre-existing asthma and other respiratory disorders (e.g. emphysema, bronchitis, reactive airways dysfunction syndrome).

Emergency Personnel Protection

First Aid responders should pay attention to self-protection and use the recommended protective clothing (chemical resistant gloves, splash protection). If the potential for exposure exists, refer to Section 8 of the Safety Data Sheet for specific personal protective equipment.

B. Fire Fighting Information

Firefighting information was obtained from the ECHA REACH database (ECHA).

Extinguishing Media

Use water fog, carbon dioxide, dry chemical or foam to extinguish combustible residues of this product

Specific Exposure Hazards

This material will not burn until the water has evaporated. Residue can burn. Some components of this product may decompose under fire conditions. The smoke may contain unidentified toxic and/or irritating compounds. Combustion products may include and are not limited to carbon monoxide and carbon dioxide.

Special Protective Equipment for Firefighters

Wear positive-pressure self-contained breathing apparatus (SCBA) and protective firefighting clothing (includes firefighting helmet, coat, trousers, boots, and gloves). Avoid contact with this material during firefighting operations. If contact is likely, change to full chemical resistant firefighting clothing with self-contained breathing apparatus. If this is not available, wear full chemical resistant clothing with self-contained breathing apparatus and fight the fire from a remote location.

C. Accidental Release Measures

Information on accidental release measures was obtained from the ECHA REACH database (ECHA).

Personal Precautions

Use appropriate safety equipment. Evacuate area. Keep upwind of the spill. Ventilate area of leak or spill. Only trained and properly protected personnel must be involved in clean-up operations.

Environmental Precautions

Spills or discharge to natural waterways is likely to kill aquatic organisms. Prevent from entering into soil, ditches, sewers, waterways and/or groundwater.

Steps to be Taken if Material is Released or Spilt

Avoid making contact with spilt material; glutaraldehyde will be absorbed by most shoes. Always wear the correct protective equipment, consisting of splash-proof mono-goggles, or both safety glasses with side shields and a wraparound full-face shield, appropriate gloves and protective clothing. A self-contained breathing apparatus or respirator and absorbents may be necessary, depending on the size of the spill and the adequacy of ventilation. Small spills: Wear the correct protective equipment and cover the liquid with absorbent material. Collect and seal the material and the dirt that has absorbed the spilt material in polyethylene bags and place in a drum for transit to an

approved disposal site. Rinse away the remaining spilt material with water to reduce odour, and discharge the rinsate into a municipal or industrial sewer. Large spills: In the case of nasal and respiratory irritation, vacate the room immediately. Personnel cleaning up should be trained and equipped with a self-contained breathing apparatus, or an officially approved or certified full-face respirator equipped with an organic vapour cartridge, gloves, and clothing impervious to glutaraldehyde, including rubber boots or shoe protection. Deactivate with sodium bisulphite (2-3 parts [by weight] per part of active substance glutaraldehyde), collect the neutralised liquid and place in a drum for transit to an approved disposal site.

D. Storage and Handling

Information on storage and handling was obtained from the ECHA REACH database (ECHA).

General Handling

Do not get in eyes, on skin, on clothing. Avoid breathing vapour. Do not swallow. Keep container closed. Use with adequate ventilation. Wear goggles, protective clothing and butyl or nitrile gloves. Wash thoroughly with soap and water after handling. Remove contaminated clothing and wash before reuse.

Other Handling Precautions

Do not spray or aerosolize the undiluted form of the product. Full personal protective equipment (including skin covering and full-face SCBA respirator) is required for dilutions or mixtures of the product used in a spray application.

Storage

Do not store in: Aluminium. Carbon steel. Copper. Mild steel. Iron. Shelf life: Use within 12 Months.

E. Exposure Controls / Personal Protection

Occupational Exposure Standards

The workplace exposure standard for glutaraldehyde in Australia is 0.1 ppm (0.41 mg/m^3) as a peak limitation, with a sensitisation notation. A peak limitation is defined by Safe Work Australia as a maximum or peak airborne concentration of a substance determined over the shortest analytically practicable period of time which does not exceed 15 minutes.

The information below on exposure controls and personal protection was obtained from the Halliburton Safety Data Sheet (SDS) on ALDACIDE® G ANTIMICROBIAL (revision date: 11-Dec-2014).

Engineering Controls

Use in a well-ventilated area. Local exhaust ventilation should be used in areas without good cross ventilation. If vapours are strong enough to be irritating to the nose or eyes, the TLV is probably being exceeded, and special ventilation or respiratory protection may be required.

Personal Protection Equipment

Respiratory Protection: If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear an NIOSH-certified, European Standard EN 149, AS/NZS 1715:2009, or equivalent respirator when using this product. Selection of and

instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional. Full Facepiece Respirator with Organic vapour cartridge with particulate pre-filter.

Hand Protection: Chemical-resistant protective gloves (EN 374) Suitable materials for longer, direct contact (recommended: protection index 6, corresponding to > 480-minute permeation time as per EN 374): Butyl rubber gloves. (>= 0.7 mm thickness) This information is based on literature references and on information provided by glove manufacturers or is derived by analogy with similar substances. Please note that in practice the working life of chemical-resistant protective gloves may be considerably shorter than the permeation time determined in accordance with EN 374 as a result of the many influencing factors (e.g. temperature). If signs of wear and tear are noticed, then the gloves should be replaced. Manufacturer's directions for use should be observed because of the great diversity of types.

Skin Protection: Butyl coated apron or clothing.

Eye protection: Splash proof chemical mono-goggles or safety glasses with side shield in conjunction with a face shield. Do NOT wear contact lenses.

Other Precautions: Eyewash fountains and safety showers must be easily accessible.

F. Transport Information

For aqueous glutaraldehyde solutions at a concentration that is corrosive (i.e., 30% and higher):

Australia Dangerous Goods

UN3265, Corrosive Liquid, Acidic, Organic, N.O.S. (Contains Glutaraldehyde)
Class 8
Packing Group III

Environmentally Hazardous Substance

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

GUAR GUM

This dossier on guar gum does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of guar gum in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Guar Gum

CAS RN: 9000-30-0

Molecular weight: 200,000 to 300,000 daltons (Glickman, 1969)

Guar gum (CAS No. 9000-30-0) is a resinous material derived from milled endosperm from guar beans of the legume *Cyamopsis tetragonolobus*. Structurally, it is a galactomannan (high molecular weight carbohydrate polymer) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages.

II. PHYSICO-CHEMICAL PROPERTIES

It is a beige powder.

III. ENVIRONMENTAL FATE PROPERTIES

Guar gum is a carbohydrate polymer consisting of D-mannose and D-galactose sugars from the guar plant or cluster bean. It is expected to be readily biodegradable and not bioaccumulate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Guar gum is exhibits very low acute toxicity by the oral route. It is non-irritating to the skin and minimally irritating to the eyes. Repeated dose toxicity studies in rats showed minimal toxicity from exposure to guar gum in the diet. Guar gum is not genotoxic or carcinogenic. Oral exposure to guar gum did not affect fertility in rats; nor was there any indication of developmental toxicity in either rats or mice.

B. Acute Toxicity

The oral LD_{50} in rats was reported to be 7,060 mg/kg (Graham *et al.*, 1981). [Kl. score = 2]

C. Irritation

Guar gum is non-irritating to the skin and minimally irritating to the eyes (McCarty *et al.*, 1990).

D. Sensitization

There were reports of workers sensitized to guar gum in a carpet-manufacturing plant. Immediate skin reactivity to guar gum was observed in 8 out of 162 employees, and 11 of 133 participants had serum IgE antibodies to guar gum. These findings are difficult to interpret since carbohydrates, such as guar gum, are generally not associated with allergenicity (Maio, 1986).

E. Repeated Dose Toxicity

Oral

Male and female Osborne-Mendel rats were given diets containing 0, 1, 2, 4, 7.5, or 15% guar gum for 91 days. The average daily intakes are: 0, 580, 1,187, 2,375, 4,561, and 10,301 mg/kg-day for males; and 0, 691, 1,362, 2,762, 5,770, and 13,433 mg/kg-day for females. There were no deaths during the study. Body weights were significantly decreased in the $\geq$1% females and the $\geq$7.5% males; biologically significant changes (>10%) were seen in the 7.5% females and the 15% males. Liver weights were decreased in the $\geq$1% dietary groups. Kidney weights were decreased in the $\geq$7.5% dietary groups and were borderline significant in the 4% group. The 15% group males had reduced bone marrow cellularity; although the level was within normal limits, several of the rats were at the lower end of the normal range. The NOAEL for this study is 4% in the diet or 2,762 mg/kg-day based on reduced body weights in the female rats (Graham *et al.*, 1981). [Kl. score = 2]

Male and female F344 rats and $B6C3F_1$ mice were given diets containing 0, 6,300, 12,500, 25,000, 50,000 or 100,000 ppm guar gum for 13 weeks. Mean body weights were decreased in the 100,000 ppm male rats and in the $\geq$50,000 ppm female mice. A dose-related decrease in feed consumption was observed for male and female rats; male and female mice were comparable or higher than that of controls. There were no compound-related clinical signs or histopathological effects. The NOAELs for this study is 50,000 and 25,000 ppm for rats and mice, respectively. Using the fraction of body weight that rats and mice consume per day as food (0.05 and 0.13, respectively; U.S. EPA), the NOAELs corresponds to 2,500 mg/kg-day for rats and 3,250 mg/kg-day for mice (NTP, 1982). [Kl. score = 2]

Male and female F344 rats and B6C3F$_1$ mice were given diets containing 0, 25,000 ppm or 50,000 ppm guar gum for 103 weeks. Mean body weights of the high-dose females were lower than those of the controls after week 20 for mice and week 40 for rats. No compound-related clinical signs or adverse effects on survival were observed. Feed consumption by dosed rats and mice of either sex was lower than that of controls. There were no non-neoplastic histopathological effects in either rats or mice that were treatment-related. The NOAEL for both rats and mice is 25,000 ppm. Using the fraction of body weight that rats and mice consume per day as food (0.05 and 0.13, respectively; U.S. EPA), the NOAELs corresponds to 1,250 mg/kg-day for rats and 3,250 mg/kg-day for mice (NTP, 1982). [Kl. score = 2]

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

Guar gum was not mutagenic to *S. typhimurium* strains TA 97, TA 98, TA 100, TA 102, TA 104, TA 1535, TA 1537, and TA1538 in the presence or absence of metabolic activation (Zeiger *et al.*, 1992). [Kl. score = 2]

In Vivo Studies

Guar gum was inactive in a rat bone marrow cytogenetic assay at doses up to 5,000 mg/kg (CIR, 2015). [Kl. score = 4]

In a rat dominant lethal mutation test, rats were dosed by oral gavage with either a single or multiple doses of up to 5,000 mg/kg guar gum. There was no indication of a mutagenic effect by guar gum (Lee *et al.*, 1981). [Kl. score = 2]

G. Carcinogenicity

Male and female F344 rats were given diets containing 0, 25,000 ppm, or 50,000 ppm guar gum for 103 weeks in a NTP chronic bioassay. There were increased incidences of adenomas of the pituitary in male rats and pheochromocytomas of the adrenal medulla in female rats that were statistically significant, but these differences were considered to be unrelated to guar gum administration. When pituitary adenomas or carcinomas and when pheochromocytomas or malignant pheochromocytomas were combined, the statistical

differences disappeared. NTP concluded that, under conditions of this bioassay, guar gum was not carcinogenic for F344 rats (NTP, 1982). [Kl. score = 2]

Male and female $B6C3F_1$ mice were given diets containing 0, 25,000, or 50,000 ppm guar gum for 103 weeks in a NTP chronic bioassay. Hepatocellular carcinomas occurred in treated male mice at incidences that were significantly lower than that in controls. The combined incidence of male mice with either hepatocellular adenomas or carcinomas was also significantly lower in the high-dose group. NTP concluded that, under conditions of this bioassay, guar gum was not carcinogenic for $B6C3F_1$ mice (NTP, 1982). [Kl. score = 2]

H. Reproductive Toxicity

Oral

Male and female Osborne-Mendel rats were fed diets containing 0, 1, 3, 4, 7.5, or 15% guar gum for 13 weeks before mating, during mating and throughout gestation. The daily intakes for the female rats during gestation were 0, 700, 1,400, 2,700, 5,200, or 11,800 mg/kg-day. Fertility was unaffected by treatment. There were slightly fewer corpora lutea and implantations in the 15% dietary group, but implantation efficiency was unaffected. The NOAEL for reproductive toxicity is 5,200 mg/kg-day (Collins *et al.*, 1987). [Kl. score = 2]

I. Developmental Toxicity

Oral

Male and female Osborne-Mendel rats were fed diets containing 0, 1, 3, 4, 7.5, or 15% guar gum for 13 weeks before mating, during mating and throughout gestation. The daily intake for the female rats during gestation were 0, 700, 1,400, 2,700, 5,200, or 11,800 mg/kg-day. There were no deaths during the study. In the 15% group, the number of viable fetuses per litter were slightly reduced, but was not statistically significantly different from controls. The authors indicated that the reduction may have been an effect of the decreased number of corpora lutea because the number of resorptions was unaffected in this treatment group. There was no treatment-related effect on fetal development or sex distribution, and there were no teratogenic effects (Collins *et al.*, 1987). [Kl. score = 2]

Pregnant female rats were dosed by oral gavage with 0, 9, 42, 200, or 900 mg/kg guar gum on GD 6 to 15. There was no maternal or developmental toxicity at any dose level. The NOAEL for maternal and developmental toxicity is 900 mg/kg-day (FDRL, 1973). [Kl. score = 2]

Pregnant female CD-1 mice were dosed by oral gavage with 0, 8, 37, 170, or 800 mg/kg

guar gum on GD 6 to 15. A significant number of deaths (6 out of 29) occurred in the 800 mg/kg dose group. There were indications of maternal toxicity in the surviving high-dose dams. There was no developmental toxicity at any dose level. The NOAELs for maternal and developmental toxicity are 170 and 800 mg/kg-day, respectively (FDRL, 1973). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for guar gum follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

In a two-year NTP chronic bioassay, female rats and mice given 50,000 ppm guar gum in their feed had lower body weights. There were no treatment-related non-neoplastic lesions in either rats or mice. The NOAEL for this study is 25,000 ppm for rats and mice, which corresponds to 1,250 mg/kg-day for rats and 3,250 mg/kg-day for mice.

The NOAEL of 1,250 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 1,250/(10 x 10 x 1 x 1 x 1) = 1,250/100 = 13 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (13 x 70 x 0.1)/2 = 46 mg/L

B. Cancer

Guar gum was not carcinogenic to rats or mice in two-year dietary studies. Thus a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Guar gum does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Guar gum is a polysaccharide polymer. It has low acute toxicity concern for fish, but exhibits medium or possibly high acute toxicity to invertebrates (*Daphnia*).

B. Aquatic Toxicity

The 96-hour LC_{50} for *Oncorhynchus mykiss* is 218 mg/L (Biesinger *et al.*, 1976). [Kl. score = 2]

The 48-hour and 96-hour LC_{50} values for *Daphnia magna* are 42 mg/L and <6.2 mg/L, respectively (Biesinger *et al.*, 1976). [Kl. score = 2]

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for guar gum follow the methodology discussed in DEWHA (2009).

PNEC water
Experimental results are available for two trophic levels. The acute $E(L)C_{50}$ values are available for fish (218 mg/L) and *Daphnia* (<6.2 mg/L). On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 6.2 mg/L for *Daphnia*. The $PNEC_{water}$ is 0.006 mg/L.

PNEC sediment
No experimental toxicity data on sediment organisms are available. The K_{ow} and K_{oc} of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

PNEC soil
No experimental toxicity data on soil organisms are available. The K_{ow} and K_{oc} of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Guar gum is a naturally occurring polysaccharide from the guar plant or cluster bean; it expected to be readily biodegradable. Thus it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons and is water-soluble. Thus guar gum is not expected to meet the criteria for bioaccumulation.

The 96-hour LC_{50} value for *Daphnia* is <6.2 mg/L. Thus guar gum may potentially meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

[Acute Aquatic Toxicity Category 2]

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes.

Skin Contact
Remove contaminated clothing. Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person.

Notes to Physician
May cause asthma-like (reactive airways) symptoms.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus for fire fighting.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Avoid dust formation.

Environmental Precautions
No special environmental precautions required.

Steps to be Taken if Material is Released or Spilled
Sweep up and dispose in suitable, closed containers.

D. STORAGE AND HANDLING

General Handling
Avoid creating or inhaling dust.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard specifically for guar gum.

Engineering Controls
Ensure adequate ventilation.

Personal Protection Equipment

Respiratory Protection:
Respiratory protection is not required.

Hand Protection:
Handle with gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Guar gum is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

HEMICELLULASE ENZYME

This dossier on hemicellulase enzyme does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of hemicellulase enzyme in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained primarily from the Human & Environmental Risk Assessment on Ingredients of European Household Cleaning Products: Alcohol Ethoxylates (HERA, 2005), and from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Not applicable

CAS RN: 9025-56-3

Molecular weight: 20,000 to 80,000 daltons (based on cellulase enzymes)

Synonyms: Hemicellulases; hemicellulase enzymes

Hemicellulases are a group of enzymes that break down hemicellulose, which are polysaccharides that are present in cell walls of all terrestrial plants. These polysaccharides have a β-(1→4)-linked backbone and are composed of pentoses (xylose, arabinoses), hexoses (mannose, glucose, galactose), and sugar acids. Unlike cellulose which are polysaccharides consisting of linear chains of several hundred to over ten thousand β-(1→4) linked D-glucoses, hemicellulases are not chemically homogeneous. The best characterized hemicellulases are the 1,4- β -D-xylanases and, in particular, those derived from fungal sources presumably because their substrates, xylans, constitute the largest proportion of hemicelluloses in pasture plants.

No information was found on hemicellulase enzyme; however, because of their similarity, information will be read-across from cellulase enzymes (HERA, 2005). Cellulases cleave the ß-1,4-glycosidic bonds in cellulose, and are used in the pulp and paper industry, the textile industry, and in detergents to remove deposits and stains. The molecular weight of cellulase is 20,000 to 80,000 daltons.

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity. For the purposes of risk assessment, the structure of hemicellulases would be expected to be similar to that of cellulases, given that hemicellulases and cellulases are both enzyme families that hydrolyze polysaccharides, although differing in their

substrates. Thus, the toxicity data on cellulases will be used as read-across to hemicellulases.

II. PHYSICO-CHEMICAL PROPERTIES

Cellulases, as pure enzyme, are white crystals or powder (HERA, 2005).

An octanol-water partition coefficient (K_{ow}) for cellulases is not available. However, the log K_{ow} of glucoamylase, which cleaves 1,4–α-D-glycosidic linkages, was experimentally determined to be <1.3 at 20ºC (ECHA). [Kl. score = 1]

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Cellulases are readily biodegradable; they are not expected to bioaccumulate or adsorb to soil.

B. Biodegradation

A cellulase enzyme was readily biodegradable in an OECD 301F test. There was ~10% degradation after one day; ~60% after 5 days; and 129% after 28 days (ECHA). [Kl. score = 1]

Three different cellulase enzymes were considered readily biodegradable based on the results of OECD 301C and 301E tests (HERA, 2005) [Kl. scores = 1]. In an OECD 301E test, there was 84% DOC removal of the enzyme Carezyme after 28 days. In another OECD 301E test, there was 92% DOC removal of the enzyme Clazinase® after 28 days. In an OECD 301C test, BOD/COD was 78% after 28 days (HERA, 2005).

C. Environmental Distribution

<u>Adsorption/desorption</u>

Proteins, such as cellulase enzyme, would not be expected to adsorb to soil. HERA (2005) listed a K_{oc} value of <1.3 for detergent amylases, cellulases, and lipases that was calculated according to the EU Technical Guidance Document (EC, 2003). No further information was provided. The K_{oc} value of 1.3 will be used to calculate the PNEC values for sediment and soil using the equilibrium partitioning method (see section XII. D.).

D. Bioaccumulation

No bioaccumulation studies have been conducted on cellulase enzymes. Cellulase enzymes are not expected to bioaccumulate due to their high molecular weight and their octanol-water partition coefficient (log K_{ow} is <1.3). Moreover, cellulases are rapidly biotransformation in an organism to lower molecular-weight protein fragments by proteolytic enzymes (proteases), and eventually to the basic amino acids by peptidase enzymes.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Cellulase enzyme has low acute toxicity by the oral, dermal, or inhalation routes. It is not askin or eye irritant; and it is not a skin sensitizer. Although there are no specific studies on cellulase enzyme, a number of enzymes from bacteria, plants, and fungi have the potential to cause occupational respiratory allergy, even asthma. Minimal toxicity was seen in rats given repeated oral doses of cellulase enzyme either by gavage or in their diet for up to 13 weeks. Cellulase enzyme is not genotoxic. There are no carcinogenicity, reproductive, or developmental toxicity studies on cellulase enzyme.

B. Acute Toxicity

The oral LD_{50} of a cellulase enzyme was calculated to be 8,000 mg/kg for mice and >10,000 mg/kg for rats (HERA, 2005) [Kl. score = 4]. The oral LD_{50} in rats for a cellulase enzyme was >2,880 mg/kg, measured as total organic soilds (ECHA) [Kl. score = 1].

The inhalation LC_{50} of a cellulase enzyme in rats was >3.48 mg/L. The mass mean aerodynamic diameter (MMAD) was 7.8 μm with a geometric standard deviation of 2.1 μm (HERA, 2005) [Kl. score = 4]. The 4-hour inhalation LC_{50} of a cellular enzyme in rats was >4.86 mg/L, which corresponds to 4.44 mg total organic solids/L). The respirable fraction was 80% (44.8% of the particles were <6 μm (ECHA) [Kl. score = 1].

No dermal toxicity studies are available.

C. Irritation

Application of 0.5 ml of a cellulase enzyme to the skin of rabbits for 4 hours under semi-occlusive conditions was minimally irritating (ECHA). [Kl. score = 1]

Instillation of 0.1 ml of a cellulase enzyme to the eyes of rabbits was non-irritating (ECHA). [Kl. score = 1]

D. Sensitization

A cellulase enzyme was not a skin sensitizer to guinea pigs in a Buehler sensitization test (HERA, 2005). [Kl. score = 2]

Although there are no specific studies on cellulase enzyme, a number of enzymes from bacteria, plants, and fungi have the potential to cause occupational respiratory allergy, even asthma (Basketter et al., 2015).

E. Repeated Dose Toxicity

Oral

Male and female rats were dosed by oral gavage with 0, 300, 1,000 or 3,000 mg/kg of a cellulase enzyme for 4 weeks. There were no treatment-related clinical signs, but a slight dose-related increase in body weight gain (approx. 7%) was seen in the males. No treatment-related changes were noted in the hematology or clinical chemistry. There were no gross or histopathologic changes that were considered treatment-related. The NOAEL is 3,000 mg/kg-day (HERA, 2005). [Kl. score = 2]

Male and female rats were fed a diet containing 0, 120, 600 or 3,000 mg/kg of a cellulase enzyme for 13 weeks. There were no treatment-related clinical signs. A reduction in body weight gain was seen in both sexes at the 3,000 mg/kg dose level (10% in males and 20% in females). A slight reduction in food consumption was also noted for the 3,000 mg/kg rats. Alkaline phosphatase was increased in the 600 and 3,000 mg/kg females in a dose-dependent manner. There were no gross or histopathologic changes that were considered treatment-related. The NOAEL for this study is 600 mg/kg-day (HERA, 2005). [Kl. score = 2]

Male and female Wistar rats were dosed by oral gavage with 0, 100, 300, or 1,000 mg/kg β-glucanase (measured as total organic solids) for 13 weeks. There were no treatment-related effects on mortality, clinical signs, body weights, food or water consumption, ophthalmoscopic findings, hematology, clinical chemistry, neurobehavior (functional observation battery), organ weights, gross or microscopic pathology. The NOAEL is 1,000 mg/kg-day expressed as total organic solids (ECHA). [Kl. score = 1]

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

The *in vitro* genotoxicity studies on cellulase enzymes are shown in Table 1.

Table 1: *In vitro* Genotoxicity Studies on Cellulase Enzyme

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	1	ECHA
Bacterial reverse mutation (*S. typhimurium* strains)	-	-	2	HERA (2005)
Chromosomal aberration (human lymphocytes)	-	-	1	ECHA

*+, positive; -, negative

In vivo Studies

Male and female SD rats were dosed by oral gavage with 0, 300, 1,000, or 3,000 mg/kg of a cellulase enzyme for five consecutive days. Chromosomal aberrations, excluding gaps, were not significantly increased at any dose level compared to controls. Chromosomal aberrations including gaps were increased in females from all dose groups, but there was no clear dose-response relationship and the difference was only statistically significant at 3,000 mg/kg. There was no treatment-related effect on the mitotic capacity of the bone marrow. It was concluded that the cellular enzyme was not genotoxic under the conditions of the assay (HERA, 2005). [Kl. score = 2]

G. Carcinogenicity

No studies are available.

H. Reproductive Toxicity

No studies are available.

I. Developmental Toxicity

No studies are available.

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for hemicellulase enzyme follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

There are two 13-week rat studies on cellulase enzyme. In a dietary study, rats were given 0, 120, 600, or 3,000 mg/kg cellulase enzyme. The LOAEL for this study is 3,000 mg/kg based on significant reduction in body weight gain in both sexes; the NOAEL is 600 mg/kg-day (HERA, 2005). In an oral gavage study, rats were dosed with 0, 100, 300, or 1,000 mg/kg β-glucanase. There were no treatment-related effects and the NOAEL for this study is 1,000 mg/kg-day, the highest dose tested (ECHA).

The NOAEL of 1,000 mg/kg-day from the 13-week rat oral gavage study will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 3
UF_D (database uncertainty) = 1

Oral RfD = 1,000/(10 x 10 x 1 x 3 x 1) = 1,000/300 = 3 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (1.0 x 70 x 0.1)/2 = 12 mg/L

B. Cancer

There are no carcinogenicity studies on cellulase enzyme. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Hemicellulase and cellulase enzymes do not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Cellulase enzyme has a moderate acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 2 lists the results of acute aquatic toxicity studies on cellulase enzyme.

Table 2: Acute Aquatic Toxicity Studies on Cellulase Enzyme

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-h LC_{50}	>100* >52.1**	1	ECHA
Brachydanio rerio	96-h LC_{50}	330*	4	HERA (2005)

Daphnia magna	48-h EC_{50}	>100* >52.1**	1	ECHA
Daphnia magna	48-h EC_{50}	>1,000**	4	HERA (2005)
Daphnia magna	48-h EC_{50}	1,000**	4	HERA (2005)
Pseudokirchneriella subcapitata	72-h EC_{50}	>100* >52.1**	1	ECHA
Scenedesmus subspicatus	72-h EC_{50}	>1,000**	4	HERA (2005)

*Total organic solids.
**Active enzyme protein.

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for cellulase enzyme follow the methodology discussed in DEWHA (2009).

PNEC water
Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (>52.1 mg aep/L), *Daphnia* (>52.1 mg aep/L), and algae (>52.1 mg aep/L). No chronic toxicity studies are available. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 100 has been applied to the lowest reported $E(L)C_{50}$ value of 52.1 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.5 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.3 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.825/1280) \times 1000 \times 0.5$
$= 0.3$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{solid}]$
$= 0.8 + [0.2 \times 0.052/1000 \times 2400]$
$= 0.825$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 1.3 \times 0.04$
$= 0.052$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for cellulase enzymes is calculated to be <1.3 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.009 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.026/1500) \times 1000 \times 0.5$
$= 0.009$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 1.3 \times 0.02$
$= 0.026$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for cellulase enzymes is calculated to be <1.3 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008). The following PBT assessment on hemicellulase enzyme is based on read-across from cellulase enzyme.

Hemicellulase enzyme is readily biodegradable; thus, it does not meet the screening criteria for persistence.

Hemicellulase enzyme has a high molecular weight (20 to 80 kD), hydrophilic properties (high water solubility, log K_{ow} <1.3), and is readily biotransformed in organisms by proteases and peptidases. Thus, hemicellulase enzyme does not meet the screening criteria for bioaccumulation.

There are no chronic toxicity studies on hemicellulase enzyme. The acute $E(L)C_{50}$ values are >1 mg/L in fish, invertebrates and algae. Thus, hemicellulase enzyme does not meet the criteria for toxicity.

The overall conclusion is that hemicellulase enzyme is not a PBT substances.

IX. CLASSIFICATION AND LABELING

A. Classification

Respiratory sensitizer Category 1

[Aquatic Acute Category 3]

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes.

Skin Contact
Remove contaminated clothing. Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person.

Notes to Physician
May cause asthma-like (reactive airways) symptoms.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon dioxide, nitrogen oxides, sulfur oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus for fire-fighting.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment. Ensure adequate ventilation. Do not breathe vapors, mists, or gas.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Collect spilled material by non-dispersive methods or with a vacuum cleaner equipped with a high efficiency filter. After spillage avoid generating aerosols or dust from dried preparation. Do not sweep, brush, use compressed air, which can create aerosols. Avoid splashing and high pressure washing. Provide for sufficient ventilation. Wash with plenty of water.

D. STORAGE AND HANDLING

General Handling
Use personal protective clothing. Avoid dust formation. Ensure adequate ventilation. Provide appropriate exhaust ventilation at places where dust is formed. Do not breathe dust. Wear respiratory protection if ventilation is inadequate. Avoid contact with skin, eye, and clothing.

Other Handling Precautions
Avoid creating or inhaling dust.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard specifically for hemicellulase enzyme. However, Workplace Australia has established an occupational exposure standard of 0.00006 mg/m^3 (peak exposure with a sensitization notation) for the proteolytic enzymes of *B. subtilisins* as 100% pure enzyme. A peak limitation is defined by Safe Work Australia as a maximum or peak airborne concentration of a substance determined over the shortest analytically practicable period of time which does not exceed 15 minutes.

Engineering Controls

Ensure adequate ventilation. Localized ventilation should be used to control dust levels below permissible exposure limits.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection when airborne concentrations are expected to exceed occupational exposure limits.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible. Remove and wash contaminated clothing before re-use. Contaminated work clothing should not be allowed out of the workplace.

F. TRANSPORT INFORMATION

Hemicellulase enzyme is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

HYDROCHLORIC ACID

This dossier on hydrochloric acid does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of hydrochloric acid in its use in drilling muds and in water treatment systems. The majority of information presented in this dossier was obtained from OECD-SIDS documents (OECD, 2002a,b), and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): Chlorane

CAS RN: 7647-01-0

Molecular formula: HCl

Molecular weight: 36.46

Synonyms: Hydrochloric acid, HCl, chlorane, hydrogen chloride, muriatic acid, chlorohydric acid,

SMILES: Cl

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Hydrochloric Acid

Property	Value	Klimisch score	Reference
Physical state at 20ºC and 101.3 kPa	Colourless to slightly yellow gas of fuming liquid with pungent, irritating odour.	2	ECHA
Melting Point	-114.22ºC	2	ECHA
Boiling Point	-85ºC	4	ECHA
Density	1.639 g/L @ 0ºC (gas) 1.194 g/mL @ 26ºC (liquid)	4	ECHA
Vapour Pressure	4,104 kPa 4,723 kPa @ 25ºC	4	ECHA
Partition Coefficient (log K_{ow})	Not applicable	-	-
Water Solubility	Very soluble	4	ECHA
Viscosity	1.7 x 10^{-6} m^2s @ 20ºC	1	ECHA

Hydrochloric acid can exist in a gaseous phase at room temperature and pressure. Hydrochloric acid is also very soluble in water and is a strong acid that dissociates completely in water to hydrogen (H^+) and chloride (Cl^-) ions.

III. ENVIRONMENTAL FATE PROPERTIES

Due to its high water solubility and low vapour pressure, hydrochloric acid will be found predominantly in the aquatic environment where it dissociates completely to hydrogen (H^+) and chloride (Cl^-) ions. Both ions are ubiquitous in the environment (UNEP, 1995).

The addition of hydrochloric acid to an aquatic ecosystem may decrease the pH depending on the buffer capacity of the receiving water. In general, the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

A release of hydrochloric acid into the aquatic environment from the use of HCl could potentially increase the chloride concentration and decrease the pH in the aquatic environment. Table 2 shows the amount of hydrochloric acid that would need to be added to bicarbonate solutions to obtain pH values of 6.0 and 4.0. The UNEP (1995) study reported that the 10th percentile, mean, and the 90th percentile of bicarbonate concentrations in 77 rivers in North America, South America, Asia, Africa, Europe, and Oceania were 20, 106, and 195 mg/L, respectively. The data show that the decrease in pH depends on the buffer capacity (bicarbonate concentration) of the receiving water. The calculated values in Table 2 were confirmed experimentally.

Table 2: Buffer capacity to maintain the pH based on bicarbonate concentration from UNEP monitoring data (de Groot and van Dijk, 2002; taken from OECD, 2002b)

Initial concentration of HCO_3^-	Final pH	Concentration of HCl required to obtain the final pH value
		Calculated [mg/L]
20 mg/LHCO_3^- (10th percentile 77 rivers)	6.0	8.28
	4.0	11.9
106 mg/L HCO_3^- (mean value of 77 rivers)	6.0	43.9
	4.0	63.2
195 mg/L HCO_3^- (90th percentile 77 rivers)	6.0	80.7
	4.0	116.3

H^+ and Cl^- ions will not adsorb on the particulate matter or surfaces and will not accumulate in living tissues (OECD, 2002a,b).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Hydrochloric acid is a corrosive liquid. Depending on the concentration, aqueous solutions of hydrochloric acid (HCl) are either corrosive, irritating, or non-irritating to the skin, eyes, and gastrointestinal tract. Vapours from aqueous solutions of HCl can cause respiratory irritation. HCl is not a skin sensitiser. Subchronic inhalation studies show localised irritation to the upper respiratory tract of rats and mice, but no systemic toxicity. No repeated dose toxicity studies have been conducted by the oral route. Positive findings have been reported in some *in vitro* genotoxicity studies, which are considered to be the result of the pH change in the test system. A lifetime inhalation study showed no carcinogenicity in rats exposed to HCl. No adequate reproductive or developmental studies have been conducted on HCl.

B. Acute Toxicity

The oral LD_{50} values in rats were reported to be 238 to 277 mg/kg and 700 mg/kg (OECD, 2002a,b). [Kl. scores = 2 and 4, respectively]

The lethal dose by dermal exposure is >5,010 mg/kg for rabbits (OECD 2002a,b). [Kl. score = 4]

The LC_{50} values in rats for HCl gas are 40,989 and 4,701 ppm for 5 and 30 minutes, respectively (ECHA) [Kl. score = 2]. The LC_{50} values in rats for HCl aerosol are 31,008 and 5,666 ppm (45.6 and 8.3 mg/L) for 5 and 30 minutes, respectively (ECHA) [Kl. score = 2].

C. Irritation

Application of a 37% aqueous solution of HCl for 1 or 4 hours was corrosive to the skin of rabbits (OECD, 2002a,b) [Kl. score = 2). Application of 0.5 mL of a 17% solution of aqueous solution of HCl for 4 hours was corrosive to the skin of rabbits (OECD, 2002a,b) [Kl. score = 3]. Moderate skin irritation was observed in rabbits following an application of 0.5 mL of a 3.3% aqueous solution of HCl for five days; no irritation was observed with 0.5 mL of a 1% aqueous solution (OECD, 2002a,b) [Kl. score = 2]. In humans, an aqueous solution of 4% of HCl was slightly irritating, while a 10% solution was sufficiently irritating to be classified as a skin irritant (OECD, 2002a,b).

Instillation of 0.1 mL of a 10% aqueous solution of HCl to the eyes of rabbits resulted in severe eye irritation (ECHA) [Kl. score = 2]. Instillation of 0.1 mL of a 5% solution of HCl produced corneal opacity, iridial lesions, conjunctival redness and chemosis in 3/3 animals at 1 hour and at day one post-instillation. There was no recovery in any animal and the study was terminated on day two (ECHA) [Kl. score = 1].

D. Sensitisation

Hydrochloric acid was not a skin sensitiser in a guinea pig maximisation test (ECHA). [Kl. score = 2]

E. Repeated Dose Toxicity

Oral

No adequate studies were located.

Inhalation

Male and female SD rats and F344 rats were exposed by inhalation to 0, 10, 20, or 50 ppm 6 hours/day, 5 days/week for up to 90 days. Clinical signs were mainly indicative of the irritant/corrosive nature of HCl. Body weights were significantly decreased in the 50 ppm male F344 rats. There were no treatment-related effects on the haematology or clinical chemistry parameters or urinalysis. At study termination, heart, kidney and testes weights were increased in the 100 and/or 50 ppm groups; these changes were considered to be mainly related to the treatment-related effect on body weight. Histopathological examination showed minimal to mild rhinitis in the $\geq$20 ppm dose groups of both strains of rats (both sexes). The NOAELs for systemic toxicity and localised irritation (site-of-contact) are 20 and 10 ppm, respectively (ECHA). [Kl. score = 1]

Male and female $B6C3F_1$ mice were exposed by inhalation to 0, 10, 20, or 50 ppm HCl, 6 hours/day, 5 days/week for up to 90 days. Clinical signs were mainly indicative of the irritant/corrosive nature of HCl. Body weights were significantly decreased in the 50 ppm groups. At study termination, absolute liver weights were decreased in the 50 ppm males. Histopathologic examination showed only

eosinophilic globules in the nasal epithelium in the 50 ppm animals. The NOAEL for this study is 20 ppm (ECHA). [Kl. score = 1]

Male SD rats were exposed by inhalation to 0 or 10 ppm HCl 6 hours/day, 5 days/week for 128 weeks. Survival and body weights were similar between treated and control groups. There was a higher incidence of hyperplasia of the larynx compared to control, but no serious irritating effects of the nasal epithelium (ECHA). [Kl. score = 2]

Dermal

No studies were located.

F. Genotoxicity

In Vitro Studies

Table 3 presents the *in vitro* genotoxicity studies on hydrochloric acid.

Table 3: In Vitro Genotoxicity Studies on Hydrochloric Acid

Test System	Results[a]		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	2	ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-	+	2	ECHA
Chromosomal aberration (CHO cells)	+	+	2	ECHA
Saccharomyces cerevisiae (mitotic recombination	-	-	2	ECHA
E. coli W3110 (pol A+) and P3078 (pol A-) repair assay	-	-	2	ECHA

a+, positive; -, negative

In the mouse lymphoma assay, the mutant frequency increased as the pH was lowered to 6.5 to 6.0 (from increased HCl) in the presence of metabolic activation. A decrease in pH from the addition of HCl to the medium also resulted in clastogenic effects to CHO cells in the absence or presence of metabolic activation. The positive findings in these two studies are considered to be the result of the pH change in the test media.

In Vivo Studies

No adequate studies were located.

G. Carcinogenicity

Oral

No studies were located.

Inhalation

Male SD rats were exposed by inhalation to 0 or 10 ppm HCl 6 hours/day, 5 days/week for 128 weeks. Survival and body weights were similar between treated and control groups. There was a

higher incidence of hyperplasia of the larynx compared to control, but no serious irritating effects of the nasal epithelium. There was no increased incidence of tumours in the HCl-treated rats compared to controls (ECHA). [Kl. score = 2]

H. Reproductive Toxicity

No studies were located.

I. Developmental Toxicity

No adequate studies were located.

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

Repeated dose, reproductive, and developmental toxicity studies by the oral route have not been conducted on hydrochloric acid. These toxicity studies would have questionable usefulness because of the corrosive/irritating nature of hydrochloric acid, which would limit the amount of absorbed HCl. Hydrochloric acid dissociates to hydrogen and chloride ions in bodily fluids, and a significant amount of these ions are already ingested in foods. Furthermore, both ions are present in the body and are highly regulated by homeostatic mechanisms. Thus, an oral toxicological reference and drinking water guidance values were not derived from hydrochloric acid.

The Australian drinking water guideline values for pH (6.5 to 8.5) and chloride (250 ppm, aesthetics) may be applicable (ADWG, 2011).

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Hydrochloric acid does not exhibit the following physico-chemical properties:

- • Explosivity
- • Flammability
- • Oxidising potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

The hazard of hydrochloric acid for aquatic organisms is caused by the hydrogen ion (H^+). The toxicity values in terms of mg/L are not relevant because of the varying buffering capacity of different test systems and different aquatic ecosystems.

B. Aquatic Toxicity

Acute Studies

The acute aquatic toxicity studies on hydrochloric acid are listed in Table 4.

Table 4: Acute Aquatic Toxicity Studies on Hydrochloric Acid

Test Species	Endpoint	Results	Klimisch score	Reference
Oncorhynchus mykiss	96-hr LC_{50}	pH 4.12 (hard water) pH 3.98 (soft water)	2	ECHA; OECD 2002a,b

Test Species	Endpoint	Results	Klimisch score	Reference
Lepomis macrochirus	96-hr LC_{50}	pH 3.25 – 3.5	2	ECHA; OECD 2002a,b
Daphnia magna	48-hr EC_{50}	pH 4.92	1	ECHA
Chlorella vulgaris	72-hr EC_{50} 72-hr NOEC	pH 4.7 [growth rate] pH 4.82 [biomass] pH 5 [yield/growth rate	1	ECHA

Chronic Studies

No chronic studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

PNEC values were not derived from hydrochloric acid because factors such as the buffer capacity, the natural pH, and the fluctuation of the pH are very specific for a certain ecosystem.

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Hydrochloric acid is an inorganic salt that dissociates completely to hydrogen and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both hydrogen and chloride ions are also ubiquitous and are present in water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Hydrogen and chloride ions are essential to all living organisms, and their intracellular, and extracellular concentrations are actively regulated. Thus, hydrochloric acid is not expected to bioaccumulate.

No chronic toxicity data exist on hydrochloric acid; however, the acute $E(L)C_{50}$ values are >1 mg/L in fish, invertebrates and algae. Thus, hydrochloric acid does not meet the screening criteria for toxicity.

The overall conclusion is that hydrochloric acid is not a PBT substance.

IX. CLASSIFICATION AND LABELLING

A. Classification

For HCl concentrations of >25%:

- Metal Corrosive Category 1
- Skin Corrosive 1B
- STOT SE Category 3 [Respiratory irritant]

In addition to the hazard statements corresponding the GHS classification for corrosive, the following non-GHS hazard statement is to be added to the SDS: AUH071: Corrosive to the Respiratory Tract.

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact

Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. Get medical attention immediately, preferably a physician for an ophthalmologic examination.

Skin Contact

For minor skin contact, avoid spreading material on unaffected skin. Remove and isolate contaminated clothing. Wash the contaminated area of the body with soap and fresh water. Get medical attention immediately.

Inhalation

Move person to fresh air. Administer oxygen if breathing is difficult. Do not use mouth-to-mouth method if victim inhaled the substance; give artificial respiration with the aid of a pocket mask equipped with a one-way valve or another proper respiratory medical device. Give artificial respiration if the victim is not breathing. Get medical attention immediately.

Ingestion

Rinse mouth and lips with plenty of water if a person is conscious. Do not induce vomiting. Do not use mouth-to-mouth method if the victim had ingested the substance. Obtain medical attention immediately if ingested.

Notes to Physician

Treat as a corrosive due to pH of the material. All treatments should be based on observed signs and symptoms of distress in the patient.

B. FIRE FIGHTING INFORMATION

Extinguishing Media

Use dry chemical, carbon dioxide, water spray or fog, or foam.

Specific Exposure Hazards

Containers may explode when heated. Emits toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following materials: halogenated compounds, may release dangerous gases (chlorine).

Special Protective Equipment for Firefighters

Structural firefighter's protective clothing provides limited protection in fire situations only; it is not effective in spill situations where direct contact with the substance is possible. Wear chemical protective clothing that is specifically recommended by the manufacturer. It may provide little or no thermal protection. Wear positive pressure self-contained breathing apparatus (SCBA). Move containers from fire area if you can do it without risk.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Ventilate enclosed areas. Do not walk through spilt material. Do not touch damaged containers or spilt material unless wearing appropriate protective clothing. Wear appropriate personal protective equipment, avoid direct contact. Do not breath mist, vapours, or spray. Do not get in eyes, on skin, or on clothing.

Environmental Precautions

Prevent entry into waterways, sewers, basements or confined areas.

Steps to be Taken if Material is Released or Spilt

ELIMINATE all ignition sources (no smoking, flares, sparks or flames in immediate area). As an immediate precautionary measure, isolate spill or leak area for at least 50 meters in all directions. Keep unauthorised personnel away. Stay upwind. Keep out of low areas. Do not get water inside container.

D. STORAGE AND HANDLING

General Handling

Handle and open container with care. Use only with adequate ventilation. Keep away from heat. Use caution when combining with water. DO NOT add water to corrosive liquid, ALWAYS add corrosive liquid to water while stirring to prevent the release of heat, steam, and fumes. Wear appropriate personal protective equipment, avoid direct contact. Do not breath mist, vapours, or spray. Do not get in eyes, on skin, or on clothing. Do not ingest. Wash thoroughly with soap and water after handling and before eating, drinking, or using tobacco.

Storage

Keep contain tightly closed. Store in a cool, dry, well-ventilated place. Keep away from incompatible materials. Keep from direct sunlight. Separate from alkalis. Do not store above 49^{o}C/120^{o}F.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

The workplace exposure standard for hydrochloric acid in Australia is 5 ppm (7.5 mg/m^3 as a peak limitation, with a sensitisation notation. A peak limitation is defined by Safe Work Australia as a maximum or peak airborne concentration of a substance determined over the shortest analytically practicable period of time which does not exceed 15 minutes.

Engineering Controls

Good general ventilation should be used. Ventilation rates should be matched to conditions. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits.

Personal Protection Equipment

Respiratory Protection: If workers are exposed to concentrations above the exposure limit, they must use appropriate, certified respirators. Use a properly fitted, air-purifying or air-fed respirator complying with an approved standard if a risk assessment indicates this is necessary. Respirator selection much is based on known or anticipated exposure levels, the hazard of the product and the safe working limits of the selected respirator.

Hand Protection: Chemical-resistant, impervious gloves complying with an approved standard should be worn at all times when handling chemical products if a risk assessment indicates this is necessary. Considering the parameters specified by the glove manufacturer, check during use that the gloves are still retaining their protective properties. It should be noted that the time to breakthrough for any glove material may be different for different glove manufacturers. In the case of mixtures, consisting of several substances, the protection time of the gloves cannot be accurately estimated.

Skin Protection: Personal protective equipment for the body should be selected based on the task being performed and the risks involved and should be approved by a specialist before handling hydrochloric acid.

Eye Protection: Wear chemical splash goggles and face shield.

Other Precautions: Wash hands, forearms, and face thoroughly after handling chemical products, before eating, smoking, and using the lavatory and at the end of the working period. Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Australian Dangerous Goods

UN 1789 (HYDROCHLORIC ACID)
Class: 8
Packing Group: II or III

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

HYDROXYPROPYL GUAR

This dossier on hydroxylpropyl guar does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of hydroxypropyl guar in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Hydroxylpropyl Guar

CAS RN: 39421-75-5

Molecular weight: 200,000 to 300,000 daltons (Glickman, 1969)

Hydroxypropyl guar a propylene glycol ether derivative of guar gum. Guar gum is a resinous material derived from milled endosperm from guar beans of the legume *Cyamopsis tetragonolobus*. Structurally, it is a galactomannan (high molecular weight carbohydrate polymer) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages.

SYNONYMS: Hydroxypropyl guar; hydroxypropyl guar gum; guar gum, 2-hydroxypropyl ether

II. PHYSICO-CHEMICAL PROPERTIES

Hydroxypropyl guar is a white to yellow fine powder that is very slightly soluble in water (Johnson et al., 2015).

III. ENVIRONMENTAL FATE PROPERTIES

No biodegradation studies are available on hydroxypropyl gum. Hydroxypropyl guar is the propylene glycol derivative of a carbohydrate polymer consisting of D-mannose and D-galactose sugars from the guar bean. It is expected to be readily biodegradable.

Hydroxypropyl guar is not expected to bioaccumulate based on its large molecular weight.

IV. HUMAN HEALTH HAZARD ASSESSMENT

As the propylene glycol derivative of guar gum, hydroxypropyl guar would be expected to have similar toxicological properties to guar gum. Thus, the toxicity data on guar gum have been used to read-across to hydroxypropyl guar.

A. Summary

There are no mammalian toxicity data available on hydroxypropyl guar, except for one *in vitro* genotoxicity study; thus data on guar gum have been used to read-across to hydroxypropyl guar. Guar gum is exhibits very low acute toxicity by the oral route. It is non-irritating to the skin and minimally irritating to the eyes. Repeated dose toxicity studies showed minimal toxicity in dietary studies. Unlike guar gum, hydroxylpropyl guar was mutagenic in an Ames test in the presence, but not absence, of metabolic activation. Oral exposure to guar gum did not affect fertility in rats; nor was there any indication of developmental toxicity in rats or mice.

B. Acute Toxicity

There are no acute toxicity studies available for hydroxypropyl guar. The oral LD_{50} for guar gum in rats was reported to be 7,060 mg/kg (Graham et al., 1981). [Kl. score = 2]

C. Irritation

There are no irritation studies available for hydroxypropyl guar. Guar gum is non-irritating to the skin, and minimally irritating to the eyes (McCarty *et al.*, 1990).

D. Sensitization

There are no animal sensitization studies available for either hydroxypropyl guar or guar gum.

E. Repeated Dose Toxicity

Oral

There are no repeated dose toxicity studies available for hydroxypropyl guar.

Male and female Osborne-Mendel rats were given diets containing 0, 1, 2, 4, 7.5, or 15% guar gum for 91 days. The average daily intakes are: 0, 580, 1,187, 2,375, 4,561, and 10,301 mg/kg-day for males; and 0, 691, 1,362, 2,762, 5,770, and 13,433 mg/kg-day for females. There were no deaths during the study. Body weights were significantly decreased in the $\geq$1% females and the $\geq$7.5% males. Liver weights were decreased in the $\geq$1% dietary groups. Kidney weights were decreased in the $\geq$7.5% dietary groups and were borderline significant in the 4% group. The 15% males had reduced bone marrow cellularity; although the level was within normal limits, several of the rats were at the

lower end of the normal range. The LOAEL for this study is 691 mg/kg-day based on reduced body weights in the female rats (Graham et al., 1981). [Kl. score = 2]

Male and female F344 rats and $B6C3F_1$ mice were given diets containing 0, 6,300, 12,500, 25,000, 50,000 or 100,000 ppm guar gum for 13 weeks. Mean body weights were decreased in the 100,000 ppm male rats and in the $\geq$50,000 ppm female mice. A dose-related decrease in feed consumption was observed for male and female rats; male and female mice were comparable or higher than that of controls. There were no compound-related clinical signs or histopathological effects. The NOAELs for this study is 50,000 and 25,000 ppm for rats and mice, respectively. Using the fraction of body weight that rats and mice consume per day as food (0.05 and 0.13, respectively; U.S. EPA), the NOAELs corresponds to 2,500 mg/kg-day for rats and 3,250 mg/kg-day for mice (NTP, 1982). [Kl. score = 2]

Male and female F344 rats and $B6C3F_1$ mice were given diets containing 0, 25,000 ppm or 50,000 ppm guar gum for 103 weeks. Mean body weights of the high-dose females were lower than those of the controls after week 20 for mice and week 40 for rats. No compound-related clinical signs or adverse effects on survival were observed. Feed consumption by dosed rats and mice of either sex was lower than that of controls. There were no non-neoplastic histopathological effects in either rats or mice that were treatment-related. The NOAEL for both rats and mice is 25,000 ppm. Using the fraction of body weight that rats and mice consume per day as food (0.05 and 0.13, respectively; U.S. EPA), the NOAELs corresponds to 1,250 mg/kg-day for rats and 3,250 mg/kg-day for mice (NTP, 1982). [Kl. score = 2]

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

Hydroxypropyl guar was not mutagenic to *S. typhiumurium* strains TA 98, TA 100, TA 1535, TA 1537, and TA 1538 in the absence of metabolic activation. In the presence of metabolic activation hydroxypropyl guar was mutagenic to S. typhimurium strains TA 98, TA 100, TA 1537, and TA 1538, but not to TA 1535 (Johnson et al., 2015).

In Vivo Studies

There are no studies available for hydroxypropyl guar.

G. Carcinogenicity

There are no studies available for hydroxypropyl guar.

H. Reproductive Toxicity

Oral

There are no studies available for hydroxypropyl guar.

Male and female Osborne-Mendel rats were fed diets containing 0, 1, 3, 4, 7.5, or 15% guar gum for 13 weeks before mating, during mating and throughout gestation. The daily intake for the female rats during gestation were 0, 700, 1,400, 2,700, 5,200, or 11,800 mg/kg-day. Fertility was unaffected by treatment. There were slightly fewer corpora lutea and implantations in the 15% dietary group, but implantation efficiency was unaffected. The NOAEL for reproductive toxicity is 5,200 mg/kg-day (Collins et al., 1987). [Kl. score = 2]

I. Developmental Toxicity

Oral

There are no studies available for hydroxypropyl guar.

Male and female Osborne-Mendel rats were fed diets containing 0, 1, 3, 4, 7.5, or 15% guar gum for 13 weeks before mating, during mating and throughout gestation. The daily intake for the female rats during gestation were 0, 700, 1,400, 2,700, 5,200, or 11,800 mg/kg-day. There were no deaths during the study. In the 15% group, the number of viable fetuses per litter were slightly reduced, but was not statistically significantly different from controls. The authors indicate that the reduction may have been an effect of the decreased number of corpora lutea because the number of resorptions was unaffected in this treatment group. There was no treatment-related effect on fetal development or sex distribution, and there was no teratogenic effects (Collins *et al.*, 1987). [Kl. score = 2]

Pregnant female rats were dosed by oral gavage with 0, 9, 42, 200, or 900 mg/kg guar gum on GD 6 to 15. There was no maternal or developmental toxicity at any dose level. The NOAEL for maternal and developmental toxicity is 900 mg/kg-day (FDRL, 1973). [Kl. score = 2]

Pregnant female CD-1 mice were dosed by oral gavage with 0, 8, 37, 170, or 800 mg/kg guar gum on GD 6 to 15. A significant number of deaths (6 out of 29) occurred in the 800 mg/kg dose group. There was indications of maternal toxicity in the surviving high-

dose dams. There was no developmental toxicity at any dose level. The NOAELs for maternal and developmental toxicity is 170 and 800 mg/kg-day, respectively (FDRL, 1973). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for guar gum follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

In a two-year NTP chronic bioassay, female rats and mice given 50,000 ppm guar gum in their feed had lower body weights. There were no treatment-related nonneoplastic lesions observed in either rats or mice. The NOAEL for this study is 25,000 ppm for rats and mice, which corresponds to 1,250 mg/kg-day for rats and 3,250 mg/kg-day for mice.

The NOAEL of 1,250 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 1,250/(10 x 10 x 1 x 1 x 1) = 1,250/100 = 13 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (13 x 70 x 0.1)/2 = 46 mg/L

B. Cancer

There are no carcinogenicity studies on hydroxypropyl guar. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Hydroxypropyl guar does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

No studies are available on the aquatic or terrestrial toxicity of hydroxypropyl guar. As the hydroxypropyl derivative of guar gum, it would be expected to have similar properties to a non-ionic polymer and exhibit low to potentially moderate acute toxicity to aquatic organisms.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Hydroxypropyl guar is a derivative of a naturally occurring polysaccharide from the guar plant or cluster bean; it expected to be readily biodegradable. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of hydroxypropyl guar ranges from 200,000 to 300,000 daltons. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

No aquatic toxicity data are available on hydroxypropyl guar. It is not possible to determine whether hydroxypropyl guar meets the toxicity criteria.

The overall conclusion is that hydroxypropyl guar is unlikely to be a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes.

Skin Contact
Remove contaminated clothing. Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person.

Notes to Physician
May cause asthma-like (reactive airways) symptoms.

B. FIRE FIGHTING INFORMATION

Extinguishing Media

Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus for fire fighting.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Avoid dust formation.

Environmental Precautions
No special environmental precautions required.

Steps to be Taken if Material is Released or Spilled
Sweep up and dispose in suitable, closed containers.

D. STORAGE AND HANDLING

General Handling
Avoid creating or inhaling dust.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard specifically for hydroxypropyl guar.

Engineering Controls
Ensure adequate ventilation.

Personal Protection Equipment

Respiratory Protection:
Respiratory protection is not required.

Hand Protection:

Handle with gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Hydroxypropyl guar is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

LACTOSE

This dossier on lactose does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of lactose in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): β-D-galacto-hexopyranosyl-(1→4)-α-D-glucose

CAS RN: 63-42-3

Molecular formula: $C_{12}H_{22}O_{11}$

Molecular weight: 342.3

Synonyms: Lactose; alpha-lactose; lactose anhydrous; β-D-galacto-hexopyranosyl-(1->4)-α-D-gluco-hexopyranose; β-D-galactopyranosyl-4)-α-D-glucopyranose; α-D-glucopyranose, 4-O- β-D-galactopyranosyl-

SMILES: O=CC(O)C(O)C(OC(OC(C(O)C1O)CO)C1O)C(O)CO

Lactose is a disaccharide sugar composed of galactose and glucose. It is naturally synthesized in the mammary gland of virtually all mammals, occurring in milk at levels between 1 and 7%. Commercially, lactose is extracted from the whey of cow's milk (whey is the residual liquid of milk following cheese and casein production) and is purified extensively to remove fats, proteins, vitamins and minerals (Baldrick and Bamford, 1997; Goodhart, 1994).

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Lactose

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White, crystalline powder	4	Lide (2007)
Melting Point	254°C	4	Lide (2007)
Density	1.59 g/cm^3 @ 20°C	4	Lide (2007)
Partition Coefficient (log	-5.03 (estimated)	-	EPA (2017)

K_{ow})			

III. ENVIRONMENTAL FATE PROPERTIES

No biodegradation studies were found on lactose. As a disaccharide of galactose and glucose sugars, lactose would be expected to be readily biodegradable. It would also not be expected to bioaccumulate or adsorb to sediments or soil.

Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} values from the molecular connectivity index (MCI) is 1 L/kg.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Lactose has essentially no acute toxicity by the oral route. Many of the findings from the oral rat studies on lactose are due to high dietary levels used in the studies, which results in a significant proportion reaching the cecum and colon where it is readily fermented by the intestinal microflora. Consequently, there is increased production of volatile fatty acids and lactic acid, and a lowering of the pH and increased osmotic pressure. These changes facilitate calcium absorption. Lactose is not genotoxic. Animal studies show no reproductive or developmental toxicity from dietary intake of lactose.

B. Pharmacokinetics/Metabolism

Following oral ingestion, lactose is readily hydrolyzed in the gastrointestinal tract to galactose and glucose by the enzyme lactase (Hansen, 1974; Williams, 1986). Lactase is a β-galactosidase found in the brush border of the intestinal epithelium. Once hydrolyzed, the monosaccharides are then readily absorbed. Lactose can also be hydrolyzed by other enzymes, such as acid β-galactosidase.

C. Acute Toxicity

The acute oral LD_{50} in rats has been reported to be >10,000 mg/kg (Baldrick and Bamford, 1997).

D. Irritation

No studies are available.

E. Sensitization

No studies are available.

F. Repeated Dose Toxicity

Oral

Male and female Wistar rats were fed diets containing 20% lactose for 12 weeks before mating, and during pregnancy and lactation. At weaning, the animals were fed the same diet and the study was terminated at week 130. There were low body weights; increased blood alkaline phosphatase and urinary calcium; decreased pH of cecum contents; enlargement/increased weight of the cecum; pelvic nephrocalcinosis of the kidneys; and increased proliferation of the bile ducts; and adrenal medullary hyperplasia. The LOAEL is 20,000 ppm lactose. Using 0.05 as the fraction of body weight that rats consume per day as food (U.S. EPA), the NOAELs corresponds to 1,000 mg/kg-day (Sinkeldam *et al.*, 1992a).

Similar findings were also observed in another study in which rats were fed 20% lactose in their diet for 130 weeks. Findings included loose feces (week one and two only); decreased pH of the feces; low body weights; increased food and water consumption; increased blood alkaline phosphatase and decreased bicarbonate; increased calcium concentration and excretion; reduced urinary pH; increased cecum weight; mineralization of the renal pelvis; increased incidence of basophilic cell foci in the adrenal medulla; and Leydig cell hyperplasia. The LOAEL is 20,000 ppm lactose. Using 0.05 as the fraction of body weight that rats consume per day as food (U.S. EPA), the NOAELs corresponds to 1,000 mg/kg-day (De Groot *et al.*, 1995).

Inhalation

A brief summary of inhalation studies conducted in rats, dogs, monkeys, and macaques showed no findings of toxicological significance (Baldrick and Bamford, 1997).

Dermal

No studies were available.

G. Genotoxicity

In Vitro Studies

Lactose was negative in an *in vitro* chromosomal aberration study with cultured human lymphocytes with or without metabolic activation (Sinkeldam *et al.*, 1992a).

In Vivo Studies

No studies are available.

H. Carcinogenicity

Male and female Wistar rats were fed diets containing 20% lactose for 12 weeks before mating, during mating, and during pregnancy and lactation. At weaning, the animals were fed the same diet and the study was terminated at week 130. There were increased adrenal medulla pheochromocytomas and Leydig cell tumors (males only) in the treated rats (Sinkeldam *et al.*, 1992a).

I. Reproductive Toxicity

In a multi-generation study, rats were fed diets containing 20% lactose over three successive generations. There were no adverse effects on fertility or reproductive performance. There was a slight decrease in the number of pups born alive, litter size at birth, viability index and pup weight for F_0 and F_1 offspring. There were signs of low body weights in the parental animals, and enlargement and increased weight of the cecum (Sinkeldam *et al.*, 1992b).

J. Developmental Toxicity

Pregnant mice were given 10,000 mg/kg lactose during gestation days 8-12. No maternal toxicity was observed and there were no effects on litter size, body weight on days 1 and 3, or neonate survival (Seidenberg *et al.*, 1986).

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for lactose follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

<u>Oral</u>

Many of the findings from the oral studies on lactose are due to high dietary levels used in the studies, which results in a significant proportion reaching the cecum and colon where it is readily fermented by the intestinal microflora. Consequently, there is increased production of volatile fatty acids and lactic acid, and a lowering of the pH and increased osmotic pressure. These changes facilitate calcium absorption.

Non-neoplastic adverse effects were noted in rats given 20% in their diet for 130 weeks (Sinkeldam *et al.*, 1992a; De Groot *et al.*, 1995). The LOAEL from these studies are 1,000 mg/kg-day. Since only one dose level was used in these studies, a NOAEL was not identified. The LOAEL of 1,000 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 10
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 1,000/(10 x 10 x 10 x 1 x 1) = 1,000/1,000 = <u>1.0 mg/kg-day</u>

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (1 x 70 x 0.1)/2 = <u>3.5 mg/L</u>

B. Cancer

Increased adrenal medulla pheochromocytomas and Leydig cell tumors were noted rats given lactose in their diet for 130 weeks (Sinkeldam *et al.*, 1992a). The adrenal medulla pheochromocytomas tumors from high dietary administration of low digestible carbohydrates (includes lactose) are thought to be secondary to increased calcium absorption from the intestine. This appears to be rat-specific; altered calcium

homeostasis does not appear to occur in humans ingesting carbohydrates such as lactose (Lynch *et al.*, 1996). Thus, the adrenal medulla pheochromocytomas are unlikely to be relevant to human. Increased Leydig cell tumors in male rats are also of questionable relevance to humans. Thus a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Lactose does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Lactose is expected to be of low toxicity concern to aquatic organisms based on QSAR modeling results.

B. Aquatic Toxicity

Acute Studies

No aquatic toxicity studies were found on lactose.

Using ECOSAR, the 96-hour LC_{50} in fish was estimated to be 93,396 mg/L; the 48-hour LC_{50} in *Daphnia* and the 96-hour EC_{50} in green algae exceed the estimated water solubility of 111,000 mg/L (U.S. EPA, 2017).

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for lactose follow the methodology discussed in DEWHA (2009).

PNEC water

No experimental results are available for lactose. Acute $E(L)C_{50}$ estimates using the QSAR model ECOSAR are: fish (93,396 mg/L), *Daphnia* (>111,000 mg/L), and algae (>111,000 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 93,396 mg/L for fish. The $PNEC_{water}$ is 93 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 59.6 mg/kg sediment wet weight.

The calculations are as follows:

$$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$$
$$= (0.82/1280) \times 1000 \times 93$$
$$= 59.6$$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed})/1000 \times BD_{solid}]$$
$$= 0.8 + [0.2 \times 0.04/1000 \times 2400]$$
$$= 0.82$$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$$Kp_{sed} = K_{oc} \times f_{oc}$$
$$= 1 \times 0.04$$
$$= 0.04$$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for lactose calculated from EPISUITE™ using lthe MCI is 1.0 L/kg .
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 1.24 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.02/1500) \times 1000 \times 93$
$= 1.24$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 1 \times 0.02$
$= 0.02$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for lactose calculated from EPISUITE™ using the MCI is 1.0 L/kg .
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

No biodegradation data are available on lactose. Lactose is a disaccharide found in milk and consists of D-galactose and D-glucose sugars. it is expected to be readily biodegradable; therefore, it does not meet the screening criteria for persistence.

Lactose is a disaccharide that has an estimated log K_{ow} of -5. It is water-soluble and is rapidly metabolized by enzymes. It is not expected to bioaccumulate.

The estimated acute $E(L)C_{50}$ value in fish is >1 mg/L. Thus it does not meet the screening criteria for toxicity.

The overall conclusion is that lactose is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

Eye Contact
Immediately flush eyes with plenty of water.

Skin Contact
Wash with soap and water.

Inhalation
If inhaled, remove from area to fresh air. If not breathing, give artificial respiration. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Do not induce vomiting. Rinse mouth with water and then drink a small amount of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Combustible dust. May form dust explosion hazard in air. May emit toxic fumes under fire conditions.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Use appropriate protective equipment. Avoid creating and breathing dust.

Environmental Precautions

No special precautions needed.

Steps to be Taken if Material is Released or Spilled

Scoop and remove.

D. STORAGE AND HANDLING

General Handling

Avoid creating or inhaling dust. Take precautionary measures against static charge.

Storage

Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational standard for lactose.

Engineering Controls

Use in a well-ventilated area. Avoid creating dust. Take precautionary measures against static charge.

Personal Protection Equipment

Respiratory Protection: Respiratory protection is not required.

Hand Protection: Use gloves.

Skin Protection: Body protection must be chosen depending on activity and possible exposure.

Eye Protection: Safety glasses with side-shields.

Other Precautions: Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Lactose is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods Code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

HYDROCARBONS, C12-C15, N-ALKANES, ISOALKANES, CYCLICS, <2% AROMATICS

This dossier on hydrocarbons, C12-C15, n-alkanes, isoalkanes, cyclics, <2% aromatics (C12-C15 aliphatic hydrocarbons (<2% aromatics)) does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of C12-C15 aliphatic hydrocarbons (<2% aromatics) in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained primarily from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Hydrocarbons, C12-C15, n-alkanes, isoalkanes, cyclics, <2% aromatics

CAS RN: 64742-47-8 [CAS No. 869062-45-3; EC No. 920-107-4]

Historically, hydrocarbons, C12-C15, n-alkanes, isoalkanes, cyclics, <2%aromatics was included within the CAS RN 64742-47-8 for distillates, (petroleum), hydrotreated, light. This CAS RN is broadly defined as "A complex combination of hydrocarbons obtained by treating a petroleum fraction with hydrogen in the presence of a catalyst. It consists of hydrocarbons having carbon number predominantly in the range of C9 to C16 and boiling in the range of approximately 150^{o}C to 290^{o}C (302^{o} to 554^{o}F)." This CAS RN can include hydrocarbon streams and solvents that can vary widely in their compositions, processing, and classifications. The EU Hydrocarbon Solvents Producers Association (HSPA), for the purposes of REACH registrations, established more precise definitions for hydrocarbon solvents and established a new substance identification and naming convention.[1] Hydrocarbons, C12-C15, n-alkanes, isoalkanes, cyclics, < 2% aromatics would have the CAS RN 869062-45-3 and EC. No. 920-107-4 and would be within the HSPA category for C9-C14 Aliphatics ($\leq$2% aromatics).

Molecular formula: Not available (UVCB substance)

Molecular weight: Not available (UVCB substance)

Synonyms: Hydrocarbons, C12-C15, n-alkanes, isoalkanes, cyclics, <2% aromatics; distillates, petroleum, hydrotreated, light; C12-C15 aliphatic hydrocarbons (<2% aromatics)

SMILES: Not available (UVCB substance)

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of C12-C15 Aliphatic Hydrocarbons (<2% Aromatics)

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

There are no biodegradation data on C11-C15 aliphatic hydrocarbons (<2% aromatics). However, a hydrocarbons, C11-14, n-alkanes, isoalkanes, cyclics (<2% aromatics) hydrocarbon fluid was shown to be readily biodegradable. The C12-C15 aliphatic hydrocarbons (<2% aromatics) are expected to highly absorb to sediment and soil. The C12-C15 aliphatic hydrocarbons (<2% aromatics) is expected to have constituents with the potential to bioaccumulate.

B. Biodegradation

No biodegradation data are available on C12-C15 aliphatic hydrocarbons (<2% aromatics).

In an OECD 301F test, degradation of hydrocarbons, C11-14, n-alkanes, isoalkanes, cyclics (<2% aromatics) hydrocarbon fluid was 69% after 28 days (ECHA) [Kl. score = 1]. The results indicate that this substance is readily biodegradable even though it did not meet the 10-day window because the criterion does not apply to multi-component substance when assessing their ready biodegradability (ECHA) [Kl. score = 1].

D. Environmental Distribution

C12-C15 aliphatic hydrocarbons (<2% aromatics) and C9-C14 aliphatic hydrocarbons (≤2% aromatics) are UVCB substances. The standard tests to determine the K_{oc} are for single substances and not for UVCB substances. Therefore, a K_{oc} value for C12-C15 aliphatic hydrocarbons (<2% aromatics) was not determined.

The calculate K_{oc} values for linear aliphatic hydrocarbons dodecane (C12) and tetradecane (C14) are 110,000 and 759,000 L/kg, respectively, using SPARC v4.2 program in the Concawe Library of Petrorisk (ECHA). These values suggest that C12-C15 aliphatic hydrocarbons (<2% aromatics) will highly absorb to sediment and soil.

E. Bioaccumulation

C12-C15 aliphatic hydrocarbons (<2% aromatics) and C9-C14 aliphatic hydrocarbons (≤2% aromatics) are UVCB substances. The calculated BCF values for linear aliphatic hydrocarbons undecane (C11), dodecane (C12), and tetradecane (C14) are 337.8, 790.9, and 962.9 L/kg, respectively using the BCFWIN V2.16 model within EPISuite 3.12. The predicted BCFs for hydrocarbons are considered to be generally overly conservative because biotransformation is not quantitatively taken into account. For these linear aliphatic hydrocarbons, the values indicate that they are not expected to bioaccumulate. However, both C12-C15 aliphatic hydrocarbons (<2% aromatics) and C9-C14 aliphatic hydrocarbons (≤2% aromatics) contain branched and cyclic aliphatic hydrocarbons that are expected to have a greater potential to bioaccumulate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The acute toxicity of C9-C14 aliphatic hydrocarbons (≤2% aromatics) is low by the oral, dermal, and inhalation route. It is, however, an aspiration hazard. C9-C14 aliphatic hydrocarbons (≤2% aromatics) are neither skin nor eye irritants or a dermal sensitizer. Repeated inhalation exposure of rats to a C9-C14 aliphatic (≤2% aromatic) hydrocarbon fluid showed no target organ effects; oral exposures to very high doses of these hydrocarbons showed irritation to the gastrointestinal tract and effects in the liver that likely represent an adaptive response to the metabolism of the hydrocarbons and not a toxic response. C9-C14 aliphatic hydrocarbons (≤2% aromatics) are not genotoxic; nor do they exhibit and evidence of reproductive or developmental toxicity in rats.

B. Acute Toxicity

The oral LD_{50} in rats for C9-C14 aliphatic, ≤2% aromatic hydrocarbon fluids is >5,000 mg/kg (ECHA) [Kl. score = 2.

The 4-hour inhalation LC_{50} in rats for C9-C14 aliphatic, ≤2% aromatic hydrocarbon fluids is > 4,951 mg/m^4 (ECHA) [Kl. scores =1 and 2].

The dermal LD_{50} in rats for C9-C14 aliphatic, ≤2% aromatic hydrocarbon fluids is >5,000 mg/kg (ECHA) [Kl. score = 2].

C. Irritation

C9-C14 aliphatic, ≤2% aromatic hydrocarbon fluids are neither skin nor eye irritants (ECHA) [Kl. scores = 1 and 2].

D. Sensitization

C9-C14 aliphatics, <2% aromatic hydrocarbon fluids were not skin sensitizers when tested in guinea pig maximization tests (ECHA) [Kl. score = 2].

A C9-C14 aliphatic, <2% aromatic hydrocarbon fluid showed no indication of skin sensitization in a human repeated insult patch test (ECHA).

E. Repeated Dose Toxicity

Oral

Male and female rats were dosed by oral gavage with 0, 500, 2,500 or 5,000 mg/kg with a C9-C14 aliphatic, <2% aromatic hydrocarbon fluid 7 days/week for 13 weeks. Additional groups of animals were dosed with 0 or 5,000 mg/kg for 13 weeks, followed by a 4-week recovery period. There were dose-related changes in the hematology and serum chemistry parameters which were consistent with changes seen in the liver. Hepatocellular hypertrophy (liver cell enlargement) were seen in both males and females in all dose groups and were reversible. The liver effects were not considered to be an indication of toxicity but an adaptive response due to the metabolism of the hydrocarbons. There were also mucosal thickening and other signs of irritation to the stomach and anus, which appeared to be the direct result of high-dose intubation of a locally irritating material. All treatment-related effects were reversible within the 4-week recovery period. The NOAEL for systemic effects in this study is considered to be 5,000 mg/kg-day (ECHA) [Kl. score = 1].

Inhalation

Male and female rats were exposed by inhalation to 0, 2,600, 5,200, or 10,400 mg/m^3 of a C9-C14 aliphatic (<2% aromatic) hydrocarbon fluid, 6 hours/day, five days/week for 13 weeks. There was no mortality or effects in either the hematology or the serum chemistry parameters. The male rats at all dose levels had increased liver and kidney weights; male heart weights were also increased at 10,400 mg/m^3; and kidney weights were increased in the 10,400 mg/m^3 group. Kidney effects indicative of alpha-2u-globulin nephropathy was observed at all dose levels. There were no other effects that were considered to be treatment-related. The alpha-2u-nephropathy in the male rats was not considered to be relevant to humans; for the organ weight changes other than the male kidneys, there were no corresponding histopathologic changes. The NOAEL for this study is 10,400 mg/m^3, the highest exposure concentration tested (ECHA) [Kl. score = 1].

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

The key *in vitro* genotoxicity studies on C9-C14 aliphatic hydrocarbons (≤2% aromatics) are presented in Table 2.

Table 2: *In vitro* Genotoxicity Studies on C9-C14 Aliphatic Hydrocarbons (≤2% Aromatics)

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	-	-	1	ECHA
Mammalian cell gene mutation (Chinese hamster V 79 cells)	-	-	2	ECHA
Chromosomal aberration (human lymphocytes)	-	-	1	ECHA

*+, positive; -, negative

In Vivo Studies

In two separate studies involving two different C9-C14 aliphatic (<2% aromatic) hydrocarbon fluids, male and female CD-1 mice were given a single oral gavage dose at concentrations of 0, 1,250, 2,500, or 5,000 mg/kg. The frequency of micronucleated polychromatic erythrocytes was not significantly increased in the treated mice compared to that in the controls (ECHA) [Kl. score = 1].

In two separate dominant lethal studies involving two different C9-C14 aliphatic (<2% aromatic) hydrocarbon fluids, male rats were exposed for 6 hours/day for five consecutive days to exposure concentrations of 0, 300, or 900 ppm. There was no evidence of a mutagenic response in the treated rats (ECHA) [Kl. score = 2].

G. Carcinogenicity

No carcinogenicity studies are available on the C9-C14 aliphatic (<2% aromatic) hydrocarbon fluids.

H. Reproductive Toxicity

A C9-C14 aliphatic (<2% aromatic) hydrocarbon fluid was tested in a combined repeated dose toxicity study with a reproductive/developmental toxicity screening test (OECD 422). Male and female SD rats were given oral gavage doses of 0, 25, 150, or 1,000 mg/kg-day. There was no

indication of reproductive toxicity at any dose level. The NOAEL for reproductive toxicity is 1,000 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 1].

A C9-C14 aliphatic (<2% aromatic) hydrocarbon fluid was tested in a reproductive/developmental toxicity screening test (OECD 421). Male and female SD rats given oral gavage doses of 0, 100, 300, or 1,000 mg/kg-day. There was no indication of reproductive toxicity or any effects on the endocrine system at any dose level. The NOAEL for reproductive toxicity is 1,000 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 1].

I. Developmental Toxicity

A C9-C14 aliphatic (<2% aromatic) hydrocarbon fluid was tested in a rat pre-natal developmental toxicity study. Pregnant female rats were exposed by inhalation to 0, 300 or 900 ppm for 6 hours/day during gestation days 6 to 15. There was no evidence of maternal or developmental toxicity at either exposure level. The NOAEL for this study is 900 ppm (ECHA) [Kl. score = 1].

Another C9-C14 aliphatic (<2% aromatic) hydrocarbon fluid was tested in a rat pre-natal developmental toxicity study. Pregnant female rats were exposed by inhalation to 0, 300 or 900 ppm for 6 hours/day during gestation days 6 to 15. There was no evidence of maternal or developmental toxicity at either exposure level. The NOAEL for this study is 900 ppm (ECHA) [Kl. score = 1].

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for C12-C15 aliphatic hydrocarbons (<2% aromatics) follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

A 13-week oral gavage study was conducted on a C9-C14 aliphatic (<2% aromatic) hydrocarbon fluid in rats. There were no adverse effects at 5,000 mg/kg-day, the highest dose tested. The NOAEL of 5,000 mg/kg-day will be used to derive the oral reference dose and the drinking water guidance value for C12-C15 aliphatic hydrocarbons (<2% aromatics).

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 3

UF_D (database uncertainty) = 1

Oral RfD = 5,000/(10 x 10 x 1 x 3 x 1) = 5,000/300 = 17 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (17 x 70 x 0.1)/2 = 60 mg/L

B. Cancer

No carcinogenicity studies are available on C9-C14 aliphatic (<2% aromatic) hydrocarbon fluids. Thus, a cancer reference value was not derived for C12-C15 aliphatic hydrocarbons (<2% aromatics).

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

C12-C15 aliphatic hydrocarbons (<2% aromatics) do not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

C12-C15 aliphatic hydrocarbons (<2% aromatics) has a low acute toxicity concern to aquatic life.

B. Aquatic Toxicity

Acute Studies

There are no aquatic toxicity data on C12-C15 aliphatic hydrocarbons (<2% aromatics). Table 3 lists the results of acute aquatic toxicity studies conducted on a C11-C14 aliphatic hydrocarbon fluid (<2% aromatics).

Table 3: Acute Aquatic Toxicity Studies on C11-C14 Aliphatic Hydrocarbon Fluid (<2% Aromatics)*

Test Substance	Test Species	Endpoint	Results (mg/L) [WAF]	Kl. score
C11-C14, n-alkanes, isoalkanes, cyclics (<2% aromatics)	*Oncorhynchus mykiss*	96-h LL_{50}	>1,000	1
C11-C14, n-alkanes, isoalkanes, cyclics (<2% aromatics)	*Daphnia magna*	48-h LL_{50}	>1,000	1
C11-C14, n-alkanes, isoalkanes, cyclics (<2% aromatics)	*Pseudokirchnerella subcapitata*	72-h LL_{50} 72-hr NOELR	>1,000	1

*All studies used the water accommodated fractions (WAFs) of the test substance.

Chronic Studies

The value for NOELRs were estimated by QSAR model – Petrotox. This model combines a partitioning model used to calculate the aqueous concentration of hydrocarbon components with the Target Lipid Model used to calculate acute and chronic toxicity of non-polar narcotic chemicals. Petrotox computes toxicity based on the summation of the aqueous-phase concentrations of hydrocarbon block(s) that represent a hydrocarbon substance and membrane-water partition coefficients that describe the partitioning of the hydrocarbons between the water and organisms.

The 28-day NOELR (No-Observed-Effect-Loading-Rate) for hydrocarbons, C12-15, aliphatic hydrocarbons (<2% aromatics) in freshwater fish is estimated to be >1,000 mg/L based on growth (ECHA) [Kl. score = 2].

The 28-day NOELR (No-Observed-Effect-Loading-Rate) for hydrocarbons, C12-15, aliphatic hydrocarbons (<2% aromatics) in freshwater invertebrates is estimated to be >1,000 mg/L based on reproduction (ECHA) [Kl. score = 2].

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for C12-C15 aliphatic hydrocarbons (<2% aromatics) follow the methodology:

PNEC water
Using the QSAR model PETRORISK v7.04, the estimated $PNEC_{water}$ value for C11-15-iso- is 0.001 mg/L (CONCAWE) [Kl. score = 2].

PNEC sediment
Using the QSAR model PETRORISK, v7.04 the estimated $PNEC_{sediment}$ value for C11-15-iso- range from 42 to 260 mg/kg soil wet weight (CONCAWE), depending on the composition of the hydrocarbon classes (n- or iso-paraffins and type of cyclic paraffins) (CONCAWE) [Kl. score = 2].

PNEC soil
Using the QSAR model PETRORISK v7.04, the estimated $PNEC_{sediment}$ value for C11-15-iso- is 17 to 100 mg/kg soil wet weight (CONCAWE), depending on the composition of the hydrocarbon classes (n- or iso-paraffins and type of cyclic paraffins) (CONCAWE) [Kl. score = 2].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Hydrocarbons, C11-14, n-alkanes, isoalkanes, cyclics (<2% aromatics) hydrocarbon fluid was readily biodegradable. Thus, C12-C15 aliphatic hydrocarbons (<2% aromatics) is not expected to meet the screening criteria for persistence.

C12-C15 aliphatic hydrocarbons (<2% aromatics) is an UVCB substance that contains constituents that have the potential to bioaccumulate. Thus, C12-C15 aliphatic hydrocarbons (<2% aromatics) meets the screening criteria for bioaccumulation.

Hydrocarbons, C11-14, n-alkanes, isoalkanes, cyclics (<2% aromatics) hydrocarbon fluid did not exhibit acute toxicity to fish, invertebrates, or algae at WAF up to 1,000 mg/L. Thus, C12-C15 aliphatic hydrocarbons (<2% aromatics) is not expected to meet the screening criteria for toxicity.

The overall conclusion is that C12-C15 aliphatic hydrocarbons (<2% aromatics) is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Aspiration Toxicity Category 1

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. If irritation occurs, get medical attention.

Skin Contact
Wash the contaminated area of with soap and water. Remove and isolate contaminated clothing. Launder contaminated clothing before reuse.

Inhalation
Move person to fresh air. If respiratory irritation, dizziness, nausea, or unconsciousness occurs, seek immediate medical assistance. Give artificial respiration if victim is not breathing.

Ingestion
Do not induce vomiting. Get medical attention immediately.

Notes to Physician
If ingested, material may be aspirated into the lungs and may cause chemical pneumonitis. Treat appropriately.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Use water spray or fog, foam, dry chemical or carbon dioxide. Do not use straight streams of water.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: carbon monoxide, carbon oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Isolate area. Keep unnecessary and unprotected personnel from entering the area. Use personal protective clothing. Ensure adequate ventilation. Wear respiratory protection if ventilation is inadequate. Do not breath mist, vapors, or spray Avoid contact with skin, eye, and clothing.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Pick up with non-combustible absorbent material and transfer to a container for chemical waste. For large amounts: dike spillage and pump off product into container for chemical waste. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling
Avoid breathing vapor or aerosol. Keep away from open flames, hot surfaces and sources of ignition. Provide sufficient ventilation in work area.

Storage
Keep container tightly closed and in a dry, well-ventilated place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure standard for C12-C15 aliphatic hydrocarbons (<2% aromatics).

Engineering Controls
Use adequate ventilation to control air-borne concentrations.

Personal Protection Equipment

Respiratory Protection:
If workers are exposed to concentrations at a level that is not adequate to protect work health, they must use appropriate, certified respirators. The following type of respirator should be considered for this material: particulate, dust or mists. For high airborne concentrations, use an approved supplied-air respirator, operated in positive pressure mode.

Hand Protection:
Use gloves chemically resistant to this material. Consult the SDS for appropriate glove barrier materials.

Skin Protection:

Use protective clothing chemically resistant to this material. Selection of specific items such as face shield, boots, apron, or full body suit will depend on the task.

Eye protection*:*
Use chemical goggles.

Other Precautions:
Wash hands, forearms, and face thoroughly after handling chemical products, before eating, smoking, and using the lavatory and at the end of the working period. Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

C12-C15 aliphatic hydrocarbons (<2% aromatics) is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

METHANOL

This dossier on methanol does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of methanol in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained primarily from the OECD-SIDS documents on methanol (OECD, 2004a, b), and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): Methanol

CAS RN: 67-56-1

Molecular formula: CH_4O

Molecular weight: 32.04

Synonyms: Methyl alcohol, carbinol, wood spirits, wood alcohol, methylol, wood, columbian spirits, colonial spirit, columbian spirit, methyl hydroxide, monohydroxymethane, pyroxylic spirit, wood naphtha.

SMILES: CO

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Physico-Chemical Properties of Methanol

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Colourless liquid	2	ECHA
Melting Point	-97.8°C	2	ECHA
Boiling Point	64.7°C	2	ECHA
Density	0.79 g/cm^3	2	ECHA
Vapour Pressure	169.27 hPa	2	ECHA
Partition Coefficient (log Pow)	-0.77	2	ECHA
Water Solubility	>1,000 g/L [miscible]	2	ECHA
Flash Point	9.7°C	2	ECHA
Auto flammability	455°C @ 1013 hPa	2	ECHA
Viscosity	0.544 – 0.59 mPa s (dynamic)	2	ECHA
Henry's Law Constant	0.461 Pa m^3/mol	2	ECHA

Methanol is a highly flammable liquid.

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Methanol is readily bioavailable. It has a low adsorptive capacity to soils and is unlikely bioaccumulate.

B. Biodegradation

Methanol is readily biodegradable. In a closed bottle test using seawater, there was 84% and 95% degradation after 10 and 20 days, respectively (Price et al., 1974; ECHA). [Kl. score = 2]

In a soil test using [^{14}C]-methanol, there was 53.4% degradation under aerobic conditions after 5 days, as measured by CO_2 evolution; and 46.3% degradation under anaerobic conditions after 5 days, as measured by CO_2 evolution (Scheunert et al., 1987; ECHA). [Kl. score = 2]

C. Environmental Distribution

Adsorption/desorption

The adsorption of methanol was investigated in three different soil types at 6°C (Lokke, 1984; ECHA). There was slight adsorption with the sandy soils tested (percentage organic matter of 0.09% and 0.1% in the samples) and with the clay soil (percentage organic matter was 0.22%). Methanol solutions of concentrations of 0.1, 1.0, 9, and 90 mg/L were used in one-hour exposure adsorption studies; the K_{oc} values were between 0.13 and 0.61 for all soil types and at all concentrations.

D. Bioaccumulation

The BCF of methanol in *Cyprinus carpio* was determined to be 1.0 (Gluth et al. 1985); in *Leuciscus idus*, the BCF was <10 (Hansch and Leo, 1985; Freitag et al. 1985).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Methanol has a low order of acute toxicity (as measured by lethality) by the oral, dermal, and inhalation routes of exposure, as measured by lethality. Sublethal doses, however, have been shown to produce central nervous system (CNS) effects and ocular injury that may result in blindness. This effect has been seen in primates but not in rodents, and is considered to be due to the differences in blood levels of the metabolites. Acute toxicity in humans is characterized in a well-defined pattern, that includes CNS effects, ocular symptoms, and acidosis. Methanol is not irritating to the skin, but it is slightly irritating to the eyes. Repeated exposures by the oral and inhalation routes have not resulted in any systemic toxicity to rodents. Methanol was not carcinogenic to rats or mice in chronic inhalation studies. Increased tumours from methanol in drinking water were reported by Soffritti et al. (2002); however, there are methodological problems with this study and questions have been raised about the validity of the results. Methanol is generally inactive in a variety of *in vitro* and *in vivo* genotoxicity studies. Conflicting results have been obtained concerning the effect of methanol on testicular hormones in rats; nevertheless, methanol does not appear to a male reproductive toxicant. The primate data indicates that methanol is unlikely to be a reproductive hazard in females. Methanol causes developmental effects at very high exposure levels in both rats (≥ 10,000 ppm) and mice (≥ 2000 ppm). There is also some evidence that it is a developmental neurotoxicant in rodents, but not in primates.

B. Toxicokinetics and Metabolism

Several reviews on the metabolism and pharmacokinetics of methanol are available (Kavet and Nauss, 1990; Liesivuori and Savolainen, 1991; Tephly, 1991; IPCS, 1997; OECD, 2004a, b). Methanol is first oxidized to formaldehyde. This initial metabolic step involves different enzymes in rats than in primates and humans, although the rates are similar. A catalase–peroxidase system is primarily responsible for the initial step in rats, whereas alcohol dehydrogenase plays a major role in humans

and monkeys. Methanol oxidation can also occur via hepatic microsomal oxidation involving the cytochrome P450 system.

Formaldehyde is converted to formic acid, which is converted to formate and a hydrogen ion. Conversion to formic acid is a two-step process, the second step is irreversible. In the first reaction, formaldehyde combines with reduced glutathione (GSH) to form S-formylglutathione. This is mediated by an NAD-dependent formaldehyde dehydrogenase. In the second reaction, thiolase catalyzes the hydrolysis of S-formylglutathione to form formic acid and GSH. A folate-dependent pathway in the liver is responsible for formate metabolism in both rats and primates. Formate first forms a complex with tetrahydrofolate (THF) that is sequentially converted to 10-formyl-THF (by formyl-THF synthetase) and then to CO2 (by formyl-THF dehydrogenase). THF is derived from folic acid in the diet and is also regenerated in the folate pathway. Although the folate pathway metabolizes formate in both rats and monkeys, rats use the pathway more efficiently.

The dermal uptake rate of liquid methanol applied to the forearm of human volunteers was 11.5 mg/cm^2/hr (Dutkiewicz et al., 1980). The dermal flux for methanol in human skin (epidermis) *in vitro* is 8.29 mg/cm^2/hr (Schueplein and Blank, 1971). When 12 human volunteers immersed one hand into a vessel containing neat methanol for up to 16 min, the maximum methanol concentration in blood was reached 1.9 $\pm$ 1.0 hr after exposure. Delivery rates from the skin into blood lagged exposure by 0.5 hours, and methanol continued to enter the blood for 4 hours following exposure. The average derived dermal absorption rate absorption rate was 8.1 $\pm$ 3.7 mg/cm^2/hr. The authors calculated that the maximum concentration of methanol in blood following immersion of one hand in methanol for approximately 20 min is comparable to that reached following inhalation exposures to 200 ppm methanol (Batterman and Franzblau, 1997).

C. Acute Toxicity

The acute oral LD_{50} for rats range from 6,200 to 13,000 mg/kg (Kimura et al., 1971; Welch and Slocum, 1943; Deichman and Mergard, 1948; Smyth et al., 1941). The acute dermal LD_{50} for rabbits was reported to be 20 mL/kg (Rowe and McCollister 1982). The inhalation 4- and 6-hour LC_{50} values in rats are 128.2 and 87.5 mg/L, respectively (BASF, 1980a, b). Sublethal doses, however, produce CNS effects and ocular injury that may result in blindness. This effect has been seen in primates, but not in rodents, and has been attributed to the differences in blood levels of the metabolite, formic acid.

Methanol is metabolized to formate, which is considered to be the ultimate toxicant in acute methanol intoxication in humans. Acute methanol toxicity in humans is characterized by CNS depression, followed by acidosis and ocular injury. Generally, transient CNS effects appear above methanol levels of 200 mg/L and serious ocular symptoms appear above 500 mg/L (OECD, 2004). This blood concentration can transiently be achieved in an adult person (70 kg) by ingestion of 0.4 ml methanol/kg (approximately 0.32 mg/kg). The minimal acute methanol dose to humans that can result in death is considered to be 300 to 1,000 mg/kg by ingestion, and fatalities have occurred in untreated patients with initial methanol blood levels in the range of 1500-2000 mg/L (OECD, 2004). However, such high blood methanol levels able to cause death are not likely to be achieved through inhalation exposure.

D. Irritation

Methanol is not irritating to the skin of rabbits (BASF, 1975), but it is slightly irritating to the eyes of rabbits (BASF, 1975).

E. Sensitization

Methanol was not considered a skin sensitiser to guinea pigs (BASF, 1979).

F. Repeated Dose Toxicity

Oral

Male and female Sprague–Dawley rats were dosed by oral gavage with 0, 100, 500, or 2,500 mg/kg of methanol for 90 days. There were no differences in body weight gain and food consumption between treated and control animals. Brain weights were decreased in both sexes in the 2,500 mg/kg dose group. Elevated serum glutamic pyruvate transaminase and alkaline phosphatase were noted in the 2,500 mg/kg dose group, but there were no adverse treatment-related effects in the gross pathology and histopathological evaluation. The NOAEL is 500 mg-kg-day (USEPA, 1986).

Sprague-Dawley rats were given in their drinking water 0, 500, 5,000 or 20,000 ppm methanol for 104 weeks, and then the animals were maintained until natural death. The study was conducted by the Ramazzini Foundation which uses their own testing guideline for carcinogenicity studies and not an internationally accepted guideline. Treatment with methanol did not decrease survival. However, there was considerable early mortality; by 18 months, 30% of the male controls had died. In females, there were no differences in survival between controls and treated groups. There was still more early mortality in the females than expected, but it was less pronounced that the males. There was no obvious effect of methanol exposure on water consumption. The 20,000 ppm males and females weighed more than the controls (up to 14% and 7%, respectively) throughout the study. The 5,000 ppm females also weighed more (4%) than the controls at 24 months, but not at earlier time points. There were no body weight differences between the remaining treatment groups and the controls. The calculated methanol doses based on water intake were: 0, 55, 542, and 1,840 mg/kg-day for males; and 0, 67, 630, and 2,250 mg/kg-day for females. Nearly all rats in all dose groups had some pathology in the lung. The finding of lung pathology was consistent regardless of the age at death (not an old age response). The lung pathology included inflammation, dysplasia, or tumours). Lung pathology was present in 70-100% of the first 10% of deaths in each group, including controls (70, 80, 80, 100% in males; and 90, 90, 100, 100% in females at 0, 500, 5,000, and 20,000 ppm). The degree of inflammation in the lungs is difficult to assess because no other lung information was recorded for the rats when a neoplasm in the lung was recorded (Soffritti et al., 2002; Cruzan, 2009; USEPA, 2013a). [Kl. score = 3]

Inhalation

Cynomolgus monkeys or Sprague–Dawley rats were exposed by inhalation to 0, 500, 2,000, or 5,000 ppm (0, 660, 2,620, or 6,552 mg/m3) methanol for 6 h/day, 5 days/ week for 4 weeks. There was no mortality and no clinical signs of toxicity among the monkeys, but there a few signs of eye and nose irritation in the rats. No differences were seen between treated and control groups in body weight gain and organ weights, with the exception being decreased absolute adrenal weight in the 5,000 ppm female monkeys and increased relative spleen weights in the 2,000 ppm female rats. These changes were not considered by the authors to be of biological significance. There were no treatment-related effects on the ophthalmoscopy, gross pathology or histopathology. The NOAEL for this study is 5,000 ppm (6,552 mg/m^3) (Andrews et al., 1987). [Kl. score = 4]

Groups of four male rats were exposed by inhalation to 0, 200, 2000, or 10,000 ppm (o, 262, 2,621, or 13,104 mg/m3) methanol for 6 hours/day, 5 days/week for 1, 2, 4, or 6 weeks. Additional groups of animals were exposed for 6 weeks followed by a 6-week recovery period. Evaluation of a number of parameters including lung weights, surfactant levels, and enzyme activities did not reveal any adverse effects on the lung. No histopathological examinations were performed (White et al. 1983). [Kl. score = 2]

Male and female F344 rats were exposed by inhalation to 0, 10, 100, or 1,000 ppm methanol 19.5 hours/day, 7 days/week for 104 weeks. The average methanol doses were: 0, 3.7, 37, and 369 mg/kg-day in males; and 0, 5.9, 60, and 599 mg/kg-day for females. There were no treatment-related clinical

signs and no effect on survival or food consumption. Lower body weights were seen in the 1,000 ppm females beginning around day 259, but after day 574, there was no difference from controls. Body weights in males were similar across all groups. There were no treatment-related effects on urinalysis, hematology, or clinical biochemistry. Nor was there any treatment-related effects on organ weights or gross lesions. Histopathologic examination showed no statistically significant differences between treated and control animals (NEDO, 1985a). [Kl. score = 2]

Male and female B6C3F1 mice were exposed by inhalation to 0, 10, 100, or 1,000 ppm methanol 19.5 hours/day, 7 days/week for 78 weeks. The average methanol doses were: 0, 9.8, 95, and 947 mg/kg-day in males; and 0, 8.1, 106, and 1,071 mg/kg-day for females. There were no treatment-related clinical signs and no effect on survival or body weight. Food consumption was decreased slightly between months 7 and 12 in the 1,000 ppm females. Urinalysis, hematology, and clinical biochemistry were similar across all groups. No differences were seen in organ weights, gross lesions, or histopathology between treated and control mice. (NEDO, 1985b). [Kl. score = 2]

Dermal

No studies were identified.

G. Genotoxicity

In Vitro Studies

Methanol was not mutagenic to *Salmonella* strains TA97, TA98, TA100, TA1535, TA1537, and TA1538 in *in vitro* bacterial mutation assays with or without metabolic activation (De Flora et al., 1984a, b; Florin et al., 1980; Gocke et al.,1981). Equivocal results were obtained with *Salmonella* strain TA102 in the presence of metabolic activation (De Flora et al. 1984b). Methanol was not mutagenic in a DNA-repair test using various strains of *Escherichia coli* WP2 (De Flora et al. 1984a) and in a forward mutation assay using *Schizosaccharomyces pombe* (Abbondandolo et al. 1980).

Methanol did not induce micronuclei in Chinese hamster lung V79 cells in vitro (Lasne et al., 1984). Methanol was mutagenic in the mouse lymphoma assay in the presence of metabolic activation (McGregor et al., 1985), but it was not mutagenic in a Basc test or in a Drosophila, sex-linked, recessive lethal mutation assay (Gocke et al., 1981). Treatment of primary cultures of Syrian golden hamster embryo cells with methanol did not lead to cell transformation (Heidelberger et al., 1983).

In Vivo Studies

Male C57BL/6J mice were exposed by inhalation 0, 800 or 4,000 ppm methanol, 6 hours/day for five days. There were no increased frequencies of micronuclei in blood cells; sister chromatid exchanges, chromosomal aberrations, or micronuclei in lung cells; or synaptosomal complex damage in spermatocytes (Campbell et al., 1991).

Normal or folate-deficient mice were given four daily intraperitoneal injections of up to 2,500 mg/kg of methanol. There was no increase in micronucleated erythrocytes in the treated mice compared to the controls (O'Loughlin et al., 1992).

Male and female NMRI mice were given a single intraperitoneal injection of 0, 1,920, 3,200, or 4,480 mg/kg methanol. There was no increase in micronuclei was observed in the bone marrow at any dose level (Gocke et al., 1981).

H. Carcinogenicity

The carcinogenicity studies conducted on methanol were reviewed by Cruzan (2009) and by the USEPA (2013).

Oral

Male and female SD rats were given in their drinking water 0, 500, 5,000, or 20,000 ppm methanol for 104 weeks. This study was conducted by the Ramazzini Foundation, which uses a unique methodology and not the standardized international testing guidelines. There was excessive early mortality, and lung pathology (inflammation, dysplasia, or tumours) was present in 87 to 94% of those dying anytime during the study. An increase in lympho-immunoblastic lymphomas was reported (Soffritti et al., 2002; Cruzan, 2009; USEPA, 2013). [Kl. score = 3]

Inhalation

Male and female F344 rats were exposed by inhalation to 0, 10, 100, or 1,000 ppm methanol 19.5 hours/day, 7 days/week for 104 weeks. The average methanol doses were: 0, 3.7, 37, and 369 mg/kg-day in males; and 0, 5.9, 60, and 599 mg/kg-day for females. There was no increase in tumours in the methanol-exposed rats and mice (NEDO, 1985a). [Kl. score = 2]

Male and female B6C3F1 mice were exposed by inhalation to 0, 10, 100, or 1,000 ppm methanol 19.5 hours/day, 7 days/week for 78 weeks. The average methanol doses were: 0, 9.8, 95, and 947 mg/kg-day in males; and 0, 8.1, 106, and 1,071 mg/kg-day for females. There was no increase in tumours in the methanol-exposed mice (NEDO, 1985b). [Kl. score = 2]

I. Reproductive Toxicity

The reproductive and developmental toxicity studies were reviewed by the NTP Centre for Evaluation of Risks to Human Reproduction (NTP-CERHR, 2003). Conflicting results have been obtained concerning the effect of methanol on testicular hormones in rats; nevertheless, methanol does not appear to a male reproductive toxicant. The primate data indicates that methanol is unlikely to be a reproductive hazard in females. Methanol causes developmental effects at very high exposure levels in both rats (≥ 10,000 ppm) and mice (≥ 2000 ppm); there is also some evidence that it is a developmental neurotoxicant in rodents, but not in primates.

NICNAS concluded in their human health Tier II assessment for methanol: "Based on the data available, [methanol] is not considered to have reproductive or developmental toxicity in humans."

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for methanol follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

A 90-day oral gavage rat study showed elevated serum enzymes and decreased brain weights in the 2,500 mg/kg-day dose group with a NOAEL of 500 mg/kg-day (USEPA, 1986). The NOAEL of 500 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 500/(10 x 10 x 1 x 10 x 1) = 500/1000 = 0.2 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD: Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2 L (ADWG, 2011)

Drinking water guidance value = (0.5 x 70 x 0.1)/2 = 1.8 mg/L

B. Cancer

Methanol was not carcinogenic to rats or mice in chronic inhalation studies. Increased tumours from methanol in drinking water were reported by Soffritti et al. (2002); however, there are methodological problems with this study and questions have been raised about the validity of the results. No cancer reference value was derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Methanol is a highly flammable liquid.

It does not exhibit the following physico-chemical properties:

- Explosivity
- Oxidising potential.

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Methanol exhibits a low toxicity concern for aquatic organisms, terrestrial invertebrates, and plants.

B. Aquatic Toxicity

Acute Studies

Table 2 lists the results of acute aquatic toxicity studies conducted on methanol.

Table 2: Acute Aquatic Toxicity Studies on Methanol

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Bluegill	96-hr LC_{50}	15,400	1	Poirer et al. 1986
Salmo gairdneri	96-hr LC_{50}	20,100	1	Call et al., 1983
Pimphales promelas	96-hr LC_{50}	28,100	1	Call et al., 1983
Daphnia magna	96-hr EC_{50}	18,260	2	Dorn et al., 2012; ECHA
Daphnia magna	48-hr EC_{50}	>10,000	2	Kuehn et al., 1989
Selenastrum capricornutum	96-hr EC_{50}	~22,000	2	Cho et al., 2008; ECHA
Chlorella pyrenoidosa	10-14 d EC_{50}	28,400	2	Stratton and Smith, 1988

Chronic Studies

No adequate chronic studies were identified.

C. Terrestrial Toxicity

The terrestrial toxicity studies on methanol are listed below in Table 3.

Table 3: Terrestrial Toxicity Studies on Methanol

Test Species (Method)	Endpoint	Results (mg/kg soil dw)	Klimisch score	Reference
Earthworm *Eisenia fetida* (OECD 222)	35-d EC_{50} 63-d EC_{50}	17,199 26,646	2	ECHA
Folsomia candida (OECD 232)	28-d EC_{25} 28-d NOEC* (reproduction)	2,842 1,000	1	ECHA
Hordeum vulgare (OECD 208)	14-d EC_{50} 14-d NOEC* (seedling emergence)	15,492 12,000	1	ECHA
	14-d EC_{25} 14-d NOEC* (shoot dry mass)	2,538 1,555		
	14-d EC_{25} 14-d NOEC* (root dry mass)	2,823 2,592		
	14-d EC_{25} 14-d NOEC* (shoot length)	4,885 2,592		
	14-d EC_{25} 14-d NOEC* (root length)	5,752 4,320		

* Since only EC_{25} values were available from the test results, NOECs were derived graphically from the representing treatment means.

D. Calculation of PNEC

The PNEC calculations for methanol follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (15,400 mg/L), *Daphnia* (>10,000 mg/L), and algae (22,000 mg/L). There are no well-conducted long-term studies on methanol. Therefore, an assessment of 1,000 has been applied to the lowest reported effect concentration of 10,000 mg/L for *Daphnia*. The $PNEC_{water}$ is 10 mg/L.

PNEC sediment

There are no adequate toxicity studies on sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 6.3 mg/kg wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.81/1280) \times 1000 \times 10$
$= 6.3$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{soilid}]$
$= 0.8 + [0.2 \times 0.02/1000 \times 2400]$
$= 0.81$

Where:
Kp = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 0.61 \times 0.04$
$= 0.02$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for methanol is 0.61.
F_{oc} = fraction of organic carbon suspended sediment = 0.04 [default].

PNEC soil

Experimental results from chronic studies are available for three trophic levels. The lowest NOEC is 1,000 mg/kg soil dry weight for the arthropod *Folsomia candida*. On the basis that the data consists of long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported long-term NOEC of 1,000 mg/kg soil dry weight. The $PNEC_{soil}$ is 100 mg/kg soil dry weight.

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009, ECHA, 2008).

Methanol is readily biodegradable and thus it does not meet the screening criteria for persistence.

Based on an experimental BCF of <10 in fish, methanol does not meet the criteria for bioaccumulation.

There are no adequate chronic toxicity studies on methanol. The acute E(L)C_{50} values of methanol in fish, invertebrates and algae is >1 mg/L; thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that methanol is not a PBT substance.

IX. CLASSIFICATION AND LABELLING

A. Classification

Flammable Liquid Category 2
Acute Toxicity Category 3 [Oral]
Acute Toxicity Category 3 [dermal]
Acute Toxicity Category 3 [inhalation]
STOT SE Category 1 [optic nerve, central nervous system]

In the EU, there are concentration limits for the STOT SE classification of methanol. This may or may not apply to GHS classifications for Australian SDS.

Concentration range (%):	
>10	STOT SE Category 1
>3 and <10	STOT SE Category 2

B. Labelling

Danger

C. Pictograms

The health hazard pictogram is omitted if the STOT SE classification for methanol does not apply. (i.e., concentration of methanol is below the concentration limits).

X. SAFETY AND HANDLING

Methanol is used in the drilling mud product ALDACIDE® G ANTIMICROBIAL at a concentration of 0.1% to 1%. The safety and handling of methanol at this concentration in ALDACIDE® G

ANTIMICROBIAL will be provided in the dossier on glutaraldehyde, the major constituent of ALDACIDE® G ANTIMICROBIAL.

Occupational Exposure Standards

The workplace exposure standard for methanol in Australia is 200 ppm (262 mg/m^3 as an 8-hr TWA and 250 ppm (328 mg/m^3) as a 15-min STEL. There is also a skin notation indicating that absorption through the skin may be a significant source of exposure.

A. Transport Information

Methanol is used drilling mud product ALDACIDE® G ANTIMICROBIAL at a concentration of 0.1 to 1%. The transportation information for ALDACIDE® G ANTIMICROBIAL will be provided in the dossier on glutaraldehyde, the major constituent of ALDACIDE® G ANTIMICROBIAL.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

MONOETHANOLAMINE BORATE

This dossier on monoethanolamine borate does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of monoethanolamine borate in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Monoethanolamine borate

CAS RN: 26038-87-9 (EC No. 701-025-6)

Molecular formula: $C_2H_7NO.xBH_3O_3$ [UVCB substance]

Synonyms: Monoethanolamine borate; orthoboric acid, compound with 2-aminoethanol; boric acid (H_3BO_3), reaction products with ethanolamine; MEA polyborate

In this dossier, data on CAS No. 68512-53-8 (Boric acid, reaction products with monoethanolamine [MEA] and triethanolamine [TEA]) has been used to read-across to monoethanolamine borate.

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Monoethanolamine Borate

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Liquid	2	ECHA
Density	$\leq$1.245 g/cm^3 @ 20°C	2	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Monoethanolamine borate is readily biodegradable. It will not adsorb significantly to suspended solids and sediments in water and would be highly mobile in soil. No information is available on the potential for monoethanolamine borate to bioaccumulate.

B. Biodegradation

Monoethanolamine borate 1:1 is readily biodegradable. In a modified Sturm test (OECD 301B), degradation was 73% after 28 days; the 10-day window was met (ECHA). [Kl. score = 1]

Monoethanolamine borate 1:3 is readily biodegradable. In a modified Sturm test (OECD 301B), degradation was 75% after 28 days; the 10-day window was met (ECHA).

D. Environmental Distribution

Adsorption/desorption

The log K_{oc} was determined for monoethanolamine borate 1:1 and monoethanolamine borate 1:3 on soil and on sewage sludge using high performance liquid chromatography (HPLC). Both the monoethanolamine and the polyborate part of both substances did not significantly adsorb to soil. The experimental log K_{oc} was determined to be approximately 1.26 [K_{oc} = 18.2 L/kg] (ECHA). [Kl. score = 1]

E. Bioaccumulation

No bioconcentration studies are available. No information is available on the octanol-water partition coefficient for monoethanolamine borate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Limited toxicity data are available for monoethanolamine borate. Data on CAS No. 68512-53-8 (boric acid reaction product with MEA and TEA) has been used to read-across to monoethanolamine borate. Monoethanolamine borate exhibits low acute toxicity by the oral and dermal routes. Monoethanolamine borate is not irritating to the skin and eyes, and has a low potential for skin sensitization. Repeated oral exposures of CAS No. 68512-53-8 to rats showed no adverse effects. Monoethanolamine borate is not genotoxic. No carcinogenicity, reproductive or developmental toxicity studies have been conducted on monoethanolamine borate or CAS No. 68512-53-8.

B. Acute Toxicity

The acute oral LD_{50} in rats is >2,000 mg/kg (ECHA) [Kl. score = 1].

No acute inhalation studies are available on monoethanolamine borate.

There are no dermal toxicity studies on monoethanolamine borate. The acute dermal LD_{50} of CAS 68512-53-8 (boric acid reaction product with MEA and TEA) in rats is >2,000 mg/kg (ECHA). [Kl. score = 1]

C. Irritation

Application of 0.5 g monoethanolamine borate to the skin of rabbits for 4 hours under semi-occlusive conditions was essentially non-irritating. The mean of the 24, 48, and 72 hour scores were approximately 0.1 for erythema and 0.00 for edema (ECHA) [Kl. score = 1).

Monoethanolamine borate 1:1 and monoethanolamine borate 1:3 were tested for eye irritancy using the Bovine Corneal Opacity and Permeability test (BCOP test). Minimal to no ocular irritation was observed in both studies (ECHA) [Kl. scores = 1].

D. Sensitization

There are no skin sensitization studies on monoethanolamine borate. CAS No. 68512-53-8 (boric acid reaction product with MEA and TEA) was not a skin sensitizer to guinea pigs using the Buehler method (ECHA) [Kl. score = 2).

E. Repeated Dose Toxicity

Oral

No studies are available on monoethanolamine borate.

Male and female SD rats were dosed daily by oral gavage with 0, 62.5, 250 or 1,000 mg/kg CAS No. 68512-53-8 (boric acid reaction product with MEA and TEA) for 28 days. There were no deaths during the study. Clinical signs, body weights, feed consumption, and neurobehavior (FOB, motor activity) were unaffected by treatment. Hematology parameters, clinical chemistry, and urinalysis were within normal range for treated and control animals. There were no treatment-related effects on organ weights, and gross necropsy findings and histopathologic examination showed no effects attributed to treatment. The NOAEL for this study is 1,000 mg/kg-day (ECHA) [Kl. score = 1].

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

The results of in vitro genotoxicity studies on monoethanolamine borate and structurally similar substance CAS No. 68512-53-8 (boric acid reaction product with MEA and TEA) are shown in Table 2.

In Vitro Studies

Table 2: *In vitro* Genotoxicity Studies on Monoethanolamine Borate and CAS No. 68512-53-8 (Boric Acid Reaction Product with MEA and TEA)

Test System	Test Substance	Results*		Klimisch Score	Reference
		-S9	+S9		
Bacterial reverse mutation (S. typhimurium strains)	CAS No. 68512-53-8**	-	-	1	ECHA
Mammalian cell gene mutation (CHL V79 cells)	CAS No. 68512-53-8**	-	-	1	ECHA
Chromosomal aberration (Human lymphocytes)	Monoethanolamine borate 1:1	-	-	1	ECHA
Chromosomal aberration (human lymphocytes)	Monoethanolamine borate 1:3	-	-	1	ECHA

*+, positive; -, negative
** Boric acid reaction product with MEA and TEA.

In Vivo Studies

No studies are available.

G. Carcinogenicity

No studies are available.

H. Reproductive Toxicity

No studies are available.

I. Developmental Toxicity

No studies are available.

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for monoethanolamine borate follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

The were no adverse effects seen in rats given oral gavage doses of CAS No. 68512-53-8 (boric acid, reaction products with MEA and TEA) for 28 days (ECHA). The NOAEL for this study is 1,000 mg/kg-day, the highest dose tested. The NOAEL from this study will be used for determining the oral Reference dose (RfD) and the drinking water guidance value for monoethanolamine borate.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 1,000/(10 x 10 x 1 x 10 x 1) = 1,000/1,000 = 1.0 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,

Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (1.0 x 70 x 0.1)/2 = 3.5 mg/L

B. Cancer

No studies have been conducted on monoethanolamine borate. Therefore, a cancer reference value has not been derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Monoethanolamine borate does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Monoethanolamine borate has moderate acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on monoethanolamine borate.

Table 3: Acute Aquatic Toxicity Studies on Monoethanolamine Borate

Test Species	Test Substance	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rario	Monoethanol-amine borate	96-h LC_{50}	>100	1	ECHA

	1:1				
Carp	Monoethanol-amine borate 1:3	96-h LC_{50}	617	1	ECHA
Daphnia magna	Monoethanol-amine borate 1:3	48-h EC_{50}	496	1	ECHA
Daphnia magna	Monoethanol-amine borate 1:1	48-h EC_{50}	423	1	ECHA
Pseudokirchneriella subcapitata	Monoethanol-amine borate 1:3	72-h EC_{50} NOEC	67 (growth rate) 72 (biomass) 18 (growth rate)	1	ECHA
Pseudokirchneriella subcapitata	Monoethanol-amine borate 1:1	72-h EC_{50}	26 (growth rate) 13 (biomass) 3.2 (growth rate)	1	ECHA

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for monoethanolamine borate follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (617 mg/L), *Daphnia* (423 mg/L), and algae (26 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 26 mg/L for algae. The $PNEC_{water}$ is 0.026 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.02 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (1.15/1280) \times 1000 \times 0.026$
$= 0.02$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [0.2 \times 0.73/1000 \times 2400]$
$= 1.15$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 18.2 \times 0.04$
$= 0.73$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The experimental K_{oc} for monoethanolamine borate is 18.2 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.006 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil}$ = (Kp_{soil}/BD_{soil}) x 1000 x $PNEC_{water}$
= (0.36/1500) x 1000 x 0.026
= 0.006

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

Kp_{soil} = K_{oc} x f_{oc}
= 18.2 x 0.02
= 0.36

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The experimental K_{oc} for monoethanolamine borate is 18.2 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Monoethanolamine borate is readily biodegradable; thus it does not meet the screening criteria for persistence.

No bioconcentration studies have been conducted on monoethanolamine borate. It is a UVCB substance and a log K_{ow} has not been determined. Thus the bioaccumulation potential for monoethanolamine borate is not known.

No chronic aquatic toxicity studies are available for monoethanolamine borate. The acute E(L)C_{50} values in fish, invertebrates and algae are >1 mg/L. Thus monoethanolamine borate does not meet the criteria for toxicity.

The overall conclusion is that monoethanolamine borate is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

[Acute Aquatic Toxicity Category 3]

B. Labelling

No signal word.

C. Pictogram

None

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. If effects occur, get medical attention immediately, preferably a physician for an ophthalmologic examination.

Skin Contact
Remove contaminated clothing. Wash thoroughly with soap and water. Seek medical attention if irritation persists.

Inhalation
If inhaled, remove from area to fresh air. Give artificial respiration if victim is not breathing. Get medical attention.

Ingestion
Rinse mouth with water and then drink a small amount of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: nitrogen oxides, carbon monoxide, carbon dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment. Handle in accordance with good industrial hygiene and safety practice. Avoid contact with skin, eyes, and clothing.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
For large amounts: dike spillage and pump off product. For residues: pick up with suitable absorbent material. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling
Ensure adequate ventilation, especially in confined areas. Avoid breathing vapors.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard for monoethanolamine borate.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection in case of vapor or aerosol release.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:

Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Monoethanolamine borate is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SILICON DIOXIDE

This dossier on silicon dioxide does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of silicon dioxide in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the OECD-SIDS documents on synthetic amorphous silica and silicates (OECD 2004a,b), and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Silicon dioxide

CAS RN: 112926-00-8

Molecular formula: $nSiO_2$

Molecular weight: 60.08

Synonyms: Silicon dioxide; synthetic amorphous silica; silica gel; precipitated silica, crystalline-free

SMILES: O=[Si]=O

Silicon dioxide is the IUPAC name for synthetic amorphous silica (SAS) [CAS No. 7631-86-9]; it can be produced by a "wet process" or by a "thermal or fumed process." Silica gel and precipitated silica, crystalline-free (CAS No. 112926-00-8) is a SAS prepared by the "wet process." Silica, amorphous, fumed, crystalline-free (CAS No. 112945-52-5) is a SAS prepared by flame hydrolysis.

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Silicon Dioxide

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Powder, granules, pellets	2	ECHA
Melting Point	1,713°C	2	ECHA

Boiling Point	2.2 g/cm^3	2	ECHA
Water Solubility	76 – 128 mg/L* (slightly soluble)	1	ECHA

*Based on dissolved SiO_2.

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Silicon oxides are the most abundant compounds in the earth's crust mass. Silicon dioxide (CAS No. 112926-00-8) released into the environment is expected to combine indistinguishably with the soil layer or sediment due to their chemical similarity with inorganic soil matter (OECD, 2004a).

Biodegradation is not applicable to silicon dioxide (CAS No. 112926-00-8). The bioavailable form of silicon dioxide (CAS No. 112926-00-8) is the dissolved form which exists exclusively monosilicic [$Si(OH)_4$] acid under environmental pH (OECD, 2004a). Although the water-soluble fraction of silicon dioxide (CAS No. 112926-00-8) acts as weak acid, pH changes are not likely to occur in the environment due to low aquatic releases and sufficient natural buffer capacities (OECD, 2004a).

Bioaccumulation of silicon dioxide (CAS No. 112926-00-8) is generally unlikely to occur. However, dissolved silica can be actively assimilated by some marine and terrestrial organisms as normal natural processes mainly related to structural function.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The oral bioavailability of silicon dioxide in animals and humans is low. Absorbed silicon dioxide is rapidly eliminated and there is no accumulation in the body. The bioavailablity of silicon dioxide by the inhalation route is low. While there is deposition in the lungs following inhalation exposure to silicon dioxide, it is rapidly eliminated. The acute toxicity of silicon dioxide is low by the oral, inhalation, and dermal routes. Silicon dioxide is not irritating to the skin and eyes. Repeated oral exposures to rodents showed no adverse effects. Repeated inhalation exposure to high respirable levels of silicon dioxide resulted in an inflammatory response in the respiratory tract and lungs, which was reversible following cessation of exposure. Silicon dioxide is not genotoxic. Although the study was of poor quality, there was no evidence of adverse effects on reproduction in rats given silicon dioxide in the diet. Animal studies showed no adverse effects on fetal development from oral exposure to silicon dioxide.

B. Toxicokinetics/Metabolism

The oral bioavailability of silicon dioxide in animals and humans is low. Absorbed silicon dioxide is rapidly eliminated and there is no accumulation in the body. The bioavailablity of silicon dioxide by the inhalation route is low. While there is deposition in the lungs following inhalation exposure to silicon dioxide, it is rapidly eliminated (OECD, 2004a,b).

C. Acute Toxicity

The oral LD_{50} of silicon dioxide (CAS No. 112926-00-8) in rats from two different studies is >5,000 mg/kg (ECHA) [Kl. scores = 1].

The 4-hour inhalation LC_{50} in rats for an aerosol of silicon dioxide (CAS No. 112926-00-8) is >0.69 mg/L, which was the maximum technically attainable concentration. The mass median aerodynamic diameter (MMAD) was approximately 0.6 μm, and approximately 65% of the mass was <6 μm (ECHA) [Kl. score = 2].

The 4-hour inhalation LC_{50} in rats for an aerosol of silicon dioxide (CAS No. 112945-52-5) is >2.08 mg/L. The mass median aerodynamic diameter (MMAD) was approximately 0.76 μm, and approximately 98-99.4% of the mass was <10 μm (ECHA) [Kl. score = 2].

The 4-hour inhalation LC_{50} in rats for an aerosol of silicon dioxide (CAS No. 112945-52-5) from a nose-only exposure is >0.14 mg/L, which was the maximum technically attainable concentration. The mass median aerodynamic diameter (MMAD) was 3.2 μm, and 47-50% of the mass was <6 μm (ECHA) [Kl. score = 2].

The dermal LD_{50} in rabbits is >5,000 mg/kg (no deaths) (ECHA) [Kl. score = 2].

D. Irritation

Application of 0.5 g silicon dioxide (CAS No. 112926-00-8) to the skin of rabbits for 4 hours under occlusive conditions was not irritating. (ECHA) [Kl. score = 1].

Instillation of 0.1 g silicon dioxide (CAS No. 112926-00-8) to the eyes of rabbits was minimally irritating (ECHA) [Kl. score = 1].

E. Sensitization

No studies are available.

F. Repeated Dose Toxicity

Oral

Male and female Wistar rats were given diets containing silicon dioxide (CAS No. 112926-00-8) for 90 days. The dietary concentrations as silica concentrations were 0, 0.4-0.7, 1.7-1.9, or 6.5-7.0% silica; this equates to 0, 300-330, 1,200-1,400, or 4,000-4,500 mg/kg CAS No. 112926-00-8. There were no treatment-related effects. The NOAEL is 4,000 to 4,500 mg/kg-day (ECHA). [Kl. score = 1]

Male and female CD rats were given diets containing silicon dioxide (CAS No. 112926-00-8) for 6 months. The estimated daily intakes were 0, 2,170, and 7,950 mg/kg-day for males, and 0, 2,420, and 8,980 mg/kg-day for females. There were no treatment-related effects. The NOAEL is 7,950 and 8,980 mg/kg-day for males and females, respectively (ECHA). [Kl. score = 1]

Male and female Fischer 344 rats were fed a diet containing a synthetic amorphous silica (CAS No. not stated) for 102 weeks. The dose levels were 0, 12,500, 25,000, and 50,000 ppm. There were no treatment-related effects on body weight gain, feed consumption, survival, or hematology parameters. Liver weights were lower (up to 15%) in the $\geq$25,000 ppm females from 12 to 24 months; a dose-related trend was not apparent. The NOAEL is 50,000 ppm. Using 0.05 as the fraction of body weight that rats consume per day as food (U.S. EPA), the NOAEL corresponds to 2,500 mg/kg-day (Takizawa *et al.*, 1988) [Kl. score = 2].

Male and female $B6C3F_1$ mice were fed a diet containing a synthetic amorphous silica (CAS No. not stated) for 93 weeks. The dose levels were 0, 12,500, 25,000, and 50,000 ppm. There were no treatment-related effects on survival or clinical signs. Body weight gain was lower in the 5% group from week 15 to week 50 for the males and from 30 to 50 for the females. Mean body weights for 5% group animals for the remainder of the study were similar to controls. The NOAEL is 50,000 ppm in the diet. Using 0.13 as the fraction of body weight that mice consume per day as food (U.S. EPA), the NOAELs corresponds to 6,500 mg/kg-day (Takizawa et al., 1988). [Kl. score = 2]

Inhalation

Male and female Wistar rats were exposed by inhalation to 0, 1, 6, or 30 mg/m^3 silicon dioxide (CAS No. 112945-52-5) 6 hours/day, 5 days/week for 13 weeks. There were no deaths during the study. Respiration rates were increased in a concentration-dependent manner. Body weight and body weight gain were unaffected in females, but were lower in the males with the 30 mg/m^3 groups significantly affected throughout the study. At $\geq$6 mg/m^3, there were hematological changes, increased lung weights, and histopathologic changes in the lungs (including collagen increase and sporadic focal fibrosis). At 1 mg/m^3, there was a slight, but fully reversible, pulmonary response indicative of an inflammatory reaction. The NOAEC for this study is 1.3 mg/m^3 (ECHA) [Kl. score = 1].

Dermal

No adequate studies are available.

G. Genotoxicity

In Vitro Studies

The results of *in vitro* genotoxicity studies on silicon dioxide are presented below in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Silicon Dioxide

Test System	Test substance	Results*		Klimisch Score	Reference
		-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* strains)	CAS No. 112926-00-8	-	-	2	Prival *et al.* (1991)
Bacterial reverse mutation (*E. coli* strains)	CAS No. 112926-00-8	-	-	2	Prival *et al.* (1991)
Bacterial reverse mutation (*S. typhimurium* strains)	CAS No. 112945-52-5	-	-	1	ECHA
Mammalian cell gene mutation (CHO cells)	CAS No. 112945-52-5	-	-	1	ECHA
Chromosomal aberration (Human embryonic lung cells, WI-38)	CAS No. 112926-00-8	NA	-	2	ECHA
Chromosomal aberration (CHO cells)	CAS No. 112945-52-5	-	-	1	ECHA
Unscheduled DNA synthesis (primary rat hepatocytes)	CAS No. 112945-52-5	NA	-	1	ECHA

*+, positive; -, negative; NA, not applicable.

In Vivo Studies

Male F344 rats were exposed by inhalation to 0 or 50 mg/m^3 silicon dioxide (CAS No. 112945-52-5) 6 hours/day, 5 days/week for 13 weeks. When tested in a HPRT assay,

there was no increase in mutation frequency in the alveolar Type II cells from exposed rats compared to controls (ECHA) [Kl. score = 2].

Male SD rats were given by oral gavage either a single dose of 0, 1,4, 14, or 140 mg/kg silicon dioxide (CAS No. 112926-00-8), or five consecutive daily doses of 0, 500, or 5,000 mg/kg silicon dioxide (CAS No. 112926-00-8). Chromosomal aberrations were not significantly increased in the treated animals compared to controls (ECHA) [Kl. score = 2].

In a dominant lethal mutation assay, male SD rats were given by oral gavage either a single dose of 0, 1,4, 14, or 140 mg/kg silicon dioxide (CAS No. 112926-00-8), or five consecutive daily doses of 0, 500, or 5,000 mg/kg silicon dioxide (CAS No. 112926-00-8). There was no indication of a mutagenic effect by silicon dioxide (CAS No. 112926-00-8) (ECHA) [Kl. score = 2].

H. Carcinogenicity

Oral

Male and female Fischer 344 rats were fed a diet containing a synthetic amorphous silica (CAS No. not stated) for 102 weeks. The dose levels were 0, 12,500, 25,000, and 50,000 ppm. The incidence of tumors was similar between treated and control animals. The number of animals used in this study was small (Takizawa *et al.*, 1988). [Kl. score = 2]

Male and female $B6C3F_1$ mice were fed a diet containing a synthetic amorphous silica (CAS No. not stated) for 93 weeks. The incidence of tumors was similar between treated and control animals (Takizawa *et al.*, 1988). [Kl. score = 2].

I. Reproductive Toxicity

A one-generation reproductive toxicity study has been conducted on silicon dioxide (CAS No. 112945-52-5). Male and female Wistar rats were given diets containing 0 or 497 mg/kg-day (males) or 509 mg/kg-day (females). In the parental animals, there were no treatment-related effects on mortality, clinical symptoms, feed consumption, body weight gain, and measured hematology parameters. There was no reproductive or developmental toxicity (ECHA) [Kl. score = 3].

J. Developmental Toxicity

Pregnant female rats were given by oral gavage doses up to 1,350 mg/kg silicon dioxide (CAS No. 112926-00-8) on GD 6-15. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity is 1,350 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 2].

Pregnant female mice were given by oral gavage doses up to 1,340 mg/kg silicon dioxide (CAS No. 112926-00-8) on GD 6-15. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity is 1,340 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 2].

Pregnant female rabbits were given by oral gavage doses up to 1,600 mg/kg silicon dioxide (CAS No. 112926-00-8) on GD 6-18. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity is 1,600 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 2].

Pregnant female Syrian hamsters were given by oral gavage up to 1,600 mg/kg silicon dioxide (CAS No. 112926-00-8) on GD 6-10. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity is 1,600 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 2].

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for silicon dioxide (CAS No. 112945-00-8) follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

There were no adverse effects seen in rats or mice fed a diet containing up to 50,000 ppm silicon dioxide (CAS No. not stated) for 102 and 93 weeks, respectively (Takizawa *et al.*, 1988). The NOAELs for rats and mice were 2,500 and 6,500 mg/kg-day, respectively. The lowest NOAEL of 2,500 mg/kg-day will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 2,500/(10 x 10 x 1 x 1 x 1) = 2,500/100 = 25 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (25 x 70 x 0.1)/2 = 88 mg/L

B. Cancer

Silicon dioxide was not carcinogenic to rats or mice in chronic dietary studies. Hence, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Silicon dioxide does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Silicon dioxide has a low acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on silicon dioxide.

Table 3: Acute Aquatic Toxicity Studies on Silicon Dioxide

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rerio	96-h LL_0	10,000*	1	ECHA
Danio rerio	96-h LL_0	10,000	1	ECHA
Daphnia magna	48-h EL_{50}	>1,000**	2	ECHA
Daphnia magna	24-h EL_{50}	>10,000	2	ECHA

*Silica, amorphous, fumed, crystalline-free (CAS No. 112945-52-5)
**Mortality may have occurred may have occurred from physical effects of unfiltered medium.

Chronic Studies

No studies are available.

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for silicon dioxide follow the methodology discussed in DEWHA (2009).

PNEC water

Silicon dioxide is a solid in powder form, which is slightly soluble in water. Acute aquatic toxicity studies on fish and *Daphnia* using excess loadings of silicon dioxide showed no acute toxicity (Table 3). Physical effects of silicon dioxide on *Daphnia* were seen in tests using unfiltered test medium (OECD, 2004a,b; ECHA). Because of the physico-chemical properties of silicon dioxide, the $PNEC_{water}$ was not determined.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. The $PNEC_{sed}$ cannot be derived using the equilibrium partitioning method.

PNEC soil

There are no toxicity data for terrestrial or soil organisms. The $PNEC_{soil}$ cannot be derived using the equilibrium partitioning method.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Silicon dioxide (CAS No. 111945-00-8) released into the environment is expected to combine indistinguishably with the soil layer or sediment due to their chemical similarity with inorganic soil matter. Biodegradation is not applicable to silicon dioxide (CAS No. 112926-00-8). For the purposes of this PBT assessment, the persistent criteria is not considered applicable to silicon dioxide (CAS No. 112926-00-8).

Silicon dioxide (CAS No. 112926-00-8)is an inorganic substance that is a slightly soluble powder. Bioaccumulation of silicon dioxide (CAS No. 112926-00-8) is generally unlikely to occur, given its low bioavailability. However, dissolved silica can be actively assimilated by some marine and terrestrial organisms as normal natural processes mainly related to structural function. For the purposes of this PBT assessment, silicon dioxide (CAS No. 112926-00-8) does not meet the criteria for bioaccumulation.

The acute toxicity of the water-soluble fraction of silicon dioxide (CAS No. 112926-00-8) is >1 mg/L. Thus, it does not meet the criteria for toxicity.

The overall conclusion is that silicon dioxide (CAS No. 112926-00-8) is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

No classified.

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes. If symptoms persist, seek medical advice.

Skin Contact
Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. If symptoms develop, seek medical advice.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
No data are available.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled

Scoop up and remove.

D. STORAGE AND HANDLING

General Handling
No special measures necessary provided product is used correctly.

Other Handling Precautions
Avoid eye and skin contact. Avoid creating or inhaling dust.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
The workplace exposure standard for silica gel (silicon dioxide, CAS No. 112926-00-8) in Australia is 10 mg/m^3 as an 8-hour TWA.

Engineering Controls
Good general ventilation should be used.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection if airborne dust levels are expected to exceed the occupational exposure guidance value.

Hand Protection:
Use gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Silicon dioxide is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SODIUM BISULFITE

This dossier on sodium bisulfite does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of sodium bisulfite in water treatment systems. The information presented in this dossier was obtained mainly from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Sodium hydrogen sulfite

CAS RN: 7631-90-5

Molecular formula: $NaHSO_3$

Molecular weight: 104.1

Synonyms: Sodium bisulfite; sodium hydrogen sulfite; sodium hydrogensulfite; monosodium sulfite; sodium sulfhydrate; hydrogen sodium sulfite; sulfurous acid, monosodium salt

SMILES: OS(=O)[O].[Na]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Physico-chemical Properties of Sodium Bisulfite

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White, crystalline, solid	-	HSDB
Melting Point	Decomposes	-	HSDB
Density	1.348 g/cm^3	1	ECHA
Vapor Pressure	Not applicable	-	-
Partition Coefficient (log K_{ow})	Not applicable	-	-
Water Solubility	Very soluble	2	ECHA

Sodium bisulfite is a weak acid with a pK_a of 6.97. Its conjugate base is the sulfite ion (SO_3^{2-}).

$NaHSO_3 \leftrightarrow Na^+ + HSO_3^-$

$HSO_3^- \leftrightarrow H^+ + SO_3^{2-}$

At neutral pH, a mixture of 50% sulfite (SO_3^{2-}) and 50% bisulfite (HSO_3^{2-}) is present.

In surface waters, sulfite is oxidized to sulfate either catalytically by air oxygen or by microbial action (OECD, 2008). The presence of cations like iron, copper or manganese in the environment accelerates the oxidation rate significantly.

Dissociation of sodium bisulfite in aqueous solutions can also liberate sulfur dioxide (SO_2), which is a gas.

III. ENVIRONMENTAL FATE PROPERTIES

At environmental pHs, sodium bisulfite dissociates in water to form sodium (Na^+) ions, bisulfite ions (HSO_3^-), sulfite (SO_2^{3-}) ions, and sulfur dioxide (SO_2) which is a gas.

Sodium bisulfite is not expected to bioaccumulate in the environment because of its dissociation to ionic species and a gas. Furthermore, sulfite will oxidize to sulfate, which is ubiquitous in the environment.

Sodium bisulfite and its dissociated species are expected to have a low potential to adsorb to soil and sediment.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Limited toxicity data are available on sodium bisulfite; therefore, structural analogues have been used to read-across to sodium bisulfite. Sodium sulfite has low acute toxicity by the oral, inhalation, and dermal routes. Sodium sulfite is minimally irritating to the skin and slightly irritating to the eyes. Sodium sulfite is not a skin sensitizer. No systemic toxicity was seen in rats when given sodium metabisulfite in their diet over a lifetime. There were, however, indications of stomach lesions as a result of localized irritation from the ingestion of sodium metabisulfite. Sodium bisulfite is not expected to be genotoxic. No reproductive or developmental toxicity was observed in any of the animal studies on sodium bisulfite or its structural analogues.

B. Acute Toxicity

No acute toxicity studies are available for sodium bisulfite.

The oral LD_{50} value in rats for sodium sulfite is 2,610 mg/kg (ECHA) [Kl. score = 2]. The oral LD_{50} values in rats for sodium metabisulfite are 1,420 mg/kg (males), 1,630 mg/kg (females), and 1,540 mg/kg (combined sexes) (ECHA) [Kl. score = 2].

The 4-hour inhalation LC_{50} in rats for sodium sulfite is >5.5 mg/L (ECHA). [Kl. score = 2]

The dermal LD_{50} in rats for sodium sulfite is >2,000 mg/kg (ECHA). [Kl. score = 2]

C. Irritation

No studies are available on sodium bisulfite.

Application of 0.5 mL of sodium sulfite to the skin of rabbits for 4 hours under occlusive conditions was minimally irritating. The mean of the 24, 48, and 72 scores were: 0.5 for erythema and 0.0 for edema (ECHA). [Kl. score = 2]

Instillation of 0.1 mL of sodium sulfite (with 0.5% cobalt sulfate) into the eyes of rabbits produced slight irritation. The mean of the 24, 48, and 72 hour scores are as follows: 0.5 for conjunctival redness; 0.5 for conjunctival chemosis; 0.0 for corneal lesions; and 0.0 for iridial lesions (ECHA). [Kl. score = 2]

D. Sensitization

No studies are available on sodium bisulfite.

Sodium bisulfite was not considered a skin sensitizer in a mouse local lymph node assay (ECHA). [K. score = 1]

E. Repeated Dose Toxicity

Oral

No studies are available on sodium bisulfite.

A study is available on sodium metabisulfite. Sodium metabisulfite dissociates in water to form sodium (Na^+) ions, disulfite ($S_2O_5^{2-}$) ions, and sulfur dioxide (SO_2). The disulfite ions can form bisulfite (HSO_3^-) and sulfite ions (SO_2^{3-}); at neutral pH, a mixture of 50% sulfite (SO_3^{2-}) and 50% bisulfite (HSO_3^{2-}) is present.

Male and female Wistar rats were fed in their diet 0, 0.125, 0.25, 0.5, 1.0, or 2.0% sodium metabisulfite for up to two years and over three generations. The diet was enriched with thiamine to prevent thiamine deficiency as a result of sulfite-induced destruction of this vitamin. During storage up to the time of consumption, the losses of sulfite from the feed containing sodium metabisulfite at levels of 0.125, 0.25, 0.5, 1.0, and 2.0% averaged 22, 14,12, 8, and 4.5%, respectively, while the decrease in thiamine was 2.7, 1.7, 8.3, 14.5, and 15.4%, respectively. Addition of thiamine to the diet prevented thiamine deficiency in rats at all dose levels based on measurements of thiamine levels in the urine and liver. The general condition of the rats was good during the first 72 weeks in the F_0 generation, as well as the other two generations. After 72 weeks, there was a rapid increase in mortality in all groups. Survival in the treated groups were generally higher than the controls, except for the 2% F_1 males; no deaths occurred in the 2% F_2 females. A marginal reduction in body weight gain was observed in the 2% dose group (both sexes) in the F_1 and F_2 generations. Feed consumption was similar between treated and control groups. There were no changes in hematology and clinical chemistry parameters and urinalysis that were considered toxicologically significant. The $\geq$1% dietary groups had occult blood in their feces. Relative kidney weights were increased in the 2% F_2 females, but there were no pathological changes noted in the kidneys from this group. Hyperplastic changes in the fore- and glandular stomachs were noted in the $\geq$1% groups in all three generations. Some slight alterations were also noted in stomachs of the 0.5% F_2 rats. The NOAEL for systemic toxicity is 1.91% in the diet. This was estimated to be 955 mg/kg-day based on a rat body weight of 400 g and a daily feed intake of 20 g. The histopathologic effects on the stomach and the occult blood in feces are considered to be the result of localized irritation (a site-of-contact effect) from the ingestion of sodium metabisulfite (Til et al., 1972; ECHA). [Kl. score = 2]

Inhalation

No studies on sodium bisulfite were located.

Dermal

No studies on sodium bisulfite were located.

G. Genotoxicity

In Vitro Studies

No *in vitro* genotoxicity studies were located for sodium bisulfite. Table 2 presents the findings from *in vitro* genotoxicity studies conducted on structural analogues of sodium bisulfite.

Table 2: *In Vitro* Genotoxicity Studies on Structural Analogues to Sodium Bisulfite

Test System	Test Substance	Results*		Klimisch Score	Reference
		-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* strains)	Sodium metabisulfite	-	-	2	ECHA
Bacterial reverse mutation (*S. typhimurium* strains)	Potassium metabisulfite	-	-	2	ECHA
Bacterial reverse mutation (*S. typhimurium* strains)	Potassium metabisulfite	-	-	2	ECHA
Bacterial reverse mutation (*S. typhimurium* and *E. coli* strains)	Sodium metabisulfite	-	-	2	ECHA

Chromosomal aberration (human lymphocytes)	Sodium metabisulfite	-	-	1	ECHA

*+, positive; -, negative

In Vivo Studies

Sodium bisulfite did not show a mutagenic response in a rat dominant lethal assay when given in feed at doses of 0, 4.5, 15, or 45 mg/kg-day (ECHA). [Kl. score = 2]

Sodium sulfite was not genotoxic in a bone marrow micronucleus test in rats. Male NMRI rats were given a single subcutaneous injection of 0, 250, 500, or 1,000 mg/kg sodium sulfite (ECHA). [Kl. score = 1]

H. Carcinogenicity

No studies are available on sodium bisulfite.

Male and female Wistar rats were fed in their diet 0, 0.125, 0.25, 0.5, 1.0, or 2.0% sodium metabisulfite for up to two years and over three generations. There was no

increased incidence of tumors in the treated groups compared to the controls (Til et al., 1972). [Kl. score = 2]

Male and female ICR/JCL mice were given in their drinking water 0, 1, or 2% potassium metabisulfite for two years. There was no increased incidence of tumors in the treated groups compared to the controls (Tanaka et al., 1979). [Kl. score = 2]

No inhalation or dermal carcinogenicity studies were located.

I. Reproductive Toxicity

No studies are available on sodium bisulfite.

Male and female Wistar rats were fed in their diet 0, 0.125, 0.25, 0.5, 1.0, or 2.0% sodium metabisulfite for up to two years and over three generations. The diet was enriched with thiamine to prevent thiamine deficiency as a result of sulfite-induced destruction of this vitamin. During storage up to the time of consumption, the losses of sulfite from the feed containing sodium metabisulfite at levels of 0.125, 0.25, 0.5, 1.0, and 2.0% averaged 22, 14,12, 8, and 4.5%, respectively, while the decrease in thiamine was 2.7, 1.7, 8.3, 14.5, and 15.4%, respectively. Addition of thiamine to the diet prevented thiamine deficiency in rats at all dose levels based on measurements of thiamine levels in the urine and liver. The effects other than reproductive and developmental toxicity are discussed above in the Repeated Dose Toxicity section. There were no treatment-related effects on female fertility, the number of young per litter, or birth weight or mortality of the offspring. The number of F_{2a} pups was significantly reduced in the $\geq$0.5% groups during the first breeding cycle, but there was no dose-response and the reduction did not occur during the second breeding cycle. Slight growth retardation was observed in the F_1 and F_2 generation rats both before and after weaning. The NOAEL for reproductive toxicity is 1.91% in the diet. This was estimated to be 955 mg/kg-day based on a rat body weight of 400 g and a daily feed intake of 20 g (Til et al., 1972; ECHA). [Kl. score = 2]

Male and female rats were given sodum metabisulfite in their drinking water for up to 2.5 years and in three successive generations. The doses were 375 and 750 ppm as sulfur dioxide (SO_2). There was no evidence of systemic toxicity in either dose group. The number of offspring of either the F_1 and F_2 generation and the proportion surviving to the end of lactation were similar between treated and control groups. The NOAEL for reproductive toxicity is 750 ppm (as SO_2) in drinking water. Assuming an average rat body weight of 400 g and a daily water intake of 28 mL, 750 ppm (as SO_2) corresponds to 53 mg/kg-day sodium metabisulfite (Lockett and Natoff, 1960; ECHA). [Kl. score = 2]

J. Developmental Toxicity

Pregnant female Wistar rats were dosed by oral gavage with up to 110 mg/kg-day sodium bisulfite during GD 6-15. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity for this study is 110 mg/kg-day (ECHA). [Kl. score = 2]

Pregnant female CD-1 mice were dosed by oral gavage with up to 150 mg/kg-day sodium bisulfite during GD 6-15. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity for this study is 150 mg/kg-day (ECHA). [Kl. score = 2]

Pregnant female Dutch-belted were dosed by oral gavage with up to 100 mg/kg-day sodium bisulfite during GD 6-18. There was no maternal or developmental toxicity. The NOAEL for maternal and developmental toxicity for this study is 100 mg/kg-day (ECHA). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for sodium metabisulfite follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

Oral

No repeated dose toxicity studies have been conducted on sodium bisulfite. In a study conducted on sodium metabisulfite, there was no evidence of systemic toxicity in rats fed up to 2% for two years (Til et al., 1972). The NOAEL for this study is 2% or 955 mg/kg-day.

Using the molecular weights of sodium metabisulfite (190.1 g/mol) and sodium bisulfite (104.1 g/mol), the NOAEL of 955 mg/kg-day for sodium metabisulfite is converted to 523 mg/kg-day for sodium bisulfite. The NOAEL of 523 mg/kg-day will be used for determining the oral reference dose (RfD) and the drinking water guidance value for sodium bisulfite.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10

UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 523/(10 x 10 x 1 x 1 x 1) = 523/100 = 5 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (5 x 70 x 0.1)/2 = 18 mg/L

The Australian drinking water guidance value for sodium is 180 mg/L based on aesthetics (ADWG, 2011).

B. Cancer

There are no carcinogenicity studies on sodium bisulfite. No carcinogenic effects were reported for sodium metabisulfite in rat and mouse chronic studies. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Sodium bisulfite does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

No aquatic toxicity studies have been conducted on sodium bisulfite. Other inorganic sulfite compounds show low to moderate toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

No acute aquatic studies are available on sodium bisulfite; however, studies are available on other inorganic sulfite compounds. The studies on these inorganic sulfite compounds can used to read-across to sodium bisulfite since sulfite ions are formed in water upon dissociation of sodium bisulfite. Table 3 lists the results of acute aquatic toxicity studies on the structural analogues of sodium bisulfite.

Table 2: Acute Aquatic Toxicity Studies on the Structural Analogues of Sodium Bisulfite

Test Species	Test Substance	Endpoint	Results (mg/L)	Klimisch score	Reference
Leuciscus idus	Potassium sulfite	96-hr LC_{50}	316	2	ECHA
Salmo gairdneri	Sodium pyrosulfite	96-hr LC_{50}	147-215 (177.8*)	2	ECHA
Brachydanio rerio	Potassium metabisulfite	96-hr LC_{50}	464-1,000 (681.2*)	1	ECHA
Daphnia magna	Sodium disulfite	48-hr EC_{50}	88.8	2	ECHA
S. subspicatus	Sodium disulfite	96-hr EC_{50} 72-hr EC_{10}	43.9 33.3	2	ECHA

*Geometric mean.

Chronic Studies

No chronic studies are available on sodium bisulfite; however, studies are available on sodium sulfite. Table 4 lists the results of chronic aquatic toxicity studies conducted on sodium sulfite.

Table 4: Chronic Aquatic Toxicity Studies on Sodium Sulfite (CAS No. 7757-83-7)

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Danio rerio	34-d NOEC	>316	1	ECHA
Daphnia magna	21-d NOEC	>10	2	ECHA

B. Terrestrial Toxicity

No studies were located.

C. Calculation of PNEC

The PNEC calculations for sodium bisulfite follow the methodology discussed in DEWHA (2009).

PNEC water

No studies have been conducted on sodium bisulfite; however, the results from studies conducted on other inorganic sulphite compounds can be used to read-across to sodium bisulfite. Hence, experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (177.8 mg/L for sodium pyrosulfite), invertebrates (88.8 mg/L for sodium sulfite), and algae (43.9 mg/L for sodium disulfite).

Results from chronic studies on sodium sulfite are also available for all three trophic levels, with the lowest NOEC being 10 mg/L for invertebrates. Using the molecular weights of sodium sulfite (126 g/mol) and sodium bisulfite (104.1 g/mol, the NOEC of 10 mg/L for sodium sulfite is converted to 8.3 mg/L. On the basis that the data consist of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 8.3 mg/L for invertebrates. The $PNEC_{water}$ is 0.8 mg/L.

PNEC sediment

No experimental toxicity data on sediment organisms are available. Sodium bisulfite dissociates completely in water with its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium bisulfite. Thus, the equilibrium partitioning method cannot be used to calculate

the $PNEC_{sed}$. Based on its properties, no adsorption of sodium bisulfite to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PNEC soil

No experimental toxicity data on soil organisms are available. Sodium bisulfite dissociates completely in water with its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium bisulfite. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on its properties, no adsorption of sodium bisulfite to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Sodium bisulfite is an inorganic compound that dissociates completely to ionic species and sulfur dioxide gas. Biodegradation is not applicable to these compounds. For the purposes of this PBT assessment, the persistent criterion is not considered applicable to sodium bisulfite or its dissociated compounds.

Sodium bisulfite is not expected to bioaccumulate because its dissociated species are inorganic ions and a gas.

There are no aquatic toxicity data on sodium bisulfite. The lowest NOEC from chronic aquatic toxicity studies on sodium sulfite, a structural analogue of sodium bisulfite, is >0.1 mg/L. Thus, sodium bisulfite is not expected to meet the criteria for toxicity.

The overall conclusion is that sodium bisulfite is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Aquatic Acute Category 3

B. Labelling

No signal word.

C. Pictogram

None

X. SAFETY AND HANDLING [for a solution of sodium bisulfite]

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes. If symptoms persist, seek medical advice.

Skin Contact
Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. If symptoms develop, seek medical advice.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
When contacted by water, sodium bisulfite releases sulfur dioxide (SO_2), a poisonous gas. In the case of fire, the following may be liberated: Sulfur oxides and sulfur dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Pick up with absorbent material. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling
No special measures necessary provided product is used correctly.

Other Handling Precautions
Avoid eye and skin contact.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards

The workplace exposure standard for sodium bisulfite in Australia is 5 mg/m^3 as an 8-hr TWA.

Engineering Controls
None

Personal Protection Equipment

Respiratory Protection:
Respiratory protection is not required.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:

Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Sodium bisulfite is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SODIUM CARBONATE

This dossier on sodium carbonate does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of sodium carbonate in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained primarily from the OECD-SIDS documents on sodium carbonate (OECD, 2002a, b) and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): disodium carbonate

CAS RN: 497-19-8

Molecular formula: $CH_2O_3.2Na$

Molecular weight: 106

Synonyms: sodium carbonate; disodium carbonate; carbonic acid, disodium salt; bisodium carbonate; soda ash, calcined soda

SMILES: C(=O)([O-])[O-].[Na+].[Na+]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-Chemical Properties of Sodium Carbonate

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Solid; white powder	1	ECHA
Melting Point	851°C	2	ECHA
Boiling Point	No data	-	-
Density	>2.52 and <2.53 (20°C)	1	ECHA
Vapour Pressure	No data	-	-
Partition Coefficient (log K_{ow})	Not applicable	-	-
Water Solubility	404 g/L* [soluble]	2	ECHA
pH	ca 11.5**	2	ECHA
Flammability	No	1	ECHA

*GLP-compliant study. The water solubility was overestimated, possibly due to the high temperature (during dissolution) or due to gel formation.

**pH value from water solubility test.

Aqueous solutions are strongly alkaline. At 25°C, the pH of 1, 5 and 10 wt% sodium carbonate solutions are 11.37, 11.58, and 11.70, respectively (Eggeman, 2001).

III. ENVIRONMENTAL FATE PROPERTIES

Due to its high water solubility and low vapour pressure, sodium carbonate will be found predominantly in the aquatic environment where it dissociates completely to sodium (Na^+) and carbonate (CO_3^{2-}) ions. Both ions are ubiquitous in the environment (UNEP, 1995).

Addition of sodium carbonate to an aquatic ecosystem will result in an increase in alkalinity and a tendency to increase the pH. The carbonate ions will react with water, forming bicarbonate (HCO_3^-) and hydroxide (OH^-) ions until an equilibrium is reached. A re-equilibration takes place when carbonate (CO_3^{2-}) is dissolved in water according to the following equations:

$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ pKa=10.33

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ pKa = 6.35

Only a small fraction of the dissolved CO_2 is present as H_2CO_3 (carbonic acid), the major part is present as CO_2. The amount of CO_2 in water is in equilibrium with the partial pressure of CO_2 in the atmosphere. The CO_2/ HCO_3^-/ CO_3^{2-} equilibria are the major buffer of the pH of freshwater.

Based on the above equations, CO_2 is the predominant species at a pH smaller than 6.35, while HCO_3^- is the predominant species at a pH in the range of 6.35-10.33 and CO_3^{2-} is the predominant species at a pH higher than 10.33.

A release of sodium carbonate into the aquatic environment from the use of sodium carbonate could potentially increase the sodium concentration and the pH in the aquatic environment. Table 2 shows the concentration of sodium carbonate needed to increase the pH to values of 9.0, 10.0, and 11.0.

Table 2: Sodium Carbonate Concentration (mg/L) Needed to Increase pH (DeGroot et al., 2002; taken from OECD, 2002b).

Buffer capacity*	Final pH**		
	9.0	10.0	11.0
0 mg/L HCO_3^- (distilled water)	11.1 (0.6)	16 (6.1)	603 (61)
20 mg/L HCO_3^- (10^{th} percentile of 77 rivers)	2.7 (21)	32 (26)	766 (81)
106 mg/L HCO_3^- (mean value of 77 rivers)	9.7 (107)	102 (112)	1467 (167)
195 mg/L HCO_3^- (90^{th} percentile of 77 rivers)	17 (196)	175 (201)	2192 (256)

*The initial pH of a bicarbonate solution with a concentration of 20-195 mg/L is 8.3 (calculated).

**The final concentration of bicarbonate is given in parentheses.

Na^+ and CO_3^{2-} ions will not adsorb on particulate matter or surfaces and will not accumulate in living tissues (OECD 2002b).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

There are limited toxicity data on sodium carbonate. It has a low order of acute toxicity by the oral, dermal, and inhalation routes. It is not a skin irritant, but it is an eye irritant. Sodium carbonate is not expected to be systemically available in the body from oral exposure due to its dissociation in bodily fluids and the neutralisation of the carbonate ion in the stomach. No developmental toxicity was seen in studies with rats, mice, or rabbits.

B. Toxicokinetics and Metabolism

Sodium carbonate will dissociate in bodily fluids into sodium (Na^+) and carbonate (CO_3^{2-}) ions. The oral uptake of sodium carbonate would lead to neutralisation of carbonate in the stomach by the gastric acids which would lead to bicarbonate and/or carbon dioxide (CO_2) formation. It is unlikely that an oral uptake of sodium carbonate would disrupt the acid-base balance of the body because CO_2 formation in the stomach would alleviate the high amounts of carbonate that would be present in the stomach from an acute exposure. The equation that describes this reaction is:

$HCO_3^- + H^+ \leftrightarrow \square H_2CO_3 \leftrightarrow CO_2 + H_2O$

C. Acute Toxicity

An acute oral LD_{50} of sodium carbonate monohydrate in rats is 2,800 mg/kg, and the acute dermal LD_{50} in rabbits is >2,000 mg/kg (OECD, 2002a,b; ECHA). [Kl. scores = 1]

An acute inhalation toxicity study was conducted on an aerosol of sodium combustion products, which contain predominantly sodium carbonate. The 2-hour inhalation LC_{50} values for this aerosol to guinea pigs, mice and rats were 800, 1,200 and 2,300 mg/m^3, respectively. The median aerodynamic diameter of the aerosol was 0.77 $\pm$ 2.1µm (OECD, 2002a, b; ECHA). [Kl. score = 1]

D. Irritation

As reviewed in the OECD-SIDS documents (OECD, 2002a,b), skin irritation studies in laboratory animals and human volunteers with sodium carbonate either as a 50% solution or as a solid showed slight to no skin irritation.

Sodium carbonate is an eye irritant (OECD, 2002a,b; ECHA). A dose of 0.1 ml sodium carbonate monohydrate was irritating to the eyes of rabbits and, in another study, 0.1 ml of sodium carbonate (anhydrous) was highly irritating to rabbit eyes. However, 0.1 g sodium carbonate (anhydrous) was found not to be an eye irritant. [Kl scores of 1, 2, 1, respectively]

E. Sensitisation

No studies were identified.

F. Repeated Dose Toxicity

No studies were identified by the oral, inhalation or dermal routes.

G. Genotoxicity

In Vitro Studies

Sodium carbonate did not induce primary DNA damage in an *E. coli* chromotest (Olivier and Marzin, 1987; OECD, 2002a, b). [Kl. score = 3]

In Vivo Studies

No studies were identified.

H. Carcinogenicity

No studies were identified.

I. Reproductive Toxicity

No studies were identified.

J. Developmental Toxicity

Pregnant rats were dosed by oral gavage with 0, 2.45, 11.4, 52.9 or 245 mg/kg sodium carbonate on gestational days 6 to 15. No maternal or developmental toxicity was observed. The NOAEL for maternal and developmental toxicity is 245 mg/kg-day, the highest dose tested (OECD, 2002a, b). [Kl. score = 2]

Pregnant mice were given doses of sodium carbonate (3.4 to 340 mg/kg) by oral gavage on gestational days 6 to 15. No maternal or developmental toxicity was observed. The NOAEL for maternal and developmental toxicity is 340 mg/kg-day, the highest dose tested (OECD, 2002a, b). [Kl. score = 2]

Pregnant rabbits were dosed by oral gavage with 0, 1.79, 8.31, or 179 mg/kg sodium carbonate on gestational days 6 to 15. No maternal or developmental toxicity was observed. The NOAEL for maternal and developmental toxicity is 179 mg/kg-day, the highest dose tested (OECD, 2002a, b). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

There are no repeated dose toxicity studies conducted on sodium carbonate by any route of exposure. Developmental toxicity studies conducted by the oral route in three animal species showed no developmental effects at the highest doses tested. Sodium carbonate dissociates to sodium and carbonate ions in bodily fluids, and significant amount of these ions are already ingested in foods. Furthermore, both ions are present in the body and are highly regulated by homeostatic mechanisms.

Sodium carbonate is used in many countries (e.g., U.S. and EU) as a food additive. It is regarded as a Generally Recognized as Safe (GRAS) substance in food with no limitation other than current good manufacturing practice (OECD, 2002a, b).

Therefore, a toxicological reference value was not derived for sodium carbonate.

The Australian drinking water guideline values for sodium (180 ppm, aesthetic) and pH may be applicable (ADWG, 2011).

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Sodium carbonate does not exhibit the following physico-chemical properties:

- Flammability
- Explosivity
- Oxidising potential.

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Sodium carbonate is of low toxicity concern to aquatic and terrestrial organisms.

B. Aquatic Toxicity

Acute Studies

The results of the aquatic toxicity studies conducted on sodium carbonate are presented in Table 3.

Table 3: Aquatic Toxicity Studies on Sodium Carbonate (OECD, 2002a,b)

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Bluegill sunfish	96-h LC_{50}	300	2	OECD, 2002a, b
Mosquitofish	96-h LC_{50}	740	2	OECD, 2002a, b
Bluefill sunfish	24-h LC_{50}	385	4	OECD, 2002a, b
Molly	50-h LC_{50}	297	4	OECD, 2002a, b
Ceriodaphnia dubia	48-h EC_{50}	200 - 227	2	OECD, 2002a, b

There are other studies conducted on invertebrates, but the results of these studies were not included in Table 3 because of the low reliability of the data (OECD, 2002a, b). No studies on algae were identified (OECD, 2002a, b).

C. Terrestrial Toxicity

No studies were identified.

D. Calculation of PNEC

The OECD-SIDS SIAR on sodium carbonate states the following regarding the aquatic toxicity studies on sodium carbonate (OECD, 2002b):

> "In general, the available toxicity studies with sodium carbonate were not conducted according to current standard guidelines. In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with sodium carbonate. In general, mortality of the test organisms was found at concentrations higher than 100 mg/l but for *Amphipoda*, salmon and trout lethal effects were already observed at 67-80 mg/l although these studies had a low reliability. The main factor explaining the acute aquatic toxicity of sodium carbonate is most likely the increase of the pH."

> "Because the natural pH, bicarbonate and also the sodium concentration (and their fluctuations in time) varies significantly between aquatic ecosystems, it is not considered useful to derive a generic PNEC or $PNEC_{added}$."

Based on the information above, PNEC values for freshwater, sediment, and soil were not derived for sodium carbonate.

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Sodium carbonate is an organic salt that dissociates completely to sodium and carbonate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and

carbonate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Sodium and carbonate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium carbonate is not expected to bioaccumulate.

No chronic aquatic toxicity data exist on sodium carbonate; however, the acute $EC(L)_{50}$s are >1 mg/L in fish, invertebrates and algae. Therefor, sodium carbonate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium carbonate is not a PBT substance.

IX. CLASSIFICATION AND LABELLING

A. Classification

Eye Irritant Category 2

B. Labelling

Warning

C. Pictograms

X. SAFETY AND HANDLING

A. First Aid

Eye Contact

Immediately flush eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. If symptoms persist, seek medical attention.

Skin Contact

Wash with soap and water.

Inhalation

If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion

Do not induce vomiting. Rinse mouth with water. Never give anything by mouth to an unconscious person. If symptoms persist, get medical attention.

B. Firefighting Information

Extinguishing Media

Water fog, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards

Decomposition in fire may produce toxic gases.

Special Protective Equipment for Fire fighters

Full protective clothing and approved self-contained breathing apparatus.

C. Accidental Release Measures

Personal Precautions

Use appropriate protective equipment. Avoid creating and breathing dust.

Environmental Precautions

Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled

Scoop up and remove.

D. Storage and Handling

General Handling

Avoid contact with eyes and skin. Avoid creating or inhaling dust.

Storage

Store away from acids. Store in a cool, dry location.

E. Exposure Controls/Personal Protection

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure limit for sodium carbonate.

Engineering Controls

Use in a well ventilated area. Localised ventilation should be used to control dust levels.

Personal Protection Equipment

Respiratory Protection: In case of insufficient ventilation, wear suitable respiratory equipment. Dust/mist respirator.

Hand Protection: Chemical resistant protective gloves.

Skin Protection: Body protection must be chosen depending on activity and possible exposure

Eye protection: Safety glasses with side-shields.

Other Precautions: Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. Transport Information

Sodium Carbonate is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SODIUM HYDROXIDE

This dossier on sodium hydroxide does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of sodium hydroxide in its use in drilling muds and hydraulic fracturing fluids. The information presented in this dossier was obtained from the OECD-SIDS documents on sodium hydroxide (OECD, 2002a, b) and the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): Sodium hydroxide

CAS RN: 1310-73-2

Molecular formula: HNaO

Molecular weight: 40 g/mol

Synonyms: Caustic soda, soda lye, NaOH

SMILES: O[Na]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Physico-Chemical Properties of Sodium Hydroxide

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Solid	2	Lide, 2009; ECHA
Melting Point	318°C (solid, 100%); 52°C (60% solution)	2	ECHA
Boiling Point	1,388°C @ 101.325 kPa	2	Lide, 2009; ECHA
Density	2.13 g/cm^2, 20°C (100%) 1.43 g/cm^2, 20°C (40%)	2	Lide, 2009; ECHA
Vapour Pressure	1 Pa @ 513°C	2	Lide, 2009; ECHA
Partition Coefficient (log Kow)	Not applicable	-	-
Water Solubility	Very soluble	2	Lide, 2009; ECHA
Dissociation Constant (pKa)	14.8 @ 25°C	2	Lide, 2009; ECHA
pH of 5% NaOH solution	14	2	O'Neil, 2006

Sodium hydroxide (NaOH) is a strong alkaline substance that dissociates completely in water to sodium (Na^+) and hydroxyl (OH^-) ions.

III. ENVIRONMENTAL FATE PROPERTIES

Due to its high water solubility and low vapour pressure, sodium hydroxide will be found predominantly in the aquatic environment where it dissociates completely to sodium (Na^+) and hydroxyl (OH^-) ions. Both ions are ubiquitous in the environment (UNEP, 1995).

The addition of sodium hydroxide to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general, the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

A release of sodium hydroxide into the aquatic environment from the use of NaOH could potentially increase the sodium concentration and the pH in the aquatic environment. Table 2 shows the concentration of sodium hydroxide needed to increase the pH to values of 9.0, 10.0, 11.0, and 12.0.

Table 2: Sodium Hydroxide Concentration (mg/L) Needed to Increase pH (DeGroot et al., 2002; taken from OECD, 2002b).

Buffer capacity*	Final pH			
	9.0	10.0	11.0	12.0
0 mg/L HCO_3 (distilled water)	0.4	4.0	40	400
20 mg/L HCO_3 (10^{th} percentile of 77 rivers)	1.0	8.2	51	413
106 mg/L HCO_3^- (mean value of 77 rivers)	3.5	26	97	468
195 mg/L HCO_3^- (90^{th} percentile of 77 rivers)	6.1	45	145	525

*The initial pH of a bicarbonate solution with a concentration of 20-195 mg/L was 8.25 to 8.35.

Na^+ and OH^- ions will not adsorb on the particulate matter or surfaces and will not accumulate in living tissues (OECD, 2002b).

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Limited toxicity data exist for sodium hydroxide (NaOH). Depending on the concentration, solutions of NaOH are corrosive, irritating, or non-irritating. These solutions cause direct effects to the skin, eyes, respiratory tract, and gastrointestinal tract. Vapors from aqueous solutions of KOH can cause respiratory irritation. NaOH is not a skin sensitiser. There are no repeated dose, reproductive, and developmental toxicity studies on potassium hydroxide.

B. Toxicokinetics/Metabolism

Sodium hydroxide dissociates completely in aqueous solutions to sodium (Na^+) and hydroxyl (OH^-) ions. Sodium is an essential nutrient involved in fluid and electrolyte balance and is required for normal cellular function (Ganong, 1995). Sodium is the major extracellular cation in the body; the total body content is tightly regulated (Ganong, 1995).

C. Acute Toxicity

There are no oral toxicity guideline studies on sodium hydroxide. An oral LD_{50} of a 1 to 10% solution of NaOH in rabbits was reported to be 325 mg/kg (expressed as 100% NaOH) (OECD, 2002a,b). Mortality was also observed when a 1% NaOH solution was dosed, but in this case, the applied volume was relatively high (24 mL per kg body weight) (OECD, 2002a,b).

Acute toxicity studies were not identified for the inhalation and dermal route.

D. Irritation

Animal studies have shown that an 8% NaOH solution is corrosive to the skin. In humans, 0.5 to 4% NaOH concentrations produced skin irritation; and, based on the results of two different human patch tests, a NaOH solution that is slightly less than 0.5% would be non-irritating to human skin (OECD, 2002a,b).

Results from animal eye irritation studies indicate that a 0.2-1.0% NaOH solution would be non-irritating, while 1.2 or >2% NaOH solutions would be corrosive (OECD, 2002a,b).

E. Sensitisation

Male volunteers were exposed on the skin of their back to solutions of 0.063 to 1.0% NaOH in the induction phase of a human patch test. After 7 days the volunteers were challenged to a concentration of 0.125% NaOH. The irritant response correlated well with the concentration of NaOH, but an increased response was not observed when the previously patch tested sites were re-challenged. Based on this study, sodium hydroxide is not a skin sensitiser (OECD, 2002a, b; ECHA). [Kl. score = 2]

F. Repeated Dose Toxicity

No studies were identified for the oral and dermal route. An inhalation study was conducted in rats exposed to aerosols of solutions of NaOH ranging from 5% to 40%. Exposures were twice weekly (hours/day and total exposure days unspecified). All animals in the 40% solution group died within a month mostly from bronchopneumonia. At the lower concentrations, respiratory tract lesions were observed; an NOAEL was not identified (NIOSH, 1975).

G. Genotoxicity

In Vitro Studies

Several *in vitro* studies have been conducted on NaOH (OECD, 2002a, b; ECHA). Although these studies reported negative results, they are considered unreliable (Kl. score = 3) due to methodological or reporting deficiencies.

In Vivo Studies

Several *in vivo* studies have been conducted on NaOH (OECD, 2002a,b; ECHA). Although these studies reported negative results, they are considered unreliable (Kl. score = 3) due to methodological or reporting deficiencies.

H. Carcinogenicity

No studies were identified.

I. Reproductive Toxicity

No valid studies were identified regarding toxicity to reproduction in animals after oral, dermal or inhalation exposure to NaOH.

J. Developmental Toxicity

No valid studies were identified regarding developmental toxicity in animals after oral, dermal or inhalation exposure to NaOH (OECD, 2002a, b; ECHA).

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

Oral and dermal repeated dose, reproductive, and developmental toxicity studies have not been conducted on NaOH. A repeated dose toxicity study was conducted by the inhalation route, but the methodology and documentation preclude its use for deriving a toxicological reference value. These toxicity studies would have questionable usefulness because of the corrosive/irritating nature of NaOH, which would limit the amount absorbed. NaOH dissociates to sodium and hydroxyl ions in bodily fluids, and a significant amount of these ions are already ingested in foods. Furthermore, both ions are present in the body and are highly regulated by homeostatic mechanisms. Thus, a toxicological reference value was not derived for NaOH.

The Australian drinking water guideline values for sodium (180 ppm, aesthetic) and pH may be applicable (ADWG, 2011).

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Sodium hydroxide does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidising potential.

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Aquatic Toxicity

The OECD-SIDS SIAR on NaOH states the following regarding the aquatic toxicity studies on NaOH (OECD, 2002b):

> "At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realised that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium, the hydroxyl ion will be neutralised, and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity, e.g.; NH_3 is more toxic than NH_4^+."

There are no guideline studies on NaOH; the studies summarised below have Klimisch scores of 3 or 4.

Acute Fish

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L. At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L.

Acute Invertebrate

The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia cf. dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

Acute Algae

No studies were identified.

B. Terrestrial Toxicity

No studies were identified.

C. Calculation of PNEC

The OECD-SIDS SIAR on NaOH states the following regarding the aquatic toxicity studies on NaOH (OECD, 2002b):

> "In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available, there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available, and the results of the tests are more or less consistent. Altogether they give a sufficient indication of acute toxicity levels of sodium hydroxide."
>
> "Furthermore, acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterised by an alkalinity/pH, and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks."
>
> "Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:
> - The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,
> - Also, the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and
> - The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water."
>
> "Although a PNEC or a PNEC added was not calculated for NaOH, there is a need to assess the environmental effect of a NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course, the pH change can also be measured very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable."

Based on the information above, PNEC values for freshwater, sediment, and soil were not derived for sodium hydroxide.

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Sodium hydroxide is an inorganic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms, and their intracellular, and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $E(L)C_{50}$ values are >1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

IX. CLASSIFICATION AND LABELLING

A. Classification

Metal Corrosive Category 1
Skin Corrosive, Category 1A
Eye Damage, Category 1

EU Concentration Limits:

≥5%: Skin Corrosive 1A

≥2 to <5%: Skin Corrosive 1B

≥0.5%to <2%: Skin Irritant Category 2

≥0.5% to <2%: Eye Irritant Category 2

In addition to the hazard statements corresponding the GHS classification for corrosive, the following non-GHS hazard statement is to be added to the SDS: AUH071: Corrosive to the Respiratory Tract.

B. Labelling

Danger

C. Pictograms

X. SAFETY AND HANDLING

A. First Aid

Eye Contact

Flush with plenty of fresh water for 15 minutes holding eyelids open, lifting eyelids occasionally to ensure complete removal of the product. Remove contacts, if present and easy to do. DO NOT allow rubbing of eyes or keeping eyes closed. Seek medical attention.

Skin Contact

Rinse with soap and plenty of water for several minutes. Remove contaminated clothing. Seek medical attention immediately.

Inhalation

Remove person to fresh air. Apply artificial respiration if not breathing. Seek medical attention.

Ingestion

Rinse mouth with water (only if the person is conscious), but do not administer fluids. Do NOT induce vomiting. Seek medical attention immediately.

B. Fire Fighting Information

Extinguishing Media

Carbon dioxide, water spray, foam, dry chemical.

Specific Exposure Hazards

Containers may explode when heated. May form explosive mixtures with strong acids. Hazardous combustion products may include the following materials: halogenated compounds, metal oxides/oxides, sodium monoxide.

Special Protective Equipment for Firefighters

Full protective clothing and approved self-contained breathing apparatus required for firefighting personnel.

C. Accidental Release Measures

Personal Precautions

Use appropriate protective equipment and avoid direct contact. Do not touch damaged containers or spilt material unless wearing appropriate protective clothing. Ventilate the area before entry.

Environmental Precautions

Prevent spills from entering storm drains or sewers and contact with soil.

Steps to be Taken if Material is Released or Spilt

Use an absorbent material to recover as much product as possible, then, rinse the affected area with water to dilute the residue. Disposal of leftover product and used containers should be carried out in accordance with all local, state and federal regulations.

D. Storage and Handling

General Handling

Wear appropriate personal protective equipment. Avoid contact with eyes, skin or clothing. Avoid breathing mist, vapours or spray. Use only with adequate ventilation. Wash hands after use. Launder contaminated clothing.

Storage

Store away from acids. Keep container closed when not in use. Store in a cool well-ventilated area.

E. Exposure Controls / Personal Protection

Occupational Exposure Standards

The workplace exposure standard for sodium hydroxide in Australia is 2 mg/m^3 as a peak limitation, with a sensitisation notation. A peak limitation is defined by Safe Work Australia as a maximum or peak airborne concentration of a substance determined over the shortest analytically practicable period of time which does not exceed 15 minutes.

Engineering Controls

Good general ventilation should be used. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits.

Personal Protection Equipment

Respiratory Protection: Use a mask or approved air-purifying respirator with appropriate cartridge or canister in spray applications or in confined spaces.

Hand Protection: Wear impervious gloves to prevent skin contact and absorption of this material. Rubber or Neoprene gloves may afford adequate skin protection.

Skin Protection: Wear appropriate clothes (i.e., coveralls). Use non-slip footwear.

Eye protection: Wear eye protection in situations where splash or thick mists are possible.

Other Precautions: Avoid contact with skin, eyes and clothing. When using, do not eat or drink. Wash hands thoroughly with soap and water before eating or drinking. Remove contaminated clothing and launder before reuse.

F. Transport Information

For sodium hydroxide solutions of >5%:
Australian Dangerous Goods
UN1824, Corrosive liquid, (Sodium hydroxide solution)
Class 8
Packing Group: II

Lower concentrations of sodium hydroxide may require a different packing group or may not require any hazard code if the concentration of NaOH is low enough not to be considered a corrosive material.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SODIUM PERSULFATE

This dossier on sodium persulfate does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of sodium persulfate in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): Disodium [(sulfonatoperoxy)sulfonyl]oxidanide

CAS RN: 7775-27-1

Molecular formula: $O_8S_2.2Na$

Molecular weight: 238.1

Synonyms: Sodium persulfate; disodium persulfate; sodium peroxodisulfate; disodium [(sulfonatoperoxy)sulfonyl]oxidanide

SMILES: [O-]S(=O)(=O)OOS(=O)(=O)[O-].[Na+].[Na+]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Sodium Persulfate

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White, crystalline, odorless solid	1	ECHA
Melting Point	Decomposes at 180°C before melting point is reached.	1	ECHA
Density	1.68 g/cm^3	1	ECHA
Vapor Pressure	Negligible	2	ECHA
Partition Coefficient (log K_{ow})	Not applicable	-	-
Water Solubility	Very soluble	2	ECHA
Oxidizing Properties	Strong oxidizer	4	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

Sodium persulfate dissociates in aqueous media to the sodium cation (Na^+) and persulfate anion ($S_2O_8^{2-}$) (OECD 2005a; ECHA). The persulfate anion will readily hydrolyze (decompose) into sulfate ions.

The rates of hydrolysis are expected to be similar for sodium persulfate, potassium persulfate, and ammonium persulfate. The rates of decomposition (hydrolysis) was measured at 50°C at various pHs. The half-lives increased from 20 hours at pH 1 to 210 hours at pH 10 (Koltoff and Miller, 1951).

Biodegradation is not applicable to inorganic compounds. Sodium persulfate is not expected to bioaccumulate; it will dissociate (and decompose) to ions that are ubiquitous in the environment. Sodium persulfate is not expected to absorb to soil or sediment because of its dissociation properties, instability (hydrolysis), and high-water solubility.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Sodium persulfate exhibits moderate acute toxicity by the oral route, and low acute toxicity by the inhalation and dermal routes. In humans, sodium persulfate has the potential for skin irritation; it is also a skin sensitizer to guinea pigs and humans. Human exposure to persulfates (including sodium persulfate) have been linked to a variety of skin and respiratory complaints indicative of sensitization. The complaints consist of immediate and delayed contact hypersensitivity, contact urticarial, rhinitis, bronchitis, and asthma. Repeated oral exposure to sodium persulfate resulted in irritation to the gastrointestinal tract; and respiratory irritation was seen in rats repeatedly exposed by inhalation to ammonium persulfate. Sodium persulfate is not genotoxic. A dermal carcinogenicity study showed no carcinogenic effects in mice. In a screening study, there was no reproductive or developmental toxicity in rats given oral gavage doses of ammonium persulfate.

B. Acute Toxicity

The oral LD_{50} in male rats is 895 mg/kg (ECHA) [Kl. score = 2].

The 4-hour inhalation LC_{50} of sodium persulfate dust is >5.1 mg/L. The mass median aerodynamic diameter (MMAD) ranged from 4.28 to 5.35 μm. The fraction of particles ≤1 μm in MMAD ranged from 0 to 5.6%. The fraction of particles ≤10 μm in MMAD ranged from 76.5 to 81.2% (ECHA) [Kl. score = 1].

The dermal LD_{50} in rabbits is >2,000 mg/kg (ECHA) [Kl. score = 1].

C. Irritation

Application of 0.5 mL of sodium persulfate (aqueous solution) to the skin of rabbits for 4 hours under occlusive conditions was not irritating (ECHA) [Kl. score = 1]. In another study, application of sodium persulfate to the skin of rabbits was not irritating (ECHA) [Kl. score = 2].

Instillation of sodium persulfate into the eyes of rabbits was slightly irritating. Slight conjunctival effects were noted in five of six animals; all observed effects were completely reversible within 24 hours (ECHA) [Kl. score = 2].

Studies in humans indicate that persulfates have the potential for skin irritation (NICNAS, 2001). Calnan and Schuster (1963) reported skin irritation in a human patch test with 5% ammonium persulfate. Jordan (1998) reported that a mixture with 17.5% persulfates (ammonium, potassium, and sodium) induced skin irritation in human subjects from patches applied under occlusive conditions.

D. Sensitization

Sodium persulfate was a skin sensitizer when tested in a guinea pig maximization test. The concentration of sodium persulfate used in the induction and challenge phases was 0.1% in physiological saline (ECHA) [Kl. score = 1]. Sodium persulfate was not a skin sensitizer to guinea pigs in a Buehler test (dermal application only). The concentration of sodium persulfate used for the induction and challenge phase was 0.3 g (ECHA) [Kl. score = 1].

Sodium persulfate was considered a strong skin sensitizer in a mouse local lymph node assay (ECHA) [Kl. score = 1].

Human exposure to persulfates have been linked to a variety of skin and respiratory complaints indicative of sensitization. The complaints consist of immediate and delayed contact hypersensitivity, contact urticarial, rhinitis, bronchitis, and asthma (NICNAS, 2001).

E. Repeated Dose Toxicity

Oral

Male and female CR strain rats were fed in their diet 0, 300, 1,000 or 3,000 ppm sodium persulfate for 90-days. On day 48 of the study, the dietary concentration of the group receiving 1,000 ppm was increased to 5,000 ppm for the remainder of the study. Body

weights was decreased in the two highest dose groups during the last six weeks of treatment. There were no treatment-related effects on urinalysis, clinical chemistry or hematology parameters. Histopathological findings were limited to the 3,000 ppm group only and consisted of necrosis and atrophy of the gastrointestinal tract epithelial lining. The absence of the gastrointestinal lesions in the group receiving 1,000 ppm for 8 weeks, followed by 5000 ppm for 5 weeks, indicates that the lesions are related both to concentration in diet (dose) and length of exposure. A clear NOAEL for this study is 300 ppm, which is estimated to be 22 mg/kg-day. Another NOAEL may be the 1,000 ppm dietary group for an 8-week exposure period. (ECHA; OECD, 2005a,b). [Kl. score = 2]

Inhalation

No studies are available on sodium persulfate.

Male and female SD rats were exposed (whole-body) by inhalation to 0, 5, 10.3, or 25 mg/m^3 ammonium persulfate dust, 6 hours/day, 5 days/week for 13 weeks. Additional groups of animals were exposed for 13 weeks, followed by either a 4- or 13-week recovery period. The MMAD was 2.5, 2.7, and 2.5 μm for the 5, 10, and 25 mg/m^3 groups, respectively. No deaths occurred during the study that were considered to be exposure-related. The 25 mg/m^3 animals showed increased respiration rates, as well as a few of the 25 mg/m^3 animals. This clinical sign disappeared during the first few weeks of the recovery period. Body weights of the 25 mg/m^3 animals were significantly lower during most of the exposure period; by the end of the recovery period the body weights were comparable to the controls. Lung weights were increased in the 25 mg/m^3 animals at the end of the 13-week exposure period, but were similar to controls after 6 weeks in the recovery period. Histopathologic changes indicative of irritation was seen in the trachea and bronchi/bronchioles in the 25 mg/m^3 animals; these lesions were not seen after 6 weeks in the recovery period. The NOAEL for this study is 10.3 mg/m^3 (ECHA). [Kl. score = 1]

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

The *in vitro* genotoxicity studies on sodium persulfate are presented below in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Sodium Persulfate

Test System	**Results***		**Klimisch Score**	**Reference**
	-S9	**+S9**		

Bacterial reverse mutation (*S. typhimurium* strains)	-	-	1	ECHA
Unscheduled DNA synthesis (rat hepatocytes)	NA	-	1	ECHA

*+, positive; -, negative; NA, not applicable

In vivo Studies

Sodium persulfate did not induce micronuclei in the bone marrow cells of male and female mice given a single intraperitoneal injection of 0, 85, 169, or 338 mg/kg sodium persulfate (ECHA) [Kl. score = 2].

G. Carcinogenicity

No studies are available on sodium persulfate.

A 51-week dermal study in female SENCAR mice exposed to 0.2 ml of a 200 mg/mL solution of ammonium persulfate showed that ammonium persulfate is neither a tumor promoter nor a complete carcinogen when applied to the skin (OECD, 2005a,b; ECHA). [Kl. score = 2]

H. Reproductive and Developmental Toxicity

No studies are available on sodium persulfate.

A reproductive and developmental toxicity screening study (OECD 421) has been conducted on ammonium persulfate. Male and female Crl:CD (SD)GS BR rats were fed in their diet 0, 40, 100, or 250 mg/kg ammonium persulfate. In the parental animals, there was no treatment-related mortality, clinical signs, body or organ weight changes, or effects seen in gross necropsy. There were no effects on reproductive performance, fertility, fetal anomalies, fetal viability, spermatogenesis, spermatogenic cycle. The NOAEL for reproductive and developmental toxicity and parental toxicity is 250 mg/kg-day, the highest dose tested (ECHA). [Kl. score = 1]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

Toxicological reference values were not derived. Sodium persulfate dissociates in water to sodium and persulfate ions. The persulfate ions will further hydrolyze to sulfate ions.

The Australian drinking water guideline value for sodium is 180 mg/L based on aesthetics (ADWG, 2011).

The Australian drinking water guideline value for sulfate is 500 mg/L based on health. Concentrations of >500 mg/L can have purgative effects. There is also an Australian drinking water guideline value for sulfate of 250 mg/L based on aesthetics; it is the taste threshold (ADWG, 2011).

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Sodium persulfate is an oxidizing solid.

Sodium persulfate does not exhibit the following physico-chemical properties:
- Explosivity
- Flammability

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Sodium persulfate has a low toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies on sodium persulfate.

Table 3: Acute Aquatic Toxicity Studies on Sodium Persulfate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Oncorhynchus mykiss	96-h LC_{50}	163	1	ECHA
Daphnia magna	48-h EC_{50}	133	1	ECHA
Selenastrum capricornutum	72-h EC_{50}	116	1	ECHA

Chronic Studies

No data are available.

C. Terrestrial Toxicity

No data are available.

D. Calculation of PNEC

The PNEC calculations for sodium persulfate follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (163 mg/L), *Daphnia* (133 mg/L), and algae (116 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 116 mg/L for algae. The $PNEC_{water}$ is 0.12 mg/L.

PNEC sediment

No experimental toxicity data on sediment organisms are available. Sodium persulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium persulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium persulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PNEC soil

No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium persulfate is dominated by its water solubility. Sorption of sodium persulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{oc} and K_{ow} parameters do not readily apply to inorganics, such as sodium persulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium persulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Sodium persulfate is an inorganic compound that dissociates completely to sodium and persulfate ions in aqueous solutions. Persulfate ions are further hydrolysed to sulphate ions. Biodegradation is not applicable to these compounds. For the purposes of this PBT assessment, the persistent criteria are not considered applicable to sodium persulfate or its dissociated compounds.

Sodium persulfate is an inorganic compound that dissociates completely in water to ionic compounds that are ubiquitous in the environment. Thus, sodium persulfate is not expected to bioaccumulate.

There are no chronic aquatic toxicity data on sodium persulfate. The acute $E(L)C_{50}$ values for fish, invertebrates, and algae are >1 mg/L. Thus, sodium persulfate does not meet the criteria for toxicity.

The overall conclusion is that sodium persulfate is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Oxidizing Solid Category 3
Acute Toxicity Category 4 [Oral]
Skin Irritant Category 2
Eye Irritant Category 2
Skin Sensitizer Category 1
Respiratory Sensitization Category 1
STOT SE Category 3 [Respiratory Irritation]

B. Labelling

Danger

C. Pictogram

X. SAFETY AND HANDLING

A. First Aid

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. Get medical attention.

Skin Contact
Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: sulfur oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use personal protective clothing. Avoid dust formation. Ensure adequate ventilation. Do not breathe dust. Wear respiratory protection if ventilation is inadequate. Avoid contact with skin, eye, and clothing.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
Scoop up and remove.

D. STORAGE AND HANDLING

General Handling
Good general ventilation should be used. Ventilation rates should be matched to conditions. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits.

Other Handling Precautions
Avoid eye and skin contact. Avoid creating or inhaling dust.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place. Do not store with alkalis, acids, or reducing agents.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
The workplace exposure standard for sodium persulfate in Australia is 0.01 mg/m^3 as a peak exposure. A peak limitation is defined by Safe Work Australia as a maximum or peak airborne concentration of a substance determined over the shortest analytically practicable period of time which does not exceed 15 minutes.

Engineering Controls

Ensure adequate ventilation. Localized ventilation should be used to control dust levels below permissible exposure limits.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection when airborne concentrations are expected to be high.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible. Remove and wash contaminated clothing before re-use. Contaminated work clothing should not be allowed out of the workplace.

F. TRANSPORT INFORMATION

UN1505 SODIUM PERSULPHATE
Class: 5.1
Packing Group: III

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SODIUM POLYACRYLATE

This dossier on sodium polyacrylate do not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of sodium polyacrylate in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the HERA document on polyacrylic acid homopolymers and their sodium salts (CAS 9003-04-7) (HERA, 2014). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch et al., 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): 1-Propenoic acid, homopolymer, sodium salt

CAS RN: 9003-04-7

Molecular formula: $(C_3H_4O_2)x$-.x-Na

Molecular weight: Variable

Synonyms: 2-Propenoic acid, homopolymer, sodium salt; polyacrylic acid, sodium salt, sodium polyacrylate; acrylic acid, polymers, sodium salt; poly(acrylic acid), sodium salt; polyacrylate sodium salt

II. PHYSICO-CHEMICAL PROPERTIES

Sodium polyacrylates are polymers that range in molecular weight (MW) from 1,000 to 78,000 (HERA, 2014). The sodium polyacrylates mostly used in detergents have a typical molecular weight of approximately 4,500 (HERA, 2014). For sodium polyacrylate (MW 4,500), the melting point is >150^{o}C, where is decomposes; and the water solubility is >400 g/L (HERA, 2014).

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Sodium polyacrylates are not readily biodegradable. Due to their high molecular weights, sodium polyacrylates are not expected to bioaccumulate. In addition, these water-soluble polymers can form insoluble calcium salts in natural waters, suggesting that bioaccumulation is unlikely.

B. Abiotic Degradation

Abiotic degradation mechanisms, such as photolytic and hydrolytic processes, do not significantly influence the environmental fate of sodium polyacrylates (HERA, 2014).

C. Biodegradation

Sodium polyacrylates are not readily biodegradable, but are partly accessible to ultimate biodegradation particularly under long incubation conditions. Sodium polyacrylates with MW of <2,000 are partly biodegradable under the conditions of soil and sediment inoculation. Test results with activated sludge inoculum indicate different elimination degrees, apparently due to adsorption and precipitation processes. The removal degrees of different sodium polyacrylates show no clear relationship between elimination extent and molecular weight (HERA, 2014).

D. Bioaccumulation

No experimental studies are available on sodium polyacrylates. Estimated bioconcentration factors based on octanol-water coefficients are not appropriate since the molecular weights of these polymers are higher than the molecular weight range for the QSAR models. Due to their high molecular weights, sodium polyacrylates are not expected to bioaccumulate. In addition, these water-soluble polymers can form insoluble calcium salts in natural waters, suggesting that bioaccumulation is unlikely.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The acute toxicity of sodium polyacrylates are very low by the oral and dermal routes. These polymers are not irritating to the skin and eyes; nor are they skin sensitizers. No systemic toxicity was observed in rats given high oral doses of a sodium polyacrylate for four weeks; pulmonary irritation was seen in rats that inhaled an aerosol or dust of a sodium polyacrylate for 13 weeks, but there was no systemic toxicity. No developmental toxicity was seen in rats when given high oral doses of sodium polyacrylates. Sodium polyacrylates are not genotoxic.

B. Acute Toxicity

Acute oral toxicity studies have been conducted in rats on sodium polyacrylates with molecular weights (MW) of 1,000 to 78,000. The oral LD_{50} values are >5,000 or >10,000 mg/kg (the highest doses tested), with the exception of one study on a 3,500 MW sodium polyacrylate, which was reported to be >1,000 mg/kg (the attainable limit dose of a 10% aqueous solution) (HERA, 2014). [Kl. scores = 2]

The dermal LD_{50} values in rabbits for sodium polyacrylates with MW of 1,000 or 4,500 are >5,000 mg/kg (HERA, 2014). [Kl. scores = 2]

No acute inhalation studies are available.

C. Irritation

The sodium polyacrylates with MW of 1,000 to 78,000 are not irritating to the skin or eyes (HERA, 2014). [Kl. scores = 2]

D. Sensitisation

Sodium polyacrylates with MW of 4,500 or 78,000 were not dermal sensitizers in the guinea pig maximization test (HERA, 2014). [Kl. scores = 2 and 4, respectively]

E. Repeated Dose Toxicity

Oral

Male rats were fed diets containing 0 or 2.5% sodium polyacrylate (MW 2,500) for four weeks. Body weight, body weight gain, and appearance of the animals were similar between treated and control animals. In the fourth week of the study, a small, but significant, decrease in total weight of bone minerals was detected and confirmed by radiographic and histological examination. There was a significant reduction in the concentration of magnesium in the bones and plasma of the treated animals. Calcium loss was slight and not statistically significant. Urinary excretion of sodium and phosphorus was markedly increased; calcium only slightly increased. The authors of the study

interpreted the finding as a metabolic imbalance rather than systemic toxicity. Sodium excretion could have been increased by the high intake of the sodium-neutralized test substance. The NOAEL for the study was considered to be 2.5% sodium polyacrylate in the diet, which was estimated to be 1,136 mg/kg-day (HERA, 2014). [Kl. score = 2]

Inhalation

Male and female rats were exposed by inhalation to 0, 0.2, 1.0, or 5.0 mg/m^3 sodium polyacrylate (MW 4,500) as an aerosol for 6 hours/day, 5 days/week for 13 weeks. Additional groups of animals were exposed for 13 weeks followed by a 91-day recovery period. There were no treatment-related effects on body weights, organ weights, feed and water consumption, clinical observations, and blood chemistry. In the histopathologic examination, the lungs of the mid- and high-dose animals showed signs of mild pulmonary irritation: increases in polymorphonuclear granulocytes or alveolar macrophages, pneumocyte hyperplasia, alveolar wall thickening and focal alveolitis. The lung effects were reversible and were not seen in the recovery group animals. The NOEC for systemic effects in this study was considered to be 5 mg/m^3, and the NOEC for localized irritation is 0.2 mg/m^3 (HERA, 2014). [Kl. score = 2]

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

The results of the *in vitro* studies on sodium polyacrylates are presented below in Table 1. All of the studies show that sodium polyacrylates are not mutagenic or genotoxic.

Table 1: In Vitro Genotoxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test System	Results*	Klimisch Score	Reference
2,000	Bacterial reverse mutation	-	2	HERA (2014)
2,000	Mouse lymphoma	-	2	HERA (2014)
2,000	Unscheduled DNA synthesis	-	2	HERA (2014)
4,500	Bacterial reverse mutation	-	2	HERA (2014)
4,500	Mouse lymphoma	-	2	HERA (2014)

4,500	Cytogenetic (CHO cells)	-	2	HERA (2014)
4,500	Bacterial reverse mutation	-	2	HERA (2014)
4,500	Mammalian cell gene mutation	-	2	HERA (2014)
4,500	Unscheduled DNA synthesis	-	2	HERA (2014)

*+, positive; -, negative

In Vivo Studies

There was no increase in micronuclei in polychromatic erythrocytes from the bone marrow of mice given a single oral gavage dose of 13,850 mg/kg sodium polyacrylate with a MW of 2,000 (HERA, 2014).

G. Carcinogenicity

No studies are available.

H. Reproductive Toxicity

No studies are available

I. Developmental Toxicity

Pregnant female rats were dosed by oral gavage with 0, 500, 1,000, or 3,000 mg/kg sodium polyacrylate (MW 4,500) on GD 6 to 15. At 3,000 mg/kg, the dams had soft or liquid stools during the treatment period. There was no maternal or developmental toxicity observed in this study. The NOAEL for maternal and developmental toxicity is 3,000 mg/kg-day (HERA, 2014). [Kl. score = 2]

Pregnant female rats were dosed by oral gavage with 0, 125, 375, or 1,125 mg/kg sodium polyacrylate (MW 90,000 as a 77.5% aq. solution) during GD 6 to 13. Some of the dams were sacrificed on GD 13 and the remaining on GD 19. One mid-dose dam and 6 high-dose dams died during the study; of these, three of the high-dose deaths were treatment-related and the remaining were considered the result of gavage errors. There was a transient decrease in feed consumption in the high-dose dams during GD 7-9, but not other indications of maternal toxicity. There was no developmental toxicity. The NOAELs for maternal and developmental toxicity are 375 and 1,125 mg/kg-day (HERA, 2014). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

NICNAS has assessed sodium polyacrylates in an IMAP Tier 1 assessment and considers it “a chemical identified as low concern to human health by application of expert validated rules”.[1]

The toxicological reference values developed for sodium polyacrylates follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

<u>Oral</u>

A 4-week dietary study showed no systemic toxicity in rats given 2.5% sodium polyacrylate (MW 2,500) in their feed. The estimated dose is 1,136 mg/kg-day. Two pre-natal developmental toxicity studies showed no effects at the highest dose tested: 3,000 and 1,125 mg/kg-day for sodium polyacrylates with MW of 4,500 and 90,000, respectively. The NOAEL of 1,136 mg/kg-day from the 4-week dietary study will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10

[1] https://www.nicnas.gov.au/chemical-information/imap-assessments/imap-assessments/tier-i-human-health-assessments#cas-A_9003-04-7

UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subacute to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 1,136 (10 x 10 x 1 x 10 x 1) = 1,136/1,000 = 1.0 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD:

Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (1 x 70 x 0.1)/2 = 3.5 mg/L

B. Cancer

No carcinogenicity studies have been conducted on sodium polyacrylates. Therefore, a cancer reference value was not derived.

VI. Human Health Hazard Assessment of Physico-Chemical Properties

Sodium polyacrylates do not exhibit the following physico-chemical properties:

- Flammability
- Explosivity
- Oxidising potential.

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Sodium polyacrylates are a low toxicity concern for aquatic organisms, terrestrial invertebrates, and plants.

B. Aquatic Toxicity

Acute Studies

Table 2 lists the results of acute aquatic toxicity studies on sodium polyacrylates.

Table 2: Acute Aquatic Toxicity Studies on Sodium Polyacrylates

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
1,000	*Brachydanio rerio*	96-hr LC_{50}	>200	1	HERA, 2014

78,000	*Scenedesmus subspicatus*	96-hr EC_{50}	44	2	HERA, 2014

Chronic Studies

Table 3 lists the results of chronic aquatic toxicity studies on sodium polyacrylates.

Table 3: Chronic Aquatic Toxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
4,500	*Pimephales promelas*	32-d NOEC	56	2	HERA, 2014
4,500	*Brachydanio rerio*	28-d NOEC	>450	1	HERA, 2014
78,000	*Brachydanio rerio*	14-d NOEC	>400	2	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	450	1	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	58	1	HERA, 2014
4,500	*Daphnia magna*	21-d NOEC	12	2	HERA, 2014
78,000	*Daphnia magna*	21-d NOEC	100	2	HERA, 2014
4,500	*Scenedesmus subspicatus*	96-hr NOEC	180	2	HERA, 2014
78,000	*Scenedesmus subspicatus*	96-hr NOEC	32.8	2	HERA, 2014

There is considerable variability in the chronic aquatic toxicity results for *Daphnia magna* for sodium polyacrylates with the same molecular weight of 4,500. This was discussed in HERA (2014) and was explained by the solubility of sodium polyacrylates in water. In distilled water, the solubility of sodium polyacrylates with the molecular weight of 4,500 is >400 mg/L; however, under test conditions water solubility will decrease due to the presence of Ca^{++} and Mg^{++} (as measured by water hardness). In a study by BASF (reviewed in HERA, 2014), the water solubility of sodium polyacrylate (MW 4,500) was determined with radiolabelled compounds in a test system with a calcium concentration of 70 mg/L, which corresponds to the mean water hardness to the media used in an OECD TG 202 test. Under these conditions, the water solubility of sodium polyacrylate was 1.3 mg/L after 24 hours. So, one explanation for the variability of the chronic *Daphnia* studies may be due to differences in water hardness.

C. Toxicity to Sediment Organisms

The 96-hr EC_0 to *Chironomus riparius* (larvae) is >4,500 mg/kg sediment dry weight (HERA, 2014).

D. Terrestrial Toxicity

The results of terrestrial toxicity studies on sodium polyacrylate polymers are listed below.

Table 3: Terrestrial Toxicity Studies on Sodium Polyacrylates (HERA, 2014)

Mean MW	Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
4,500	*Eisenia foetida foetida*	14-d EC_0	1,000	1	HERA, 2014
78,000	*Eisenia foetida andrei*	14-d EC_0	1,000	2	HERA, 2014

*Soil organisms

E. Calculation of PNEC

The PNEC calculations for sodium polyacrylates follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute E(L)C_{50} values are available for fish (>200 mg/L), invertebrates (>200 mg/L), and plants (40 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 12 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 12 mg/L for invertebrates. The $PNEC_{water}$ is 1.2 mg/L.

PNEC sediment

Experimental results are available for one trophic level. There were no visual signs of toxicity to *Chironomus riparius* (larvae) at the highest concentration tested (>4,500 mg/kg sediment dry weight) (HERA) 2014). The EC_0 is considered to be above 4,500 mg/kg and an assessment factor cannot apply. Thus, the equilibrium partitioning method will be used to determine the $PNEC_{sed}$. The HERA (2014) risk assessment calculated a $PNEC_{sed}$ of 130 mg/kg sediment wet weight using the default of

0.05 as the weight fraction of organic carbon in sediment according to the EU Technical Guidance Document (TGD) (EU 2003).

PNEC soil

Experimental results are available for three trophic levels. An acute LC_{50} value is available for earthworms (1,000 mg/kg soil dry weight). A 21-day NOEC for *Brassica rapa* was reported to be 1,000 mg/kg soil dry weight. Results from two long-term studies are available for soil microorganisms, with the NOECs for nitrogen and carbon transformation being >2,500 mg/kg soil dry weight. On the basis that the data consists of short-term tests, as well as one long-term test from one trophic level, an assessment factor of 100 has been applied to the lowest reported long-term NOEC of >2,500 mg/kg soil dry weight. The $PNEC_{soil}$ is 25 mg/kg soil dry weight.

VIII. PBT ASSESSMENT

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009, ECHA, 2008).

The sodium polyacrylates are not readily biodegradable; thus they meet the screening criteria for persistence.

The sodium polyacrylates are expected to have high molecular weights and are not expected to be bioavailable. Thus these polymers do not meet the criteria for bioaccumulation.

Chronic NOECs for fish, daphnia and algae are available for sodium polyacrylates, and the NOEC values are >0.1 mg/L. Thus sodium polyacrylates do not meet the screening criteria for toxicity.

The overall conclusion is that sodium polyacrylates are not PBT substances.

IX. CLASSIFICATION AND LABELLING

A. Classification

Aquatic Acute Toxicity Category 3

B. Labelling

No signal word.

C. Pictograms

None.

X. SAFETY AND HANDLING

A. First Aid

Eye Contact

In case of contact, immediately flush eyes with plenty of water for at least 5 minutes. If symptoms persist, seek medical advice.

Skin Contact

Wash thoroughly with soap and water..

Inhalation

If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion

Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. If symptoms develop, seek medical advice.

B. Firefighting Information

Extinguishing Media

Water fog, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards

Burning produces harmful and toxic fumes. Heat from fire may melt, decompose polymer, and generate flammable vapors. Combustion products may include: Carbon monoxide, carbon dioxide, and unburned hydrocarbons (smoke). Dust can accumulate static charges which can cause an incendiary electrical discharge. Fine dust dispersed in air in sufficient concentrations, and in the presence of an ignition source, is a potential dust explosion hazard.

Special Protective Equipment for Firefighters

Wear a self-contained breathing apparatus.

C. Accidental Release Measures

Personal Precautions

Use appropriate protective equipment. Potential combustible dust hazard. Avoid generating dust. Creates dangerous slipping hazard on any hard smooth surface.

Environmental Precautions

Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilt

Scoop up and remove.

D. Storage and Handling

General Handling

Avoid dust accumulation in enclosed space. Avoid generating dust; fine dust dispersed in air in sufficient concentrations, and in the presence of an ignition source is a potential dust explosion

hazard. Electrostatic charge may build up during handling. Equipment, container and metal containers should be grounded and bonded.

Storage

Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place. Use adequate ventilation to avoid excessive dust accumulation. Store away from excessive heat and away from strong oxidizing agents. Take measures to prevent the build up of electrostatic charge.

E. Exposure Controls/Personal Protection

Occupational Exposure Standards

Workplace Australia has not established an occupational exposure limit for sodium polyacrylates.

Engineering Controls

Use in a well ventilated area. Avoid creating dust. Take precautionary measures against static charge.

Personal Protection Equipment

Respiratory Protection: Not normally needed. But if significant exposures are possible then the following respirator is recommended: Dust/mist respirator.

Hand Protection: Normal work gloves.

Skin Protection: Normal work coveralls.

Eye protection: Wear safety glasses or goggles to protect against exposure.

Other Precautions: Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. Transport Information

Sodium polyacrylates are not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

SODIUM SULFATE

This dossier on sodium sulfate does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of sulfate in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained the OECD-SIDS documents on sodium sulfate (OECD, 2005a,b), and from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBSTANCE IDENTIFICATION

Chemical Name (IUPAC): Disodium sulfate

CAS RN: 7757-82-6

Molecular formula: Na_2SO_4

Molecular weight: 142.04

Synonyms: Sodium sulfate; disodium sulfate; sodium bisulfate; sulfuric acid, disodium salt

SMILES: [O-]S(=O)(=O)[O-].[Na+].[Na+]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Sodium Sulfate

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White crystalline solid,	2	ECHA
Melting Point	ca. 884°C	2	ECHA
Density	2.7 g/cm^3 @ 20°C	2	ECHA
Water Solubility	445.5 g/L @ 20°C	1	ECHA
Auto flammability	Not auto-flammable	1	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

Sodium sulfate dissociates in aqueous media to sodium (Na^+) and sulfate (SO_4^{2-}) ions in water.

Biodegradation is not applicable to inorganic compounds. Sodium sulfate is not expected to bioaccumulate; it will dissociate to ions that are ubiquitous in the environment. Sodium sulfate is not expected to absorb to soil or sediment because of its dissociation properties and high water solubility.

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

Sodium sulfate exhibits low acute toxicity by the oral and inhalation routes. It is not irritating to the skin and eyes; and it is not a skin sensitizer. In a reproductive and developmental toxicity screening study, there was no indication of any toxicity in rats given oral doses as high as 1,000 mg/kg-day. Sodium sulfate is not genotoxic.

B. Acute Toxicity

The oral LD_{50} in rats is >2,000 mg/kg (ECHA) [Kl. score = 1]. The 4-hour inhalation LC_{50} for an aerosol of sodium sulfate is >2.4 mg/L, which was the highest technically feasible aerosol concentration. The mas median aerodynamic diameters (MMAD) were 2.65 to 2.71 μm (ECHA) [Kl. score = 1]. There are no data on acute dermal toxicity.

Human data indicate a very low acute toxicity of sodium sulfate. High oral doses of sodium sulfate, from 300 mg/kg up to 20 grams for an adult, are well tolerated, except from (intentionally) causing severe diarrhea (OECD, 2005a,b).

C. Irritation

Application of 0.5 g sodium sulfate (in PEG 400) to the skin of rabbits for 4 hours was not irritating (ECHA) [Kl. score = 1].

Instillation of 90 mg sodium sulfate to the eyes of rabbits was not irritating (ECHA) [Kl. score = 1].

D. Sensitization

Sodium sulfate was not considered a skin sensitizer in a mouse local lymph node assay (ECHA). [Kl. score = 1]

E. Repeated Dose Toxicity

Oral

In a reproductive and developmental toxicity screening (OECD 421) study, male and female Wistar rats were dosed by oral gavage with 0, 100, 300, or 1,000 mg/kg sodium sulfate for a total of 4 weeks for males and 7 weeks for females. There was no evidence of toxicity at any dose level. The NOAEL for systemic toxicity is 1,000 mg/kg-day, the highest dose tested.

Inhalation

No studies are available.

Dermal

No studies are available.

F. Genotoxicity

In Vitro Studies

The *in vitro* genotoxicity studies on sodium sulfate are presented in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Sodium Sulfate

Test System	Results*		Klimisch Score	Reference
	-S9	+S9		
Bacterial reverse mutation (*S. typhimurium* and E. coli strains)	-	-	1	ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-	-	1	ECHA
Chromosomal aberration (Chinese hamster lung fibroblasts)	-	-	1	ECHA

*+, positive; -, negative

In Vivo Studies

No studies are available.

G. Carcinogenicity

No valid studies are available.

H. Reproductive/Developmental Toxicity

A reproductive and developmental toxicity screening (OECD 421) study has been conducted on sodium sulfate. Male and female Wistar rats were dosed by oral gavage with 0, 100, 300, or 1,000 mg/kg sodium sulfate. There were no deaths during the study and no clinical signs. Body weights, body weight gain, and feed consumption were similar across all groups. There was no reproductive or developmental toxicity at any dose level. The NOAEL for systemic, reproductive, and developmental toxicity is 1,000 mg/kg-day, the highest dose tested (ECHA) [Kl. score = 1].

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

Toxicological reference values were not derived. Sodium sulfate dissociates in water to sodium andsulfate ions.

The Australian drinking water guideline value for sodium is 180 mg/L based on aesthetics (ADWG, 2011).

The Australian drinking water guideline value for sulfate is 500 mg/L based on health. Concentrations of >500 mg/L can have purgative effects. There is also an Australian drinking water guideline value for sulfate of 250 mg/L based on aesthetics; it is the taste threshold (ADWG, 2011).

B. Cancer

There are no valid carcinogenicity studies on sodium sulfate. Thus, a cancer reference value was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Sodium sulfate does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Sodium sulfate is of low acute concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on sodium sulfate.

Table 3: Acute Aquatic Toxicity Studies on Sodium Sulfate

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-h LC_{50}	7,960	2	Mount *et al.* (1997)
Daphnia magna	48-h EC_{50}	4,736*	2	Davies and Hall (2007)

* Standard test conditions: 100 mg $CaCO_3$/L and Ca:Mg ratio of 0.7.

Chronic Studies

The lowest 7-day NOEC from a *Ceriodapnia dubia* reproduction study, in which the test media contained varying degrees of water hardness, was 1,109 mg/L (Soucek, 2007).

C. Sediment Toxicity

The lowest 96-hour LC_{50} value to *Hyalella azteca* in series of studies involving different hardness of water was 757 mg/L (Soucek and Kennedy, 2005). In another study with *Hyalella Azteca*, the lowest 96-hour LC_{50} value (in water with the lowest hardness) was 841 mg/L (Davies and Hall, 2007). The lowest 96-hour LC_{50} value to *Chironomus tentans* in series of studies involving different hardness of water was 20,899 mg/L (Soucek and Kennedy, 2005).

D. Terrestrial Toxicity

No adequate studies were located.

E. Calculation of PNEC

The PNEC calculations for sodium sulfate follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for two trophic levels. Acute $E(L)C_{50}$ values are available for fish (7,960 mg/L) and *Daphnia* (4,736 mg/L). A chronic toxicity study has also been conducted on *Ceriodapnia dubia*, but this study is considered inadequate for deriving a PNEC value. On the basis that the data consists of short-term results from two trophic levels, an assessment factor of 1,000 has been applied to the lowest reported $E(L)C_{50}$ value of 4,736 mg/L for *Daphnia*. The $PNEC_{water}$ is 4.7 mg/L.

PNEC sediment

No reliable experimental toxicity data on sediment organisms are available. Sodium sulfate dissociates completely in water with its environmental distribution is dominated by its high water solubility. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium sulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium sulfate to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PNEC soil

No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium sulfate is dominated by its water solubility. Sorption of sodium sulfate should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. K_{ow} and K_{oc} parameters do not readily apply to inorganics, such as sodium sulfate. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium sulfate is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Sodium sulfate is an organic salt that dissociates completely to sodium and sulfate ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and sulfate ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to sodium sulfate or its dissociated ions.

Sodium and sulfate ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus sodium sulfate is not expected to bioaccumulate.

The NOEC from a chronic toxicity study in *Ceriodaphnoa rerio* is >0.1 mg/L, and the acute E(L)C_{50} values for fish and *Daphnia* are >1 mg/L. Thus sodium sulfate does not meet the screening criteria for toxicity.

The overall conclusion is that sodium sulfate is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal words.

C. Pictogram

None

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact

Immediately flush eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. If symptoms persist, seek medical attention.

Skin Contact

Wash with soap and water.

Inhalation

If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion

Do not induce vomiting. Rinse mouth with water and then drink a small amount of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: sodium and sulfur oxides.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Use appropriate protective equipment. Avoid creating and breathing dust.

Environmental Precautions

Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled

Scoop and remove.

D. STORAGE AND HANDLING

General Handling

Avoid creating or inhaling dust.

Storage

Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational standard for sodium sulfate.

Engineering Controls

Use in a well-ventilated area.

Personal Protection Equipment

Respiratory Protection: Respiratory protection is not required.

Hand Protection: Chemical resistant protective gloves.

Skin Protection: Body protection must be chosen depending on activity and possible exposure.

Eye Protection: Safety glasses with side-shields.

Other Precautions: Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Sodium sulfate is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods Code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

TRIETHANOLAMINE

This dossier on triethanolamine does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of triethanolamine in its use in drilling muds and hydraulic fracturing fluids. The majority of information presented in this dossier was obtained from the ECHA database that provides information on chemicals that have been registered under the EU REACH (ECHA). Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): 2-[bis(2-hydroxyethyl)amino]ethan-1-ol

CAS RN: 102-71-6

Molecular formula: $C_6H_{15}NO_3$ or $(CH_2OHCH_2)_3N$

Molecular weight: 149.19

Synonyms: Triethanolamine; 2,2',2"-nitrilotriethanol; 2,2',2"-nitrilotris[ethanol]; ethanol, 2,2',2"-nitrilotri- (8Cl); ethanol, 2,2',2"-nitrilotris- (9Cl); nitrilotriethanol; TEA; tris(beta-hydroxyethyl)amine; tris(2-hydroxyethyl)amine

SMILES: C(CO)N(CCO)CCO

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Triethanolamine

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Colorless to pale-yellow liquid with an amine-like odor.	2	ECHA
Melting Point	20.5°C	2	ECHA
Boiling Point	336.1°C	2	ECHA

Auto flammability	324°C	2	ECHA
Viscosity	830.2 mm^2/s @ 20°C 181.5 mm^2/s @ 40°C	2	ECHA

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

Triethanolamine is readily biodegradable, and it has a low potential to bioaccumulate. Triethanolamine will not adsorb significantly to suspended solids and sediments in water and would be highly mobile in soil.

B. Biodegradation

Triethanolamine is readily biodegradable. In an OECD 301E test, there was 96% degradation after 19 days (ECHA). [Kl. score = 2]

Triethanolamine was completely degraded after incubation in municipal activated sludge for 1 or 5 days (West and Gonsior, 1996). The rate constants in all test batches for degradation and mineralization were reported to be >0.359. Thus, triethanolamine can be considered to be readily biodegradable. [Kl. score = 2]

C. Environmental Distribution

Adsorption/desorption

No experimental data are available for triethanolamine. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} value from log K_{ow} is 0.3046 L/kg. The estimated K_{oc} value from the molecular connectivity index (MCI) is 10 L/kg.

E. Bioaccumulation

Triethanolamine has been tested in a bioconcentration flow-through fish (OECD 305) test using *Cyprinus carpio*. The BCF was determined to be <0.4 and <3.9 at triethanolamine concentrations of 2.5 and 0.25 mg/L, respectively (ECHA). [Kl. score = 2]

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

The acute toxicity of triethanolamine by the oral, dermal, and inhalation routes is very low. Triethanolamine is not a skin or eye irritant; it is not a skin sensitizer to guinea pigs, but it may cause an allergic skin reaction in a small proportion of individuals. Repeated exposure by the oral route in rats showed no adverse effects. Repeated exposure by the inhalation caused effects to the respiratory tract and skin, respectively, in rats as a result of chronic irritation; but no target organs were identified from systemic exposure. Triethanolamine is not genotoxic, and lifetime oral and dermal studies in rats showed no clear carcinogenic effects. Developmental toxicity was seen in rats at oral doses that caused maternal toxicity.

B. Acute Toxicity

The oral LD_{50} in rats is 6,400 mg/kg (ECHA) [Kl. score = 2], and the dermal LD_{50} in rabbits is >2,000 mg/kg (ECHA) [Kl. score = 2]. No deaths seen in rats following an 8-hour exposure to a saturated vapor atmosphere [approximately 1.8 mg/m^3] (ECHA) [Kl. score = 2].

C. Irritation

Application of 0.5 mL to the skin of rabbits for 4 hours under occlusive conditions was not irritating. The mean of the 24, 48, and 72 hours erythema and edema scores were zero (ECHA). [Kl. score = 1]

Instillation of 0.1 mL into the eyes of rabbits were minimally irritating (Griffith *et al.*, 1980). [Kl. score = 2]

D. Sensitization

Triethanolamine was not considered a skin sensitizer when tested in a guinea pig maximization test (ECHA). [Kl. score = 1]

Patch test results with triethanolamine on patients from 1992 to 2007 were collected and evaluated. There were 85,098 patients that were tested with triethanolamine; of these, 323 (0.35%) patients tested positively to triethanolamine. The positive reactions that were interpreted as allergic seem to be caused by exposure to triethanolamine in cosmetics and/or topical therapeutic preparations possibly on damaged skin (Lessmann *et al.*, 2009).

E. Repeated Dose Toxicity

<u>Oral</u>

Male and female Cox CD rats were fed diets containing 0, 250, 500 or 1,000 mg/kg triethanolamine for 91 days. There were no effects that were considered treatment-related. The NOAEL for this study is 1,000 mg/kg-day (ECHA). [Kl. score = 2]

Inhalation

Male and female Wistar rats were exposed (nose-only) by inhalation to 0, 0.02, 0.1, or 0.5 mg/L triethanolamine aerosol 6 hours/day, 5 days/week for 28 days. There was no mortality; the only clinical signs were reddish crusts on the nasal edges in the 0.5 mg/L animals during the second half of the exposure period. Body weights and body weight gain were similar across all groups. There was no treatment-related changes in the hematology parameters, clinical chemistry, and neurobehavioral endpoints. Local inflammatory changes were observed in the submucosa of the larynx region. In both sexes, there was a tendency for a concentration-dependent increase in incidence and severity of the inflammatory lesions, with the effects greater in males than females. The NOAEC for systemic effects is 0.5 mg/L; the NOAEC for localized effects is 0.02 mg/L (ECHA) [Kl. score = 1].

Dermal

Male and female F344 rats were given dermal applications of 0, 125, 250, 500, 1,000, and 2,000 mg/kg triethanolamine 5 days/week for 90 days. There was deaths during the study. Body weight gain was significantly reduced (-33%) in the 2,000 mg/kg males compared to controls. Body weight gain was also significantly reduced (-13% to 36%) for the ≥125 mg/kg females. The mean final body weights of the 2,000 mg/kg males and females were significantly reduced. The only treatment-related clinical signs occurred at the site of dermal application. Brain weights relative to body weights were significantly elevated in the 2,000 mg/kg animals; because absolute brain weights were unaffected, the changes in brain weights is likely due to reduced body weights in these animals. Absolute kidney weights were increased in the ≥1,000 mg/kg animals; relative kidney weights were elevated in the ≥250 mg/kg males and ≥1,000 mg/kg females. Absolute and relative spleen weights were lower in the 2,000 mg/kg females; relative spleen weights were elevated in the ≥1,000 mg/kg males. Absolute and relative thymus weights were increased in the 2,000 mg/kg males. Relative liver weights were increased in the 500 and 1,000 mg/kg males. Absolute and relative lung weights were lower in the 2,000 mg/kg males. Relative testes weights were increased in the 2,000 mg/kg males. Hematological changes were seen in the 2,000 mg/kg animals and were considered to be due to an inflammatory response from dermal irritation at the application site. Elevated SGOT levels were noted in the 250 and 2,000 mg/kg males; and mean SGPT levels were significantly increased in the 2,000 mg/kg males. Elevated serum urea nitrogen, albumin, SGOT, and SGPR levels were noted in the 2,000 mg/kg females. At study termination, the specific gravity of urine was elevated in the 2,000 mg/kg males; urine protein levels for the ≥500 mg/kg males were significantly lower. The specific gravity of urine was elevated in the ≥1,000 mg/kg females; urine

glucose concentrations were also increased in these two dose groups. Apart for skin lesions at the site of application, there were no treatment-related histopathologic changes. The NOAEL for localized effects is 125 mg/kg-day based on chronic-active inflammation and acanthosis at the site of application in males. The NOAEL for systemic toxicity is 125 mg/kg-day based on increased relative kidney weights in males (ECHA) [Kl. score = 2].

F. Genotoxicity

In Vitro Studies

The findings from the *in vitr*o genotoxicity studies on triethanolamine are presented below in Table 2.

Table 2: *In vitro* Genotoxicity Studies on Triethanolamine

Test System	**Results***		**Klimisch Score**	**Reference**
	-S9	**+S9**		
Bacterial reverse mutation (*S. typhimurium* strains)	-	-	2	Mortelsman *et al.* (1986); ECHA
Mammalian cell gene mutation (mouse lymphoma L5178Y cells)	-	-	1	ECHA
Chromosomal aberration (CHO cells)	-	-	2	Galloway *et al.* (1987); ECHA
Sister chromatid exchange (CHO cells)	-	-	2	Galloway *et al.* (1987); ECHA

*+, positive; -, negative

In Vivo Studies

Male and female $B6C3F_1$ mice were given dermal applications of triethanolamine, 5 days/week for 13 weeks. There were no increase in the frequency of micronucleated erythrocytes in the peripheral blood (NTP, 2004).

Triethanolamine did not induce sex-linked recessive lethal mutations in germ cells of adult male *Drosophila melanogaster* exposed by feeding or injection (Yoon *et al.*, 1985).

G. Carcinogenicity

Oral

Male and female F344 were given triethanolamine in their drinking water for two years. The doses were 0, 1, and 2%; but starting on week 69, the doses for females were 0.5 and 1%. The estimated daily intakes for 1 and 2% dose groups were approximately 667 and 1,333 mg/kg-day; and the estimated daily intakes for the 0.5% and 1% in females were approximately 333 and 667 mg/kg-day. There were no statistically significant increases in the incidence of tumors between treated and control groups when analyzed by Chi-square test. However, there was an increase in nephrotoxicity which appeared to have an adverse effect on the life expectancy of the treated animals, especially the females. So, an age-adjusted statistical analysis was conducted. There was a positive trend ($p<0.05$) in the occurrence of liver tumors in males and of uterine endometrial sarcomas and renal-cell adenomas in females. These tumors have been observed spontaneously in this strain of rats, and their incidences in the controls were lower than historical controls for other laboratories. The results may indicate that a positive trend in the occurrence of these tumors is not attributable to triethanolamine exposure. Increased incidence of kidney tumors in the high-dose females may have been connected with kidney damage. Histopathologic examination of the kidney effects observed in the treated groups, especially the high-dose females, showed acceleration of chronic nephropathy. Also, mineralization of the renal papilla, nodular hyperplasia of the pelvic mucosa, and pyelonephritis with or without papillary necrosis were also observed (Maekawa *et al.*, 1986; ECHA) [Kl. score = 2]

Male and female B6C3F$_1$ mice were given in their drinking water 0, 1 or 2% triethanolamine (0 and approximately 1,600 and 3,200 mg/kg-day) for 82 weeks. Mortality, organ weights and tumor incidences were similar between treated and control animals (Konishi *et al.*, 1992; ECHA). [Kl. score = 2]

Inhalation

No studies are available.

Dermal

Male and female F344 rats were given dermal applications of triethanolamine, 5 days/week for two years. The doses were: 0, 32, 63 or 125 mg/kg-day for males, and 0, 63, 125 or 250 mg/kg-day for females. There were no treatment-related carcinogenic effects in either sexes (NTP, 1999). [Kl. score = 1]

Male and female B6C3F$_1$ mice were given dermal applications of triethanolamine, 5 days/week for two years. The doses were: 0, 200, 630 and 2,000 mg/kg-day for males, and 0, 100, 300 and 1,000 mg/kg-day for females. In females, there was some evidence of carcinogenicity activity based on increased incidences of hepatocellular adenomas. In males, there was equivocal evidence of carcinogenicity activity based on the incidence of liver hemangiosarcomas (NTP, 2004). [Kl. score = 1]

H. Reproductive/Developmental Toxicity

In a reproductive and developmental toxicity screening (OECD 421) study, male and female Wistar rats were dosed by oral gavage with 0, 100, 300 or 1,000 mg/kg-day triethanolamine. Most of the 1,000 mg/kg-day animals and one 100 mg/kg-day animals showed transient salivation for a few minutes immediately after each treatment. This effect was considered to be induced by the unpalatability of the test substance or from local irritation of the upper digestive tract. Body weight gain was slightly lower in the 1,000 mg/kg-day females during gestation and was considered to be caused by the increased postimplantation loss rather than by a systemic effect of the test substance. In the 1,000 mg/kg-day group, there were lower mean number of implantation sites, increased postimplantation loss, and lower average litter size. There were no treatment-related effects in the F_1 pups. The NOAEL for systemic toxicity is 1,000 mg/kg-day. The NOAEL for reproductive toxicity is 1,000 mg/kg-day. The NOAEL for developmental toxicity is 300 mg/kg-day (ECHA). [Kl. score = 1]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for triethanolamine follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

There were no effects seen in a 91-day dietary study in rats, with a NOAEL of 1,000 mg/kg-day (ECHA). This NOAEL will be used for determining the oral Reference dose (RfD) and the drinking water guidance value.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 1,000/(10 x 10 x 1 x 10 x 1) = 1,000/1,000 = <u>1.0 mg/kg-day</u>

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (1.0 x 70 x 0.1)/2 = 3.5 mg/L

B. Cancer

There were no carcinogenic effects in male and female mice given triethanolamine in their drinking water for 82 weeks (Konishi et al., 1992). In a two-year drinking water study, age-adjust tumor incidence showed increased liver tumors in males, and uterine endometrial sarcomas and renal tubule adenomas in females. These tumors were not attributed to triethanolamine exposure because, in comparison with historical control incidences, the tumors reflected low incidences in the control groups rather than increased incidences in the exposed groups.

In dermal carcinogenicity studies, there was no evidence of carcinogenicity in male and female rats (NTP, 1999). In female mice, there was some evidence of carcinogenicity activity based on increased incidences of hepatocellular adenomas. In male mice, there was equivocal evidence of carcinogenicity activity based on the incidence of liver hemangiosarcomas (NTP, 2004).

A cancer reference value for triethanolamine was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Triethanolamine does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

Triethanolamine has low acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 3 lists the results of acute aquatic toxicity studies conducted on triethanolamine.

Table 3: Acute Aquatic Toxicity Studies on Triethanolamine

Test Species	Endpoint	Results (mg/L)	Klimisch score	Reference
Pimephales promelas	96-h LC_{50}	11,800	2	ECHA
Ceriodaphnia dubia	48-h EC_{50}	610	2	Warne and Schifko, 1999
Desmodesmus subspicatus	72-h EC_{50} EC_{10}	512 (neutralized) 216 (un-neutralized) 26 (neutralized)	2	ECHA

Chronic Studies

In a 21-day *Daphnia* reproduction test, the NOEC for mortality is 16 mg/L, the NOEC for reproduction rate was 125 mg/L, and the NOEC for reproduction on the appearance of first offspring was 250 mg/L (Kuehn *et al.*, 1989). [Kl. score = 2]

C. Terrestrial Toxicity

No studies are available.

D. Calculation of PNEC

The PNEC calculations for triethanolamine follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (11,800 mg/L), invertebrates (610 mg/L), and plants (512 mg/L). Results

from chronic studies are available for invertebrates (NOEC = 16 mg/L) and algae (EC_{10} = 26 mg/L). On the basis that the data consists of chronic studies for two trophic levels, an assessment factor of 50 has been applied to the lowest reported EC_{10} of 16 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is 0.32 mg/L.

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 0.25 mg/kg sediment wet weight.

The calculations are as follows:

$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$
$= (0.99/1280) \times 1000 \times 0.32$
$= 0.25$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed})/1000 \times BD_{solid}]$
$= 0.8 + [0.2 \times 0.4/1000 \times 2400]$
$= 0.99$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).
BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
$= 10 \times 0.04$
$= 0.4$

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for triethanolamine calculated from EPISUITE™ using MCI is 10 L/kg .
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil

There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 0.04 mg/kg soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
$= (0.2/1500) \times 1000 \times 0.32$
$= 0.04$

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
$= 10 \times 0.02$
$= 0.2$

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for triethanolamine calculated from EPISUITE™ using the MCI is 10 L/kg .
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Triethanolamine is readily biodegradable; thus it does not meet the screening criteria for persistence.

The BCF values for triethanolamine in fish was <3.9; thus it does not meet the criteria for bioaccumulation.

The NOEC or EC_{10} values from chronic aquatic toxicity studies on triethanolamine is >0.1 mg/L. Thus triethanolamine does not meet the criteria for toxicity.

The overall conclusion is that triethanolamine is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None.

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
Immediately flush open eyes with plenty of water for at least 15 minutes. Remove contacts, if present and easy to do. If effects occur, get medical attention immediately, preferably a physician for an ophthalmologic examination.

Skin Contact
Remove contaminated clothing. Wash thoroughly with soap and water. Seek medical attention if irritation persists.

Inhalation
If inhaled, remove from area to fresh air. Give artificial respiration if victim is not breathing. Get medical attention.

Ingestion
Rinse mouth with water and then drink plenty of water. Get medical attention. Never give anything by mouth to an unconscious person.

B. FIRE FIGHTING INFORMATION

Extinguishing Media
Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Keep product and empty container away from heat and sources of ignition. May emit toxic fumes under fire conditions. Depending on conditions, decomposition products may include the following: nitrogen oxides, carbon monoxide, carbon dioxide.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and chemical-protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment. Handle in accordance with good industrial hygiene and safety practice. Avoid contact with skin, eyes, and clothing.

Environmental Precautions
Prevent from entering sewers, waterways, or low areas.

Steps to be Taken if Material is Released or Spilled
For large amounts: dike spillage and pump off product. For residues: pick up with suitable absorbent material. Dispose of contaminated material as prescribed.

D. STORAGE AND HANDLING

General Handling
Keep product and empty container away from heat and sources of ignition. Ensure adequate ventilation, especially in confined areas.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
The workplace exposure standard for triethanolamine in Australia is 5 mg/m^3 as an 8-hour TWA, with a sensitization notation.

Engineering Controls
Good general ventilation should be used. Use local exhaust ventilation, or other engineering controls to maintain airborne levels below exposure limit guidelines.

Personal Protection Equipment

Respiratory Protection:
Use respiratory protection in case of vapor or aerosol release.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Wearing of closed work clothing is recommended. Ensure that eyewash stations and safety showers are close to the workstation location.

F. TRANSPORT INFORMATION

Triethanolamine is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

TRIBUTYL TETRADECYL PHOSPHONIUM CHLORIDE

This dossier on tributyl tetradecyl phosphonium chloride (TTPC) does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of TTPC in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name (IUPAC): Tributyl(tetradecyl)phosphonium;chloride

CAS RN: 81741-28-8

Molecular formula: $C_{26}H_{56}PCl$

Molecular weight: 435.15

Synonyms: Tributyl tetradecyl phosphonium chloride; TTPC; tri-n-butyltetradecylphosphonium chloride; Bellacide 350; Bellacide 355

SMILES: CCCCCCCCCCCCCC[P+](CCCC)(CCCC)CCCC.[Cl-]

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of TTPC

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	Clear, colorless liquid	4	BWA Additives (2016)
Boiling Point	100°C*	4	BWA Additives (2016)
Specific Gravity	0.98 – 1.00 @ 20°C	4	BWA Additives (2016)
Partition Coefficient (log K_{ow})	2.45	4	BuruEnergy
Viscosity	55-65 mm^2/s @ 25°C	4	BWA Additives (2016)

*5% aqueous solution of TTPC

TTPC is a non-oxidizing biocide. Information on TTPC in this dossier has been obtained from BWA™ Water Additives, a producer of TTPC. BWA™ Water Additives produces a 5% or 50% aqueous solution of TTPC, which is sold under the product names Bellacide® 355 and Bellacide® 350, respectively.

III. ENVIRONMENTAL FATE PROPERTIES

A. Summary

TTPC is stable over a wide pH range and is not susceptible to photodegradation. TTPC is biodegradable, but not readily biodegradable. It will strongly adsorb to soil and sediment. TTPC is not expected to bioaccumulate.

B. Abiotic Degradation

Hydrolysis

TTPC is stable over a wide pH range (BuruEnergy). [Kl. score = 4]

Photolysis

TTPC is not susceptible to photodegradation. (BuruEnergy). [Kl. score = 4]

C. Biodegradation

TTPC was not readily biodegradable in an OECD 301 test (BuruEnergy). [Kl. score = 4]

A die-away [simulation] test was conducted with radiolabelled TTPC for 168 hours at concentration of 0.31 mg/L. The first-order rate constant was 0.69/hour and the half-life was 6.6 hours. After 24 and 168 hours, degradation was >81% and >98%, respectively (BuruEnergy). [Kl. score = 4]

TTPC was evaluation in a simulation test over a 40-day period using double ^{14}C labeled TTPC. In activated sludge, there was >40% degradation after 30 days with 50 ppb TTPC and >30% degradation after 7 days with 5 ppb TTPC. In river water, there was >20% after 35 days with 5 ppb TTPC. In sea water, there was >30% degradation after 35 days with 5 ppb TTPC (BuruEnergy). [Kl. score = 4]

D. Environmental Distribution

Adsorption/desorption

TTPC strongly adsorbs to soil. In a study involving three different soil types (sand, silt, and clay), 93 to 96% of TTPC adsorbed to soil (BuruEnergy). [Kl. score = 4]

No experimental studies are available for determining the K_{oc} of TTPC. Using KOCWIN in EPISUITE™ (EPA, 2017), the estimated K_{oc} value for TTPC using the MCI method is 4.555×10^7 L/kg.

E. Bioaccumulation

No bioaccumulation studies are available on TTPC. TTPC is not expected to bioaccumulate based on the experimental log K_{ow} of 2.45 (BuruEnergy). [Kl. score = 4]

IV. HUMAN HEALTH HAZARD ASSESSMENT

A. Summary

TTPC exhibits moderate acute toxicity by the oral route, but is very highly toxic by the inhalation route. It is corrosive to the skin and eyes, but it is not a skin sensitizer. No target organ effects were noted in a 90-day rat drinking water study. TTPC was not mutagenic in a bacterial reverse mutation (Ames) test. There are no carcinogenicity studies on TTPC. In rats, developmental toxicity was shown to occur at oral dose levels that were not maternally toxic; whereas, in rabbits, developmental toxicity occurred only at maternally toxic doses.

B. Acute Toxicity

An oral LD_{50} in rats for Bellacide 350 (50% aq. solution of TTPC) was reported to be >1,002 mg/kg (BWA Additives, 2011) [Kl. score = 4]. An oral LD_{50} in rats for Bellacide 355 (5% aqueous solution of TTPC) was reported to be >4,000 mg/kg (BWA Additives, 2009) [Kl. score = 4].

The 4-hour inhalation LC_{50} in male and female rats for a 50% aq. solution of TTPC was <0.05 mg/L (aerosol). The mass median aerodynamic diameter for the aerosol was 1.93 μm (Cytec, 2012) [Kl. score = 1]. The 1-hour inhalation LC_{50} in male and female rats for a 50% aq. solution of TTPC is 0.227 mg/L (aerosol). The mass median aerodynamic diameter for the aerosol was 1.92 μm (Cytec, 2013) [Kl. score = 1].

C. Irritation

Both Bellacide 350 (50% aq. solution TTPC) and Bellacide 355 (5% aq. solution TTPC) are considered to be corrosive to the skin and eyes (BWA Additives, 2011; 2015). [Kl. score = 4]

D. Sensitization

TTPC is not considered to be a skin sensitizer (BWA Additives, 2011; 2015). [Kl. score = 4]

E. Repeated Dose Toxicity

Oral

A 90-day rat drinking water study has been conducted on a product containing TTPC. The LOAEL for the active ingredient (TTPC) is 27.2 and 32.3 mg/kg-day in males and females, respectively, based on various clinical signs and significantly reduced body weights, feed and water consumption. The NOAEL for this study is 8.66 mg/kg-day (EPA, 2006). [Kl. score = 2]

Inhalation

No data are available.

Dermal

No data are available.

F. Genotoxicity

In Vitro Studies

TTPC was not mutagenic in a reverse mutation bacterial (Ames) test (BWA Additives, 2015). [Kl. score = 4]

In vivo Studies

No studies are available.

G. Carcinogenicity

No studies are available.

H. Reproductive Toxicity

No studies are available.

I. Developmental Toxicity

Female Tif:RAIf(SPF) rats were dosed by oral gavage with 0, 20, 60, or 120 mg/kg Belclene® [50% active ingredient: TTPC] during gestational days (GD) 6 through 15. In the high-dose group, there were two possible treatment-related spontaneous deaths (GD 9 and 14) and another death on GD 15 due to an intubation error. Clinical signs included dyspnea in one mid-dose and 4 high-dose animals, and vaginal bleeding in one mid-dose female on GD 15. In the high-dose group, maternal body weight gain was significantly lower during the treatment period (GD 6-15) and throughout the gestational period (GD 0-20). Mean food consumption was significantly reduced during GD 6-11 for both the mid- and high-dose animals. The number of females with implantations and the number of implantations/females were similar across all groups. Embryonic and fetal deaths were similar between treated and control groups. There were no soft tissue changes. There was an increased incidence of incomplete ossification of the 5th sternebra in the mid- and high-dose groups. The NOAELs for maternal and developmental toxicity for the active ingredient TTPC in this study is 30 and 10 mg/kg-day, respectively (EPA, 2006). [Kl. score = 2]

Female chinchilla rabbits were dosed by oral gavage with 0, 7.5, 22.5, or 45 mg/kg Belclene® [50% active ingredient: TTPC] during gestational days (GD) 6 through 18. In the mid- and high-dose groups, body weight gain was significantly reduced during GD 6-18 and feed consumption was reduced during GD 6-11. Fetal body weights were significantly reduced in the mid-(males only) and high-dose dose groups. There was also an increased incidence of delayed ossification of the hindlimb phalangeal nuclei in the mid- and high-dose groups. The NOAEL for maternal and developmental toxicity for the active ingredient TTPC in this study is 3.75 mg/kg-day (EPA 2006). [Kl. score = 2]

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

The toxicological reference values developed for TTPC follow the methodology discussed in enHealth (2012). The approach used to develop drinking water guidance values is described in the Australian Drinking Water Guidelines (ADWG, 2011).

A. Non-Cancer

<u>Oral</u>

The NOAEL from a rat 90-day drinking water study based on various clinical signs and significantly reduced body weight and reduced feed and water consumption is 8.66 mg a.i./kg-day (EPA, 2006). This NOAEL will be used to derive the oral Reference Dose.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 10
UF_D (database uncertainty) = 1

Oral RfD = 8.66/(10 x 10 x 1 x 10 x 1) = 8.66/1000 = 0.009 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.009 x 70 x 0.1)/2 = 0.03 mg/L

B. Cancer

No carcinogenicity studies are available on TTPC. Thus, a cancer reference dose was not derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

TTPC does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

A. Summary

TTPC has a very high acute toxicity concern to aquatic organisms.

B. Aquatic Toxicity

Acute Studies

Table 2 lists the results of acute aquatic toxicity studies conducted on TTPC.

Table 2: Acute Aquatic Toxicity Studies on TTPC

Test Species	Endpoint	Results (µg/L)	Klimisch score	Reference
Bluegill sunfish	96-h LC_{50}	58.6	2	ECOTOX
Common Carp	96-h LC_{50}	87	2	ECOTOX
Rainbow trout	96-h LC_{50}	490	2	ECOTOX
Rainbow trout	96-h LC_{50}	200	2	ECOTOX
Daphnia magna	48-h EC_{50}	25.2	2	ECOTOX
Selenastrum capricornutum	72-h EC_{50}	19	4	BuruEnergy

Chronic Studies
No studies are available.

C. Terrestrial Toxicity

Table 3 lists the avian toxicity studies conducted on TTPC.

Table 3: Avian Toxicity Studies on TTPC

Test Species	Endpoint	Results	Kl. score	Reference
Bobwhite Quail	8-d dietary	LC_{50}: 4,215 ppm NOEL: 1,980 ppm	2	ECOTOX

Mallard Duck	8-d dietary	LC_{50}: 3,663 ppm NOEL: 1,780 ppm	2	ECOTOX
Mallard Duck	14-d oral gavage	LD_{50}: 232 mg/kg NOEL: <178 mg/kg	2	ECOTOX

D. Calculation of PNEC

The PNEC calculations for TTPC follow the methodology discussed in DEWHA (2009).

PNEC water

Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (58.6 µg/L), *Daphnia* (25 µg/L), and algae (19 µg/L). No chronic toxicity studies are available on TTPC. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the effect concentration of 19 µg/L for algae. The $PNEC_{aquatic}$ is calculated to be 0.019 µg/L (1.9×10^{-5} mg/L).

PNEC sediment

There are no toxicity data for sediment-dwelling organisms. Therefore, the $PNEC_{sed}$ was calculated using the equilibrium partitioning method. The $PNEC_{sed}$ is 12,982 µg/kg (13.0 mg/kg) sediment wet weight.

The calculations are as follows:

$$PNEC_{sed} = (K_{sed\text{-}water}/BD_{sed}) \times 1000 \times PNEC_{water}$$
$$= (874{,}561/1280) \times 1000 \times 0.019$$
$$= 12{,}982$$

Where:
$K_{sed\text{-}water}$ = suspended matter-water partition coefficient (m^3/m^3)
BD_{sed} = bulk density of sediment (kg/m^3) = 1,280 [default]

$$K_{sed\text{-}water} = 0.8 + [0.2 \times Kp_{sed}/1000 \times BD_{solid}]$$
$$= 0.8 + [0.2 \times 1{,}822{,}000/1000 \times 2400]$$
$$= 874{,}561$$

Where:
Kp_{sed} = solid-water partition coefficient (L/kg).

BD_{solid} = bulk density of the solid phase (kg/m^3) = 2,400 [default]

$Kp_{sed} = K_{oc} \times f_{oc}$
= 45,550,000 x 0.04
= 1,822,000

Where:
K_{oc} = organic carbon normalized distribution coefficient (L/kg). The K_{oc} for TTPC calculated from EPISUITE™ using the MCI method is 4.555×10^7 L/kg.
F_{oc} = fraction of organic carbon in sediment = 0.04 [default].

PNEC soil
There are no toxicity data for terrestrial or soil organisms. Therefore, the $PNEC_{soil}$ was calculated using the equilibrium partitioning method. The $PNEC_{soil}$ is 11,539 µg/kg (11.5 mg/kg) soil dry weight.

The calculations are as follows:

$PNEC_{soil} = (Kp_{soil}/BD_{soil}) \times 1000 \times PNEC_{water}$
= (911,000/1500) x 1000 x 0.019
= 11,539

Where:
Kp_{soil} = soil-water partition coefficient (m^3/m^3)
BD_{soil} = bulk density of soil (kg/m^3) = 1,500 [default]

$Kp_{soil} = K_{oc} \times f_{oc}$
= 45,550,000 x 0.02
= 911,000

Where:
K_{oc} = organic carbon normalised distribution coefficient (L/kg). The K_{oc} for TTPC calculated from EPISUITE™ using the MCI method is 4.555×10^7 L/kg.
F_{oc} = fraction of organic carbon in soil = 0.02 [default].

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

In a simulation test using river water, there was >20% after 35 days; however, no information is available on longer time points. TTPC is not readily biodegradable; thus it meets the screening criteria for persistence.

The log K_{ow} for TTPC is 2.45. Thus, TTPC does not meet the screening criteria for bioaccumulation.

There are no chronic aquatic toxicity studies available on TTPC. The lowest acute $E(L)C_{50}$ value for TTPC is <1 mg/L in algae. Thus TTPC meet the criteria for toxicity.

The overall conclusion is that TTPC is not a PBT substance.

IX. CLASSIFICATION AND LABELING (Australia GHS)

A. Classification

Acute Toxicity Category 4 [Oral]
Acute Toxicity Category 1 [Inhalation]
Skin Corrosion Category 1
Eye Damage Category 1
STOT RE Category 2
Aquatic Acute Category 1
Aquatic Chronic Category1

B. Labelling

Danger

C. Pictogram

In addition to the hazard statements corresponding the GHS classifications, the following non-GHS hazard statement is to be added to the SDS: AUH071: Corrosive to the Respiratory Tract.

X. SAFETY AND HANDLING

A. First Aid

<u>Eye Contact</u>

Flush with plenty of fresh water for 15 minutes holding eyelids open, lifting eyelids occasionally to ensure complete removal of the product. DO NOT allow rubbing of eyes or keeping eyes closed. Remove contact lenses. Seek medical advice.

Skin Contact

Rinse with soap and plenty of water for several minutes. Remove contaminated clothing. Seek medical attention immediately.

Inhalation

Remove person to fresh air. Apply artificial respiration if not breathing. Seek medical attention.

Ingestion

Rinse mouth with water (only if the person is conscious). Do NOT induce vomiting. Seek medical advice immediately.

B. FIRE FIGHTING INFORMATION

Extinguishing Media

Suitable Extinguishing Media: carbon dioxide, water spray, foam, dry chemical.

Specific Exposure Hazards

Containers may explode when heated. May form explosive mixtures with strong acids. Hazardous combustion products may include the following materials: carbon monoxide, carbon dioxide, phosphorus oxides, chlorine.

Special Protective Equipment for Firefighters

Full protective clothing and approved self-contained breathing apparatus required for firefighting personnel.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions

Use appropriate protective equipment and avoid direct contact. Do not touch damaged containers or spilled material unless wearing appropriate protective clothing. Ventilate the area before entry.

Environmental Precautions

Prevent spills from entering storm drains or sewers and contact with soil.

Steps to be Taken if Material is Released or Spilled

Use an absorbent material to recover as much product as possible, then, rinse the affected area with water to dilute the residue. Disposal of leftover product and used containers should be carried out in accordance with all local, state and federal regulations.

D. STORAGE AND HANDLING

General Handling

Wear appropriate personal protective equipment. Avoid contact with eyes, skin or clothing. Avoid breathing mist, vapours or spray. Use only with adequate ventilation. Wash hands after use. Launder contaminated clothing.

Storage

Keep container closed when not in use. Store in a cool well ventilated area.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard for TTPC.

Engineering Controls

Good general ventilation should be used. Ventilation rates should be matched to conditions. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits. If exposure limits have not been established, maintain airborne levels to an acceptable level.

Personal Protection Equipment

Respiratory Protection: Use a mask or approved air-purifying respirator with appropriate cartridge or canister in spray applications or in confined spaces.

Hand Protection: Wear impervious gloves to prevent skin contact and absorption of this material. Rubber or Neoprene gloves may afford adequate skin protection.

Skin Protection: Wear appropriate clothes (*i.e*., coveralls). Use non-slip footwear.

Eye protection: Wear eye protection in situations where splash or thick mists are possible.

Other Precautions: Avoid contact with skin, eyes and clothing. When using, do not eat or drink. Wash hands thoroughly with soap and water before eating or drinking. Remove contaminated clothing and launder before reuse.

F. TRANSPORT INFORMATION

UN2922 CORROSIVE LIQUID, TOXIC N.O.S. (contains tributyltetradecyl phosphonium chloride)
Class 8 and 6.1
Packing Group: II

Environmentally Hazardous Substance

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

ULEXITE

This dossier on ulexite does not represent an exhaustive or critical review of all available data. Rather, it presents the most critical studies pertinent to the risk assessment of ulexite in its use in drilling muds and hydraulic fracturing fluids. Where possible, study quality was evaluated using the Klimisch scoring system (Klimisch *et al.*, 1997).

I. SUBTANCE IDENTIFICATION

Chemical Name: Sodium-calcium pentaborate octahydrate

CAS RN: 1319-33-1

Molecular formula: $(NaCaB_5O_6(OH)_6 \bullet 5H_2O)$

Molecular weight: Not applicable

Synonyms: Ulexite; sodium-calcium pentaborate octahydrate

II. PHYSICO-CHEMICAL PROPERTIES

Table 1: Overview of the Physico-chemical Properties of Commercially Available Ulexite

Property	Value	Klimisch score	Reference
Physical state at 20°C and 101.3 kPa	White, granular, ground, or powder form	4	Etimine USA, Inc. (2016)
Melting Point	870°C	4	Etimine USA, Inc. (2016)
Bulk Density	1,410 to 1,500 kg/m^3	4	Etimine USA, Inc. (2016)
Water solubility	26.67% as dissolved Ulexite @ 25°C by weight of solution	4	American Borate Company (2016)

Ulexite is a naturally-occurring mineral that is slightly soluble in water.

In a study investigating the relative rates of boron from soluble and controlled-release boron fertilizers, ulexite showed releases of boron of 20% in just under 10 weeks; 40% in approximately 25 weeks; 60% by 40 weeks; and 80% by 60 weeks (Broschat, 2008).

III. ENVIRONMENTAL FATE PROPERTIES

No information is available. Ulexite is a naturally-occurring mineral and is not expected to biodegrade or bioaccumulate.

IV. HUMAN HEALTH HAZARD ASSESSMENT

No information is available.

V. DERIVATION OF TOXICOLOGICAL REFERENCE AND DRINKING WATER GUIDANCE VALUES

No values were derived.

VI. HUMAN HEALTH HAZARD ASSESSMENT OF PHYSICO-CHEMICAL PROPERTIES

Ulexite does not exhibit the following physico-chemical properties:

- Explosivity
- Flammability
- Oxidizing potential

VII. ENVIRONMENTAL HAZARD ASSESSMENT

No information is available.

VIII. PBT Assessment

The methodology for the Persistent, Bioaccumulative and Toxic (PBT) substances assessment is based on the Australian and EU Reach Criteria methodology (DEWHA, 2009; ECHA, 2008).

Ulexite is a naturally-occurring mineral. For the purposes of this PBT assessment, the persistence criteria is not considered applicable to this inorganic substance.

Bioaccumulation is not applicable to naturally-occuring minerals, such as ulexite. Although boron is slowly released from ulexite, limited data indicate that bioaccumulation is not significant in aquatic and terrestrial food chains. Thus, it does not meet the criteria for bioaccumulation.

There are no mammalian or aquatic toxicity studies on ulexite. Ulexite, being a slightly water-soluble mineral, is not expected to be bioavailable. Thus, it does not meet the criteria for toxicity.

The overall conclusion is that ulexite is not a PBT substance.

IX. CLASSIFICATION AND LABELING

A. Classification

Not classified.

B. Labelling

No signal word.

C. Pictogram

None

X. SAFETY AND HANDLING

A. FIRST AID

Eye Contact
In case of contact, immediately flush eyes with plenty of water for at least 15 minutes. If symptoms persist, seek medical advice.

Skin Contact
Wash thoroughly with soap and water.

Inhalation
If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Ingestion
Rinse mouth with water and then drink plenty of water. Never give anything by mouth to an unconscious person. If symptoms develop, seek medical advice.

B. FIRE FIGHTING INFORMATION

Extinguishing Media

Water spray, carbon dioxide, foam, dry chemical.

Specific Exposure Hazards
Ulexite is non-flammable, combustible, or explosive. It is a flame retardant.

Special Protective Equipment for Firefighters
Wear self-contained breathing apparatus and protective clothing.

C. ACCIDENTAL RELEASE MEASURES

Personal Precautions
Use appropriate protective equipment.

Environmental Precautions
Ulexite is slightly water-soluble; at high concentrations it may cause damage to trees or vegetation by root absorption. Do not flush to drains.

Steps to be Taken if Material is Released or Spilled
Scoop up and remove.

D. STORAGE AND HANDLING

General Handling
No special measures necessary provided product is used correctly.

Other Handling Precautions
Avoid eye and skin contact. Avoid creating or inhaling dust.

Storage
Keep container tightly closed and in a dry and well-ventilated place. Keep in a cool place.

E. EXPOSURE CONTROLS / PERSONAL PROTECTION

Occupational Exposure Standards
Workplace Australia has not established an occupational exposure standard for ulexite.

Engineering Controls
None

Personal Protection Equipment

Respiratory Protection:
Respiratory protection is not required.

Hand Protection:
Chemical resistant protective gloves.

Skin *Protection*:
Body protection must be chosen depending on activity and possible exposure.

Eye protection*:*
Safety glasses with side-shields.

Other Precautions:
Handle in accordance with good industrial hygiene and safety practice. Eyewash fountains and safety showers must be easily accessible.

F. TRANSPORT INFORMATION

Ulexite is not considered hazardous for purposes of transportation by road or rail. An Australian Dangerous Goods code is not required.

XI. DISPOSAL

Disposal should be in accordance with all local, state, and federal regulations.

XII. REGULATORY INFORMATION

Australian AICS Inventory: Listed.

APPENDIX H OTHER ASSESSED HYDRAULIC FRACTURING FLUID AGENTS

APPENDIX H.1 ENVIRONMENTAL HAZARD ASSESSMENT OF POTASSIUM CHLORIDE

TECHNICAL MEMORANDUM

DATE 13 December 2011

PROJECT No. 117636002-7000-008-TM-Rev0

TO Paul Wybrew

CC Carolyn Brumley, Len Turczynowicz

FROM Lange Jorstad

ENVIRONMENTAL HAZARD ASSESSMENT OF POTASSIUM CHLORIDE

1.0 INTRODUCTION

Santos Ltd (Santos) has requested that Golder Associates Pty Ltd (Golder) undertake a review of the chemical potassium chloride in regard to its toxicity to human health and toxicity to both aquatic and terrestrial environments.

The human health toxicity profile attached presents an overview of the toxicity of potassium chloride to human receptors. The chemical information sheet attached presents the available chemical and aquatic ecotoxicological data for potassium chloride.

1.1 Chemical Information

Potassium chloride is a metal halide salt composed of potassium and chlorine. Potassium chloride is highly water soluble, and readily undergoes dissociation (SIDS, 2001). Potassium chloride can be used as a shale stabiliser when drilling through hydro sensitive clays and shales. The potassium ion enters between individual clay platelets in the shale so that they are held together; thus eliminating entry of water from the drilling fluid (AMC, 2011).

Potassium is an essential element for animals and plants. Potassium is a neurotransmitter and is ubiquitous in living cells. Proteins called potassium channels located on cell membranes regulate the uptake and removal of ions in cells. Consequently potassium is actively regulated in organisms and is unlikely to be readily taken up by organisms exposed to high concentrations.

Chloride ions are similarly regulated in plant and animal cell membranes. Marine animals and plants regulate uptake and removal of chloride ions from their surrounding environment. Groundwaters are saline environments to which the native flora and fauna are well adapted.

2.0 POTASSIUM CHLORIDE HEALTH HAZARD ASSESSMENT

The assessment of human health toxicity represents an assessment of hazard and an intrinsic potential based on toxicological properties rather than risk. The aim of the hazard assessment is to provide a semi-quantitative hierarchy or hazard ranking of chemicals based on human health toxicity including both physical and chemical hazards to identify contaminants of potential concern (COPC). Further evaluation of the risk posed by such COPCs in terms of exposure pathways and fate and transport modelling has been presented in Section 7 of the previous Golder CSHF Risk assessment, dated 12 July 2011 (Ref No 117636002-7000-004-R). While this has not focussed on potassium chloride, other inorganic COPCs would reflect similar physico-chemical properties to potassium chloride and hence fate and transport characteristics.

Section 6 (pp130-143) of the CSHF Risk assessment, (Golder (2011), Ref No 117636002-7000-004-R) provides a detailed basis to the human health hazard ranking and is not reproduced here. The methodology in general terms is based on range of toxicological and fate and transport properties with associated ranking thresholds consistent with OECD and UN Global Harmonisation Systems. The use of these thresholds

BRW CLIENT CHOICE AWARDS 2011 WINNER

Golder Associates Pty Ltd

allows a qualification and scoring across these parameters with an averaging of the scoring across data sets. No weighting is placed on the various parameters examined.

Preliminary examination of potassium chloride based on the NOHSC (2004) "*Approved Criteria for Classifying Hazardous Substances, 3rd Edition*" in terms of its notification indicates it is not listed as a hazardous substance on the Safework Australia, Hazardous Substances Information System. While this provides some confidence in terms of its toxicity, a review was undertaken as a precautionary measure. The summary of the hazard ranking is provided in Table 1 below. The overall toxicity score reports a low to moderate level of concern (Score 1.67). This reflects the dissociative nature of this inorganic substance when introduced to water and its ability to introduce potassium ions into the environment.

Table 1: Potassium chloride human health toxicity score

Chemical Name	Hazard Classification NOHSC (2004)	Carcinogenicity	Mutagenicity/ genotoxicity	Developmental toxicity	Acute toxicity	Systemic toxicity/ Organ effects	Overall Toxicity Score
Potassium chloride	**Review**	**1**	**1**	**1**	**2**	**3**	**1.67**

The concluding summary comments from the toxicity profile put the hazard score in perspective:

"Potassium is an essential element in the body and the main intracellular cation with 98% of total body potassium located within the cells. Potassium chloride also occurs widely in the environment, including natural and drinking water as a consequence of the use of water treatment chemicals. Potassium chloride is used for the prevention and treatment of potassium deficiency, e.g. when thiazide diuretics or corticosteroids are used in case of excessive vomiting or diarrhoea, or diets poor in potassium or in the treatment of cumulative digitalis poisoning.

The most common form of ingestion is through drinking water. It is not considered necessary to establish a health-based guideline value for potassium in drinking water due to its lack of toxicity. Occupational exposure to potassium chloride may occur through inhalation of dust and dermal contact of this compound at workplaces where potassium chloride is produced or used. Specific occupational exposure limits (OELs) and actual exposure levels in the mining, refining, fertilizer and other industries are not available.

Acute effects are rare in humans although under particular circumstances severe effects may occur. Lethal effects were observed in a 2 month old baby fed 15,000 mg potassium chloride for 2 days and in another case report where an adult woman had ingested slow released potassium chloride tablets (35, 000 mg).Potassium chloride has not been evaluated and is not listed by the IARC as a carcinogen. In a long-term study performed with KCl, no carcinogenic effects were observed in male rats and it is a slight skin and eye irritant.

In the environment and in contact with water, potassium chloride dissociates readily into its component ions. No further degradation subsequently results. In soil, transport and leaching of potassium and chloride ions in solution is affected by surrounding conditions".

2.1 Conclusion : health hazard assessment

Taken collectively the potassium chloride toxicity and hazard ranking is of a low to moderate concern. Ingestion of high levels of dissolved potassium chloride in water at levels producing severe health effects is unlikely due to the rapid dilution of potassium chloride following environmental introduction into sub-surface waters, however, this requires qualification in terms of the masses of potassium chloride introduced.

Occupational exposures and short-term environmental spills may lead to short-term irritant effects depending on the nature of the exposure and are the main areas warranting consideration.

3.0 ECOLOGICALTOXICITY ASSESSMENT

3.1 Aquatic toxicity assessment

An environmental hazard assessment was undertaken of potassium chloride, used as a fracturing chemical, based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT). The methodology used to assess potassium chloride is outlined in Chapter 4 of report 117636002-7000-004-Rev0. The environmental hazard assessment categorizes a chemical as having a high, moderate or low risk to the environment.

The Chemical Information Sheet presents the available ecotoxicological data for freshwater organisms. The concentrations of potassium chloride required to illicit toxic effect are consistent with the expectation that this substance is inherently non-toxic and will only result in adverse effects in excess concentrations and when cellular mechanisms of active regulation are impaired.

An overall score (the environmental hazard score) for potassium chloride was calculated based on the toxicity scores. Potassium chloride is inorganic so it has not been assessed for bioaccumulation potential. Potassium chloride is also highly water soluble, and readily dissociates into naturally occurring ions in aquatic systems (SIDS, 2001). As such, potassium chloride was not scored for persistence. Table 2 below summarises the overall hazard score for potassium chloride.

Table 2: Toxicity score for potassium chloride

Chemical	Bioaccumulation Score	Persistence Score	Toxicity Score	Overall Hazard Score
Potassium Chloride	NA	NA	**2**	**2**

Based on the PBT ranking, potassium chloride has been given an overall hazard score of 2 and is considered to pose a moderate hazard to the aquatic environment. To obtain a moderate hazard score the PBT score must be between 1.65 and 2.34. The moderate hazard ranking was based on acute toxicological effects in a freshwater mussel. These effects relate to the exposure of a freshwater organism to a salty medium.

Terrestrial toxicity assessment

The lowest terrestrial toxicity data for modelled (QSAR earthworm) and measured (mammalian LD50) is presented in Table 3 below.

Table 3: Terrestrial toxicity data for potassium chloride

		QSAR earthworm LC50	Mammalian LD50
		mg/L	**mg/kg bw/d**
Potassium chloride	7447-40-7	2.33	383

NEPC (2010) provides only limited discussion on how the environmental fate and persistence of inorganic substances should be assessed. Further assessment of the hazards of the inorganic chemicals to terrestrial receptors has not been undertaken.

Potassium chloride and salinity

Increased concentrations of cations and anions such as potassium and chloride in groundwater amount to changes in salinity. Increased salinity can impact adversely on aquatic and terrestrial ecosystems.

Groundwater dependent ecosystems include surface water bodies such as wetlands, rivers and lakes, and also some terrestrial ecosystems.

Available data suggest that aquatic biota may be adversely affected as salinity exceeds 1,000 mg/L but there is limited information on how increasing salinity will affect the various life stages of the biota. Salinisation can lead to changes in the physical environment that will affect ecosystem processes (Hart *et al*., 2003). However, the tolerances of freshwater fish, aquatic plants and invertebrates to increased salinity vary, with invertebrates possibly the most sensitive organisms (adverse effects noted at 1,000 mg/L) and fish the least (generally tolerant up to 10,000 mg/L).

Conclusions: ecological toxicity

Based on the information considered, potassium chloride is considered to pose a moderate hazard to the freshwater environment. The moderate hazard evaluation is considered to be conservative given the active regulation of potassium and chloride in living cells. However, it is possible that adverse effects may occur in organisms where potassium and / or chloride are present in excess.

On this basis, potassium chloride is not considered a COPC for the purposes of either a human health or ecological risk assessment. Further, the operational controls established at well pads during and following hydraulic stimulation events should substantially reduce the potential for complete exposure pathways to occur.

Name	Potassium Chloride
Synonyms	Sylvite, Muriate of potash
CAS number	7447-40-7
Molecular formula	KCl
Molecular structure	K^+-- --Cl^-

Overview	References
Potassium is an essential element in the body. It is the main intracellular cation with 98% of total body potassium located within the cells. It is mainly used in fertilisers, medicine, lethal injections, scientific applications, feedstock, food processing and as a sodium substitute in table salt.	6
Potassium chloride is an essential element with homeostatic physiological processes regulating levels in the body. In cases of increased exposure to high levels of potassium significant health effects in people with kidney disease or other conditions, such as heart disease may result.	1
Potassium chloride as an inorganic salt is not subjected to further degradation processes in the environment once it dissociates into its respective ions. In water, potassium chloride is highly water soluble, and readily undergoes dissociation. In soil, transport and leaching of potassium and chloride ions is affected by the clay minerals (type and content), pH, and organic matter.	6

Human Health Toxicity Summary	Reference
Inhalation Occupational exposure to potassium chloride may occur through inhalation of dust at workplaces where potassium chloride is produced or used.	2
Carcinogenicity Potassium chloride has not been evaluated and is not listed by the IARC as a carcinogen. In a long-term study, male rats (50 per group) were fed potassium chloride in the diet at levels of 110, 450 or 1820 mg/kg bw/day for 2 years. No carcinogenic effects were observed in male rats.	3 6
Dermal Slight skin and eye irritant. A threshold concentration for skin irritancy of 60% was seen when potassium chloride in aqueous solution was in contact with skin of human volunteers. The threshold concentration when applied to broken skin was 5%.	2 4 6
Developmental A developmental study revealed no foetotoxic or teratogenic effects of potassium chloridel in doses up to 235 mg/kg/day (mice) and 310 mg/kg/day (rats). No fertility study has been located. Further human and ecological assessment was not recommended by the OECD SIDS.	6
Mutagenicity/genotoxicity No gene mutations were reported in bacterial tests, with and without metabolic activation. However, high concentrations of potassium chloride showed positive results in a range of genotoxic screening assays using mammalian cells in culture. The action of potassium chloride in culture seems to be an indirect effect therefore further *in vivo* studies were not considered necessary (OECD SIDS).	6
Therapeutic dosage Adult: In case of potassium deficiency, the dose should be adjusted to the needs of the patient. For the prevention of hypokalaemia the usual dose is 20-30 mEq of potassium per day; and 40- 100 mEq or more per day (approximately 40-100 mg/kg bw per day) for the treatment of potassium	5

depletion. Children: The dose usually indicated in children is 2 mmol/kg/day of potassium (approximately 15 mg/kg bw/d for a child with a body weight of 10 kg)	

Toxicity Values	Value	Reference
Animal Studies	**Oral, LD50**	
Guinea pig	2500 mg/kg bw	2
Mouse	383 mg/kg bw	2
Rat	2600-3020 mg/kg bw	2
Human Toxicity Values		
Acute oral toxicity	Rare	6

Concluding Summary Comments

Potassium is an essential element in the body and the main intracellular cation with 98% of total body potassium located within the cells. Potassium chloride also occurs widely in the environment, including natural and drinking water as a consequence of the use of water treatment chemicals. Potassium chloride is used for the prevention and treatment of potassium deficiency, e.g. when thiazide diuretics or corticosteroids are used in case of excessive vomiting or diarrhoea, or diets poor in potassium or in the treatment of cumulative digitalis poisoning.

The most common form of ingestion is through drinking water. It is not considered necessary to establish a health-based guideline value for potassium in drinking water due to its lack of toxicity. Occupational exposure to potassium chloride may occur through inhalation of dust and dermal contact of this compound at workplaces where potassium chloride is produced or used. Specific occupational exposure limits (OELs) and actual exposure levels in the mining, refining, fertilizer and other industries are not available.

Acute effects are rare in humans although under particular circumstances severe effects may occur. Lethal effects were observed in a 2 month old baby fed 15,000 mg potassium chloride for 2 days and in another case report where an adult woman

had ingested slow released potassium chloride tablets (35, 000 mg).Potassium chloride has not been evaluated and is not listed by the IARC as a carcinogen. In a long-term study performed with KCl, no carcinogenic effects were observed in male rats and it is a slight skin and eye irritant.

In the environment and in contact with water, potassium chloride dissociates readily into its component ions. No further degradation subsequently results. In soil, transport and leaching of potassium and chloride ions in solution is affected by surrounding conditions.

Taken collectively the potassium chloride toxicity and hazard ranking is of a low to moderate concern. Ingestion of high levels of dissolved potassium chloride in water at levels producing severe health effects is unlikely due to the rapid dilution of potassium chloride following environmental introduction into sub-surface waters, however, this requires qualification in terms of the masses of potassium chloride introduced. Occupational exposure s and short-term environmental spills may lead to short-term irritant effects depending on the nature of the exposure and are the main areas warranting consideration.

The asterisk (*) denotes several meanings depending upon the field you are viewing. An asterisk can be used in these fields:

- *Concentration:* This means the reported concentration has been recalculated to meet database conformity. For example, the concentration unit was reported as Molar units, but the standard database unit is micrograms per liter. Anther example would be if the reported value was as a metal compound and it was recalculated to the ion level. Note: These recalculations are no longer performed.
- *Endpoint*: This denotes the reported endpoint acronym provided was modified to conform to the standard database acronym terminology. For example, if the author reported a TLM, the endpoint was coded as an LC50*.

APPENDIX H.2 ENVIRONMENTAL HAZARD ASSESSMENT OF CONSTITUENTS IN POLAR PROP

TECHNICAL MEMORANDUM

DATE 23 March 2012

PROJECT No. 117636002-7000-010-TM-Rev0

TO Paul Wybrew

CC Carolyn Brumley, Len Turczynowicz

FROM Lange Jorstad

ENVIRONMENTAL HAZARD ASSESSMENT OF CONSTITUENTS IN POLAR PROP

1.0 INTRODUCTION

Santos Ltd (Santos) has requested that Golder Associates Pty Ltd (Golder) undertake a review of Polar Prop in regard to its toxicity to human health and toxicity to both aquatic and terrestrial environments. Polar Prop is a proppant used in hydraulic stimulation activities; the product comprises crystalline silica with a surface coating of phenol-formaldehyde resin ('novolac'). According to a material safety data sheet (MSDS) provided by Schlumberger (Santrol MSDS, 2012), there are three compounds present within Polar Prop; crystalline silica (95%), novolac (3 – 5%) and hexamethylenetetramine (0.1%).

This Technical Memorandum discusses each constituent of Polar Prop with regard toxicity to human health and the environment. Golder has previously undertaken a risk assessment for Schlumberger hydraulic stimulation chemicals detailed in the following report:

- Golder Associates (2011). Coal Seam Hydraulic Fracturing Risk Assessment. Reference 117636002-7000-004-R, dated 12 July 2011.

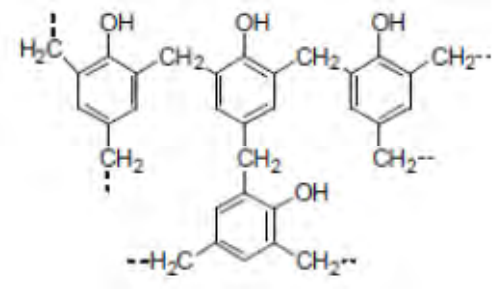
Where possible the techniques for assessment that were employed in the Golder (2011) Risk Assessment have been utilised to assess the constituents of Polar Prop. However, there was insufficient chemical information to enable a quantitative risk assessment for novolac. As such, a qualitative assessment has been undertaken for novolac utilising available information.

This hazard assessment did not consider the combined effects of the constituents when present in a mixture (Polar Prop). Assessment of mixtures is considered beyond the scope of a screening level human health and ecological risk assessment. For more information on assessment of mixtures see Section 4.6.7 of the Golder (2011) Risk Assessment.

2.0 NOVOLAC

The human health toxicity profile discussed below presents an overview of the toxicity of phenol formaldehyde resins and their impurities. The description is generic to the class of resins known as phenol formaldehyde resins as the exact nature of the resin in Polar Prop is confidential and has not been disclosed to Golder.

2.1 Chemical Information



Phenol formaldehyde resins are a product of the polymeric reaction of phenol and formaldehyde crosslinked with an amine compound (hexamethylenetetramine). The polymer is categorised with the chemical abstract services number 9003-35-4 (Santrol MSDS, 2012). The resulting resin has a variable composition that can be described as a mixture of crosslinked 2-ring bisphenol F plus components with 3 or more rings. The number average molecular weight of a cured crosslinked novolac polymer is typically much greater than 1000 daltons (US EPA 1998). Polar Prop has a low residual hexamethylenetetramine content <0.01%)

(Santrol MSDS, 2012). Although not specified, it is anticipated that the free formaldehyde content will also be very low (<0.1%)due to the catalytic and exothermic nature of the reaction. A typical structure is provided in Figure 1.

Figure 1: Typical structure of phenol formaldehyde resins (Danish EPA 2004).

Novolac resins are commonly used in a wide variety of industrial and also food contact applications. A similar polymer, epoxy phenolic novolac resins (Novolac Glycidyl Ether, NOGE) are used in the production of heavy duty coatings applied as clear coats in food packaging applications. The use of these coatings has been reviewed by the European Food Safety Authority (EFSA 2005).

2.2 Phenol-formaldehyde Resins Health Hazard Assessment

The assessment of human health toxicity represents an assessment of hazard (i.e. intrinsic toxicological properties rather than the probability of adverse human health effects during use). The aim of the hazard assessment is to provide a semi-quantitative hierarchy or hazard ranking of chemicals based on human health toxicity including both physical and chemical hazards to identify contaminants of potential concern (COPC). Further evaluation of the risk posed by such COPCs in terms of exposure pathways and fate and transport modelling has been presented in Section 7 of the previous Golder (2011) Risk assessment, dated 12 July 2011 (Ref No 117636002-7000-004-R).

Section 6 (pp130-143) of the Risk Assessment, (Golder, 2011), provides a detailed basis to the human health hazard ranking and has not been reproduced here. The methodology in general terms is based on the range of toxicological and fate and transport properties with associated ranking thresholds consistent with the Organisation for Economic Co-operation and Development (OECD) and United Nations (UN) Global Harmonisation Systems. The use of these thresholds allows a qualification and scoring across these parameters with an averaging of the scoring across data sets. No weighting is placed on the various parameters examined.

Novolac polymers are not classified as hazardous substances by the supplier (Santrol MSDS 2012). There is no reason to suspect that this classification is inaccurate based on the present assessment (according to the NOHSC (2004) "*Approved Criteria for Classifying Hazardous Substances, 3rd Edition*"). The crosslinked novolac polymer is likely to have a number average molecular weight of greater than 1000 (US EPA 1998) and as such is unlikely to cross biological membranes to cause toxicity. The European Food Safety Authority has evaluated the safety of low molecular weight (2250-900 daltons) epoxy phenolic novolac resins (Novolac Glycidyl Ether, NOGE). The NOGE is analogous substance to the non-crosslinked novolac polymer. The European Food Safety Authority (EFSA 2005) did not identify any safety concerns for the use of NOGE as a starting material in food contact applications. The summary of the hazard ranking is provided in Table 1 below. The overall toxicity score reports a low level of concern (Score 1.0). This reflects the low toxicity potential of cured novolac polymers.

Table 1: Novolac polymer in PolyProp human health toxicity score

Chemical Name	Hazard Classification NOHSC (2004)	Carcinogenicity	Mutagenicity/ genotoxicity	Developmental toxicity	Acute toxicity	Systemic toxicity/ Organ effects	Overall Toxicity Score
Novolac polymer in PolyProp	**Non hazardous**	**1**	**1**	**1**	**1**	**1**	**1**

2.3 Conclusion : Health Hazard Assessment

Taken collectively the cured novolac polymer in Poly Prop toxicity and hazard ranking is of a low concern from a human health perspective. Ingestion of trace levels of this polymer is unlikely to result in adverse health effects. Occupational exposures and short-term environmental spills are also unlikely to result in adverse human health effects.

2.4 Aquatic Toxicity Assessment

Chemical data for novolac was insufficient to be able to undertake the aquatic toxicity assessment based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT) as outlined in Chapter 4 of the Golder (2011) Risk Assessment. As such, a qualitative assessment has been undertaken for novolac utilising available information.

Ecotoxicological data and physic-chemical parameters were not found for novolac in the form used in Polar Prop. For polymeric substances both the molecular weight and their reactive functional groups are important in understanding their environmental hazard potential. Thus information on compounds with similar functional groups and a high molecular weight can inform the hazard assessment. A fatty acid modified epoxy Novolac acrylate (polymer CN-113) which is used as a binder in printing ink formulationshas been assessed in a full public report (NICNAS, 1996).

The NICNAS (1996) review on CN-113 states that no ecotoxicological data were provided, which is acceptable for polymers of number average molecular weight of greater than 1000, according to the Industrial Chemicals (Notification and Assessment) Act 1989. NICNAS considered that, due to its high number average molecular weight, the polymer is not expected to cross biological membranes. They note that the maximum percentage of low molecular weight species present in the mixture is <25% for molecular weight <1000 and <5% for molecular weights <500. NICNAS note that CN-113 is formulated into a printing ink, which is cured by UV light and used on paper/plastic bottles. Once cured, polymer is inextricably bound within the matrix of the printing ink.

The NICNAS (1996) review concludes that the low level of environmental exposure of the polymer as a result of normal use, together with its expected lack of biological activity, indicate that the overall environmental hazard of CN-113 should be negligible.

The crosslinked novolac polymer present in Polar Prop is also likely to have a number average molecular weight of greater than 1000 (US EPA 1998) and as such it is considered likely that novolac will exhibit the following characteristics:

- Very low water solubility;
- Non-volatile;
- Immisciblity with water;
- Low likelihood it will cross biological membranes to cause toxicity.

Hexamethylenetetramine is used as a cross-linker to contribute an element of hardness to the coating. As pure uncured novolac resin will not be introduced into the environment in this instance, and based on the

likelihood that the resin is not biologically active in this form, the conclusions regarding minimal hazard drawn from the NICNAS (1996) review of CN-113 may be considered applicable here.

While it should be noted that there is insufficient evidence to confirm that this compound will be stable under the pressures and temperatures that may be experienced during hydraulic stimulation, it is considered likely that this substance will be stable in the environment.

2.5 Terrestrial Toxicology

There was insufficient chemical information for novolac and its surrogate polymer CN-113 to be able to carry out a risk assessment for terrestrial toxicology.

2.6 Conclusions: Ecological Toxicity

There is limited information available relating to the ecological toxicity of the phenol-formaldehyde polymer novolac. Based on professional judgment of the likely physico-chemical parameters for this polymer, novolac in its current form is unlikely to pose a significant toxicological hazard to the freshwater environment.

On this basis, novolac is not considered a COPC for the purposes of either a human health or ecological risk assessment. Further, the operational controls established at well pads during and following hydraulic stimulation events should substantially reduce the potential for complete exposure pathways to occur.

3.0 HEXAMETHYLENETETRAMINE

Hexamethylenetetramine is used as a curing agent for phenolic resins and also as a urinary tract anti infective drug (Ymparisto, 2012). Hexamethylenetetramine is also used in eye make up preparations; as a preservative in lotions and creams; as a textile treating agent; a rubber accelerator and a chemical intermediate. Chemical information for hexamethylenetetramine is attached to this Technical Memorandum in the form of a chemical product sheet.

3.1 Human Health

A brief summary of human health effects of hexamethylenetetramine has been completed with information obtained from the hazardous substances data bank (HSDB).

Hexamethylenetetramine is used as a urinary tract anti infective drug (Swift et al., 2003). Adverse effects following administration have been reported in less than 3.5% of patients receiving hexamethylenetetramine and its salts. The most frequent adverse effects are gastro intestinal disturbances including nausea, vomiting, diarrhoea, abdominal cramps, and anorexia. Rarely, hypersensitivity reactions including rash, pruritus, urticaria, and stomatitis have occurred. Other adverse effects reported rarely are headache, dyspnea, generalised edema, tinnitus, muscle cramps, dysuria, and microscopic or, rarely, gross haematuria (HSDB, 2012).

Large oral doses of hexamethylenetetramine have been observed to causes irritation (vomiting and pain) with inflammatory lesions in renal tubules and renal pelvis causing impaired renal function. Hexamethylenetetramine is distributed into breast milk and has the potential for serious adverse effects in nursing infants. HSDB (2012) also states that a probable lethal dose for humans is approximately 0.5 kg for a 70 kg man.

Hexamethylenetetramine is a skin sensitiser and an irritant to the skin, eyes and mucous membranes. Inhalation may cause asthma-like reactions in previously sensitized individuals (HSDB, 2012).

3.2 Aquatic Toxicity

Sufficient chemical information is available for hexamethylenetetramine to be able to complete an aquatic toxicity assessment. The methodology used to assess hexamethylenetetramine is outlined in Chapter 4 of the Golder (2011) Risk Assessment.

Hexamethylenetetramine was scored based on its persistence (P), potential to bioaccumulate (B) and toxicity (T) to the aquatic environment. Possible overall scores range from a minimum of 1 (low hazard), to a maximum of 3 (high hazard). The use of averages ensures that where there are one or more data gaps, the score represents the average of available parameters. In the assessment of toxicity, the highest hazard score assigned to either acute or chronic data was adopted at the final hazard score for T.

An overall score (the environmental hazard score) for hexamethylenetetramine was calculated based on the average of the sum of the P, B and T scores. The overall score for hexamethylenetetramine is presented in Table 2 below.

Table 2: Environmental Hazard Score for Hexamethylenetetramine.

Fraccing Chemical	CASRN	Overall Environmental Hazard Score	Environmental Hazard Category
Hexamethylenetetramine	**100-97-0**	**1.4**	**Low**

Hexamethylenetetramine has been assigned an environmental hazard score of 1.4 and is ranked as a 'low hazard'. This score reflects a very low order of aquatic toxicity, a low potential for bioaccumulation and a moderate potential for persistence. As hexamethylenetetramine is not ranked as 'high hazard' it is not considered to be a COPC from an aquatic toxicology perspective.

3.3 Terrestrial Toxicity

Sufficient chemical information is available for hexamethylenetetramine to be able to complete a terrestrial toxicity assessment.

Terrestrial toxicity data and chemical data were used to rank hexamethylenetetramine using the following techniques:

- Mammalian LD50 data;
- Lettuce QSAR (Huzelbos *et al*. 1991); and
- Earthworm QSAR (Van Gestel 1992).

Full details of these techniques are provided in Section 5 of the Golder (2011) Risk Assessment. It was not possible to assess hexamethylenetetramine using the Earthworm QSAR (EPISUITE) as this data was not available.

Although an assessment of exposure concentrations and associated risks has not been made for the chemicals under consideration in Polar Prop, hexamethylenetetramine is likely to be present as an impurity within the polymer matrix rather than a compound that may drive risks (the Santrol MSDS reports hexamethylenetetramine at concentrations less than 0.01% in Polar Prop). Hexamethylenetetramine does not rank in the top three most hazardous chemicals in each of the three techniques used in the assessment, when assessed with other Schlumberger chemicals. According to the process outlined in the risk assessment for the Schlumberger methodology, hexamethylenetetramine is not considered to be a COPC with regard terrestrial toxicity.

4.0 CRYSTALLINE SILICA

Crystalline silica has not been assessed for aquatic toxicity and terrestrial toxicity as it is considered essentially sand and based on physical properties it was not considered appropriate to assess the limited aquatic and terrestrial data in the hazard ranking. Available chemical information for crystalline silica is provided in the Golder (2011) Risk Assessment.

4.1 Human Health

A human health toxicity overview for crystalline silica is attached to this Technical Memorandum. Inhalation of dust is considered the most significant pathway for crystalline silica. Respirable quartz dust particles can be inhaled and deposited in the lung. Silicosis and pulmonary tuberculosis are associated with occupational exposure to quartz dust. Also, there is sufficient evidence in humans for the carcinogenicity of inhaled crystalline silica.

Statistically significant increases in deaths or cases of bronchitis, emphysema, chronic obstructive pulmonary disease, autoimmune related diseases (scleroderma, rheumatoid arthritis, systemic lupus erythematosus) and renal diseases have also been reported.

5.0 CONCLUSIONS

The individual constituents of Polar Prop are considered unlikely to pose a hazard to people and the environment. Although assessing the hazard from the combined effects of the constituents when present in a mixture (Polar prop) was beyond the scope of this assessment, Polar Prop is also considered unlikely to pose a hazard to people and the environment.

6.0 LIMITATIONS

Your attention is drawn to the document “Limitations”, which is included as an attachment to this Technical Memorandum. The statements presented in this document are intended to advise you of what your realistic expectations of this Technical Memorandum should be. The document is not intended to reduce the level of responsibility accepted by Golder Associates, but rather to ensure that all parties who may rely on this report are aware of the responsibilities each assumes in so doing.

Name	Silica
Synonyms	Crystalline silica (Quartz)
CAS number	14808-60-7
Molecular formula	SiO_2

Human Health Toxicity Overview	References
Silicon is the second most abundant chemical element, after oxygen, in the earth' s crust accounting for 28.15% of its mass and quartz, is by far the most common form of silica in nature, it comprises 12% by volume of the crust. It is a frequently occurring solid component of most natural mineral dusts. Human exposures to quartz occur most often during occupational activities that involve the movement of earth, disturbance of silica containing products (masonry, concrete), or use or manufacture of silica containing products. Environmental exposure to ambient quartz dust can occur during natural, industrial and agricultural activities.	1

Human Health Toxicity Summary	Reference
Inhalation Respirable quartz dust particles can be inhaled and deposited in the lung. There are many epidemiological studies of occupational cohorts exposed to respirable quartz dust. Silicosis, lung cancer and pulmonary tuberculosis are associated with occupational exposure to quartz dust. Statistically significant increases in deaths or cases of bronchitis, emphysema, chronic obstructive pulmonary disease, autoimmune related diseases (scleroderma, rheumatoid arthritis, systemic lupus erythematosus) and renal diseases have been reported. Silicosis is the critical effect for hazard identification and risk assessment.	1
Carcinogenicity There is sufficient evidence in humans for the carcinogenicity of inhaled crystalline silica in the form of quartz or cristobalite from occupational sources. There is sufficient evidence in experimental animals for the carcinogenicity of quartz and cristobalite Crystalline silica inhaled in the form of quartz or cristobalite from occupational sources is carcinogenic to humans (Group 1). APPENDIX H.3 ENVIRONMENTAL HAZARD ASSESSMENT OF OF CONSTITUENTS IN LITEPROP 125

7 May 2013 Project No. 117636002-7000-011-L-Rev0

Andrew Stannard
Santos Ltd
Level 22, 32 Turbot Street
Brisbane Qld 4000
(GPO Box 1010, Brisbane Qld 4001)

ENVIRONMENTAL HAZARD ASSESSMENT OF CONSTITUENTS IN LITEPROP 125

Dear Andrew,

1.0 INTRODUCTION

Santos Ltd (Santos) has requested that Golder Associates Pty Ltd (Golder) undertake a review of LiteProp 125 in regard to its toxicity to human health and toxicity to both aquatic and terrestrial environments. LiteProp 125 is a resin coated cellulose and is used a "proppant" to break open oil-bearing rock beneath the earth's surface (BJ Services, 2004). There are three compounds present within LiteProp 125, namely:

- Raw Walnut Hulls (85.56%);
- Plenco resin (12.83%); and
- Mod Acid (1.6%).

This letter discusses each of these constituents of LiteProp 125 (raw walnut hulls, Plenco resin and Mod Acid) with regard toxicity to human health and the environment. Where possible the techniques used to assess the human health and environmental toxicity of constituents in LiteProp 125 have followed the approach outline in Attachment 1. However, where there was insufficient chemical information to be able to undertake a quantitative hazard assessment for a constituent, a qualitative assessment was undertaken using available information.

This hazard assessment did not consider the combined effects of the constituents when present in a mixture (LiteProp 125). Assessment of mixtures is considered beyond the scope of a screening level human health and ecological risk assessment.

2.0 RAW WALNUT HULLS

2.1 Human Health Hazard Assessment

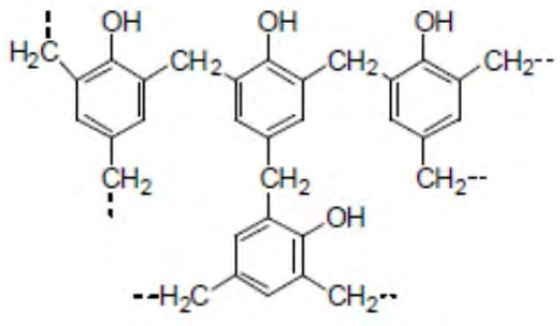
Raw walnut shells are naturally occurring products that on initial review present limited hazards to human health, but these require some qualification. Hazards associated with these shells may include physical, chemical and biological. Should these shells be ground into a fine particulate, (e.g. similar to dusts) then the inhalation of such dusts has been associated with adverse cardio-pulmonary health effects, both acute and chronic. Control of exposure to such dusts would be a risk management measure, particularly in the occupational setting but also if in close proximity to residential areas. As an organic dust, the hazards of exposure are more diverse than for inorganic dust due to compositional variance. Organic dusts in addition to risks associated with the physical particle size (i.e. inspirable and respirable intakes) may contain microbial agents and microbial toxins (e.g. endotoxins and mycotoxins, see Rylander and Shilling, 1998). Furthermore certain chemicals such as tannins are associated with adverse organic dust exposures, while

BRW CLIENT CHOICE AWARDS 2012 WINNER

Golder, Golder Associates and the GA globe design are trademarks of Golder Associates Corporation.

additional hazardous chemicals may include chlorinated cyclodiene pesticide residues if these shells are sourced from third world countries still using these environmentally incalcitrant pesticides which exhibit a long biological half-life in the human body.

2.2 Ecological Hazard Assessment



Raw Walnut Hulls are used as a substitute for sand particles and have not been assessed for aquatic toxicity and terrestrial toxicity as the particles are considered essentially non-hazardous if they are in their natural state (i.e., have not been treated with pesticides as described in section 2.1 above).

3.0 PLENCO RESIN

Plenco resin refers to the manufacturing company, Plenco, a plastics engineering company. Plenco manufactures Novolac resins which are phenol-formaldehyde polymers and Resol resins which are phenol-methylene glycol polymers (Plenco, 2012).

The human health toxicity profile discussed below presents an overview of the toxicity of phenol formaldehyde resins and their impurities. The description is generic to the class of resins known as phenol formaldehyde resins as the exact nature of the resin in LiteProp 125 is confidential. The constituents and percentages provided to Golder Associates of residual phenol and formaldehyde levels in the polymer are as follows; phenol (<1.5%) and formaldehyde (<1%). In the resin manufacturing process, the phenol and formaldehyde combine to form the resin; the process, chemistries, and residual concentrations are understood to be the same as in most common pre-cured resin-coated proppants (pers comm. Baker Hughes). A typical structure of a phenol formaldehyde resin is provided in Figure 1.

Figure 1: Typical Structure Phenol Formaldehyde Resin

3.1 Chemical Information

Phenol formaldehyde resins are a product of the polymeric reaction of phenol and formaldehyde crosslinked with an amine compound (hexamethylenetetramine). The polymer is categorised with the chemical abstract services number 9003-35-4 (BJ Services, 2006). The resulting resin has a variable composition that can be described as a mixture of crosslinked 2-ring bisphenol F plus components with 3 or more rings. The number average molecular weight of a cured crosslinked novolac polymer is typically much greater than 1000 daltons (US EPA 1998). No information was provided to Golder Associates that LiteProp 125 has residual hexamethylenetetramine content, however, information on hexamethylenetetramine has been provided in this letter as the cross-linking agent is common to these polymers (BJ Services, 2006).

Plenco (Novolac) resins are commonly used in a wide variety of industrial and also food contact applications. A similar polymer, epoxy phenolic novolac resins (Novolac Glycidyl Ether, NOGE) is used in the production of heavy duty coatings applied as clear coats in food packaging applications. The use of these coatings has been reviewed by the European Food Safety Authority (EFSA 2005).

3.2 Novolac Resins

This assessment of phenol-formaldehyde resins represents an assessment of hazard (i.e. intrinsic toxicological properties) rather than an assessment of risks (i.e., the probability of adverse human health

effects during use). The aim of the hazard assessment is to provide a semi-quantitative hierarchy or hazard ranking of chemicals based on human health toxicity including both physical and chemical hazards to identify contaminants of potential concern (COPC). Further evaluation of the risk posed by such COPCs in terms of exposure pathways and fate and transport modelling has been presented in Section 7 of the Golder Associates (2011) Risk Assessment, dated 12 July 2011 (Ref No 117636002-7000-004-R).

Section 6 (pp130-143) of the Risk Assessment, (Golder 2011), provides a detailed basis to the human health hazard ranking. An extract of the report is presented in the attachment to this letter. This methodology in general terms is based on a range of toxicological and fate and transport properties with associated ranking thresholds consistent with OECD and UN Global Harmonisation Systems. The use of these thresholds allows a qualification and scoring across these parameters with an averaging of the scoring across data sets. No weighting is placed on the various parameters examined.

Novolac polymers are not classified as hazardous substances by the supplier (BJ Services, 2006). There is no reason to suspect that this classification is inaccurate based on the present assessment (according to the NOHSC (2004) "*Approved Criteria for Classifying Hazardous Substances, 3rd Edition*"). The cross-linked Novolac polymer is likely to have a number average molecular weight of greater than 1000 (US EPA 1998) and as such is unlikely to cross biological membranes to cause toxicity. The European Food Safety Authority has evaluated the safety of low molecular weight (2250-900 daltons) epoxy phenolic novolac resins (Novolac Glycidyl Ether, NOGE). The NOGE is an analogous substance to the non-crosslinked novolac polymer. The European Food Safety Authority (EFSA 2005) did not identify any safety concerns for the use of NOGE as a starting material in food contact applications. The summary of the hazard ranking for Plenco (Novolac) resin is summarised in Table 1 below. The overall toxicity score reports a low level of concern (Score 1.0). This reflects the low toxicity potential of cured Novolac polymers.

Table 1: Plenco (Novolac) Polymer in Human Health Toxicity Score

Chemical Name	Hazard Classification NOHSC (2004)	Carcinogenicity	Mutagenicity/ genotoxicity	Developmental toxicity	Acute toxicity	Systemic toxicity/ Organ effects	Overall Toxicity Score
Plenco (Novolac) polymer in LiteProp 125	**Non hazardous**	**1**	**1**	**1**	**1**	**1**	**1**

Both monomers used in the production of this resin are left in low residual amounts in the final polymer which is a "brown, granular solid with a mild odour" (BJ Services, 2006) (refer above). While both phenol and formaldehyde exhibit moderate to high hazards (refer attached toxicity profiles) in terms of the pure substances, these residual amounts in the polymer are low and in general terms would present a low hazard. In certain circumstances (e.g. where large masses of this polymer are present within confined environments), off-gassing may result in higher atmospheric concentrations and these may warrant closer attention. These would tend to prevail in the occupational setting.

3.3 Hexamethylenetetramine

Hexamethylenetetramine is used as a curing agent for phenolic resins and also as a urinary tract anti infective drug (Ymparisto, 2012). Hexamethylenetetramine is also used in eye make-up preparations; as a preservative in lotions and creams; as a textile treating agent; a rubber accelerator and a chemical intermediate. When heated during the phenol-formaldehyde resin curing process, hexamethylenetetramine thermally decomposes to ammonia and formaldehyde. Chemical information for hexamethylenetetramine is attached to this letter in the form of a chemical product sheet.

A brief summary of human health effects of hexamethylenetetramine has been completed with information obtained from the hazardous substances data bank (HSDB, 2012).

Adverse effects of hexamethylenetetramine following administration in the treatment of urinary tract infections have been reported in less than 3.5% of patients receiving hexamethylenetetramine and its salts.

The most frequent adverse effects are gastro-intestinal disturbances including nausea, vomiting, diarrhoea, abdominal cramps, and anorexia. Rarely, hypersensitivity reactions including rash, pruritus, urticaria, and stomatitis have occurred. Other adverse effects reported rarely are headache, dyspnea, generalised edema, tinnitus, muscle cramps, dysuria, and microscopic or, rarely, gross haematuria (HSDB, 2012).

Large oral doses of hexamethylenetetramine have been observed to cause irritation (vomiting and pain) with inflammatory lesions in renal tubules and renal pelvis causing impaired renal function. Hexamethylenetetramine is distributed into breast milk and has the potential for serious adverse effects in nursing infants. HSDB (2012) also states that a probable lethal dose for humans is approximately 0.5 kg for a 70 kg man.

Hexamethylenetetramine is a skin sensitiser and an irritant to the skin, eyes and mucous membranes. Inhalation may cause asthma-like reactions in previously sensitized individuals (HSDB, 2012).

Further evaluation of the LiteProp 125 polymer could made if the presence and residual concentration or absence of this cross-linking agent could be verified.

3.4 Human Health Hazard Assessment Summary

Taken collectively, the cured Plenco (novolac) polymer in LiteProp 125 exhibits a low order of human health toxicity and hazard ranking. Ingestion of trace levels of this polymer is unlikely to result in adverse health effects. Qualifying comments include the potential for off-gassing of low concentrations of residual monomers in certain confined occupational settings which may warrant closer examination. Short-term environmental spills in open environments are unlikely to result in exposures leading to adverse human health effects. The content and implications of residual hexamethylenetetramine (cross-linking agent) require confirmation.

3.5 Aquatic Ecological Hazard Assessment

Chemical data for plenco resin was insufficient to be able to undertake the aquatic toxicity assessment based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT) as outlined in Attachment 1. As such, a qualitative assessment has been undertaken for phenol-formaldehyde resins utilising available information. In general, polymers such as phenol-formaldehyde resins which are characterised by high molecular weights and negligible solubility are slow to biodegrade (Kaplan, 1979) and are considered environmentally inert and persistent.

Insufficient information was available for the proprietary Plenco resin in LiteProp 125 to identify ecotoxicological data and physico-chemical parameters. Information relating to the fatty acid modified epoxy Novolac acrylate (polymer CN-113, used as a binder in printing ink formulations) was reviewed for information that may be used as a surrogate in assessing hazard. This information was obtained from a full public report on CN-113 (NICNAS, 1996).

The NICNAS (1996) review on CN113 states that no ecotoxicological data were provided, which is acceptable for polymers of number average molecular weight of greater than 1000, according to the Industrial Chemicals (Notification and Assessment) Act 1989. NICNAS considered that, due to its high number average molecular weight, the polymer is not expected to cross biological membranes. They note that the maximum percentage of low molecular weight species present in the mixture is <25% for molecular weight <1000 and <5% for molecular weights <500. NICNAS note that CN-113 is formulated into a printing ink, which is cured by UV light and used on paper/plastic bottles. Once cured, the polymer is inextricably bound within the matrix of the printing ink.

The NICNAS (1996) review concludes that the low level of environmental exposure of the polymer as a result of normal use, together with its expected lack of biological activity, indicate that the overall environmental hazard should be negligible.

The phenol/formaldehyde polymer present in LiteProp 125 is also likely to have a number average molecular weight of greater than 1000 and as such it is considered likely that plenco resin will exhibit the following characteristics:

- Very low water solubility;
- Non-volatile;

- Immisciblity with water;
- Low likelihood it will cross biological membranes to cause toxicity.

Mod Acid is used as a curing agent for the phenol-formaldehyde resin to contribute an element of hardness to the coating. As pure uncured phenol/formaldehyde (Plenco) resin will not be introduced into the environment in this instance, and based on the likelihood that the resin is not biologically active in this form, the conclusions regarding minimal hazard drawn from the NICNAS (1996) review of CN-113 may be considered applicable here.

3.6 Terrestrial Ecological Hazard Assessment

There was insufficient information for plenco resin and its surrogate polymer CN-113 to be able to carry out a terrestrial hazard assessment.

3.7 Ecological Hazard Assessment Summary

There is limited information available relating to the ecological toxicity of the phenol-formaldehyde polymer plenco resin. Based on professional judgment of the likely physico-chemical parameters for this polymer, plenco resin in its current form is unlikely to pose a significant toxicological hazard to the freshwater environment.

4.0 O,P-TOLUENESULFONIC ACID / XYLENESULFONIC ACID MIXTURE

The primary constituent of Mod Acid, which is used as a curing agent for the phenol-formaldehyde resin, is o,p -toluenesulfonic acid and xylenesulfonic acid mixture (CAS # 25321-41-9, >92%). Also present are sulphuric acid (<2%), toluene (<1%) and xylene (<1%). During the manufacturing process the solvents are driven off through evaporation (pers comm. Baker Hughes, May 2012). Chemical information for o,p-toluenesulfonic acid/ xylenesulfonic acid mixture (CAS #25321-41-9) is attached to this letter in the form of a chemical product sheet. Due to the limited experimental chemical data available for this mixture a chemical product sheet for p-toluenesulfonic acid (CAS# 104-15-4) is also attached.

As various salts, toluenesulfonate and xylenesulfonate, are hydrotropes commonly used as coupling agents to solubilise the water insoluble and often incompatible functional ingredients of household and industrial cleaning products and personal care products. HERA (Human and Environmental Risk Assessments on ingredients of household cleaning products) have undertaken a risk assessment on hydrotopes, including the sodium salts of toluenesulfonate and xylenesulfonate (HERA, 2005). In solution these salts will dissociate and become acids. In the absence of available environmental fate and toxicological information on o,p-toluensulfonic acid/xylenesulfonic acid mixture, information available for the sulfonate salts of xylene and toluene have been considered in the environmental assessment. Human health data were available on hydrotropes as a functional group.

4.1 Human Health Hazard Assessment

While sulphuric acid, toluene and xylene exhibit a moderate to high order of health hazard this assessment reflects exposure to the pure substances or to high concentrations. The use of sulphuric acid as an acidic catalyst (trace) and the low residual levels of toluene and xylene are not considered to reflect a level of concern as they represent a trace concentration within a low percentage component (Mod acid) of the final polymer.

The major component of Mod acid comprises a mixture of hydrotropes, specifically, o,p -toluenesulfonic acid and xylenesulfonic acid. These are a part of a group or similar organic sulfonates used specifically as coupling agents to solubilise the water soluble and incompatible functional ingredients of household and institutional cleaning and personal care products. The toxicity profile and hazard ranking is provided in the attachments. The hydrotropes in general exhibit a close consistency in their structure, use, fate and health and environmental effects. They exhibit a low order of acute and chronic toxicity and hazard to human health. Their major adverse health effects are limited to irritant effects on skin, eyes and mucous membranes and systemic effects at high doses and these reflect exposure to the pure or high concentration solutions. At final use concentrations in the order of a few percent the low hazard ranking is further reduced.

4.2 Aquatic Ecological Hazard Assessment

The methodology used to assess the PBT potential of ,p-toluenesulfonic acid/xylenesulfonic acid mixture and potential surrogates is outlined in Attachment 1.

Sufficient chemical information is available for o,p-toluenesulfonic acid/xylenesulfonic acid mixture and p-toluenesulfonic acid to be able to complete an assessment of PBT using data from EPISUITE.

An assessment of PBT of the sulfonate salts of toluene and xylene correlates well with the assessment of o,p-toluenesulfonic acid/xylenesulfonic acid mixture and supports the use of the sulfonate salts as surrogates for the assessment of o,p-toluenesulfonic acid/xylenesulfonic acid mixture. A summary of bioaccumulation and persistence data used in the assessment is provided in Table 2 below. The values corresponding to the highest hazard score were used in the assessment.

Table 2: Persistence and Bioaccumulation Data Used in the Aquatic Toxicity Assessment

Fraccing Chemical	Solubility mg/L	Henry's Law Constant atm-m^3/mol	Log Koc	Log Kow	BCF L/kg	Anaerobic degradation in Water
o,p-toluenesulfonic acid/xylenesulfonic acid mixture	$5.9x10^{4}$ – $1x10^{6}$ (est)	$1.64x10^{-11}$ – $3.06x10^{-9}$ (est)	0.886-1.420 (est)	-0.07 (est)	3.162 (est)	No
p-toluenesulfonic acid	620,000 (exp)	$3.248x10^{-12}$ – $2.78x10^{-9}$ (est)	0.582-1.206 (est)	-0.62 (est)	3.162 (est)	No
Xylene and Toluene sulfonate salts	400,000-553,000 (exp)	$3.06x10^{-9}$ (est)	N/A	-2.7 (exp)	3 (est)	No

The persistence and bioaccumulation scores for the toluene and xylene sulfonate salts were combined with toxicity scores from the aquatic toxicity data reported in the HERA assessment (HERA, 2005). In summary the sulfonate salts of xylene and toluene exhibit low acute and chronic toxicity. Acute toxicity data is available for fish, invertebrate and algae. LC50 data range from 1060 mg/L for Bluegill to >400 mg/L for flathead minnows. Only two chronic toxicity data are available for xylene sulfonate salts. The NOECs for the Na and Ca xylene sulfonate salts are 31 mg/L and 75 mg/L, respectively, based on a 96-hr *Selenastrum* test (HERA, 2005).

In the absence of aquatic toxicity data for o,p-toluenesulfonic acid/xylenesulfonic acid mixture, data were modelled using EPISUITE™ ECOSAR™ software. ECOSAR™ (Ecological Structure Activity Relationships) estimates the toxicity of chemicals to fish, aquatic invertebrates and algae in water. ECOSAR™ predicted toxicity values all indicate that the o,p-toluenesulfonic acid/xylenesulfonic acid mixture would have a low hazard ranking and would be less toxic than the experimental results for the sulfonate salts of xylene and toluene presented above (see the chemical product sheet attached).

The o,p-toluenesulfonic acid/xylenesulfonic acid mixture and the combined data for the xylene and toluene sulfonate salts were scored based on the PBT potential to the aquatic environment. Possible overall scores range from a minimum of 1 (low hazard), to a maximum of 3 (high hazard). The use of averages ensures that where there are one or more data gaps, the score represents the average of available parameters. In the assessment of toxicity, the highest hazard score assigned to either acute or chronic data was adopted at the final hazard score for T. For o,p-toluenesulfonic acid/xylenesulfonic mixture a low hazard ranking of 1 for T was adopted based on the ECOSAR™ results and the use of surrogate toxicity data.

Overall scores (the environmental hazard scores) were calculated based on the average of the sum of the P, B and T scores. The overall score for o,p-toluenesulfonic acid/xylenesulfonic acid mixture, p-toluenesulfonic acid and the combined assessment of toluene and xylene sulfonate salts are presented in Table 3 below.

Table 3: Environmental Hazard Score for o,p-toluenesulfonic acid/xylenesulfonic acid mixture and surrogates

Fraccing Chemical	CASRN	Overall Environmental Hazard Score	Environmental Hazard Category
o,p-toluenesulfonic acid/xylenesulfonic acid mixture	25321-41-9	1.3	Low
p-toluenesulfonic acid	104-15-4	1.3	Low
Xylene and Toluene sulfonate salts	various	1.3	Low

The o,p-toluenesulfonic acid/xylenesulfonic acid mixture and the surrogates used to supplement environmental fate and toxicity data have been assigned environmental hazard scores of 1.3 and are ranked as a 'low hazard'. The similar hazard scores of the xylene and toluene salts and p-toluenesulfonic acid support the 'low hazard' rank of o,p-toluenesulfonic acid/xylenesulfonic acid mixture. As o,p-toluenesulfonic acid/xylenesulfonic acid mixture is not ranked as 'high hazard' it is not considered to be a chemical of potential concern (COPC) from an aquatic toxicology perspective.

4.3 Terrestrial Ecological Hazard

No terrestrial toxicity data were identified for o,p-toluenesulfonic acid/xylenesulfonic acid mixture or for the sulfonate salts of toluene or xylene in the preparation of this letter. However given the low potential for the acid to reach the terrestrial compartment and the low likelihood of persistence or bioaccumulation HERA did not consider this a deficiency in their assessment of xylene and toluene sulfonate salts (HERA, 2005). Based on the HERA assessment of xylene and toluene sulfonate salts, and professional judgment of the likely physic-chemico parameters for o,p-toluenesulfonic acid/xylenesulfonic acid mixture it is not considered to be a COPC from an terrestrial toxicology perspective.

5.0 SUMMARY

Based on the available information, the main constituents of LiteProp (raw walnut hulls, Plenco resin and Mod Acid) would support the case of presenting a low hazard to human health and the environment. Additional confidence to this assessment requires information on the following:

- the walnut hulls (whether they may contain residual biological or chemical hazards);
- the exact nature of the phenol-formaldehyde resin and it's chemical and toxicological properties including residual impurities;
- the hazards of these constituents in a mixture, e.g. a review of the toxicodynamic properties; and
- whether the hazards of each constituent would change in high temperature and pressure environments.

1.0 ENVIRONMENTAL HAZARD ASSESSMENT

An environmental hazard assessment was undertaken to rank the hydraulic fracturing chemicals based on persistence (P), bioaccumulation (B) and toxic (T) potential (hereafter referred to as PBT). From this assessment, those chemicals ranked as a high hazard are considered to be COPC. It should be noted that the selection of a chemical as a COPC does not indicate an unacceptable risk; rather it indicates that potential exposures to these chemicals should be evaluated in greater detail to assess whether they might present an unacceptable risk.

1.1 Chemical information sheets

In order to assess environmental hazards, readily available chemical and physical properties and ecotoxicological data were collated for the chemicals assessed. In addition, published water quality guidelines were identified and collated. This information was compiled into a chemical information sheet for each chemical.

1.1.1 Chemical and physical properties

Chemical and physical properties were obtained from the following sources in order of priority:

1) The Material Safety Datasheet (MSDS) and Product Disclosure Statement provided to Golder Associates by Santos and Baker Hughes (BJ Services, 2004; Fritz Industries 2012);

2) Hazardous Substances Databank (HSDB);

3) Modelled data from USEPA (2012) EPISUITE™ (Estimation Programs Interface Suite™ for Microsoft® Windows) modelling software (only when data were not available from the MSDS or the HSDB).

USEPA (2012) EPISUITE™ software is developed by Syracuse Research Corporation (SRC) for the USEPA Office of Pollution Prevention and Toxics. EPISUITE™ provides a package of modelling software programs that can estimate physical/chemical, environmental fate and ecotoxicity data for organic chemicals. Inorganic chemicals should not be evaluated using EPISUITE™ because the estimation methods used are developed based on organic chemicals.

In using EPISUITE™, the following limitations for modelling organic chemicals are noted:

Chemicals that rapidly hydrolyse are unsuitable to be modelled namely, acid halides, isocyanates, sulphonyl chlorides, siloxanes, and alpha-chloro ethers. No such chemicals were identified in the list of hydraulic fracturing chemicals considered for this study.

Data generated for organic salts may not be reliable, namely cationic salts of Group I, Group II, transition metals, Actinides, and Lanthanides. These should not be profiled because there are not adequate data in the estimation models databases to predict properties with confidence. Organic salts however of Sodium (Na), Potassium (K), and Ammonium (NH_4^+) may be evaluated reliably. No such chemicals are identified in the list of the hydraulic fracturing chemicals considered for this study.

Organo metallic compounds should not be evaluated. No such chemicals were identified in the list of the hydraulic fracturing chemicals considered for this study.

Highly reactive compounds should not be modelled. No such chemicals were identified in the list of the hydraulic fracturing chemicals considered for this study.

High molecular weight compounds with a molecular weight greater than1000 should not be modelled. As gelatine and Guar gum are identified in the list of hydraulic fracturing chemicals and would fall into this category, they have therefore not been subject to modelling by EPISUITE™.

The EPISUITE™ estimation programs are simple to use, requiring only one input (e.g., CASRN or SMILES notation[1]) from the user and a nomination of the program to be used based on the data required by the user. EPISUITE™ includes a database of chemical and physical properties, algorithms, and Quantitative Structure Activity Relationships (QSAR) models with which to estimate parameters. The following programs were used to generate physical and chemical data for this study:

- KOWWIN™ - octanol/water partition coefficient (Kow);
- HENRYWIN™ - Henry's Law Constant;
- BIOWIN™ - Biodegradation rate;
- LEV3EPI™ - Fugacity model to estimate partitioning to soil air, water and sediment;
- KOCWIN™ - Soil organic carbon partition coefficient (Koc);and
- BCFBAF™ - Bioconcentration factor.

1.1.2 Environmental and drinking water guidelines

In addition to the chemical, physical and toxicological data collated for use in the environmental hazard assessment, environmental and human health guidelines were also obtained. These guidelines were not used in the assessment of environmental hazard but may be used in the exposure assessment of chemicals which are the subject of environmental fate and transport modelling. Guidelines were obtained from the following sources in order of priority:

1) Australian and New Zealand Guidelines for Fresh and Marine Water Quality for protection of aquatic ecosystems and stock watering (ANZECC & ARMCANZ, 2000);
2) Australian Drinking Water Guidelines (NHMRC and NRMMC, 2004);
3) World Health Organisation (WHO, 2006) Guidelines for Drinking-water Quality (Third Edition);
4) United States Environment Protection Authority (USEPA) National Recommended Water Quality Criteria (2009) for protection of aquatic life and human health;
5) International Agency for Research on Cancer (IARC) Monographs on the Evaluation of Carcinogenic Risks to Humans; and
6) Drinking-water Standards for New Zealand 2005 (Revised 2008, Ministry of Health).

1.1.3 Toxicity information

Acute and chronic aquatic ecotoxicological data were obtained from the following sources in order of priority:

1) USEPA (2009) ECOTOXicology Database Version 4.0; and
2) Australasian Journal of Ecotoxicology.

Where ecotoxicological data were not available for the chemicals of interest or a suitable surrogate, data were modelled using EPISUITE™ ECOSAR™ software. ECOSAR™ (stands for Ecological Structure Activity Relationships) estimates the toxicity of chemicals to fish, aquatic invertebrates and algae in water. Toxic effect predictions are made using a set of quantitative structure-activity relationships (QSARs) models. QSARs predict the aquatic toxicity of untested chemicals based on their structural similarity to chemicals for which aquatic toxicity data are available. The toxicity data used to build the QSARs come from a database of publicly available and confidential data submitted to the US EPA New Chemicals Program. The QSARs used in ECOSAR™ correlate a compound's physicochemical properties and its aquatic toxicity within

[1] SMILES (**S**implified **M**olecular **I**nput **L**ine **E**ntry **S**ystem) string is a linear notation for chemical structures.

specific chemical classes, and applies rules for selecting the appropriate chemical class for the compound. ECOSAR™ generates acute (short-term) toxicity and, when available, chronic (long-term or delayed) toxicity.

1.2 Hazard versus risk

The approach presented in the following paragraphs is an assessment of environmental hazard, rather than environmental risk. Risk assessment of chemicals in the environment is based on a comparison between the levels to which an organism in a particular environmental compartment (e.g. water) is exposed, and a maximum level which an organism can tolerate based on a defined exposure scenario (in an environmental compartment) without significant adverse effect. The environmental hazard assessment presented herein, is not a risk assessment *per se* because it does not consider likely exposure concentrations for most of the hydraulic fracturing chemicals. A qualitative assessment of the risk will be conducted based on an identification of relevant exposure pathways and fate and transport modelling of COPC associated with the hydraulic fracturing fluid.

Approaches to ranking or screening chemicals for the purposes of assessing relative "hazard" or "risk" include likelihood and consequence matrices. In these matrices, a chemical may be scored high for consequence (which may be a function of PBT) but low for likelihood (which may be a function of whether the chemical is considered likely to be present in the environment at hazardous concentrations). Overall, such a chemical may then score a relatively lower hazard or risk than would be identified from its consequence score alone. The environmental hazard assessment approach here works on the premise of potential for PBT; that is, the data that may apply to "consequence". The assessment of "likelihood" is assessed for those chemicals selected as COPC through fate and transport modelling and the assessment of complete exposure pathways.

1.3 Hazard assessment approach

The environmental hazard assessment approach developed for this study is consistent with national and international guidance for assessment of potential for PBT in the risk assessment, classification, and regulation of chemicals. Physical and chemical properties that affect the fate and behaviour of chemicals in the environment, degradation rates, partition coefficients, and aquatic ecotoxicological data are used in assessment of environmental mobility and PBT potential.

The Australian National Framework for Chemicals Environmental Management (NChEM) guidance manuals were consulted in preparation of the environmental hazard assessment approach, namely:

- EPHC (2009a). Environmental Risk Assessment Guidance Manual for Industrial Chemicals; and
- EPHC (2009b). Environmental Risk Assessment Guidance Manual for Agricultural and Veterinary Chemicals.

These guidance manuals present the data requirements and methodology for assessment for environmental hazard and risk assessment of industrial and agriculture and veterinary chemicals, consistent with international best practice. NChEM guidance is prepared by the National Environment Protection and Heritage Council (EPHC) for the Department of the Environment, Water, Heritage and the Arts (DEWHA). DEWHA undertakes environmental risk assessments of industrial chemicals for the National Industrial Chemicals Notification and Assessment Scheme (NICNAS) and of agricultural and veterinary chemicals for the Australian Pesticides and Veterinary Medicines Authority (APVMA).

In addition, the following international literature for PBT assessment was consulted:

- CCME (2008) Canadian Council of Ministers of the Environment The National Classification System for Contaminated Sites (NCSCS) Guidance Document;
- Christensen et al. (2003) Assessment Tools under the New European Union Chemicals Policy;

- Environment Canada (2003) Existing Substances Branch Guidance Manual for the Categorization of Organic and Inorganic Substances on Canada's Domestic Substances List, Determining Persistence, Bioaccumulation Potential, and Inherent Toxicity to Non-human Organisms;
- European Commission (2003) Technical Guidance Document on Risk Assessment in support of Commission Directive 93/67/EEC on Risk Assessment for New Notified Substances, Part II Chapter 3 Environmental Risk Assessment;
- ECETOC (2005) Risk Assessment of PBT Chemicals;
- Franke et al. (1994) The Assessment of Bioaccumulation;
- Langley (1993) Refining Exposure Assessment. In: The Health Risk Assessment and Management of Contaminated Sites. Proceeding of the Second National Workshop on the Health Risk Assessment and Management of Contaminated Sites;
- Swann et al. (1983) A rapid method for the estimation of the environmental parameters octanol/water partition coefficient, soil sorption constant, water to air ratio, and water solubility. Residue Reviews; and
- UNECE (2009) Globally Harmonised System (GHS) of Classification and Labelling of Chemicals. Revision 3. Part 4 Environmental Hazards and Annex 9 Guidance on hazards to the aquatic environment.

1.4 Environmental hazard scores

The environmental hazard assessment approach presented herein awards highest scores to those physical, chemical and toxicological values considered to pose high environmental hazard. The parameter ranges and scores assigned to each physical, chemical and toxicological value used are discussed in the following sections. The environmental hazard assessment categorised chemicals into three hazard scenarios, as follows:

- High Hazard – assigned scores of 3;
- Moderate Hazard - assigned scores of 2; and
- Low Hazard - assigned scores of 1.

For each chemical, an average score for each of P and B was calculated. The use of averages ensures that where there are one or more data gaps, the score represents the average of available parameters. In the assessment of T, the highest hazard score assigned to either acute or chronic data was adopted at the final hazard score for T. The approach for assessment of T differed from P and B because some chemicals have few aquatic ecotoxicological data. This resulted in weighting of the assessment towards T and is considered conservative and appropriate for a screening level risk assessment. An overall score (the environmental hazard score) for each chemical was calculated based on the average of the sum of the P, B and T scores. Possible overall scores range from a minimum of 1 (low hazard), to a maximum of 3 (high hazard). The overall hazard score is calculated to one significant figure, whereas the individual and total P, B or T scores represent whole numbers.

The scoring system is semi-quantitative in that scores are assigned to ranges for a particular parameter (see section 1.6). The scores are largely assigned using professional judgement following consideration of the guidance for chemical assessment in the literature for PBT assessment as identified in section 1.6.

The hazard assessment was limited to PBT, consistent with the parameters identified in the published literature. Not all the physical and chemical parameters collated for the hydraulic fracturing chemicals presented in the chemical information sheets were used in the environmental hazard assessment.

The ranges set for this study are considered a *relative assessment*. The ranges were assigned with the intent of incorporating the precautionary principle i.e., designed to be inherently conservative and therefore biased towards capturing, rather than rejecting chemicals that are likely to pose PBT hazard.

The individual scores assigned to the respective ranges for each parameter are presented in section 1.6.

1.5 Assessment of organic versus inorganic substances

The approach for the assessment of inorganic and organic substances differs. The approach for the assessment of inorganic substances[2] was devised based predominantly on guidance published by Environment Canada (2003). Environment Canada (2003) describe an approach for the assessment of "metal-containing inorganic salts, organic-metal salts, and ionizable inorganics". Following the Environment Canada (2003) approach, toxicity is considered in conjunction with persistence, and bioaccumulation is considered only if persistence cannot be assessed. The assessment of bioaccumulation potential of inorganic chemicals is more difficult to interpret in hazard assessment.

Non-metal-containing inorganic substances may be assessed following guidance for organic substances.

Justification for the scores assigned to the individual parameters and the adopted ranges are discussed in the following section.

1.6 Environmental hazard assessment parameters

The physical, chemical and ecotoxicological data collated and assessed in the environmental hazard assessment are presented in the chemical information sheets and summarised below in Table 1.

Table 1: Physical, chemical and toxicological parameters used in environmental hazard assessment

PBT	Applicable to Organic / Inorganic Chemicals	Parameter	Units
Persistence	Inorganic / Organic	Solubility	g/m^3
	Organic	Henry's Law constant	atm m^3/mol
	Organic	log K_{oc}	L/kg
	Organic	Anaerobic degradation in water	Qualitative
Bioaccumulation	Organic	BCF	unitless
	Organic	log K_{ow}	unitless
Toxicity	Inorganic / Organic	Aquatic ecotoxicological data for: • Plants; • Invertebrates; and • Fish. Acute LC50 Chronic NOEC Chronic LOEC Chronic EC50	mg/L

The following sections describe in more detail the parameters used, the ranges set and the scores assigned in the environmental hazard assessment.

[2] Inorganic substances may be described as metal-containing inorganic salts, organic-metal salts, and ionizable inorganics.

1.6.1 Data gaps

Where data was not available for a chemical, data for a suitable surrogate was used in the hazard assessment. Surrogates were identified from the MSDS in that where a hydraulic fracturing additive is a mixture; the chemical representing the greatest proportion of the additive (usually greater 95% of the mixture) was adopted. Where a suitable surrogate chemical was not available, data were modelled using EPISUITE™. Where data could not be modelled, the parameter was excluded from the environmental hazard assessment.

1.6.2 Persistence

The approach for assessment of persistence for inorganic and organic chemicals differs.

Inorganic chemicals were assessed based on solubility, and solubility was considered in conjunction with toxicity.

Organic chemicals were assessed based on solubility, Henry's Law Constant, K_{oc}, and aerobic degradation half-life in water. In all cases, the assessment of persistence in organic chemicals was based on at least three out of a total of four persistence parameters.

1.6.3 Solubility

Aqueous solubility is measured in units of mg/L (or g/m^3) at temperatures of 20°C – 25°C. Aqueous solubility is temperature dependent. The solubility of a chemical will influence the rate of migration (or mobility) of that chemical in the environment. An increase in solubility leads to a decrease in adsorption to soil and greater mobility (Langley, 1993). Poor solubility may result in low bioavailability and lower biodegradation rates. A poorly soluble chemical may be considered to have a tendency to persist and therefore have more time to exert a toxic effect. Conversely, high solubility could also imply greater mobility, greater bioavailability and greater hazard. Solubility, rather than effective solubility[3], was adopted in this hazard assessment for simplicity. Effective solubility is a more accurate measure of chemical availability and mobility. However, effective solubility cannot be reliably predicted or modelled and is dependent on the chemical mixture and environmental factors (e.g. pH, temperature, oxidising or reducing conditions, etc). Solubility is a conservative and simple measure of mobility and availability of a chemical in groundwater and hence was used in this hazard assessment.

Organic substances with low water solubility typically have high predicted bioaccumulation factors and / or high log K_{ow} and hence may be considered highly bioaccumulative unless there is evidence to suggest otherwise (Environment Canada, 2003).

Inorganic substances generally need to be dissolved in water to exert deleterious effects (to aquatic receptors) and consequently solubility should be considered in conjunction with aquatic toxicity, as recommended by Environment Canada (2003). Environment Canada (2003) recommends that when the solubility of the substance is greater than the acute toxicity, the substance is likely to pose a hazard. Herein, the lowest acute ecotoxicological endpoint obtained for the chemical of interest was used for data considered in assessment of toxic potential). Where solubility data were not found for the inorganic chemicals considered, solubility was assumed to be greater than acute toxicity. This is conservative and results in a high hazard classification.

Low solubility was assigned a high hazard (based on likelihood of persistence and high bioaccumulation tendency) for organic chemicals. Conversely, low solubility was assigned a low hazard for inorganic chemicals. The hazard category ranges and scores adopted in this study are summarised in Table 2 and Table 3 for organic and inorganic substances, respectively. These have been derived based on professional judgement (noting that the UNECE (2009) consider a substance with a solubility of less than 1 mg/L to be poorly soluble).

[3] Effective Solubility is the solubility of a compound that will dissolve from a chemical mixture (e.g., gasoline). The effective solubility of a compound from a chemical mixture is less than its aqueous solubility

Table 2: Solubility ranges and scores for organic substances

Hazard Category	Solubility Range (mg/L)	Score
High Hazard	<10	3
Moderate Hazard	10-100	2
Low Hazard	>100	1

Table 3: Solubility ranges and scores for inorganic substances

Hazard Category	Solubility Range (mg/L)	Score
High Hazard	>10	3
Moderate Hazard	1 – 10	2
Low Hazard	<1	1

The ranges and scores for the assessment of solubility in conjunction with aquatic toxicity for inorganic chemicals are presented in Table 4. The ranges are set following Environment Canada (2003). Because only two categories exist in this threshold assessment of solubility in conjunction with acute toxicity, scores of 1 or 3 are assigned. A moderate hazard score of 2 is not possible.

Table 4: Solubility considered in conjunction with acute toxicity (Inorganic substances), ranges and scores

Hazard Category	Solubility Range (mg/L)	Score
High Hazard	Solubility > acute toxicity	3
Moderate / Low Hazard	Solubility < acute toxicity	1

1.6.3.1 Henry's Law Constant

Henry's Law is a partition coefficient which is a measure of the tendency of a substance to partition into air from water at constant temperature and pressure. It can be used as a measure of environmental fate and transport of a substance. Henry's Law Constant is calculated using vapour pressure, molecular weight and water solubility for a chemical and is commonly expressed either as 'dimensionless' (i.e., no units) or in 'dimensions' (i.e., units of atmospheres (atm) m^3/mol or Pa m^3 mol^{-1}). Henry's Law Constant data are used in the environmental hazard assessment even though one of the parameters on which it is based (namely solubility) is assessed and scored separately.

Interpreted ranges (in terms of volatility and hence environmental persistence potential) for Henry's Law Constant were available in the literature reviewed as part of this report.

Organic chemicals with a low Henry's Law Constant (i.e., low volatility and high solubility) are likely to be more persistent in the environment. Organic chemicals with a high Henry's Law Constant (i.e., high volatility, low water solubility) are likely to be less persistent in the environment. Organic chemicals with a low Henry's Law Constant were scored a greater environmental hazard in this assessment.

Henry's Law Constant scores are assigned based on ranges provided in CCME (2008), Langley (1993) and professional judgement. The parameter ranges are summarised in Table 5.

Inorganic chemicals were not assessed using Henry's Law Constant.

Table 5: Henry's Law Constant ranges and scores

Hazard Category	Henry's Law Constant Range (atm m^3/mol)	Score
High Hazard	$<6.1x10^{-09}$	3
Moderate Hazard	$6.1x10^{-09}$- $6.1x10^{-05}$	2
Low Hazard	$>6.1x10^{-05}$	1

1.6.3.2 Soil adsorption partition coefficient (Koc)

The soil organic carbon-water partitioning coefficient is the ratio of the mass of a chemical that is adsorbed in the soil per unit mass of organic carbon in the soil. It is a measure of the tendency for organic substances to be adsorbed by soil or sediment. K_{oc} values are useful in predicting the mobility of organic contaminants in soil and sediment. Higher K_{oc} values correlate to less mobile organic chemicals while lower K_{oc} values correlate to more mobile organic chemicals. Less mobile organic chemicals (i.e., greater tendency to persist) are considered in this assessment to be a greater environmental hazard. The parameter ranges and assigned scores for K_{oc} used are presented in Table 6. These ranges were derived after consideration of information provided in CCME (2008); Langley (1993) and Swann et al. (1983) and professional judgement.

Inorganic chemicals were not assessed using K_{oc}.

Table 6: Log K_{oc} ranges and scores

Hazard Category	Log K_{oc} Range (L/kg)	Score
High Hazard	>3.7	3
Moderate Hazard	3.7-2.7	2
Low Hazard	<2.7	1

1.6.3.3 Biodegradation

Degradation takes into account physical, biological, and chemical changes in a chemical over time (Langley, 1993). Biodegradation is "the process by which organic substances is decomposed by micro-organisms (mainly aerobic bacteria) into simpler substances such as carbon dioxide, water and ammonia" (UN, 1997 cited in OECD, 2010). The rate of biodegradation is frequently described by the half-life (days) as an indication of the length of time required for the chemical to reach half its original concentration. The longer the time taken for a substance to degrade, the more environmentally persistent that chemical is considered to be. Longer biodegradation rates were considered to be indicative of higher environmental hazard. Anaerobic biodegradation half-lives were sought on the basis that the groundwater environment is likely to be anaerobic. The lack of quantitative, measured data in the literature reviewed resulted in generating modelled data from EPISUTE™ BIOWIN™. The modelled data produced by BIOWIN™ are qualitative only, not half-lives, and represent one of two potential outputs: biodegrades fast, or does not biodegrade fasts. A summary of the nominated anaerobic degradation hazards in and the associated scores assigned is presented in Table 7. These ranges are based on professional judgement.

Table 7: Anaerobic biodegradation ranges in water and scores

Hazard Category	Anaerobic Biodegradation Range in Water (days)	Score
High Hazard	Does not biodegrade fast	3
Moderate Hazard	Not assigned	Not assigned

Hazard Category	Anaerobic Biodegradation Range in Water (days)	Score
Low Hazard	Biodegrades fast	1

1.6.4 Bioaccumulation

Assessment of bioaccumulation potential was assessed for organic chemicals only. Two parameters were assessed, and an average of the scores calculated.

Bioaccumulation was not assessed for inorganic chemicals in accordance with guidance in Environment Canada (2003).

1.6.4.1 Octanol / water partition coefficient (Kow)

The octanol-water partition coefficient (K_{ow}) is the ratio of the solubility of a chemical in octanol divided by its solubility in water. It is a measure of the preference for an organic substance to dissolve in an organic solvent or water and is used as a measure of lipophilicity and movement of a substance across a cell membrane. It is usually expressed as Log K_{ow}. It can be used as a measure of environmental fate and transport of a chemical.

There is general consensus in the literature that a Log K_{ow} of less than 3.5 represents low or moderate potential to bioaccumulate, and a Log K_{ow} of greater than 3.5 represents an increased potential to bioaccumulate. UNECE (2009) consider that substances with Log K_{ow} less than 4 have no potential to bioaccumulate. UNECE (2009) and CCME (2008) consider that substances with Log K_{ow} greater than 4 have the potential to bioaccumulate. European Commission (2003) consider that substances with Log K_{ow} greater than 4.5 have the potential to bioaccumulate. The ranges and the associated scores adopted in this study are summarised in Table 8 and are largely based on the classes provided by European Commission (2003), UNECE (2009), CCME (2008) and professional judgment.

K_{ow} is assessed for organic chemicals only.

Table 8: Log K_{ow} ranges and scores

Hazard Category	Log K_{ow} Range (unitless)	Score
High Hazard	>4	3
Moderate Hazard	2-4	2
Low Hazard	<2	1

1.6.4.2 Bioconcentration factor (BCF)

The bioconcentration factor (BCF) is a measure of the tendency for a substance in water to accumulate in organisms, in particular, fish. This parameter is an important determinant for uptake into organisms, potential for biomagnification and secondary poisoning (food chain transfer to higher trophic levels). The higher the BCF, the greater the potential for bioconcentration and, therefore, secondary poisoning. The parameter ranges and scores used are summarised in Table 9. These ranges have been derived after consideration of information provided in Franke et al. (1994, predominantly); European Commission (2003); UNECE (2009) and professional judgment.

BCF is assessed for organic chemicals only.

Table 9: BCF ranges and scores

Hazard Category	BCF Range (unitless)	Score
High Hazard	>100	3
Moderate Hazard	100-30	2
Low Hazard	<30	1

1.6.5 Toxicity

In the assessment of T potential, the highest hazard score assigned to either the acute or chronic data was used because there were frequently insufficient data to enable an assessment of both acute and chronic toxicity. This results in weighting of the assessment towards T. This approach considered conservative and appropriate for a screening level hazard assessment.

1.6.5.1 Aquatic ecotoxicology

To assess the toxic (T) potential of the chemicals, readily available acute (i.e., predominantly L(E)C_{50}[4]) and chronic (i.e., NOEC[5], LOEC[6], MATC[7] and EC_{50}) data for aquatic organisms were collated.

Chronic ecotoxicology data are preferred over acute because exposure occurs over a longer time-period, usually during a significant period of the organism's life-cycle or during a sensitive life-stage. However, there is a predominance of acute ecotoxicological data available in the literature compared to chronic. The species groupings considered (plants, invertebrates and fish) and endpoints considered (acute, chronic) were given equal weighting.

The following trophic level groupings were considered for aquatic organisms:

- Plant;
- Invertebrate; and
- Fish.

As freshwater aquatic organisms are considered the receptor of concern for the hydraulic fracturing chemicals, freshwater ecotoxicological data were used in the assessment of toxic potential. There are generally few aquatic ecotoxicological data available for amphibians and reptiles, and no guidance was found in the international literature on the assessment of hazard for these receptor groups. Hence these receptors groups were excluded from the assessment of T.

The data downloaded data from USEPA ECOTOX database were screened. The following endpoints were selected: mortality (acute), growth (chronic) and reproduction (chronic) for plants, invertebrates and fish. Additional screening included the following:

- Studies shorter than 24hrs were not considered;
- Chronic mortality exposures were not considered; and
- L(E)C_x endpoints other than L(E)C_{50} were not considered, namely EC_0, EC_{100}, EC_{10}, EC_{20}, etc.

Although included in the environmental hazard assessment, NOECs are not statistical or empirical point estimates of ecological effect. NOECs are hypothesis based and reflect the test design (i.e., concentrations

[4] Lethal (or effect) concentration that kills (or effects) 50% of the test population.

[5] No observed effect concentration.

[6] Lowest observed effect concentration.

[7] Maximum acceptable tolerable concentration.

of exposure) rather than the dose-response curve. However, NOECs are well documented in the literature and are commonly used in ecological risk assessment and in derivation of risk-based ecological guidelines. Additional chronic endpoints namely LOEC, MATC and EC_{50} were included in the hazard assessment to reduce the uncertainly associated with NOEC data.

Where modelled data were generated using EPISUITE™ ECOSAR™ the chronic data do not specify the endpoint (i.e., it is not known if the endpoint is NOEC or LOEC/MATC, or EC_{50}.) The chronic data were assumed to be LOEC/MATC or EC_{50} endpoints which results in a higher (more conservative) hazard classification.

The chronic aquatic ecotoxicology ranges (for plants, invertebrates and fish) were assigned after consideration of information provided in European Commission (2003); UNECE (2009) and professional judgement. As a conservative approach to assessment of T, the lowest chronic effect concentration for each of NOEC, LOEC/MATC, and EC_{50}, and the lowest acute effect concentration for $L(E)C_{50}$ was identified for each chemical and scored. The ranges and scores adopted in the hazard assessment are summarised in Table 10 and Table 11.

Table 10: Chronic aquatic NOEC ecotoxicology ranges and scores

Hazard Category	Chronic Aquatic NOEC Range (mg/L)	Score
High Hazard	<0.01	3
Moderate Hazard	0.01 – 0. 1	2
Low Hazard	>0.1	1

Table 11: Chronic aquatic LOEC/MATC and EC_{50} ecotoxicology ranges and scores

Hazard Category	Chronic Aquatic LOEC, MATC and EC_{50}Range (mg/L)	Score
High Hazard	<0.1	3
Moderate Hazard	0.1 – 1	2
Low Hazard	>1	1

The acute aquatic ecotoxicity ranges (for plants, invertebrates and fish) were assigned after consideration of information provided in European Commission (2003); UNECE (2005) and professional judgement. The ranges and scores adopted in the Hazard Ranking Scheme are summarised in Table 12.

Table 12: Acute aquatic $L(E)C_{50}$ ecotoxicology ranges and scores

Hazard Category	Acute Aquatic $L(E)C_{50}$ Range (mg/L)	Score
High Hazard	<1	3
Moderate Hazard	1 – 100	2
Low Hazard	>100	1

1.6.6 Environmental hazard ranking

As described in section 1.4, for each chemical, an average score for each of P and B was calculated. Possible overall scores range from a minimum of 1 (low hazard), to a maximum of 3 (high hazard). The use

of averages ensures that where there are one or more data gaps, the score represents the average of available parameters.

In the assessment of T, the highest hazard score assigned to either acute or chronic data was adopted at the final hazard score for T. Again, possible scores range from a minimum of 1 (low hazard), 2 (moderate hazard) to a maximum of 3 (high hazard). The approach for assessment of T differed from P and B because some chemicals have few aquatic ecotoxicological data. This resulted in weighting of the assessment towards T and is considered conservative and appropriate for a screening level risk assessment.

An overall score (the environmental hazard score) for each chemical was calculated based on the average of the sum of the P, B and T scores and ranged from a minimum of 1 to a maximum of 3. The overall hazard score is calculated to one significant figure, whereas the individual and total P, B or T scores represent whole numbers.

It should be noted that aquatic toxicological scores for some chemicals were based on modelled, rather than measured data. The modelled toxicological data were from EPISUITE (refer to section 1.1.3). The degree of uncertainty associated with the toxicological data increases when modelled data are used, and the ranks of chemicals scored using these data should be interpreted with this in mind.

1.6.7 Identification of aquatic chemicals of potential concern (COPC)

Based on the ranking of the hydraulic fracturing chemicals, the organic chemicals identified with a high hazard ranking were selected as COPC.

1.6.8 Evaluation of mixture toxicity

It is noted that the CG requirements in (b) refer to the provision of "...*toxicity data for each active ingredient and any mixture toxicity information*". In the environmental hazard evaluation, consideration was given to the available environmental fate, persistence and toxicity information presented in the material safety data sheet (MSDS). Where additional information was required to assess environmental hazard, data were sought for the appropriate chemical constituent namely, the active ingredient(s). Where data for active ingredients were unavailable, data for a suitable surrogate chemical were adopted. This is documented in this report for transparency.

The environmental hazard assessment did not consider the combined effects of the hydraulic fracturing chemicals when present in mixture. Assessment of mixtures is considered beyond the scope of a screening level risk assessment. Approaches for environmental risk assessment of individual chemicals are inherently conservative and designed to over-estimate risk as a precautionary approach and in recognition of the uncertainty surrounding effects of mixtures. This is implicit in the approach adopted in this report for the ecological risk assessment of hydraulic fracturing chemicals.

Methodologies for estimating combined effects of mixtures are in development. The current, international best practice and accepted approach for assessment of mixtures remains the additive approach as a default, conservative position. Additive approaches assume chemicals have the same mechanism of action, in other words toxic effect is manifest in the same manner (e.g., narcosis) at the same location (e.g., central nervous system).

Guidance in Australia for assessment of mixtures is limited to direct toxicity assessment (DTA) described in the Australian Water Quality Guidelines (ANZECC & ARMCANZ, 2000). Direct toxicity assessment entails collection of an environmental sample containing the chemical mixture and undertaking ecotoxicological testing (exposing test organisms to the environmental sample and measuring effect). The National framework for Chemicals Environmental Management (NChEM) guidance remains largely silent on approaches for assessment of mixtures and instead advocates consideration of individual chemical constituents in risk assessment, which was the approach adopted in this risk assessment. The National Environmental Protection Council (NEPC) released a Draft of the National Environment Protection (Site Assessment) Measure (NEPM) revision for public consultation in October 2010. In this draft document reference is made to use of the additive approach in assessment of mixtures.

A recent study (Kortenkamp et al., 2009) was published documenting a review of the current scientific knowledge and regulatory approaches for assessment of mixtures. This study was commissioned by the European Commission Directorate General for Environment and released in December 2009 for public comment. The Environment Council is expected to respond to these comments in December 2010 and so the report remains a study of approaches and is not policy or regulatory guidance.

Hence, pending the formalization and regulatory endorsement of mixture toxicity assessment guidelines in Australia, the conservative assessment of the individual active ingredients of hydraulic fracturing fluid mixtures (or their surrogates) was considered appropriate for this ecological risk assessment.

1.7 Exclusions and limitations

The environmental hazard assessment is a relative assessment and not a comprehensive evaluation of environmental hazards. The following limitations with regard to the hazard assessment and source data are noted:

- The approaches consulted for assessment of PBT in devising the environmental hazard assessment approach are predominantly focussed on the assessment of organic chemicals. There is limited guidance for PBT assessment of inorganic chemicals;
- The environmental hazard assessment approach is subject to professional judgment and the evaluator's subjectivity in designating the parameter ranges for each parameter assessed;
- The environmental hazard assessment did not consider, *inter alia*:
  - breakdown or reactive products of the chemicals that may pose more or less of an environmental hazard than the parent compound;
  - the quality, adequacy or accuracy of the available information sourced, noting that only sources considered to be reputable were used;
  - endocrine disruption effects that are not assessed by standard ecotoxicological tests;
  - the combined effects of these chemicals when present in mixture (see comments in section 1.6.8 regarding mixture toxicity information);
- The data collated in the chemical information sheets were treated the same regardless of whether the data are measured experimental values or estimated / calculated values;
- The test endpoint description in the (secondary) sources consulted was relied upon although it should be noted that true chronic and acute NOEC, LOEC, MATC and L(E)C_{50} are dependent on a variety of factors such as test duration, species tested, stage in the life-cycle, etc. which can only be verified by review of the primary literature;
- It is noted in relation to the aquatic ecotoxicological data that the species *Daphnia magna* are a sensitive species, frequently displaying sensitivity to chemicals orders of magnitude greater than other invertebrate species;
- Sources of Australian aquatic ecotoxicological data were consulted but the information is very limited. Furthermore, many species reported in the Australian literature are not necessarily indigenous species;
- The environmental hazard assessment approach devised for this study will not adequately assess chemicals which are:
  - hydrophilic i.e., are highly soluble and have low K_{ow}. Where aquatic ecotoxicological data are limited for these types of chemicals, toxicity may be underestimated because there is potential for these chemicals to be highly toxic.

  - poorly biodegradable, have low acute toxicity, but are bioaccumulative (based on the BCF or K_{ow}). These chemicals may exert chronic toxicity.

- Use of surrogate toxicity data for hydraulic fracturing chemicals which are best described as mixtures may further bias the hazard assessment towards assessment of T potential. Where a highly toxic chemical is present in only small quantities the effect on the overall hazard assessment is greater compared to a chemical with lower toxicity.

- Toxicological data were obtained for surrogate chemicals and/or modelled data using ECOSAR, as discussed above.

2.0 HUMAN HEALTH TOXICITY ASSESSMENT

2.1 Objective

The assessment of toxicity represents an assessment of hazard rather than risk. The aim of the hazard assessment is to provide a semi-quantitative hierarchy of health concern or hazard ranking of chemicals based on human health toxicity to identify COPC. Further evaluation of the risk posed by the COPC can be provided with an evaluation of exposure pathways and fate and transport modelling. There are various qualifications related to the hazard ranking process and these are summarised in the concluding comments of each human health toxicity profile.

2.2 Hazard Ranking Methodology

A variety of hazard ranking or chemical screening methods are available and some have been published in the peer-reviewed literature. These include:

- The Waste Minimisation Prioritization Tool (WMPT) and the Toxic Equivalency Potential (TEP) that were developed by the United States Environment Protection Agency (USEPA), described in Pennington and Bare (2001). The former examines screening in terms of key physical-chemical properties and includes measures for persistence, bioaccumulation and toxicity (PBT) that are calculated. Each PBT measure is scored to provide a single measure of relative concern. TEPs evaluate chemical fate, multi-pathway exposure and toxicity using a model-based approach. The latter was considered by the authors to represent a less subjective and thus improved approach. TEPs are based on a generic version of CalTox, an integrated multimedia fate, multi-pathway exposure and toxicity model initially developed for human health risk assessments.

- Pittinger et al. (2003) discussed approaches from a number of areas. These included:

  - the American Industrial Health Council (AIHC);

  - European Risk Ranking Method (EURAM);

  - US Chemical Hazard Evaluation for Management Strategies (CHEMS-1);

  - US Risk Screening Environmental Indicators;

  - US EPA Clusters Scoring System for particular tasks;

  - Exposure, Fate Assessment Screening Tool (E-FAST) used in US EPA's New Chemicals Program; and

  - the Organisation for Economic Co-operation and Development's (OECD's) "*Tools for R&D Screening*" which is part of the OECD's Chemical Risk Management Program.

  In all of these approaches the nature of the hazard, the specific scenario and exposure determinants tend to dictate the tools to be used.

- More recent approaches included the use of indoor air exposure data against air health guidelines to rank 267 chemicals to 31 chemicals posing hazards with nine chemicals eventually identified as priority pollutants (Logue et al., 2011) and an approach for a relative risk ranking of selected substances on the Canadian National Pollutant Release Inventory (Dunn, 2009).

- OECD (2001) published an initial approach to a harmonised integrated classification system for human health and environmental hazards of chemical substances and mixtures which was updated to a Globally Harmonised System of Classification and Labelling of Chemicals (GHS) in 2003, with updates in 2005, 2007 and then in 2009 (UN, 2009). These guidelines provide categorisation across ten toxicity parameters and provide specific guidance for separation into those categories based on available toxicological data. The approach ranks substances within the respective categories but not across the toxicological parameters.

- US EPA Design for the Environment (DfE). DfE focuses on the principles of green chemistry and applies these principles to work towards the replacement of hazardous chemicals by safer chemicals and considers a broader range of variables.

A recent open source document from the Clean Production Organisation (2009) considered a ranking approach for these principles with the objectives of achieving safer chemical use. This "*Green Screen for Safer Chemicals*" (Green Screen) provides an integration of data and categorisations from US EPA, European Union (EU), United Nations GHS, International Agency for Research on Cancer (IARC) and US National Toxicology Program (NTP) sources to establish Very High (VH), High (H), Moderate (M), and Low (L) categories. The basis of the evaluation is to produce an overall categorisation into four benchmark levels with Benchmark 4 reflecting a preferred safer chemical – a "green" objective. While the overall objectives differ somewhat from the objectives of this study the basis to the use of data reflects current approaches in hazard categorisation and includes toxicological parameters drawn from the UN GHS, IARC and other reputable sources. It also includes a consideration of endocrine disruptor potential and the physical hazards of being explosive and flammable. As such this approach to the hazard ranking has been utilised.

It should be noted that Green Screen includes an evaluation of persistence, bioaccumulation and aquatic toxicity (PBT). Rather than use the classification outlined in Green Screen the PBT analysis is treated separately in the ecotoxicological evaluations. This is considered appropriate as this evaluation considers a comprehensive evaluation looking at multiple parameters. In addition the classification of high, medium and low categories utilises more sensitive values for the cut off parameters and is therefore considered a more conservative assessment. The classification scheme does not use a Very High grouping with any chemical placed in the High group considered a COPC. The Very High grouping in Green Screen relates only to the PB assessment, as such this grouping has not been used in this assessment.

The parameters evaluated in Green Screen are:

- Bioaccumulation potential
- Persistence
- Aquatic Toxicity
- Acute toxicity (oral, dermal or inhalation)
- Corrosion/irritation of the skin or eye
- Sensitisation of the skin or respiratory system
- Carcinogenicity
- Developmental toxicity
- Mutagenicity/genotoxicity

- Reproductive toxicity
- Neurotoxicity
- Endocrine disruption
- Systemic toxicity/Organ effects
- Immune system effects
- Explosive potential
- Flammable potential.

Further discussion of these parameters is provided in the subsequent sections, including the threshold values used for each parameter.

2.2.1 Human Health Parameters

A description of each parameter is provided below, along with the threshold values for each parameter as presented in Table 1, Green Screen. The threshold values in Green Screen are drawn from the following sources:

- EU's recently enacted chemicals policy legislation (Registration, Evaluation and Authorization of Chemicals–REACH) (EU 2006);
- United Nations (2009) Globally Harmonized System of Classification and Labelling of Chemicals (GHS). Second revised edition. United Nations, New York and Geneva;
- The International Agency for Research on Cancer (IARC) monographs on Carcinogens, available at http://monographs.iarc.fr;
- US Environmental Protection Agency, Design for Environment Program. (USEPA DfE) 2005. Environmental Profiles of Chemical Flame-Retardant Alternatives for Low-Density Polyurethane Foam;
- US Department of Health and Human Services, Public Health Service, National Toxicology Program (US NTP). 2005. Report on Carcinogens, Eleventh Edition;
- State of California, Environmental Protection Agency, Office of Environmental Health Hazard Assessment. 2006. Chemicals Known to the State to Cause Cancer or Reproductive Toxicity;
- Japan Ministry of Environment. 1998. Endocrine Disrupting Chemicals Database, Table of Chemicals Suspected of Having Endocrine Disrupting Effects; and
- US Department of Labour Occupational Safety and Health Administration (OSHA) List of OSHA carcinogens, available at http://www.epa.gov/tri/chemical/carcinog.pdf.

2.2.1.1 Acute Toxicity

Acute toxicity refers to the occurrence of adverse effects following exposure to a single dose of a substance or multiple doses within a 24 hour period (OECD 2009). In toxicity studies acute effects are often characterised by lethality, commonly reported in lethal dose or concentration at which 50% of the animals tested die (LD50 or LC50). Non-lethal acute effects are sometimes included. Routes of administration commonly used are the oral, dermal and inhalation pathways.

The threshold values for acute toxicity are presented in Table 13.

Table 13: Acute toxicity (oral, dermal or inhalation) threshold values

High	Medium	Low
■ LD50 <50 mg/kg bodyweight (oral) ■ LD50 <200 mg/kg bodyweight (dermal) ■ LC50 <500 ppm (gas) ■ LC50 <2.0 mg/l (vapour) ■ LC50 <0.5 mg/l (dust or mist) ■ US EPA Extremely Hazardous Substance List ■ GHS Category 1 or 2	■ LD50 50-2000 mg/kg bodyweight (oral) ■ LD50 200-2000 mg/kg bodyweight (dermal) ■ LC50 500-5000 ppm (gas) ■ LC50 2-20 mg/l (vapour) ■ LC50 0.5-5 mg/l (dust or mist) ■ GHS Category 3 or 4	No basis for concern identified

2.2.1.2 Corrosion/Irritation of skin or eye

Skin corrosion is the production of irreversible damage to the skin namely, visible necrosis through the epidermis and into the dermis following the application of a substance for up to four hours (OECD, 2009). Corrosion is often indicated by ulcers and bleeding and after 14 days discolouration of the skin, alopecia and scars. Skin irritation is the production of reversible damage to the skin following application of a substance (OECD, 2009).

Serious eye damage (i.e. corrosion) is indicated by tissue damage of the eye or serious physical decay of vision following application of the anterior surface of the eye which is not fully reversible within 21 days (OECD, 2009). Eye irritation is indicated by changes in the eye following application of the anterior surface of the eye which is fully reversible within 21 days (OECD, 2009).

The threshold values for corrosion/Irritation of the skin or eye are presented in Table 14.

Table 14: Corrosion/Irritation of the skin or eye ranking threshold

High	Medium	Low
■ Evidence of irreversible effects in studies of human populations ■ Weight of evidence of irreversible effects in animal studies ■ GHS Category 1 (skin or eye)	■ Evidence of reversible effects in humans or animals ■ GHS Category 2 or 3 — skin irritation ■ GHS Category 2A or 2B — eye	No basis for concern identified

2.2.1.3 Sensitisation of skin or respiratory system

A respiratory sensitiser is a substance that will lead to hypersensitivity of the airways following inhalation of the substance. A skin sensitizer is a substance that will lead to an allergic response following skin contact (OECD 2009).

The threshold values for sensitisation of the skin or respiratory system are presented in Table 15.

Table 15: Sensitisation of the skin or respiratory system ranking threshold

High	Medium	Low
■ Evidence of adverse effects in humans; ■ Weight of evidence demonstrates potential for adverse effects in humans ■ GHS Category 1 – (skin or respiratory) ■ Positive responses in predictive Human Repeat ■ Insult Patch Tests (HRIPT) (skin)	■ Suggestive animal studies ■ Analog data ■ Chemical class known to produce toxicity	■ No basis for concern identified

2.2.1.4 Carcinogenicity

A carcinogen is a substance or a mixture which induces cancer or increases its incidence. The classification of a substance or mixture as a carcinogenic hazard is based on its inherent properties and does not provide information on the level of human cancer risk which the use of a substance may represent (OECD, 2009).

The threshold values for carcinogenicity are presented in Table 16.

Table 16: Carcinogenicity ranking thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans ■ NTP known or reasonably anticipated to be human carcinogen ■ OSHA carcinogen ■ California Prop 65 ■ IARC Group 1 or 2A ■ EU Category 1 or 2 ■ GHS Category 1A or 1B	■ Suggestive animal studies ■ Analog data ■ Chemical class known to produce toxicity ■ IARC Group 2B ■ EU Category 3 ■ GHS Category 2	■ No basis for concern identified ■ IARC Group 3 or 4

2.2.1.5 Developmental toxicity

Developmental toxicity refers to the *in utero* effects such as death, malformations, functional deficits and developmental delays (enHealth, 2004). It can also include delayed toxicity associated with epigenic effects during the sensitive phases of foetal development.

The threshold values for developmental toxicity are presented in Table 17.

Table 17: Developmental toxicity ranking threshold

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans ■ NTP Center for the Evaluation of Risks to Human Reproduction ■ California Prop 65	■ Suggestive animal studies; ■ Analog data ■ Chemical class known to produce toxicity	■ No basis for concern identified

2.2.1.6 Mutagenicity/Genotoxicity

Mutagenesis occurs when chemicals cause changes in the genetic material which can be transmitted during call division (Davis et al., 1994). The OECD (2009) indicate a mutagen is a chemical that may cause mutations in the germ cells of humans that can be transmitted to the progeny. A mutation is defined as a permanent change in the amount or structure of the genetic material in a cell. The more general terms genotoxic and genotoxicity apply to agents or processes which alter the structure, information content or segregation of DNA (OECD, 2009).

The threshold values for mutagenicity and genotoxicity are presented in Table 18.

Table 18: Mutagenicity/genotoxicity ranking thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans ■ EU Category 1 o r 2 ■ GHS Category 1A or 1B	■ Suggestive animal studies; ■ Analog data ■ Chemical class known to produce toxicity ■ EU Category 3 ■ GHS Category 2	■ No basis for concern identified

2.2.1.7 Reproductive toxicity

Reproductive toxicity includes adverse effects on sexual function and fertility in adult males and female as well as developmental toxicity in the offspring (OECD, 2009). This may include effects on mating behaviour, gonadal function, oestrous cycling, conception, implantation, parturification and lactation (Draft enHealth, 2010).

The threshold values for reproductive toxicology are presented in Table 19.

Table 19: Reproductive toxicity ranking thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans ■ NTP Centre for the Evaluation of Risks to Human Reproduction ■ California Prop 65 ■ EU Category 1 or 2 ■ GHS Category 1A or 1B	■ Suggestive animal studies; ■ Analog data ■ Chemical class known to produce toxicity ■ EU Category 3 ■ GHS Category 2	■ No basis for concern identified

2.2.1.8 Neurotoxicity

Neurotoxicity refers to any adverse effects on the structure or functional integrity of the developing or adult nervous system. Neurotoxic effects may involve a spectrum of biochemical, morphological, behavioural, and physiological abnormalities whose onset can vary from immediate to delayed following exposure to a toxic substance, and whose duration may be transient or persistent (US Department of Food and Drug Administration, 2000).

The threshold values for neurotoxicity are presented in Table 20.

Table 20: Neurotoxicity Ranking Thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans	■ Suggestive animal studies ■ Analog data ■ Chemical class known to produce toxicity	No basis for concern identified

2.2.1.9 Endocrine disruption

Endocrine disruptors are chemicals that may interfere with the body's endocrine system and produce adverse developmental, reproductive, neurological, and immune effects (OECD, 2009).

The threshold values for endocrine disruption are presented in Table 21.

Table 21: Endocrine Disruption Ranking Thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates that mechanisms of action lead to adverse effects	■ Suggestive animal studies; ■ Analog data ■ Chemical class known to produce toxicity ■ EU Draft List - Category 1 or 2 ■ Japanese list	No basis for concern identified

2.2.1.10 Systemic toxicity/organ effects

This relates to substances that produce specific non- lethal organ toxicity arising either from a single or repeated dose. All significant health effects that can impair function, both reversible and irreversible, immediate and/or delayed are included (OECD, 2009).

The threshold values for systemic toxicity / organ effects are presented in Table 22.

Table 22: Systemic toxicity ranking thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans ■ GHS Category 1 — organ/systemic toxicity following single or repeated exposure	■ Suggestive animal studies; ■ Analog data ■ Chemical class known to produce toxicity ■ GHS Category 2 or 3 single exposure ■ Category 2 repeated exposure	No basis for concern identified

2.2.1.11 Immune system effects

The threshold values for immune system effects are presented in Table 23.

Table 23: Immune system ranking thresholds

High	Medium	Low
■ Evidence of adverse effects in humans ■ Weight of evidence demonstrates potential for adverse effects in humans	■ Suggestive animal studies ■ Analog data ■ Chemical class known to produce toxicity	No basis for concern identified

2.2.1.12 Explosive potential

An explosive substance is a solid or liquid which is capable by chemical reaction of producing gas at such high temperature and pressure and at such a speed as to cause damage to the surroundings (OECD, 2009).

The threshold values for explosive potential effects are presented in Table 24.

Table 24: Explosive potential threshold values

High	Medium	Low
■ GHS Category: Unstable Explosives or Divisions 1.1, 1.2 or 1.3	■ GHS Category: Divisions 1.4, 1.5	■ No basis for concern identified

2.2.1.13 Flammable Potential

A flammable liquid means a liquid having a flash point of not more than 93°C (OECD, 2009). A flammable solid is one which is readily combustible or may cause or contribute to fire through friction. A readily combustible solid is a powdered, granular or pasty substance which is dangerous if it can be ignited by brief contact with an ignition source and the flame spreads rapidly (OECD, 2009).

The threshold values for flammable potential effects are presented in Table 25.

Table 25: Flammable potential ranking thresholds

High	Medium	Low
■ GHS Category 1 - Flammable Gases ■ GHS Category 1 - Flammable Aerosols ■ GHS Category 1 or 2 — Flammable Liquids	■ GHS Category 2- Flammable Gases ■ GHS Category 2- Flammable Aerosols ■ GHS Category 3 or 4 — Flammable Liquids	No basis for concern identified

2.3 Human health toxicity ranking

2.3.1 Process of toxicity review

All chemicals considered are reviewed to determine if classified as "*hazardous*" or "*non-hazardous*" based on the NOHSC (2004) "*Approved Criteria for Classifying Hazardous Substances, 3rd Edition*". These classifications are based on a range of toxicological properties consistent with approaches used in hazard ranking and health risk assessment and are listed on the Safework Australia, Hazardous Substances Information System (HSIS). If chemicals are classified as non-hazardous due to no listing on HSIS no further review of human health toxicity is undertaken unless specific concerns were raised requiring further analysis. Limitations of the HSIS database are that the absence of a chemical may also be based on an absence of review although there are now some 900 substances on the HSIS database. Chemicals classified as hazardous are selected for review of human health toxicity information.

Toxicity information is collected from readily available human health toxicity data from the following online data bases:

- Safework Australia sources, specifically the Hazardous Substances Information System (HSIS)
- World Health Organisation sources such as International Program of Chemical Safety (IPCS) INCHEM, including International Chemical Assessment documents (CICADS) and Environmental Health Criteria (EHC) monographs
- United States sources such as:
  - United States National Medical Library of Medicine Toxicology (Toxnet) and Hazardous substances Data Bank (HSDB)
  - United States Environmental Protection Agency (US EPA) Integrated Risk Information System (IRIS)
  - Agency for Toxic Substances and Disease Registry (ASTDR) toxicological profiles
  - Risk Assessment Information System (RAIS).

If no information is available from these databases then the search is extended to access other sources of toxicity information with preference given to peer-reviewed data.

Toxicity information for each parameter is then categorised as High, Medium or Low concern according to the thresholds described in previous sections. The categories are numerically converted as follows:

- High = 3
- Moderate = 2
- Low = 1

The overall toxicity score for each chemical is generated by calculating the average based on the available data so that the scores are not biased by the amount of data for any one chemical, e.g. data on ten parameters, the summed total is divided by ten, data on four parameters, the summed total should be divided by 4, etc.The overall human health toxicity score is calculated to two significant figures, whereas the individual parameter scores represent whole numbers.

The scoring system is semi-quantitative in that scores are assigned to ranges for a particular parameter. The scores are largely assigned using some quantitative data and professional judgement following consideration of the guidance from the ranking thresholds specified for each parameter. There is no weighting applied for the severity of the adverse health effects.

2.4 Selection of human health COPC

From this assessment, chemicals identified as High and Moderate in the human health toxicity ranking according to the process outlined and where a score of 2.0 or greater is recorded are considered a COPC for human health. It should be noted that the selection of a chemical as a COPC does not indicate an unacceptable risk; rather it indicates that potential exposures to these chemicals should be evaluated in greater detail to test whether they might present an unacceptable risk.

As a qualifying comment it is important to note that adverse health effects are a reflection of intrinsic chemical or physical toxicity, the physico-chemical parameters of the substance concerned and the nature of the exposure setting and affected populations. It is not possible within a numerical ranking system to capture all possible exposure settings that may apply with product use and the subsequent potential chemical exposures. Subsequently qualitative comments have been provided for each of the ranked chemicals as concluding summary comments. In the case of those substances ranked in the >1.0 to <2.0 range these qualifying comments should be understood.

2.5 Combined PBT and human health COPC

The PBT analysis and the human health toxicity may be then considered together to provide an overall score to identify chemicals of high concern. The average of the PBT and human health scores are taken to provide an overall score. To remain consistent with the PBT analysis all chemicals with an overall score above 2.5 are considered of high concern.

Chemical Information Sheet - Hexamethylenetetramine

Name	Hexamethylenetetramine
Synonyms	Hexamine; Methenamine; Urotropine; 1,3,5,7-tetraazaadamantane, Formin, Aminoform
CAS number	100-97-0
Molecular formula	C6H12N4
Product name	Hexamethylenetetramine

Physical Properties	Value	Reference
Phase/state	White, crystalline powder or colorless, lustrous crystals	3
Molecular weight	140.19 g/mol	3
Melting point	65.06 °C	1
	>250 °C	2
	280°C sublimes	4
Boiling point	208.59 °C	1
	sublimes	2
Density/ specific gravity	1.331 at -5°C	3
	1.7 at 25°C	3
Vapour pressure	4.0X10-3 mmHg at 25 °C (experimental)	3
Solubility	76.7 g/m^3 at 25°C	1
	1g soluble in 1.5ml water, 12.5ml alcohol, 320ml ether, 10ml chloroform	3
Henrys law constant	1.6X10-9 atm m^3/mole (derived)	3
Log organic carbon partition coefficient (log Koc)	1.74 (based on Koc 55 (SRC))	3
Log octanol-water partition coefficient (log Kow)	-4.15 (estimated)	3

Persistence/ Bioaccumulation	Value	Reference

Name	Phenol
Synonyms	Numerous synonyms including, benzenol, carbolic acid, hydroxybenzene, monohydroxybenzene, monophenol, oxybenzene, phenic acid, phenyl hydrate, phenyl hydroxide, phenylic acid, phylic alcohol
CAS number	108-95-2
Molecular formula	C_6H_6O
Molecular Structure	

Overview	References
Phenol is used ubiquitously and can be found in industrial, professional and consumer products. It is used as a general disinfectant and antiseptic, for the manufacture of colourless or light coloured artificial resins, in medical and industrial compounds and dyes and as a reagent in chemical analysis. Phenol is bactericidal in concentrations above 1% and fungicidal above 1.3%. Phenol is released into the environment by wood stoves, vehicle exhaust and other combustion processes. It is also naturally produced in decaying organic matter. Phenol in its crystalline form is colourless to light pink. It has a sweet and acrid odour and a sweet and sharp burning taste in its natural form (crystals). Phenol is caustic both as crystals and in solution.	1

Human Health Toxicity Summary	Reference
Inhalation Mortality was observed in human babies exposed to phenol via inhalation when it was used as a cleaner and disinfectant in nurseries. The cause of death was hyper-bilirubinaemia (jaundice). Other symptoms in humans exposed via inhalation include pulmonary irritation and oedema, coughing, stridor and aromatic odour of the breath. In animal species, inhalation has often resulted in stimulation of the central nervous system (CNS), severe CNS depression, hyperaemia (increased blood flow) of the lungs, bronchopneumonia, purulent bronchitis and hyperplasia of the peri-bronchial tissues. Guinea pigs exposed to concentrations up to 50 ppm for 20 days presented signs of toxicity in post-mortem examination of the lung, heart, liver and kidneys. Rats exposed to 25 ppm continuously for 15 days showed signs of neurological impairment including muscle twitching, disturbed walking rhythm and posture	1

although these symptoms were reversible on cessation of exposure.	
Irritancy The substance is irritating to the eyes and the skin. In humans, dermal exposure can result in exfoliation, cauterization and discolouration of the skin. Eye exposure may result in complete recovery, blindness and loss of an eye. In animals, dermal exposure has resulted in eczema, inflammation, discolouration, necrosis, sloughing and gangrene and exposure of the eyes has caused irritation, visual effects and glaucoma in some species. No signs of increased sensitivity, after prolonged or repeated exposures was reported in human or animal studies. Oral ingestion in humans and animals can result in muco-cutaneous and gastrointestinal corrosions and necrosis and mouth sores.	1
Carcinogenicity Phenol has not been reported by IARC or US EPA to have carcinogenic effects on humans or research animals.	1
Developmental In developmental studies with rats and mice, phenol reduced litter survival in rats at a concentration of 5000 ppm. In mice it was found to not be a developmental toxicant, except perhaps at maternally toxic concentrations.	1
Mutagenicity/genotoxicity No evidence of mutagenicity/genotoxicity has been reported for humans. In animal studies however exposure has resulted in induction of skin tumours in mice and mutagenicity in Salmonella, *E. Coli* and Drosophila.	1
Systemic toxicity/Organ effects Effects noted in both human and animal studies have included muscle spasms, weak and rapid pulse, accelerated respiration, tachycardia, seizures, collapse, unconsciousness, renal, kidney and liver damage with failure and death. Ingestion in humans has resulted in mouth sores, vomiting, diarrhea, oral and gastric ulcers and dark urine. Systemic complaints from acute exposure include CNS stimulation and depression, seizures, coma, tachycardia, ventricular dysrhythmias, hypotension, hypothermia, metabolic acidosis, and acute tubular necrosis. Neurotoxic effects include damage to nerve cells resulting in vasometer centre depression, cardiac arrest, vascular failure, coma and death.	1

Concluding Summary Comments

Phenol in its pure form exhibits a range of toxicity which is predominantly associated with acute exposure. Phenol is irritant and corrosive with a degree of volatility that warrants evaluation of atmospheric exposures. The latter may be flammable and explosive thus compounding the risks associated with chemical effects. All pathways require evaluation with an emphasis on inhalation and dermal exposures due to the potent necrotic action on skin, mucous membranes and respiratory tract. While these effects are based on the pure substance in the hydraulic fracturing scenario the phenol is a component of a granular (phenol-formaldehyde) resin with a “mild odour” with the latter representing emissions from the solid form of the volatile components – both phenol and formaldehyde. Residual phenol concentrations are reported as less than 1.5%. Taking this information into consideration the phenol represents a low order of concern relative to the moderate to high level of concern from the hazard ranking. This, however, requires evaluation in terms of mass exposure, i.e. where there are large masses or stockpiles of the resin in confined or enclosed environments or where a large-scale spill scenario occurs. These occupational and environmental settings would then require appropriate risk management measures to mitigate exposures.

Name	Formaldehyde
Synonyms	Numerous synonyms including, formalin, formic acid, karsan, lysoform, methyl aldehyde, methylene oxide, oxomethane and paraform.
CAS number	50-00-0
Molecular formula	CH_2O
Molecular Structure	

Overview	References
Formaldehyde can be found in industrial, professional and consumer products. Formaldehyde has many uses including as a pesticide, in histological labs, as a germicide, textile finish, preservative, stabilizer, disinfectant and antibacterial food additive. It is also used in the production of resins, wood products, plastics, fertilizers and foam insulation. Formaldehyde is a nearly colourless gas with a pungent suffocating odour.	1, 2

Human Health Toxicity Summary	Reference
Inhalation In both human and animal studies, effects following inhalation have included irritation of the throat and respiratory tract with resultant cough, chest tightness and wheezing. Other symptoms include headaches, weakness and heart palpitations.	2
Irritancy/Hypersensitivity Formaldehyde is irritating to the eyes, skin, respiratory and gastrointestinal tracts. Symptoms include conjunctivitis and corneal burns, skin discoloration, dermatitis and increased sensitization, burning in the mouth and throat, nausea and vomiting. Formaldehyde is a respiratory sensitiser.	2
Carcinogenicity There is sufficient evidence in humans and experimental animals for the carcinogenicity of **formaldehyde**. **Formaldehyde** is considered carcinogenic to humans (Group 1) by the IARC (International Agency for Research on Cancer) and a probable human carcinogen by the US EPA (United States Environmental Protection Agency - Group B1). These findings are based on human data from nine studies that show statistically significant associations between site-specific respiratory neoplasms and exposure to **formaldehyde** or **formaldehyde**-containing products. An increased incidence of nasal squamous cell carcinomas was observed in long-term inhalation studies in rats and in mice. The classification is supported by in vitro genotoxicity data and **formaldehyde's** structural relationships to other carcinogenic aldehydes such as acetaldehyde.	2
Systemic Local effects on the eyes and skin include conjunctivitis, corneal burns, brownish discoloration of skin, dermatitis, hives, and pustule-vesicular eruption. Effects from inhalation exposure include rhinitis and anosmia (loss of sense of smell), pharyngitis, laryngospasm, tracheitis and bronchitis, pulmonary eodema, cough, constriction in the chest, dypsnea (difficulty in breathing), headache, weakness, palpitation (rapid heartbeat), gastro-enteritis (inflammation of the stomach and intestines). Following ingestion, effects include burning in mouth and eosophagus, nausea and vomiting, abdominal pain, diarrhea, vertigo (dizziness), unconsciousness, jaundice, albuminuria, hematuria, anuria, acidosis, convulsions.	2

F**ormaldehyde once absorbed,** depresses the CNS and symptoms equivalent to alcohol intoxication are noted, consisting of vertigo, depression, and coma. Rarely convulsions are observed.	
Reproductive/Developmental An investigation of reproductive function in female workers exposed to **formaldehyde** in the garment industry revealed increased incidence of menstrual disorders, inflammatory disease of the reproductive tract, sterility, anaemia, and low birth weights among offspring. In animal studies no side effects were noted in rat embryos following exposure to formaldehyde.	2
Mutagenicity/genotoxicity **Formaldehyde is a genotoxin as it has been observed to** induce gene mutation in bacteria, fungi, yeast, and *Drosophila* larvae as well as in cultured rodent and human cells. In part, these mutations appear to be the consequence of DNA damage. A second mechanism by which **formaldehyde** may damage the genome is considered to be through inhibition of DNA repair.	2
Systemic toxicity/Organ effects **Exposure to formaldehyde has resulted in liver toxicity in a number of animal studies. Limited information was available on organ effects in humans.**	2

Concluding Summary Comments

Formaldehyde in its pure form has been associated with a range of acute and chronic hazards varying from the ability to produce nasal carcinomas to local and systemic effects over all exposure pathways with an emphasis on the inhalation pathway. Its volatility may result in elevated atmospheric concentrations which if confined could result in eye, nose and throat irritation and hypersensitivity responses. The latter are of particular concern due to the respiratory sensitising nature of formaldehyde that may then result in adverse effects at markedly low atmospheric concentrations. This, combined with its flammable and explosive nature indicated that pure formaldehyde is a substance of significant health concern and hazard warranting attention and evaluation of any potential exposures.

In the current hydraulic fracturing scenario this substance has been reviewed on the basis of a monomer within a polymerisation reaction that yields a phenol-formaldehyde resin. This resin subsequently coats a cellulose substrate and has the appearance of a "brown, granular solid with a mild odour". The resultant residual formaldehyde concentrations are reported below 1% in the polymer. The resultant "mild odour" associated with the polymer would reflect off-gassing of the volatile residual monomers, including formaldehyde. While this does not necessarily reflect a serious hazard concern compared with the use of the pure substance, caution is required where occupational exposures may result due to the presence of large quantities of the polymer, particularly in confined settings where atmospheric concentrations may be elevated. On an equivalent basis large scale accidental release of the polymer in environmental settings may result in short-term-exposures to sensitive subgroups such as asthmatics and this hazard should be recognised. Dermal and inhalation pathways are the critical pathways with the irritant respiratory sensitising properties a key determinant.

Name	Xylene
Synonyms	Numerous synonyms including, benzene dimethyl, dimethylbenzene, kyslen, methyl toluene, xylenen, xylol, xylole.
CAS number	1330-20-7
Molecular formula	C_8H_{10}
Molecular Structure	

Overview	References
Xylene can be found in industrial, professional and consumer products. Xylene has many uses including as an aquatic herbicide, a pesticide, in histological labs, in the manufacture of fibres, dyes, resins, paints, coatings/varnishes and inks. It is also added to gasoline to improve octane ratings. Xylene is a clear colourless liquid with a distinctive sweet smell.	1, 2

Human Health Toxicity Summary	Reference
Inhalation In both human and animal inhalation studies, effects have included irritation of the throat and respiratory tract. Central nervous system effects in both animals and humans are also common at high concentrations (systemic effects).	1, 2
Irritant Xylene is irritating to the eyes of both humans and animals. In mild cases it can cause slight irritation and redness but at higher concentrations and/or longer exposure durations, conjunctivitis and eye lesions have been reported. Multiple exposures to xylene may lead to effects on the skin in humans including flaking to moderate dermatitis, rashes, irritation, dryness and cracking.	2
Carcinogenicity IARC report that there is inadequate evidence for the carcinogenicity of xylene in humans. There is evidence suggesting lack of carcinogenicity in experimental animals and therefore not classifiable as to its carcinogenicity to humans.	2

Systemic General human health effects include central nervous system effects such as dizziness, headaches, short term memory loss, decreases in reaction time, confusion, slurred speech, tremors, and loss of consciousness. Other effects include eye, skin and respiratory tract irritation and vomiting. Animal studies have reported laboured breathing and pulmonary inflammation, congestion of cells in the liver, spleen and kidneys, decreased white blood cell counts, and weight loss. Most of these effects have occurred at high exposure levels.	2
Developmental No development effects were observed in humans exposed to xylene. Studies in hamsters have reported decreased foetal size and bodyweight and an increased incidence of prenatal deaths following exposure to xylene. Chickens exposed *in ovo* had increased incidences of malformations. In rats, studies have observed an increased incidence of bone retardation and extra ribs, and increased effects on the brain, liver and heart.	2
Mutagenicity/genotoxicity There is no indication based on available reported research and case studies that xylene has genotoxic effects on humans or animals.	2
Systemic toxicity/Organ effects **The critical target organ following xylene exposure to high concentrations in animals is the central nervous system and to a lesser extent the liver, kidneys and spleen. Most of the effects observed were reversible following cessation of exposure.**	1, 2

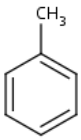
Concluding Summary Comments



The hazard ranking of moderate to high concern reflects pure xylene and its respective isomers. This needs to be considered in light of the low potential for limited exposure associated with a residual level of less than 1% in the Mod Acid which comprises a very low percentage of the LiteProp 125. Once baked and cured it is unlikely to contain xylene levels of sufficient magnitude to warrant a health concern should small amounts of resin be used. If there are particular settings where large masses of resin are confined within enclosed areas where occupational exposures may result, consideration of residual off-gassing and suitable mitigation measures may be required.

Name	Toluene
Synonyms	Numerous synonyms including, methacide, methylbenzene, methylbenzol, toluol, phenylmethane
CAS number	108-88-3
Molecular formula	C_7H_8
Molecular Structure	

Overview	References
Toluene can be found in a range of industrial, professional and consumer products. It occurs naturally in crude oil and in the tolu tree. Toluene is produced in the process of making gasoline and other fuels from crude oil and in the making of coke from coal. Toluene is used in making paints, paint thinners, fingernail polish, lacquers, explosives, dyes, adhesives, solvents, cosmetics, antifreeze, inks, rubber and in some printing and leather tanning processes. Toluene is a clear colourless liquid with a distinctive sweet smell. Toluene is highly flammable.	1, 2

Human Health Toxicity Summary	Reference
Inhalation Adverse inhalation effects in exposed humans are both time and concentration dependent. General effects include headaches, blurred vision, dizziness, anaesthesia, and with high level exposures, respiratory arrest. Sudden death among people who deliberately inhale toluene in other products has been observed to be a result of cardiac arrest. In one study of 2 children sniffing toluene containing glue, adverse effects included reduced appetite, nightmares, incoordination and loss of consciousness. A 27-year-old male developed cerebral and cerebellar atrophy over a period of five years of extensive glue sniffing. He also developed bilateral optic atrophy with blindness and severe hearing loss.	1 and 2
Irritant Toluene vapours irritate both the eyes and upper respiratory tract in humans and liquid toluene also irritates the eyes. If aspirated, coughing, gagging, distress, and rapidly developing pulmonary	2

oedema may result. If ingested, toluene causes vomiting, griping, diarrhoea, and depressed respiration. Kidney and liver damage may follow ingestion. Toluene has been shown to cause defatting of skin which can lead to dryness, fissuring and secondary infections.	
Carcinogenicity IARC report that there is inadequate evidence for the carcinogenicity of toluene in humans. There is evidence suggesting lack of carcinogenicity in experimental animals. Toluene is therefore considered by IARC to be not classifiable as to its carcinogenicity to humans. In an animal study exposing mouse skin to painting with toluene there was negative tumour development.	2
Systemic General health effects following human exposure include dizziness, headaches, sore throats, eye irritation and difficulty in sleeping. Systemic effects include growth retardation, liver and kidney damage and miscellaneous effects. High level exposure may lead to death. Epidemiological and clinical reports have recorded neurobehavioral effects such as activity and sleep changes, performance and learning impacts and electro-physiological effects. Studies of women exposed to solvents such as benzene, **toluene**, and xylene have shown menstrual disturbances, principally associated with abnormal bleeding. In animals exposed to toluene, effects have included muscle weakness (rats), reduced coordination and muscle tremors (puppies, kittens and calves), lung and spleen inflammation (dogs and goats) and mild tremors/CNS effects (dogs and cats).	2
Developmental/Reproductive/Teratogenicity Exposure to toluene via maternal spray paint or glue sniffing has been observed to lead to maternal complications including renal tubular acidosis, hypokalaemia, hypocalcaemia, cardiac arrhythmias, rhabdomyolysis, and premature labour. Premature **toluene** exposure leads to a characteristic pattern of anomalies similar to findings in infants exposed to alcohol in utero, consisting of an increased incidence of malformations, poor growth, and developmental delays. In other studies children born to mothers who abused toluene by inhalation during pregnancy had adverse effects including microcephaly, minor craniofacial and limb anomalies, central nervous system defects, attention disorders, developmental delay, learning disorders, and language deficits. The pregnancies of four of five women associated with gross **toluene** abuse (0.5 to 2 cans of spray paint/day for 6 months to 11 years) resulted in evidence of renal toxicity (as evidenced by severe renal tubular acidosis), foetal toxicity (manifested as intrauterine growth retardation), and teratogenicity (e.g. deformed external ears, ventricular septal defect). Women workers exposed to high air concentrations of **toluene** (50-150 ppm) appeared to have a higher incidence of spontaneous abortion than a similar group of women with no occupational exposure to **toluene**. The offspring of mice exposed to toluene had an increased incidence of soft palates. Fertile chicken eggs exposed to increasing doses of toluene had decreasing hatchability. There were no teratogenic effects in rats exposed to toluene via inhalation throughout gestation although there	2

was some growth retardation of the offspring.	
Mutagenicity/genotoxicity In experiments in vitro, toluene did not change the number of sister-chromatid exchanges or the number of chromosomal aberrations in human lymphocytes. In 32 male workers there was no significant difference from controls in the frequency of chromosome aberrations and sister chromatid exchanges following exposure to toluene. Toluene did not induce gene mutations in Salmonella typhimurium, however chromosomal aberrations were observed in the bone marrow cells of male albino rats after chronic inhalation exposure.	2
Systemic toxicity/Organ effects **The most significant effects following exposure to toluene is on the cardiovascular (heart and blood vessels) and nervous systems.** **In humans, toluene** abuse (exposure to 10,000 ppm) has been linked with kidney disease as evidenced by blood (haematuria), protein (proteinuria), albumin (albuminuria), and pus (pyuria) in the urine, accompanied by elevated serum creatinine, decreased urinary output, and metabolic and renal tubular acidosis. **Toluene** appears to produce reversible effects upon liver, renal, and nervous systems. The nervous system appears to be the most sensitive to the effects of **toluene** with high level **toluene** exposures producing in-coordination, ataxia, unconsciousness and eventually, death. Lower level acute exposures in people can produce dizziness, exhilaration and confusion.	1, 2

Concluding Summary Comments

The hazard ranking of moderate to high concern is based on the pure substance and reflects a range of acute and chronic toxicities combined with flammable and explosive properties. This should be assessed against the low exposure potential associated with residual toluene in the Mod Acid used in the resin mixture. This represents less than 1% of a very low percentage of Mod Acid in the final LiteProp 125 mixture. As a consequence exposure to toluene from resin off-gassing is considered unlikely. Should there be large masses of resin within confined settings where the residual toluene composition is elevated risk mitigation measures may be required.

Name	Sulphuric acid
Synonyms	Sulfuric acid, dihydrogen sulphate, oil of vitriol
CAS number	7664-93-9
Molecular formula	H_2SO_4
Molecular Structure	

Overview	References
Sulphuric acid is a strong acid used as a chemical ingredient in a range of industrial applications such as chemical synthesis and manufacture, electrical engineering, mining and metal extraction, and in cleaning supplies. Sulphuric acid occurs as a colourless and odourless dense viscous liquid with a high melting point. It is stable at room temperature and is corrosive and highly irritating.	1

Human Health Toxicity Summary	Reference
Inhalation Human and animal inhalation studies report that sulphuric acid is corrosive to the eyes, skin and mucous membranes but is not considered an allergen following skin contact by humans. Acute inhalation in humans causes a range of adverse respiratory effects. Reports of accidental human skin burns from acute and prolonged exposure are well documented. Inhalation LC50 values in the rat, mouse and rabbit are 0.375-0.425 mg/L, 0.600-0.850 mg/L and 1.470 mg/L-1.610 mg/L, respectively, depending on the exposure time. Guinea pigs appear to be the most sensitive to acute inhalation effects.	1,2
Irritant Sulphuric acid was irritating to the skin in concentrations over 10% in rabbit, guinea pig, and human studies. Results of eye irritation studies are inconsistent, reporting both irritating and severely irritating reactions. In animal studies oral exposure resulted in irritation/corrosion of the gastrointestinal tract. It is toxic to tissue, resulting in rapid destruction of tissue, causing severe burns. No data are available on the acute toxicity by other routes. It is not considered a skin allergen by contact.	2,3
Carcinogenicity IARC has concluded that "occupational exposure to strong inorganic mists containing **sulfuric acid** is carcinogenic for humans (Group 1)."	4

Developmental/Reproductive/Teratogenicity No information is available regarding developmental effects following exposure to sulphuric acid to humans or animals. No evidence of foetotoxicity or teratogenicity was seen in an inhalation study on mice and rabbits.	1, 2
Mutagenicity/genotoxicity **In vitro bacterial** genetic toxicity studies did not show toxic effects however in an *in vitro* non-bacterial test, chromosomal aberrations were observed and assumed to be caused by reduced pH (strong acid). There are no data from *in-vivo* mutagenicity studies available.	2
Systemic toxicity/Organ effects Lungs and tooth enamel may be affected by repeated or prolonged exposure to an aerosol of this substance. Repeated dose inhalation tests in rat, guinea pig, rabbit, monkey, hamster and dog studies consistently showed adverse effects such as altered respiratory function; histopathology of the larynx and changes in the clearance of particles from the tracheobronchial/respiratory system. Repeat dose toxicity via oral or dermal routes has not been investigated.	1,5

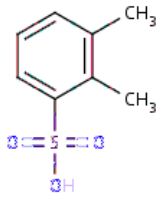
Concluding Summary Comments



Sulphuric acid is a highly corrosive inorganic acid with a moderate to high toxicity hazard ranking reflecting its irritant and corrosive properties on biological matter. This reflects its pure or highly concentrated form which presents with elevated acute exposure concerns. In cases where it is used in dilute solutions or as an acid catalyst in polymerisation reactions the level of hazard is significantly reduced as a consequence of markedly reduced corrosive potential.

Name	o,p-toluenesulfonic acid/xylene sulfonic acid
Synonyms	Numerous synonyms including, benzenesulfonic acid, dimethyl; dimethylbenzenesulfonic acid; xylene sulfonic acid, sodium salt; conco sxs, cylophil sxs30, eltesol sx30, naxonate g, richonate sxs and stephanate x.
CAS number	25321-41-9
Molecular formula	$C_8H_{10}O_3S$
Molecular Structure	

Overview	References
The major use of xylene sulfonic acid is as a hydrotrope in liquid household detergents and shampoos. It is also used as a degreasing compound; in printing pastes in the textile industry and as an additive in glue in the leather industry. It is used in detergents, handwashing, dishwashing and laundering and in many cleaning products, where high concentrations of organic surfactants need to be kept in homogenous solution. The general structure of these compounds is a hydrocarbon chain linked to an ionic group (anionic or cationic) or an alcohol group (non-ionic). Soaps are salts of a fatty acid made by the action of alkali or natural fats and oils.	1

Human Health Toxicity Summary	Reference
Inhalation Aspiration can cause upper airway irritation, upper airway oedema and respiratory distress.	1
Irritancy/Hypersensitivity Detergents dissolve lipid layers in tissues and can produce local irritation and injury. The most common effects are skin, mucosal and eye irritation. Skin irritation, dryness and contact dermatitis can result from skin exposure. If eyes are exposed there can be momentary irritation although no permanent damage has been observed. Ingestion can cause gastric injury and oral, pharyngeal and oesophageal burns. Clinical signs observed in acute dermal exposure have included erythema with additional	1

desquamation of the treated skin. Sodium xylene sulfonate is not a skin irritant and there is no indication that hydrotopes cause skin sensitisation in animal studies. There are no reliable human data for sensitisation.	
Carcinogenicity There is inadequate evidence for the carcinogenicity of xylene sulfonic acid in humans and animals. Rats and mice exposed via their skin had no increased evidence of carcinogenic effects.	1
Systemic Clinical signs following acute oral toxicity studies included decreased activity, weakness, prostration, increased salivation, diarrhoea and anogenital staining. No significant systemic toxicity has been observed in dermal studies with test durations from 17 days up to 2 years and exposure doses from 6 to 2000 mg a.i./kg bodyweight by the dermal route. Local effects were reported in one of six dermal studies and a LOAEL for sodium xylene sulfonate calculated of 1300 mg a.i./kg bodyweight per day and NOAEL of 440 mg a.i./kg bodyweight per day.	3
Developmental/Reproductive There is no evidence from repeat dose animal studies to suggest hydrotropes have adverse effects on reproductive organs.	3
Mutagenicity/genotoxicity The hydrotropes category has been assessed for mutagenic potential in a variety of *in vivo* and *in vitro* assays and no positive results were observed in any of the studies.	3
Systemic toxicity/Organ effects Necropsy data from acute animal studies reported slight pulmonary inflammation, gastrointestinal inflammation and haemorrhage, mild liver changes, congestion of the liver, kidneys, adrenal glands and gastrointestinal tract and redness of the stomach mucosa in animals that died.	3

Concluding Summary Comments

Hydrotropes in general exhibit a close consistency in their structure, use, fate and health and environmental effects. They exhibit a low order of acute and chronic toxicity and hazard to human health. Their major adverse health effects are limited to irritant effects on skin, eyes and mucous membranes and systemic effects at high doses. These reflect the pure or high concentration solutions. At final use concentrations in the order of a few percent the low hazard ranking is further reduced.

Santos

APPENDIX H.4 RADIOACTIVE TRACER AND PERFORATION BALL

MEMO

To: Andrew Stannard

From: Tom Biksey and Chris Bevan

CC: Nigel Goulding

Date: 2 July 2013

Re: **Radioactive Tracer and Perforation Ball Environmental Hazard and Dosage Assessment**

Introduction

Santos GLNG (Santos) is looking to trial and if successful, implement a new multi-zone hydraulic fracturing process called Just In Time Perforating (JITP). This process uses an Exxon Mobil patented process to streamline the entry and exit of equipment out of the casing, and saving considerable time in execution of hydraulic fracturing.

Unlike the approach currently used by Santos, which uses a coil tubing rig and associated zonal isolation packers (above and below the perforation intervals), the approach simply uses perforation balls to provide isolation. Identical to the methodology outlined in the hydraulic fracturing risk assessment, hydraulic fracturing is conducted from the bottom upwards; but unlike the previous methodology, the process is more streamlined with equipment not moved in and out of the casing hole. In the process, perforation balls are used to provide the required zone isolation in the previous perforated and hydraulically fractured intervals. The perforation balls are added at the end of each hydraulic fracturing injection cycle to temporarily clog the perforations, and to provide isolation so the interval above can be hydraulically fractured.

As a traditional packer is not utilised in this process, complete isolation between individual treatment stages is harder to achieve. Hence, it is important to utilise alternative tools to evaluate which seams have been treated, and to evaluate the effectiveness of the treatment itself and the treatment process. To facilitate the use of diagnostic techniques to assess the efficacy of the isolation and fracturing, radioactive tracers are added to the proppant to facilitate tracing of the placement of sands. These tracers are mix with the sand during the injection cycle with different tracers used for every stage.

The following products were evaluated in this assessment for environmental hazards and, in the case of the radioactive tracer, for determining the dosage from exposure. **Attachment 1** includes the Material Safety Data Sheets (MSDSs) for the radioactive tracers and one performance ball, and **Attachment 2** includes manufactures information on the radioactive tracers and the other performance ball.

Tom Biksey • 311 Crabapple Drive, Washington, PA 15301
724.884.6724 • tom.biksey@ehs-support.com • www.ehs-support.com

Product	Description
J144 Perforation Balls	Rubber-coated phenolic high temperature, high pressure ball sealers
Associated Research Development LTD (ARD) Thermoset polyurethane sealer balls	Polyurethane sealer balls
ProTechnics Iridium ZeroWash® bead tracers	Ceramic beads embedded with radionuclide Iridium-192 (as iridium oxide)
ProTechnics Scandium ZeroWash® bead tracers	Ceramic beads embedded with radionuclide Scandium-46 (as scandium oxide)
ProTechnics Antimony ZeroWash® bead tracers	Ceramic beads embedded with radionuclide Antimony-124 (as antimony oxide)

To address the proposed use of perforation balls and radioactive tracers in future hydraulic fracturing events, the following environmental hazard and dosage assessment was conducted to ensure compliance with Conditions of Santos' Gas Field Environmental Authorities (e.g., the Roma Shallow Gas Project Area East Environmental Authority PEN103814911).

As part of this assessment, EHS Support obtained additional physical, chemical and toxicological data on the radioactive tracers in accordance with the previous risk assessment methodologies, as detailed in the *GLNG Coal Seam Hydraulic Fracturing Quantitative Risk Assessment for Schlumberger Chemistry Report* (EHS Support, October 2012). In addition, radiation dose studies on potential human exposure to the radionuclide bead tracers were sought from the manufacturers and summarised in the dosage assessment as part of this study (see **Attachment 3**).

For the environmental hazard assessment, a PBT (persistence, bioaccumulative, toxic) assessment was conducted in accordance with the guidance developed by Department of the Environment, Water, Heritage, and the Arts (DEWHA, 2009). The PBT assessment is conducted because of specific concerns for substances that can be shown to persist for long periods in the environment, to bioaccumulate in food chains, and can give rise to toxic effects after a longer time and over a greater spatial scale than chemicals without these properties. These effects may be difficult to detect at an early stage because of long-term exposures at normally low concentration levels and long life-cycles of species at the top of the food chain.

PBT Assessment

Perforation Balls (J144)

J144 perforation balls are rubber-coated phenolic high temperature, high pressure ball sealers. These balls are covered with an oil and temperature resistant black rubber (composition not provided). Information from the supplier states that no degradation is expected at temperatures less than 375^{o}C.

Persistence

Biodegradation of the J144 perforation balls under operational and field conditions is unlikely. Elastomers, such as nitrile rubber, by their nature are generally not considered to be biodegradable (Boethling and Nabholz, 1997). Therefore, J144 perforation balls are considered persistent in the environment.

Bioaccumulation

J144 perforation balls are not bioavailable due to their physical size and resistance to biodegradation (Boethling and Nabholz, 1997). Thus, J144 perforation balls do not have the ability to bioaccumulate.

Toxicity

No toxicity studies have been conducted on J144. However, J144 perforation balls are insoluble in water, and their physical size and resistance to biodegradation limits their bioavailability (Boethling and Nabholz, 1997). Thus, J144 perforation balls are not expected to be harmful to aquatic organisms.

Conclusion

J144 perforation balls are not PBT substances. These balls are not expected to degrade or breakdown in the environment by microorganisms. Their size (similar to shotgun pellets) and their insolubility in water will prevent their uptake of these balls by aquatic organisms and thus J144 perforation balls will not be harmful to aquatic organisms. If ingested, J144 perforation balls will also not be toxic to humans.

ARD Thermoset Polyurethane Sealer Balls

Persistence

Biodegradation of ARD Thermoset polyurethane sealer balls under operational and field conditions are unlikely. Polymers, such as polyurethane, by their nature are generally not considered to be biodegradable (Boethling and Nabholz, 1997). Therefore, ARD Thermoset polyurethane sealer balls are considered persistent in the environment.

Bioaccumulation

ARD Thermoset polyurethane sealer balls are not bioavailable due to their physical size and their resistance to biodegradation (Boethling and Nabholz, 1997). Thus, ARD Thermoset polyurethane sealer balls do not have the ability to bioaccumulate.

Toxicity

No toxicity studies were found on ARD Thermoset plastic sealer balls. However, these balls are insoluble in water, and their physical size and resistance to biodegradation limits their bioavailability (Boethling and Nabholz, 1997). Thus, ARD Thermoset polyurethane sealer balls are not expected to be harmful to aquatic organisms.

Conclusion

ARD Thermoset polyurethane sealer balls are not PBT substances. These balls are not expected to degrade or breakdown in the environment by microorganisms. Their size (similar to shotgun pellets) and their insolubility in water will prevent their uptake of these balls by aquatic organisms and thus ARD polyurethane sealer balls will not be harmful to aquatic organisms. If ingested, these balls will also not be toxic to humans.

ZeroWash bead tracers

The ProTechnics ZeroWash® bead tracers are manufactured using a patented process that prevents the radioisotope from being washed off the proppant-emulating carrier particle (ProTechnics, undated). This process fixes non-water soluble metals in a ceramic matrix. After the resulting ceramic beads are kiln fired and sieved, they are activated by neutron bombardment in a nuclear reactor. In the United States, ProTechnics ZeroWash® bead tracers are approved for burial by the United States Nuclear Regulatory Commission (NRC).

The following ProTechnics ZeroWash® bead tracers were included in the PBT Assessment:

- Iridium ZeroWash® Bead Tracer (radionuclide: [Iridium-192] iridium oxide)
- Antimony ZeroWash® Bead Tracer (radionuclide: [Antimony-124] antimony oxide)
- Scandium ZeroWash® Bead Tracer (radionuclide: [Scandium-46] scandium oxide)

Persistence

The ceramic beads are not expected to biodegrade, and the metal oxides embedded in the ceramic beads are naturally occurring minerals so that biodegradation does not apply. Biodegradation also does not apply to the radionuclide component of these tracer beads. Nevertheless, the radionuclides are relatively short-lived: the half-lives of iridium-192 (Ir-192), antimony-124 (Sb-124) and scandium-46 (Sc-46) are 74, 60.2 and 83.8 days, respectively. Thus, ProTechnics ZeroWash® bead tracers are expected to be persistent in the environment based on its chemical composition, whereas the radioactivity associated with these bead tracers will not be persistent because of the short half-lives of the radionuclides.

Bioaccumulation

No specific data on bioaccumulation were located on the ProTechnics ZeroWash® bead tracers. These tracer beads, given their chemical composition and physico-chemical properties, are not expected to be bioavailable by any route of exposure. They are non-water soluble metals in a ceramic matrix bead, with mesh sizes of 40 to 70 (approximately 200 to 400 microns). Because these tracer beads are not bioavailable (not absorbed into the body), they do not have the ability to bioaccumulate.

Toxicity

Aquatic

ProTechnic ZeroWash® bead tracers are not expected to be toxic to aquatic organisms based on the chemical composition; these bead tracers are not likely to be bioavailable because of their insolubility and particle size. The radiation effects of the radioisotopes to aquatic organisms is unknown.

Mammalian

Exposure to these radionuclides can increase the risk for human cancer because of their high-energy gamma radiation. Gamma radiation is high-energy electromagnetic radiation emitted by certain radionuclides when their nuclei transition from a higher to a lower energy state. These rays have high energy and a short wave length. Gamma rays penetrate tissue farther than beta or alpha particles, but leave a lower concentration of ions in their path to potentially cause cell damage. Gamma rays are very similar to x-rays.

Conclusion

ProTechnic ZeroWash® bead tracers containing the radioisotopes Ir-192, Sb-124 and Sc-46 (as oxides) are not considered to be PBT substances. These bead tracers are not expected to degrade or breakdown in the environment by microorganisms. Their size (similar to sand) and their insolubility in water will prevent these bead tracers from being taken by aquatic organisms. For the radionuclides present in these beads, they have very short half-lives (less than 84 days), meaning that they will decay rapidly. Whereas the radioactivity from the bead tracers may pose a potential human health concern (discussed more fully below), the tracer bead itself is an inert particle and is not expected to be harmful to aquatic organisms, wildlife or humans.

Dosage Assessment

Perforation Balls (J144) and ARD Thermoset Polyurethane Sealer Balls

As the J144 Perforation Balls and ARD Thermoset Polyurethane Seal Balls are inert substances, no potential routes of exposures to the compounds within these materials were identified. The J144 Perforation Balls and ARD Thermoset Polyurethane Seal Balls have been determined to pose no potential adverse impacts on human health and the environment and introduce no additional environmental hazards of risks. On this basis, no further assessment of this product is recommended.

ProTechnic ZeroWash® Bead Tracers

ProTechnic ZeroWash® bead tracers consist of water-insoluble metals embedded in a ceramic matrix bead, with mesh sizes of 40 to 70 (ProTechnics, undated), which is approximately 200 to 400 microns in diameter. The metal is an integral part of the bead, and thus it cannot be washed off or stripped away. Furthermore, these bead tracers, unlike sand, are not easily crushed, having crush strength greater than 8,000 pounds per square inch (psi) (ProTechnics, undated). The metals are oxides of iridium, scandium and antimony, which are activated by neutron bombardment in a nuclear reactor, resulting in the formation of iridium-192 (Ir-192), scandium (Sc-46) and antimony-124 (Sb-124).

The ProTechnic ZeroWash® tracer beads are mixed in with injection proppant for the fracturing operations. It is not known what the concentration of the tracer isotope in the injection proppant will be, that is planned specifically for each of the fracturing operations. However, ProTechnic documents from the literature review have stated that the tracer isotope injection concentration in operations in the United States and in Canada is approximately 1.0 microcurie (μCi) of tracer per kilogram (kg) of proppant (ProTechnics, undated; ProTechnics (Canada), undated; Baker Botts LLP, 2012). Thus, a concentration of 1.0 μCi/kg proppant will be used for this dosage assessment. It will also be assumed that the concentration of tracer beads in the proppant does not change during the operation; therefore, the specific activity of the isotopes in the flowback will be 1.0 μCi/kg. The actual concentration of the tracer isotope will actually be less than 1.0 μCi/kg proppant because of radioactive decay (the half-lives of these radionuclides are less than 84 days). Because of the unique properties of ProTechnics ZeroWash® tracer beads, only the solid proppant in a flowback (not the fluid) are treated as though they contain radioactive material.

Potential Health Effects

The risk for human cancer can increase through human exposure to Ir-192, Sc-46, or Sb-124 due to their high-energy gamma radiation. Gamma radiation is high-energy electromagnetic radiation emitted by certain radioisotopes when their nuclei transition from a higher to a lower energy state. These rays have high energy and a short wave length. Gamma rays penetrate tissue farther than do beta or alpha particles, but leave a lower concentration of ions in their path to potentially cause cell damage.

Radioactive materials are quantified by units of activity: how many atoms are disintegrating in a unit of time (disintegrations per second or minute) A curie (Ci), for instance, is equivalent to 3.7×10^{10} disintegrations per second (dps) or 2.22×10^{12} disintegrations per minute (dpm). The absorbed dose is the amount of energy that ionizing radiation imparts to a given mass of matter, with the units being the gray (Gy) or the rad. Because different materials that receive the same exposure may not absorb the same amount of radiation, the dose equivalent relates the absorbed dose to the biological effect of that dose. The rem (R) or sievert (Sv) is the derived unit of equivalent radiation dose, effective dose, and committed dose. Quantities that are measured in rems or sieverts are designed to quantify the stochastic biological effects of radionuclides, primarily radiation-induced cancer. These units are a complex weighted average of absorbed dose (a physical quantity measured in rads). Rems and sieverts are used primarily in occupational settings where the regulatory concern is risk management; for example, the risk of future cancer induction. Regulatory limits and chronic doses are often given in units of mSv/a or Sv/a, where they are understood to represent an average over the entire year.

The Australian Radiation Protection and Nuclear Safety Agency (ARPANSA) have set dose limits for ionizing radiation from both occupational and public exposure (ARPANSA, 2002). The effective radiation dose limit for occupationally-exposed humans is 20 mSv (2 rems) per year averaged over a period of five (5) consecutive years. The effective dose is not to exceed 50 mSv (5 rems) in any given year. For the public, the effective dose limit for radiation is 1 mSv (0.1 rem) per year; a higher value of effective dose could be allowed in a single year, provided that the average over five (5) years does not exceed 1 mSv (0.1 rem) per year. The effective dose equivalent is a weighted sum of doses to all irradiated organs or tissues.

In the United States, where the annual limit for a total effective dose equivalent is 50 mSv or 5 rems, there are also annual limit on intake (ALI) for radionuclides, which are regulatory limits for internal contamination. It is the amount of radioactive material, that if taken into the body, results in an annual regulatory dose limit being met. The ALIs for Ir-192, Sb-124, and Sc-46 are 900, 500 to 600, and 900 μCi, respectively. These ALI values would be applicable to Australia since the ARPANSA has set the annual effect dose limit for occupational exposure to not exceed 50 mSv (5 rems) in a year.

Human exposure to radioactivity from the ProTechnic ZeroWash® beads in the flowback material can occur by two routes: external and internal.

The internal exposure would be from ingestion of the tracer beads present in the solids of the flowback. The particle size (200 to 400 microns) of these beads is too large for these beads to be respirable. Because the tracer beads are not soluble in water, and the radionuclides are bound in the bead, radioactivity exposure by ingestion is limited to the resident time in the body. Based on the tracer isotope injection concentration of 1 μCi/kg, an individual would have to ingest at least 900, 500 to 600, or 900 kg of flowback solid material containing Ir-192, Sb-124, or Sc-46 to reach the ALI. It is unrealistic to consider that humans could ingest these large quantities of flowback material in order to meet the regulatory annual limits of these radionuclides. Thus, it can be assumed that the presence of these tracer beads in flowback material would result in a negligible cancer risk to humans from ingestion.

Exposure to radioactivity from the tracer beads in flowback material can also occur from external exposure. This may occur from exposure of workers and trespassers to flowback material, in the transport of the flowback material to a waste disposal site, and at the disposal site.

Transportation

The Santos D&PE Hazard Analysis and Risk Control Form (MOC D&PE 107, 16 Sep 2011) evaluated the transport, storage, use and removal of radioactive tracers during the Moomba fracturing campaign. It was estimated that a person would need to be within one (1) metre of 1,000 pounds (454

kg) of contaminated flowback material in the typical quantities for 177 days to receive the yearly legal dose limit for a radiation worker. This estimate is highly conservative as sand containing the radioactive tracers in most cases will not come back to ground surface and in the event that sand 'blow out' is to occurring during hydraulic fracturing, the sand materials will be excavated and either buried and/or transported off-site for disposal. The estimate given in the Santos D&PE Hazard Analysis and Risk Control Form indicates that the flowback material containing ProTechnic ZeroWash® bead tracers would pose a negligible risk to trespassers.

ProTechnics has estimated that the maximum radiation effective dose rate, at a distance of 1-foot (0.3m) from a vehicle transporting flowback waste containing ProTechnic ZeroWash® bead tracers, would be on the order of 0.1 mR/hour. The radiation effective dose rate in the cab of the transport vehicle would be on the order of 0.004 mR/hour. Using an average transport time of 1-hour, and assuming the same driver was used for all of the expected disposals (10 per year), the effective dose to the driver of the vehicle would be 0.04 mR. Due to its low radiation level and radioactive concentration, an accident causing the release of the waste returns from the transport vehicle would result in a low effective dose to workers or members of the public during the subsequent clean-up efforts (Federal Register, 2003).

Disposal

ProTechnics requested that the Texas Commission on Environmental Quality (TCEQ) adopt a rule that would conditionally exempt minimal amounts of properly disposed radioactive proppant tracers in hydraulic fracturing flowback from TCEQ low level radioactive waste licensing and disposal requirements (Baker Botts LLP, 2012; see **Attachment 3**). In this petition, ProTechnics has estimated that tracer injection operations at the disposal pit are automated to minimise the time require for personnel to be in the immediate area of the injected material. Assuming an injection time of 4 hours per disposal, and an individual within 1-foot (0.3m) of the radioactive material during the injection operation, the total effective dose per year would not be expected to exceed 4 mR from this operation (Federal Register, 2003).

The earthen pit disposal of ProTechnics ZeroWash® tracer beads is not expected to result in harm to public health and safety (Baker Botts LLP, 2012). Doses were calculated for varying amounts of flowback (from 500 to 23,000 pounds) containing the maximum 1 μCi/kg ProTechnics ZeroWash® tracer concentration of Sc-46. Dose was also calculated over a range of possible physical geometries. A worst-case scenario was chosen in which an individual standing on top of a covered earthen pit and standing next to an uncovered pit for a year to determine maximum exposure to ProTechnics ZeroWash® tracer flowback. The results showed that a person standing on a covered earthen pit for twenty-four hours a day for an entire year would accumulate only 5.56 mrems. This value is roughly 18 times lower than the annual dose limit for the public of 0.1 rems. No elevated readings have ever been measured above one of ProTechnics' covered earthen pits (Baker Botts LLP, 2012). These earthen pits are covered with at least two feet of overburden soil. For a person standing next to an uncovered earthen pit for four hours/day for an entire year, the effective dose is still only 66 mrem per year (Baker Botts LLP, 2012), which is lower than the regulatory annual dose limit for the public of 0.1 rem.

The following table compares some radiation dosages from sources that people are exposed to in everyday life with those dosages that may occur from exposure to ProTechnics ZeroWash® bead tracers in flowback material. The radiation dose from short-term exposures to flowback material containing these radioactive bead tracers are similar in magnitude (or even lower) to radiation doses that people may receive from medical and dental x-rays, and even from natural background radiation found all around us. Long-term exposure to these bead tracers that may occur when disposed of in pits would result in radiation doses that are well below the yearly doses that people receive from natural background radiation.

A Comparison of Typical Effective Radiation Doses from Various Sources [a, b] to Doses from Exposure to Radioactive Tracers in Flowback Materials

mrem	Description of Source
0.1-1.0	Hourly cosmic dose to a commercial flight
1	**Approximate daily dose from natural radiation, including radon**
2-4	Chest X-ray exam (single exposure)
2-9	Dental X-ray exam (single exposure)
3.5	Hourly dose for a worker standing within 1 metre of 454 kg of containing flowback material with radioactive tracer beads
5	Yearly dose for a person standing next to covered pit with flowback material containing radioactive tracer beads (4 hours per day)
40-70	Spinal X-ray exam (single exposure)
66	Yearly dose for a person standing next to uncovered pit with flowback material containing radioactive tracer beads (4 hours per day)
120	Abdominal X-ray exam (single exposure)
300	**Yearly dose to people in the United States from natural background radiation**

[a]Sources and Effects of Ionizing Radiation, Volume 1, Annex B. United Nations Scientific Committee on the Effects of Atomic Radiation UNSCEAR 2000 Report to the General Assembly, with Scientific Annexes (http://www.unscear.org/unscear/en/publications/2000_1.html)
[b]Health Physics Society (http://hps.org/hpspublications/radiationfactsheets.html)

Conclusion

Human exposure to flowback material containing Technics ZeroWash® bead tracers (containing the radionuclides Ir-192, Sb-124 and Sc-46) is expected to result in radiation doses that are similar in magnitude to sources that people are exposed to in everyday life. On this basis, the existing exposure controls implemented by Santos for hydraulic fracturing activities and management of flowback water are considered sufficient for management of potential impacts on human health and the environment.

MATERIAL SAFETY DATA SHEET

1. PRODUCT IDENTIFICATION

PRODUCT NAME:	IRIDIUM ZERO WASH® BEAD TRACER
RADIONUCLIDE:	IRIDIUM-192 (IR-192)
CHEMICAL FORM:	IRIDIUM OXIDE
PHYSICAL FORM:	SOLID

2. MATERIAL COMPOSITION

Hazardous Components:	Radioactive Iridium-192
Type of Hazard:	• (beta), • (gamma)

3. HAZARD IDENTIFICATION

Inhalation: Due to the bead size, inhalation is not a potential health hazard.

Ingestion: Bead is not soluble in the human body. May cause mechanical irritation in digestive tract.

Skin Contact: If in contact with skin, bead may cause mechanical skin irritation.

Eye Contact: The bead may cause mechanical eye irritation.

Lower exposure limits apply for pregnant women working in the restricted area.

4. FIRST AID MEASURES

Inhalation: Irrigate nose with saline solution to remove any beads in the nose.

Ingestion: If swallowed, obtain competent medical attention immediately. Beads will be removed during the normal digestive tract elimination process.

Skin Contact: In case of skin contact, wash area with water and mild detergent. Survey area with radiation instrument equipped with end window Geiger-Mueller probe to determine cleaning effectiveness. If bead is on clothing, use adhesive tape to remove the bead. Treat tape and cleaning fluid as radioactive waste and place in proper storage container.

Eye Contact: In case of contact with eye, flush with copious amounts of water for at least 15 minutes. Survey and place any beads removed from the eye into a radioactive waste container.

5. FIRE FIGHTING MEASURES

Fire and Explosion Hazard is Negligible

Autoignition Temperature is not applicable

Extinguishing Media: Carbon Dioxide or Halon. This reduces the spread of the radioactive beads.

Special Hazards: No special hazards. Normal fire-fighting PPE is sufficient protection.

6. ACCIDENTAL RELEASE MESURES

Control the area. Do not move personnel from the area until they have been surveyed with a G-M survey instrument. If radioactive beads are not present, the personnel may leave the area. Wear protective clothing, safety eyewear, impervious boots and rubber gloves. Clean up area by scooping up spilled material and transfer to a container. It may be necessary to remove some soil or other items indicating the presence of radioactive material. If clothing indicates the presence of radioactive material, remove the bead with adhesive tape, hold tape containing the bead for decay in proper storage area and treat as radioactive waste per regulatory requirements.

7. HANDLING AND STORAGE

The package should be appropriately shielded and handled minimally. Store the package away from fire hazards. The handling, storage and disposal of the radioactive material should be performed with compliance to local, federal or state government agency license for the use of the material. The material should be handled only by qualified personnel.

8. PERSONNEL EXPOSURE CONTROLS

When the packaging and interior of the container are in good condition, the risk of exposure is minimized.

Respiratory Protection: Not required.

Skin Protection: Plastic, latex or rubber gloves are recommended.

Eye Protection: Safety goggles or safety glasses should be worn to protect the eyes.

Other Protective Measures: Personnel should survey frequently to determine if contamination is present. There should be no smoking, eating or drinking in the restricted area.

9. PHYSICAL AND CHEMICAL PROPERTIES

Appearance: Gray to beige beads

Odor: No odor

Solubility: Insoluble in most fluids

Boling point: Not applicable

Melting point: Not applicable

Half-life: 74 days

10. STABILITY AND REACTIVITY

Stable under most conditions and hazardous polymerization will not occur. The source is considered to be stable when exposed to ignition sources and excessive heat.

11. TOXICOLOGICAL INFORMATION

Exposure to large amounts of radiation can cause biological effects. Acute exposure is not anticipated but the committed annual external whole body exposure is 50 mSv. The annual limit of external skin exposure is 500 mSv.

12. ECOLOGICAL INFORMATION

No information found.

13 DISPOSAL CONSIDERATION

Waste can be held for decay or disposed by a licensed waste disposal company. Follow local, federal and state government regulations for proper disposal of waste.

14. TRANSPORTATION INFORMATION

Shipping Name: Radioactive Material, Type A Package

Hazard Class: 7

Identification Number: UN 2915

15. REGULATORY INFORMATION

UN 2915 Radioactive Material, Type A Package, Class 7

16. **OTHER INFORMATION**

No other paperwork required by Regulation

The material presented above is believed to be correct, but does not purport to be all inclusive and shall be used as a guide only. SpectraTek shall not be liable for any damage resulting from the use of this information.

(US) +1 866-430-2775

10/07/2011

+011-886-2-2712-5668 MSDSRequest@chemtura.com

SECTION 2. HAZARDS IDENTIFICATION

Emergency Overview

Form: solid
Hazard Summary : No information available.

Potential Health Effects

Symptoms of Overexposure : No information available.

SECTION 3. COMPOSITION/INFORMATION ON INGREDIENTS

Hazardous components

No dangerous ingredients according to Regulation (EC) No. 1907/2006

SECTION 4. FIRST AID MEASURES

First aid procedures

General advice	:	No hazards which require special first aid measures.
Inhalation	:	Move to fresh air in case of accidental inhalation of dust or fumes from overheating or combustion. If symptoms persist, call a physician.
Skin contact	:	Wash off with soap and plenty of water.
Eye contact	:	Flush eyes with water as a precaution. Remove contact lenses. Protect unharmed eye. Keep eye wide open while rinsing.
Ingestion	:	Clean mouth with water and drink afterwards plenty of water. Do not give milk or alcoholic beverages. Never give anything by mouth to an unconscious person.

Notes to physician

Symptoms	:	No information available.
Risks	:	No information available.
Treatment	:	No information available.

SECTION 5. FIRE-FIGHTING MEASURES

Flammable properties

Ignition temperature	:	> 392 °F (> 200 °C)

Fire fighting

Suitable extinguishing media	:	Use extinguishing measures that are appropriate to local circumstances and the surrounding environment.
Further information	:	Standard procedure for chemical fires.

Protective equipment and precautions for firefighters

Specific hazards during fire fighting	:	No information available.
Special protective equipment for fire-fighters	:	In the event of fire, wear self-contained breathing apparatus.

SECTION 6. ACCIDENTAL RELEASE MEASURES

Personal precautions	:	Not expected to present a significant inhalation hazard under anticipated conditions of normal use.
Environmental precautions	:	No special environmental precautions required.
Methods for containment /	:	Sweep up and shovel.

Methods for cleaning up	Keep in suitable, closed containers for disposal.

SECTION 7. HANDLING AND STORAGE

Handling

Handling procedures	:	For personal protection see section 8. No special handling advice required.
Advice on protection against fire and explosion	:	Avoid dust formation. Provide appropriate exhaust ventilation at places where dust is formed.

Storage

Requirements for storage areas and containers	:	Keep in a dry, cool and well-ventilated place.
Advice on common storage	:	No special restrictions on storage with other products.
Other data	:	No decomposition if stored and applied as directed.

SECTION 8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Exposure Guidelines

Engineering measures

Personal protective equipment

Eye protection	:	Safety glasses
Hand protection	:	For prolonged or repeated contact use protective gloves.
Skin and body protection	:	Protective suit
Respiratory protection	:	No personal respiratory protective equipment normally required.
Hygiene measures	:	General industrial hygiene practice.

SECTION 9. PHYSICAL AND CHEMICAL PROPERTIES

Appearance

Form	:	solid

Safety data

Ignition temperature	:	> 392 °F (> 200 °C)
Density	:	1.2 g/cm3

Specific Gravity	:	1.2 at
Water solubility	:	Note: insoluble

SECTION 10. STABILITY AND REACTIVITY

Conditions to avoid	:	Remarks: no data available
Materials to avoid	:	Remarks: None known.
Hazardous decomposition products	:	Note: Carbon monoxide, carbon dioxide and unburned hydrocarbons (smoke). Hydrocarbons Hydrogen cyanide

SECTION 11. TOXICOLOGICAL INFORMATION

Skin irritation	:	Remarks: According to the classification criteria of the European Union, the product is not considered as being a skin irritant.
Eye irritation	:	Remarks: According to the classification criteria of the European Union, the product is not considered as being an eye irritant.
Sensitisation	:	Remarks: no data available
Further information	:	no data available

12. ECOLOGICAL INFORMATION

Ecotoxicity effects
Elimination information (persistence and degradability)

Bioaccumulation	:	Remarks: no data available
Mobility	:	Remarks: no data available
Biodegradability	:	Remarks: no data available

Further information on ecology

Additional ecological information	:	There is no data available for this product.

SECTION 13. DISPOSAL CONSIDERATIONS

Further information : Offer surplus and non-recyclable solutions to a licensed disposal company.

Contaminated packaging : Empty remaining contents.
Empty containers should be taken to an approved waste handling site for recycling or disposal.

SECTION 14. TRANSPORT INFORMATION

DOT
Not dangerous goods

TDG
Not dangerous goods

IATA
Not dangerous goods

IMDG
Not dangerous goods

RID
Not dangerous goods

SECTION 15. REGULATORY INFORMATION

SECTION 16. OTHER INFORMATION

Further information

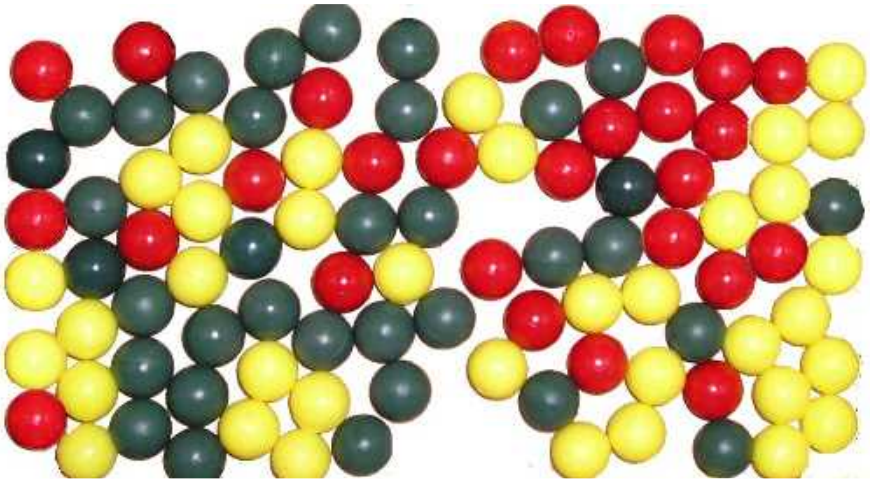
ATTACHMENT 2 MANUFACTURER INFORMATION FOR RADIOACTIVE TRACERS AND PERFORMANCE BALLS

SEALER BALLS

Associated Research Developments Ltd. (ARD) is Canada's largest sealer ball manufacturer.
ARD has been producing high quality sealer balls for international and domestic markets for nearly 40 years.



Polyurethane

ARD Thermoset polyurethane balls are hand cast, hand trimmed and individually inspected. The polyurethane balls have proved to have excellent performance under a combined state of high pressure and temperature. These balls are produced in a variety of sizes ranging from 5/8" (16mm) to 1-1/2" (38mm). Thermoset polyurethane sealer balls are also offered in three different, color-coded specific gravities: 0.9 (yellow), 1.1 (red) and 1.3 (green). All three specific gravities are available in all the different sizes offered.

Thermo Plastic

ARD Thermo plastic sealer balls perform well under a combined state of high pressure and temperature. These balls are a more recent addition to our product line. There is currently a limited range of sizes (7/8" or 22mm only) and specific gravities but we will continue to add new ones as the R&D is completed. The performance of the thermoplastic balls is excellent and the cost is lower.

ProTechnics

SPECTRA™ **STIM** ZeroWash®

ZeroWash® has been awarded the Meritorious Award for Engineering Innovation
Hart's Petroleum Engineer INTERNATIONAL

SPECTRA**STIM**™ is a proppant tracing technology that involves the precise injection of uniquely identifiable Zero**Wash**® tracers. Engineered for maximum diagnostic value, SPECTRA**STIM** tracers are designed to target specific stages or segments and different proppant or fluid types in hydraulic fracture and other completion operations.

Zero**Wash** tracers are the only means to accurately pinpoint completion placement. A post-stimulation spectral gamma ray log is run to precisely identify and quantify the Zero**Wash** tracer placement in the completion operation.

SPECTRA**STIM** provides direct measurements to develop and refine completion procedures and processes to optimize production.

SPECTRA**STIM** is a proven diagnostic tool in the following applications:

- **Hydraulic Fracturing Treatments**
- **Acid Treatments**
- **Cementing** (Channel Identification, Squeeze Coverage, Top of Cement)
- **Horizontal Well Completions**
- **Mechanical Integrity Tests**
- **Conformance Control**
- **Polymer Treatments**
- **Gravel and Frac Pack Treatments**
- **Pre-Frac Diagnostic Testing**

SPECTRA**STIM** is essential in determining:

- **Fracture Height**
- **Staging Performance and Efficiency**
- **Mechanical Integrity (Internal and External)**
- **Wellbore/Fracture Connectivity**
- **Fracture Orientation Signature** (Transverse/Longitudinal)
- **Perforation Cluster Strategy and Effectiveness**
- **Interwell/Offset Fracture Communication**

Zero**Wash** tracers are manufactured using a patented process that fixes the non-water-soluble tracer metal into the matrix of a high strength ceramic particle. Independently tested and certified to perform in the most extreme downhole environments.

Zero**Wash** tracers are so effectively formed with no potential for wash-off they are:

- **Client HSE Preferred**
- **US Nuclear Regulatory Commission (NRC) Approved**
- **Safe to Transport, Handle, Store and Dispose**

Zero**Wash**®
CERAMIC PROPPANT BEAD

Mr. Zak Covar
Executive Director
Texas Commission on Environmental Quality
12100 Park 35 Circle, Building F
Austin, Texas 78753

Re: Petition for Rulemaking under TEX. HEALTH & SAFETY CODE § 401.106(a)

Dear Mr. Covar:

This rulemaking petition is submitted on behalf of the ProTechnics Division of Core Laboratories LP, 6510 W. Sam Houston Parkway N., Houston, Texas 77041 ("ProTechnics") pursuant to TEX. HEALTH & SAFETY CODE § 401.106(a) and 30 TEX. ADMIN. CODE § 20.15. ProTechnics specifically requests that the Texas Commission on Environmental Quality ("TCEQ") adopt a rule that would conditionally exempt minimal amounts of properly disposed radioactive proppant tracers in hydraulic fracturing flowback from TCEQ low level radioactive waste licensing and disposal requirements.

BACKGROUND

Since May 12, 1992, ProTechnics has overseen the management and disposal of flowback containing proppant with ZeroWash® tracers in earthen pits. These earthen pits are, and have been managed by oil and gas well operators under the jurisdiction of the Railroad Commission. For two decades, this method of management and disposal has been authorized by the Department of State Health Services (*see* Attachment 1) and the Nuclear Regulatory Commission (*see* Attachment 2) through a license exemption. In fact, the Nuclear Regulatory Commission recently confirmed ProTechnics' method of management and disposal of ZeroWash® tracers via a license amendment issued on August 30, 2012. With the passage of S.B. 1604 (80th Leg., 2007) and subsequent TCEQ rulemakings under that act, it appears that a licensing exemption from TCEQ may now be required so that this product can continue to be managed in the same manner going forward.

1. FACTUAL BACKGROUND

For over two decades, ProTechnics has been an innovator in "completion diagnostic" services that enable oil and gas companies to optimize reservoir performance and maximize hydrocarbon recovery from producing fields. A key feature of the services provided

by ProTechnics to its clients over the last twenty years involves the established use of ZeroWash® proppant tracer beads in hydraulic fracturing operations. These tracers are introduced at low concentrations into hydraulic fracturing fluid containing proppant during hydraulic fracturing operations. The tracers provide a small signal above background that enables well operators taking subsequent well log measurements to identify the interval(s) where the proppant and tracers were placed, allowing well operators to increase recoverable reserves by identifying and recovering bypassed pay and providing information that identifies opportunities to optimize well completion processes.

This use of ZeroWash® tracers takes place at various drilling sites across the world. In Texas, it is authorized by Department of State Health Services License No. L03835 (the "DSHS License"). Historically, when ZeroWash® tracer material was released during a "sandout" or returned to the surface in flowback, the DSHS License authorized the diversion of the released and/or returned material to earthen pits subject to the jurisdiction of the Railroad Commission and the subsequent covering of that material with two feet of clean soil. ZeroWash® tracer flowback has been disposed of in this manner for the last twenty years.

The Department of State Health Services previously authorized this method of disposal, as did the Nuclear Regulatory Commission, because it does not result in a significant risk to public health and safety or the environment, and because it complies with the "as low as reasonably achievable" ("ALARA") principle for exposure to radiation. Critical in both agencies' decision-making was the unique properties of ProTechnics' tracers—ProTechnics uses ZeroWash® proppant tracer beads consisting of an insoluble material that ensures by its design that radioactivity will not migrate or leach into groundwater (*see* Attachments 3 & 6).

2. BRIEF EXPLANATION OF PROPOSED RULE

ProTechnics markets and sells its ZeroWash® tracers to oil and gas companies across the world. Current regulatory uncertainty regarding the management of flowback in Texas hampers ProTechnics' business goals and threatens the viability of a valuable service used in various shale plays across the United States. ProTechnics and its customers need certainty regarding acceptable management and disposal of ZeroWash® tracer flowback. ProTechnics believes that pursuant to TEX. HEALTH & SAFETY CODE § 401.106(a), the Commission should reach the same conclusion that the Department of State Health Services and the Nuclear Regulatory Commission have reached—that this long-standing disposal practice does not result in a significant risk to public health and safety or the environment, and thus should be conditionally exempt from TCEQ licensing and disposal requirements. ProTechnics also believes that the long standing management and disposal practices previously approved by Department of State Health Services and the Nuclear Regulatory Commission should continue to be available in lieu of, or in addition to the State's otherwise applicable disposal rules.

3. INJURY AND INEQUITY THAT COULD RESULT FROM THE FAILURE TO ADOPT THE PROPOSED RULE

Without a rule from TCEQ, the regulated community is left with serious uncertainty regarding the acceptability of a longstanding, safe, sound and economical management practice for disposing of such wastes, a practice approved by the Texas Department of State Health Services (*see* Attachment 1) and the Nuclear Regulatory Commission (*see* Attachment 2). The conditional exemption would apply only if disposal of the flowback material is conducted in accordance with the proposed TCEQ rule requirements.

TECHNICAL ANALYSIS

Adoption of a rule conditionally exempting disposal of ZeroWash® tracer flowback from licensing and disposal requirements will not pose a significant risk to public health and safety or the environment. This is a sound conclusion from a technical perspective for three reasons.

First, ZeroWash® tracer flowback has been disposed of in earthen pits since May 12, 1992, without any reported or known harm to public health and safety or the environment. Not only do the typical isotopes ProTechnics is licensed to use by the Department of State Health Services have a half-life of less than 90 days, but only a very small amount of tracer material is used to log a well—a 20-mCi vial containing 15 ccs of ZeroWash® tracer material traces 50,000 pounds of proppant (*see* Attachment 4). Further, the concentration of any tracers brought to the surface in flowback will always be relatively low because the tracer material is mixed into fracturing proppant prior to being injected into a well, meaning that only a small fraction of the proppant tracer returns to the surface. Additionally, although flowback sometimes occurs in fracturing operations, based on experience, flowback of ZeroWash® tracer only occurs in approximately one in ten applications.

Second, ProTechnics has undertaken calculations—computed over a broad and systematic range of possible scenarios with worst-case conditions of exposure time, isotope energy and half-life—to demonstrate that earthen pit disposal of ZeroWash® tracer flowback will not result in harm to public health and safety. For purposes of the calculations, dose was calculated for varying amounts of flowback (from 500 pounds to 23,000 pounds), containing the maximum 1,000 pCi/g ZeroWash® tracer concentration of Scandium-46. Dose was also calculated over a range of possible physical geometries. To be conservative, ProTechnics used worst case scenarios of an individual standing on top of a covered earthen pit and standing next to an uncovered pit for a year to determine maximum exposure to ZeroWash® tracer flowback.

The results of the calculations demonstrate that a rule which conditionally exempts from licensing and disposal flowback containing ZeroWash® tracer and similar products will not result in a significant risk to public health and safety. A person standing on a covered earthen pit for twenty-four hours a day for an entire year would accumulate only 5.56 mrem (*see*

Attachment 5).[1] To put this in context, a similar amount of radiation could be expected in a roundtrip flight from New York to Los Angeles (0.5 mrem/Hr). In addition, without any half-life decay, the first day calculates an activity above background at the surface of only 0.0057 mrem/Hr. No elevated readings have ever been measured above one of ProTechnics' covered earthen pits.[2] The parameters for the above calculations reflect *worst-case scenarios*, and when more realistic exposure times and distances are used, the dose is *essentially negligible*. All worst case scenarios clearly exhibit that exposure levels to the general public will be well below the 100 mrem limit allowed per year under TCEQ rules.

Third, the unique characteristics of ProTechnics' patented ZeroWash® tracer material protect against any dangers of leaching or migration into groundwater. Testing performed by scientists at Texas A&M University confirm that there is no appreciable "wash-off" from ProTechnics' ZeroWash® tracer material (*see* Attachment 6). This means that the tracer material will not contaminate any other materials it contacts, thereby leaving fluids and solids free of contamination from the tracer material so that there is no danger of transfer to a water table and no significant risk to the environment. Because of the unique properties of the ZeroWash® tracer material, regulatory agencies of the United States and Canada have approved elevated release limits.

The characteristics of ProTechnics' ZeroWash® tracers ensure that flowback disposal in earthen pits regulated by the Railroad Commission will not result in a significant risk to public health and safety or the environment. And because any alternative method of disposal would require pre-disposal transportation, disposal on-site in earthen pits is at least as protective, if not more protective, of public health, safety and the environment than other waste disposal methods. As such, disposal on-site in earthen pits complies with the "as low as reasonably achievable" ALARA principle for exposure to radiation.

STATUTORY AUTHORITY FOR PROPOSED RULEMAKING

The Texas Radiation Control Act grants TCEQ the general power and authority to adopt rules relating to control of sources of radiation. *See* TEX. HEALTH & SAFETY CODE § 401.051. The TCEQ has general jurisdiction to regulate and license the disposal of radioactive substances. *See id.* at § 401.011(b). Pursuant to TEX. HEALTH & SAFETY CODE § 401.106(a), the TCEQ has specific authority to exempt flowback containing ZeroWash® tracer from licensing and disposal requirements. Texas Health and Safety Code Section 401.106(a) provides:

---

[1] Attachment 5 is confidential under Texas Public Information Act § 552.110, and is being submitted separately.

[2] Because the ZeroWash® tracer flowback is always covered with at least 2 feet of overburden soil, and that is the requirement for the conditional exemption in the proposed rule to apply, this is the calculation that is most useful for purposes of showing protectiveness. However, even if you assume that a person stands next to an uncovered earthen pit for four hours a day for an entire year, the exposure is still only 66 mrem per year.

> The board or commission[3] by rule may exempt a source of radiation or a kind of use or user from the licensing or registration requirements provided by this chapter and under the agency's jurisdiction if the board or commission finds that the exemption of that source of radiation or kind of use or user will not constitute a significant risk to the public health and safety and the environment.

Id. at § 401.106(a).

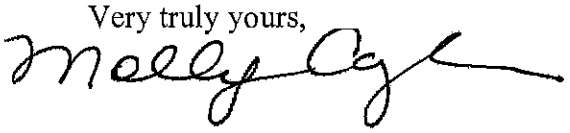
The Memorandum of Understanding ("MOU") between the TCEQ, the State Department of Health Services, and the Railroad Commission, which is codified in the Texas Administrative Code, specifically contemplates that disposal of radioactive tracer material will qualify for an exemption under Section 401.106(a). The applicable sections of the MOU provide:

> (f) Radioactive material.
>
> ...
>
> (4) Management of radioactive tracer material.
>
> > (A) Radioactive tracer material is subject to the definition of low-level radioactive waste under Texas Health and Safety Code, §401.004, and must be handled and disposed of in accordance with the rules of the TCEQ and the Department of State Health Services.
> >
> > (B) Exemption. Under Texas Health and Safety Code, §401.106, the TCEQ may grant an exemption by rule from a licensing requirement if the TCEQ finds that the exemption will not constitute a significant risk to the public health and safety and the environment.

16 TEX. ADMIN. CODE § 3.30(f)(4).

The TCEQ is also specifically authorized to provide exemptions from records relating to the disposal of a source of radiation by rule. *See id.* at § 401.057(b).

TEXT OF PROPOSED RULE



The proposed text of the rule is enclosed and has been included electronically on CD.

* * * * *

[3] "Commission" means the Texas Commission on Environmental Quality. TEX. HEALTH & SAFETY CODE § 401.003(2).

We appreciate your consideration of this rulemaking petition. Should you have any questions about the petition or the draft rule, please do not hesitate to contact me at 512.322.2535 or molly.cagle@bakerbotts.com.

Very truly yours,

Molly Cagle

TEXT OF PROPOSED RULE

Texas Administrative Code

TITLE 30	ENVIRONMENTAL QUALITY
PART 1	TEXAS COMMISSION ON ENVIRONMENTAL QUALITY
CHAPTER 336	RADIOACTIVE SUBSTANCE RULES
SUBCHAPTER C	GENERAL LICENSING REQUIREMENTS
RULE §336.230	**Disposal of Radioactive Tracer Material Used in Oil and Gas Exploration or Production Operations**

(a) Purpose. The purpose of this Section is to conditionally exempt the on-site disposal of qualified tracer materials used in oil and gas operations pursuant to 30 TAC §336.203 and Texas Health & Safety Code §401.106(a).

(b) Eligibility and Qualification for the conditional exemption. Only Radioactive Materials License Holders may apply for the conditional exemption provided by this Section. In order for the disposal of solid tracer material used in oil and gas exploration and/or production operations to qualify for the conditional exemption from general licensing and disposal requirements provided by this Section, the following requirements must all be met:

(1) The Radioactive Materials License Holder seeking the conditional exemption must file an administratively complete registration with the Executive Director in accordance with this Section, and the Executive Director must confirm that the registration is accepted and that tracer materials are qualified tracer materials.;

(2) The tracer materials for which the conditional exemption is sought must meet the following criteria:

(A) The tracer materials are short half-life isotopes Iridium (Ir)-192, Scandium (Sc)-46 or Antimony (Sb)-124;

(B) The tracer materials are mixed with a combination of inorganic earthen material in the form of metal oxides and sintered at up to 500° C to form a strong ceramic structure incorporating a small amount of isotopes Ir, Sc, or Sb;

(C) The Ir, Sc or Sb isotopes are in a form that is non-water soluble; and

(D) The total radioactive concentration of all Ir, Sc or Sb isotopes is 1,000 picocuries/gram or less, and the physical half life of the qualified tracer materials is less than 90 days; and

(3) The qualified tracer materials are disposed of in accordance with the Registration, Disposal, Closure, and Annual Certification requirements of this Section.

(c) Definitions. The following words and terms when used in this section shall have the following meanings:

(1) "Closure" means the amount of time needed to return a pit to unrestricted release levels.

(2) "Flowback" means the process of allowing fluids to flow from the oil and gas well following a treatment, either in preparation for a subsequent phase of treatment or in preparation for cleanup and returning the well to production.

(3) "Job Site Survey Form" means a form signed by the Operator or Well Owner and Logging/Tracer Supervisor with survey information indicating that the pit where qualified tracer materials are disposed is at unrestricted release levels.

(4) "Logging/Tracer Supervisor" means an individual trained in a training program for the handling and disposal of qualified tracer materials including 25 TAC §289.253(o) requirements.

(5) "Operator" means the person responsible for managing oil and gas exploration and production activities and flowback at an oil and gas well site.

(6) "Pit" means earthen barrier used to dispose of qualified tracer material used in oil and gas exploration and/or production operations and permitted under applicable Railroad Commission rules.

(7) "Proppant" means sand or any natural or man-made material that is used in a hydraulic fracturing treatment to prop open the artificially created or enhanced fractures once the treatment is completed.

(8) "Qualified Tracer Materials" means radioactive tracer materials that meet all the criteria under Subsection (b)(2) of this Section.

(9) "Radioactive Materials License Holder" means a person issued a license by the Texas Department of State Health Services authorizing the licensee to receive, acquire, store, possess and transfer radioactive material listed in the license.

(10) "Tracer Material" means radioactive material with half-lives less than 90 days used in subsurface oil and gas exploration and production operations.

(11) "Well Owner," if different from the Operator, means the oil and gas lessee responsible for contracting with the Operator for oil and gas exploration and production activities and flowback at an oil and gas well site.

(12) "Well reversal material" means solid material, such as sand and other proppants used in hydraulic fracturing, flowing from the well following a treatment.

(13) "Well Site Agreement" means an agreement signed by the Operator or Well Owner and Radioactive Materials License Holder providing for each person's respective responsibilities in handling and disposing of qualified tracer materials.

(d) Registration. A Radioactive Materials License Holder seeking the conditional exemption from licensing and disposal requirements under this Section shall submit a registration, on a form prepared by the Executive Director. The registration shall include:

(1) A demonstration that tracer materials are qualified tracer materials;

(2) A complete description of the qualified tracer materials for which the conditional exemption is sought, including the identity, form and estimate of the typical total radioactive concentration of the qualified tracer material used per well in oil and gas exploration and/or production operations;

(3) a description of how qualified tracer materials are used in oil and gas exploration and/or production operations;

(4) information related to the training of a Logging/Tracer Supervisor;

(5) a description of the procedures a Logging/Tracer Supervisor will use to monitor and otherwise confirm and prepare a record to document closure of pits where qualified tracer materials are disposed; and

(6) a description of how and where the Radioactive Materials License Holder will maintain records showing compliance with this Section.

(e) Disposal. All of the following disposal procedures must be followed for qualified tracer materials to be conditionally exempt from Chapter 336 licensing and disposal requirements:

(1) A Radioactive Materials License Holder and Operator or Well Owner shall sign a Well Site Agreement indicating that the Operator or Well Owner has been informed of disposal procedures for on-site disposal of qualified tracer materials in a pit in accordance with this Subsection.

(2) An Operator or Well Owner disposing of qualified tracer materials must:

(A) Direct well reversal material (including any proppant or sand screened out of flowback fluid) to an on-site pit; and

(B) Backfill the pit with two (2) feet of clean soil within 30 days of final well clean up.

(f) Closure. The Radioactive Materials License Holder must:

(1) Maintain as part of the Well Site Agreement, an agreement with the Operator or Well Owner to control access to the pit until the radioactivity has decayed to unrestricted release levels, subject to inspection by representatives of the Executive Director; and

(2) Complete a Job Site Survey Form within 30 days of receipt of notice of closure of the pit documenting that a Logging/Tracer Supervisor has surveyed the pit with an End Window Geiger Muller Detector or equivalent device and found radioactivity at unrestricted release levels and identifying all information on which that documentation is based; and

(3) Maintain for a period of two years after closure the Well Site Agreement and Job Site Survey Form (including back-up documentation) associated with each pit where qualified tracer materials are disposed in lieu of any other recordkeeping requirements under Texas Health & Safety Code §401.057 relating to disposal of tracer materials under this Section. Records must include information regarding the date of disposal, the survey instrument used, the background radiation level, the radiation level measured at the surface of each disposal area, and the name of the Logging/Tracer Supervisor who completed the Job Site Survey Form. Records shall be kept readily available for inspection by representatives of the Executive Director.

(g) Annual certification. To maintain its eligibility for the conditional exemption provided by this Section, a Radioactive Materials License Holder shall submit a certification to the TCEQ on an annual basis confirming the accuracy or otherwise demonstrating compliance with the registration information and requirements under Subsection (d).

Attachment 1

Department of State Health Services

RADIOACTIVE MATERIAL LICENSE

Pursuant to the Texas Radiation Control Act and Texas Department of State Health Services (Agency) regulations on radiation, and in reliance on statements and representations heretofore made by the licensee, a license is hereby issued authorizing the licensee to receive, acquire, possess and transfer radioactive material listed below; and to use such radioactive material for the purpose(s) and at the place(s) designated below. This license is subject to all applicable rules, regulations and orders of the Agency now or hereafter in effect and to any conditions specified below.

LICENSEE	
1. Name	PROTECHNICS DIVISION OF CORE LABORATORIES LP ATTN WILL C WILLIAMS
2. Address	6510 WEST SAM HOUSTON PKWY STE 100 HOUSTON TX 77041

This license is issued in response to a letter

Dated: November 14, 2011

Signed by: Will Williams

3. License Number	Amendment Number
L03835	59

PREVIOUS AMENDMENTS ARE VOID

4. Expiration Date: August 31, 2015

RADIOACTIVE MATERIAL AUTHORIZED

5. Radioisotope	6. Form of Material	7. Maximum Activity	8. Authorized Use
A. Any radioactive material with atomic number less than 83 (except Se-75) and with a half-life less than 120 days	A. Any (except sealed sources)	A. No single unit quantity to exceed 40 millicuries Total activity of any single radioisotope not to exceed 100 millicuries	A. Tracer studies in oil, gas and geothermal wells. Field flood studies and inter-well tracer studies.
B. Ir-192, Ir-194	B. Any (except sealed sources)	B. No tracer single unit quantity to exceed 40 millicuries of either isotope. Markers not to exceed 50 microcuries each Total: 15 curies	B. Tracer studies in oil, gas and geothermal wells. Field flood studies and inter-well tracer studies and radioactive markers.
C. Sc-46	C. Any (except sealed sources)	C. No tracer single unit quantity to exceed 40 millicuries of either isotope. Markers not to exceed 50 microcuries each Total: 4000 millicuries	C. Tracer studies in oil, gas and geothermal wells. Field flood studies and inter-well tracer studies and radioactive markers.

Department of State Health Services

RADIOACTIVE MATERIAL LICENSE

LICENSE NUMBER	AMENDMENT NUMBER
L03835	59

5. Radioisotope (Continued...)	6. Form of Material (Continued...)	7. Maximum Activity (Continued...)	8. Authorized Use (Continued...)
L. Xe-133	L. Any (except sealed sources)	L. No single unit quantity to exceed 100 millicuries Total: 2 curies	L. Casing integrity tests on injection wells in gas storage fields.

9. Radioactive material shall only be stored at:

Site Number	Location
007	Midland - 2001 Commerce Street
009	Fort Worth – 518 Aviator Drive
010	Houston – 6510 West Sam Houston Pkwy, Ste. 100
011	Alice – 5038 South Highway 281
012	Kilgore – **183 Old Post Oak Road**

10. The authorized place of use is at temporary sites, in areas not under exclusive Federal jurisdiction, throughout Texas.

11. Radioactive material shall not be stored or used at a permanent site unless that site is specifically authorized on this license. A site is considered permanent if radioactive material is stored and/or used at that location for more than 90 days in any twelve-month period.

12. The licensee shall limit storage of Ir-192 and Ir-194 to 5000 millicuries at all storage locations except the Kilgore, Texas facility which is authorized to maintain no more than 15 curies of Ir-192 and Ir-194 total. This condition does not supersede the maximum allowable activity authorized in Part B of Condition 7.

13. The individual designated to perform the functions of Radiation Safety Officer (RSO) for activities covered by this license and Site 010 is Will C. Williams. The Site Radiation Safety Officer (SRSO) for Site 007 is Roberto Sanchez. The SRSO for Site 009 is David R. Jackson. The SRSO for Site 011 is Frank Garcia. The SRSO for Site 012 is Todd Sasche.

14. The licensee shall comply with the provisions (as amended) of Title 25 Texas Administrative Code (TAC) §289.201, §289.202, §289.203, §289.204, §289.205, §289.251, §289.252, §289.253 and §289.257.

15. Radioactive material shall be used by, or under the direct supervision of, individuals designated by the RSO only after each worker has successfully completed an Agency accepted training course. Documentation verifying the successful completion of the training for each worker shall be maintained by the licensee for inspection by the Agency.

Department of State Health Services

RADIOACTIVE MATERIAL LICENSE

LICENSE NUMBER	AMENDMENT NUMBER
L03835	59

20. The licensee is exempted from the requirements of 25 TAC §289.253(o)(1)(D) only for users of radioactive material authorized in Part I of Conditions 5, 6, 7 and 8. The licensee shall maintain a separate utilization log containing, as a minimum, the make and model number and/or serial number (or if absent, a unique description) of each sealed source authorized by Part I of Conditions 5, 6, 7 and 8 removed from storage, the identity of the logging supervisor receiving the sources of radiation, the locations where used and dates of use. These utilization logs shall be kept available for inspection by the Agency for five years from the date of the recorded event.

21. Except as specifically provided otherwise by this license, the licensee shall possess and use the radioactive material authorized by this license in accordance with statements, representations, and procedures contained in the following:

application dated July 22, 2005,
letters dated October 6, 2006, January 8, 2008, February 5, 2008, July 29, 2010, August 13, 2010, September 21, 2010, February 19, 2011, March 7, 2011.
facsimiles received January 23, 2007 and February 28, 2007.

Title 25 TAC §289 shall prevail over statements contained in the above documents unless such statements are more restrictive than the regulations.

Houston, Texas 77040

SUBJECT: LICENSE AMENDMENT

Please find enclosed copy of Amendment Number 44 to NRC License Number 42-26928-01. **As a result of your July 30, 2012 letter, the NRC has created a new license condition 18 reinstating an alternate disposal method that was previously approved, by means of tie-down conditions, on February 21, 1996, with the issuance of Amendment No. 18 to this license. The new license condition 18 makes it easier to the reader to understand what authorization is being granted as opposed to an authorization granted by tie-down conditions. Other license conditions were also updated. For your benefit, these changes are identified in boldface. In addition, I have included copies of the tie-down letters referenced in conditions 20.A. through 20.G. for your review.**

An environmental assessment for this action is not required, since this action is categorically excluded under 10 CFR 51.22(c)(14)(xi). You should review the enclosed document carefully and be sure that you understand all conditions. You can contact me at 817-200-1189 if you have any questions about this license.

The NRC's Safety Culture Policy Statement became effective in June 2011. While a policy statement and not a regulation, it sets forth the agency's expectations for individuals and organizations to establish and maintain a positive safety culture. You can access the policy statement and supporting material that may benefit your organization on NRC's safety culture Web site at http://www.nrc.gov/about-nrc/regulatory/enforcement/safety-culture.html. We strongly encourage you to review this material and adapt it to your particular needs in order to develop and maintain a positive safety culture as you engage in NRC-regulated activities.

NRC's Regulatory Issue Summary (RIS) 2005-31, provides criteria to identify security-related sensitive information and guidance for handling and marking of such documents. This ensures that potentially sensitive information is not made publicly available through ADAMS. The RIS may be located on the NRC Web site at: http://www.nrc.gov/reading-rm/doc-collections/gen-comm/reg-issues/2005/. Pursuant to NRC's RIS 2005-31, the enclosed materials license will not be made publicly available.

NRC expects licensees to conduct their programs with meticulous attention to detail and a high standard of compliance. Because of the serious consequences to employees and the public that can result from failure to comply with NRC requirements, you must conduct your radiation safety program according to the conditions of your NRC license, representations made in your license application, and NRC regulations. In particular, note that you must:

1. Operate by NRC regulations 10 CFR Part 19, "Notices, Instructions and Reports to Workers: Inspection and Investigations," 10 CFR Part 20, "Standards for Protection Against Radiation," and other applicable regulations.

2. Notify NRC in writing of any change in mailing address.

3. By 10 CFR 30.36(d) and/or license condition, notify NRC, promptly, in writing, and request termination of the license:

    a. When you decide to terminate all activities involving materials authorized under the license whether at the entire site or any separate building or outdoor area;

    b. If you decide not to acquire or possess and use authorized material; or

    c. When no principal activities under the license have been conducted for a period of 24 months.

4. Request and obtain a license amendment before you:

    a. Change Radiation Safety Officers;

    b. Order byproduct material in excess of the amount, radionuclide or form authorized on the license;

    c. Add or change the areas or address(es) of use identified in the license application or on the license; or

    d. Change the name or ownership of your organization.

5. Submit a complete renewal application or termination request at least 30 days before the expiration date on your license. You will receive a reminder notice approximately 90 days before the expiration date. Possession of radioactive material after your license expires is a violation of NRC regulations.

NRC will periodically inspect your radiation safety program. Failure to conduct your program according to NRC regulations, license conditions, and representations made in your license application and supplemental correspondence with NRC may result in enforcement action against you. This could include issuance of a notice of violation; imposition of a civil penalty; or an order suspending, modifying, or revoking your license as specified in the NRC Enforcement Policy. The NRC Enforcement Policy is available on the following internet address: http://www.nrc.gov/about-nrc/regulatory/enforcement/enforce-pol.html.

In accordance with 10 CFR 2.390 of the NRC's "Rules of Practice," a copy of this letter will be available electronically for public inspection in the NRC Public Document Room or from the NRC's document system (ADAMS). ADAMS is accessible from the NRC Web site at http://www.nrc.gov/reading-rm/adams.html.

Thank you for your cooperation.

Sincerely,

Roberto J. Torres, Senior Health Physicist
Nuclear Materials Safety Branch B

Docket: 030-30429

Enclosure: As stated

NRC FORM 374 PAGE 1 OF 6 PAGES

U.S. NUCLEAR REGULATORY COMMISSION Amendment No. 44

MATERIALS LICENSE

Pursuant to the Atomic Energy Act of 1954, as amended, the Energy Reorganization Act of 1974 (Public Law 93-438), and Title 10, Code of Federal Regulations, Chapter I, Parts 30, 31, 32, 33, 34, 35, 36, 39, 40, and 70, and in reliance on statements and representations heretofore made by the licensee, a license is hereby issued authorizing the licensee to receive, acquire, possess, and transfer byproduct, source, and special nuclear material designated below; to use such material for the purpose(s) and at the place(s) designated below; to deliver or transfer such material to persons authorized to receive it in accordance with the regulations of the applicable Part(s). This license shall be deemed to contain the conditions specified in Section 183 of the Atomic Energy Act of 1954, as amended, and is subject to all applicable rules, regulations, and orders of the Nuclear Regulatory Commission now or hereafter in effect and to any conditions specified below.

Licensee	In accordance with letter dated July 30, 2012
1. Core Laboratories, Inc. dba ProTechnics Division of Core Laboratories 2. 6316 Windfern Road Houston, Texas 77040	3. License number 42-26928-01 is amended in its entirety to read as follows: 4. Expiration date February 28, 2016 5. Docket No. 030-30429 Reference No.

6. Byproduct, source, and/or special nuclear material	7. Chemical and/or physical form	8. Maximum amount that licensee may possess at any one time under this license
A. Hydrogen-3	A. Any	A. Not to exceed 999 millicuries total and 100 millicuries per injection
B. Scandium-46	B. Any	B. Not to exceed 8,000 millicuries total and 40 millicuries per injection
C. Bromine-82	C. Any	C. Not to exceed 3,000 millicuries total and 400 millicuries per injection
D. Zirconium-95	D. Any	D. Not to exceed 750 millicuries total and 40 millicuries per injection
E. Antimony-124	E. Any	E. Not to exceed 8,000 millicuries total and 40 millicuries per injection
F. Iodine-131	F. Any	F. Not to exceed 200 millicuries total and 50 millicuries per injection
G. Iridium-192	G. Any	G. Not to exceed 12,000 millicuries total and 40 millicuries per injection
H. Gold-198	H. Any	H. Not to exceed 1,000 millicuries total and 200 millicuries per injection
I. Bromine-82	I. Any	I. Not to exceed 3,000 millicuries total and 400 millicuries per injection
J. Barium-133	J. Sealed Source (Isotope Products Labs. Model HEG-133 Series, Capsule A-3015)	J. No single source to exceed 2 millicuries; total possession 40 millicuries

6. Byproduct, source, and/or special nuclear material	7. Chemical and/or physical form	8. Maximum amount that licensee may possess at any one time under this license
K. Cesium-137	K. Sealed Source (Isotope Products Model HEG-137 Series, Capsule A-3015)	K. No single source to exceed 500 millicuries; total possession 10 curies
L. Americium-241	L. Sealed Source (Gammatron AN-H, Gulf Nuclear VL-1)	L. No single source to exceed 500 microcuries; 10 millicuries total
M. Americium-241	M. Sealed Source (IPL HEG-241 Series, Capsule A-3015)	M. No single source to exceed 500 microcuries; 10 millicuries total
N. Scandium-46	N. Solid	N. No single marker to exceed 50 microcuries
O. Cobalt-60	O. Solid	O. No single marker to exceed 50 microcuries
P. Antimony-124	P. Solid	P. No single marker to exceed 50 microcuries
Q. Cesium-137	Q. Solid	Q. No single marker to exceed 100 microcuries
R. Iridium-192	R. Solid	R. No single marker to exceed 50 microcuries

9. Authorized use:

A. through H. For use in tracer studies in oil, gas, and geothermal wells.

I. For use in above ground tracer studies in process equipment and pipelines.

J. and K. For use in Cedar Bluff Group Fluid Identification logging tool.

L. and M. For use as a calibration/stabilization source in Halliburton Model TSCAN logging tool.

N. through R. For use in pipe collar markers in oil and gas wells.

CONDITIONS

10. Licensed material shall be stored or used only at the following:

    A. i. Alaska Department of Natural Resources, Deadhorse Tract 57, Spine Road, Prudhoe Bay, Alaska
    ii. 1701 Old St. Mary's Pike, Parkersburg, West Virginia
    iii. 570 Jonah Drive, Rock Springs, Wyoming, and
    iv. 1030 Silurian Lane, Sidney, Montana

    B. Licensed material may be stored at Shell Offshore, Inc. Gas Well: OSG-C 11553, Well No. 2, Field: Garden Banks Block 602, Offshore Louisiana, in accordance with letter December 16, 1999, pending final abandonment

    C. Licensed material identified in letter dated March 02, 2006, may be stored at Exxon Mobil Production Company's Gas Well: Tip Top T65-30G2, Section 30 Township 29N Range 113W, Sublette County Wyoming, API #49-035-2389, in accordance with letter dated March 02, 2006, pending final abandonment.

    D. Licensed material identified in letter dated May 08, 2006, may be stored at Anadarko Petroleum Company's Well: Green Canyon 518#1 St00BP2, Offshore Gulf of Mexico, OCS-G21801, API#60-811-40377-02, in accordance with letter dated May 08, 2006, pending final abandonment.

    E. Temporary job sites anywhere in the United States where the U.S. Regulatory Commission maintains jurisdiction for regulating the use of licensed material, including areas of exclusive Federal jurisdiction within Agreement States.

    If the jurisdiction status of a Federal facility within an Agreement State is unknown, the licensee should contact the federal agency controlling the job site in question to determine whether the proposed job site is an area of exclusive Federal jurisdiction. Authorization for use of radioactive materials at job sites in Agreement States no under exclusive Federal jurisdiction shall be obtained from the appropriate state regulatory agency.

11. A. Licensed materials shall be used by or under the supervision and in the physical presence of, or individuals who have been trained as specified in letters dated December 16, 2005 and February 21, 2006.

    B. The Radiation Safety Officer for this license is Will C. Williams.

12. The licensee shall not vacate or release to unrestricted use a field office or storage location whose address is identified in Condition 10, without prior U.S. Nuclear Regulatory Commission approval.

13. The licensee is authorized to transport licensed material only in accordance with the provisions of 10 CFR Part 71, "Packaging and Transport of Radioactive Material."

NRC FORM 374A U.S. NUCLEAR REGULATORY COMMISSION	PAGE 4 of 6 PAGES
MATERIALS LICENSE **SUPPLEMENTARY SHEET**	License Number 42-26928-01
	Docket or Reference Number 030-30429
	Amendment No. 44

14. Pursuant to 10 CFR 39.91, the licensee is exempted from the requirements of 10 CFR 39.63(b) for use of remote handling tools. This exemption will remain in effect until formally withdrawn by the U.S. Nuclear Regulatory Commission.

15. Notwithstanding the periodic leak test required by 10 CFR 39.35, the requirement does not apply to sources, except sources containing plutonium, that are stored and not being used. The sources exempted from this periodic test shall be tested for leakage before use or transfer to another person. No sealed source shall be stored for a period of more than 10 years without being tested for leakage and/or contamination.

16. Notwithstanding the requirements of 10 CFR 39.47 and pursuant to 10 CFR 39.91, and in accordance with the statements, representations and procedures contained in letters dated July 14, 1997 **(ML003724357)**, **November 14, 1997 (ML003724675)**, **January 20, 1998 (ML003724684)**, February 4, 1998 **(ML003724694)**, and February 27, 2004 **(ML040580735)**, the licensee may use radioactive markers with activities of 50 microcuries or less of iridium-192, scandium-46, antimony-124, and cobalt-60, and 100 microcuries or less of cesium-137 as pipe collar markers in oil and gas wells.

17. The licensee is authorized to hold byproduct material with a physical half-life of less than or equal to 120 days for decay-in-storage before disposal without regard to its activity if the licensee:

    A. Monitors byproduct material at the surface before disposal and determines that its radioactivity cannot be distinguished from the background radiation level with an appropriate radiation detection survey meter set on its most sensitive scale and with no interposed shielding; and

    B. Removes or obliterates all radiation labels, except for radiation labels on materials that are within containers and that will be managed as biomedical waste after they have been released from the licensee; and

    C. Maintains records of the disposal of licensed materials for up to 3 years. The record must include the date of disposal, the survey instrument used, the background radiation level measured at the surface of each waste container, and the name of the individual who performed the disposal.

18. **Notwithstanding the requirements of 10 CFR 20.2007, pursuant to 10 CFR 20.2002, and in accordance with the statements, representations, and procedures contained in correspondence dated May 4, 1993 (ML12243A227), April 20, 1994 (ML12243A209), January 17, 1996 (ML12243A188), February 13, 1996 (ML12243A188), and December 16, 2005 (ML060260462), the licensee may release well-logging sandouts and well returns, containing residual radioactive materials, into on-site shallow earthen pit provided that:**

    A. **The total radioactive concentration of all isotopes is 1,000 picocuries/gram or less, and the physical half-life of the radioactive material is 120 days or less.**

    B. **The residual radioactive tracer material (scandium-46, bromine-82, zirconium-95, antimony-124, iodine-131, iridium-192, or gold-198) being disposed of will be in the form of the patented "Zero-Wash" product in sandouts or well returns.**

NRC FORM 374A U.S. NUCLEAR REGULATORY COMMISSION	PAGE 5 of 6 PAGES
MATERIALS LICENSE SUPPLEMENTARY SHEET	License Number 42-26928-01
	Docket or Reference Number 030-30429
	Amendment No. 44

C. The licensee is required to use well logging beads known as "Zero-Wash", which are insoluble where the radioactivity will not migrate or leach into groundwater, as described in letter dated July 11, 1991 (ML033040193).

D. The on-site shallow earthen pit disposal method has been permitted by the State, Territory, or Federal jurisdiction regardless of whether the job site is in an area where the U.S. Nuclear Regulatory Commission maintains jurisdiction for regulating licensed material, including areas of exclusive Federal jurisdiction within Agreement States.

E. The licensee is required to maintain access control over the on-site shallow earthen pit until the radioactivity has decayed to unrestricted release levels.

F. The licensee maintains an agreement with the owner or operator to control access to the on-site shallow earthen pit until the radioactivity has decayed to unrestricted release levels.

G. The licensee is required to maintain records of disposal in accordance with 10 CFR 20.2108.

19. Notwithstanding the requirements of 10 CFR 20.2007, pursuant to 10 CFR 20.2002, and in accordance with the statements, representations, and procedures contained in correspondence dated August 23, 2000 **(ML003758270)**, January 23, 2002 **(ML033070068)**, and October 30,2003 **(ML033070340)**, the licensee may release well-logging sandouts and well returns containing residual radioactive materials, into Class II Disposal Wells provided that:

A. The total radioactive concentration of all isotopes is 1,000 picocuries/gram or less, and the physical half-life of the radioactive material is 120 days or less.

B. The residual radioactive trace material (scandium-46, **bromine-82**, **zirconium-95**, antimony-124, **iodine-131**, iridium-192, or gold-198) being disposed of will be in the form of the patented "Zero-Wash" product in sandouts or well returns.

C. The licensee is required to use well logging beads known as "Zero-Wash", which are insoluble where the radioactivity will not migrate or leach into groundwater, as described in letter dated July 11, 1991 (ML033040193).

D. The well has been permitted by the State, Territory, or Federal jurisdiction to accept non-hazardous oil and gas waste regardless of whether the job site is in an area where the U.S. Nuclear Regulatory Commission maintains jurisdiction for regulating licensed material, including areas of exclusive Federal jurisdiction within Agreement States.

E. The licensee is required to maintain access control over the Class II Disposal Well until the radioactivity has decayed to unrestricted release levels.

F. The licensee maintains an agreement with the owner or operator to control access to the Class II Disposal Well until the radioactivity has decayed to unrestricted release levels.

ZeroWash®
Isotope Tracer Technology

ZeroWash® tracers are manufactured using a patented process that prevents the isotope from being washed off the proppant-emulating carrier particle.This process fixes non-water-soluble metals in a ceramic matrix. After the resulting ceramic beads are kiln fired and sieved, they are activated by neutron bombardment in a nuclear reactor.

Because the resulting tracer particles are so effectively formed with no potential for wash off, ZeroWash® tracers provide unsurpassed environmental stewardship. They are HSE preferred and U.S. Nuclear Regulatory Commission (NRC) approved for burial.

ZeroWash® tracers, available in three primary isotopes, are produced in two forms:

- ZeroWash® ZW – an intermediate strength ceramic particle
- ZeroWash® ZWLD – a low-density ceramic particle

ISOTOPE TABLE

Isotope	Symbol	Form	Half Life Days	Energy Spectrum (million electron volts)
Iridium 192	Ir-192	ZW, ZWLD	74 days	0.315, 0.470, 0.605
Scandium 46	Sc-46	ZW, ZWLD	83.8 days	0.889, 1.121
Antimony 124	Sb-124	ZW, ZWLD	60.2 days	0.603, 0.722, 1.69

TRACER PROPERTIES AND USAGE

Tracer Form	Description	Mesh Size	Specific Gravity	Crush Strength (psi)	Color	Application
ZeroWash® (ZW)	Intermediate strength ceramic bead imbedded with oxide form of the isotpe	40/70 16 - 80 mesh available	2.65	>8,000	Various shades of gray	Designed to emulate particulate materials. Primarily used to trace pad fluids and acids at matrix rate
ZeroWash® (ZWLD)	Low density ceramic bead imbeded with oxide form of the isotope	40/70 30-100 mesh available	1.3 - 1.48	1,500 - 2,000	Dark green to brown	Designed to emulate fluid and low density materials. Used to trace pad fluids and acids at matrix rate

Attachment 4

Visual of Low Concentration

A 20-mCi vial of ZeroWash® traces 50,000 pounds of proppant

This low concentration is what allows us to operate without potential for exposure to the public.

We have completed the wash test on your patent pending radioactive carrier PTI-ZW under the testing criteria that you included in your guidelines and our input that we discussed. The test was performed and completed on June 19, 1991. Listed below are the test results.

Sincerely,

John L. Krohn
Assistant Director

RECEIVED 13 JUL 1991

JLK/ym

Radioactive Wash Test Results
(PTI-ZW)

	Temp	KCL Water	15% HCL
Washoff	80° F	12/1000 of 1%	17/1000 of 1 %
Washoff	180° F	40/1000 of 1%	41/1000 of 1 %

Note : These washoff amounts could be considered negligible in view of the probability of filter washby of production fines.

Santos

APPENDIX H.5 HALLIBURTON – CARBONRT

MEMO

To: Monique Harrison

From: Tom Biksey and Chris Bevan

CC: Nigel Goulding

Date: June 23, 2015

Re: **CARBONRT® ECONO Fluid System PBT Assessment and Comparison to Previous Hydraulic Fracturing Fluid**

Introduction

Santos GLNG (Santos) is looking to use a new proppant called CARBONRT® ECONO (CarboNRT), developed by CARBO Ceramics Inc., in their hydraulic fracturing process. CarboNRT is a non-radioactive tracer that can help measure fracture height and proppant location. The new proppant will be used in a Halliburton fluid system in conjunction with sand, water, bactericides, breakers, clay control, gelling agents, and pH control. **Attachment 1** provides the *Santos Prejob CarboNRT* disclosure for three concentration alternatives including a listing of the chemical constituents, CAS number and percent of total volume in the fluid system. The fluid system components provided in Attachment 1, with the exception of CarboNRT, were addressed previously as part of the Hydraulic Fracturing Risk Assessment Compendium (RA Compendium) by Santos GLNG Projects (2014). Specifically, the fluid system components were addressed either in the Delta 140 fluid system (Appendix C2 and C5 of the RA Compendium), or in the CleanStimAU fluid system (Appendix C3 of the RA Compendium).

To address the proposed use of CarboNRT in the new Halliburton fluid system for future hydraulic fracturing events, the following environmental hazard assessment was conducted to ensure compliance with Conditions of Santos' Gas Field Environmental Authorities (e.g. the Roma Shallow Gas Project Area East Environmental Authority PEN103814911). As part of this assessment, EHS Support obtained physical, chemical and toxicological data on the CarboNRT constituents. In addition, the drinking water guidelines and predicted no-effects concentrations (PNECs) for aquatic life in accordance with the previous risk assessment methodologies presented in the RA Compendium were reviewed and compiled for the environmental hazard assessment. **Attachment 2** includes the detailed human health and environmental toxicological profiles for the hydraulic fracturing chemicals with the exception of CarboNRT, which is inert (see PBT Assessment section below for summary of characteristics). **Attachment 3** includes the Safety Data Sheets for the hydraulic fracturing chemicals.

For the environmental hazard assessment, a PBT (persistence, bioaccumulative, toxic) assessment was conducted in accordance with the guidance developed by DEWHA (2009), as presented in the RA Compendium. The PBT assessment is conducted because of specific concerns for substances that can be shown to persist for long periods in the environment, to bioaccumulate in food chains, and can give rise to toxic effects after a longer time and over a greater spatial scale than chemicals without these properties. These effects may be difficult to detect at an early stage because of long-term exposures at normally low concentration levels and long life-cycles of species at the top of the food chain.

PBT Assessment

The results of the PBT assessment for the chemical constituents in the CarboNRT fluid system are summarised in **Table 1**. CarboNRT is a ceramic proppant (semi-crystalline alumina silicate; sintered kaolite), and an inorganic, nonmetalllic, inert solid particle. The following summarises these characteristics:

- Human health: CarboNRT is not expected to be absorbed by the oral, dermal, or inhalation routes of exposure due to its physical size. It is expected to be stable in biological media and resistant to metabolism, and essentially acutely non-toxic by the oral, dermal, and inhalation routes of exposure. Under certain conditions, dusts may be formed, which is to be considered as a nuisance dust. It is expected to be non-irritating and not a dermal sensitiser. CarboNRT is not expected to exhibit any systemic toxicity.
- Environmental: CarboNRT is persistent in the environment. It is not expected to bioaccumulate or to be toxic to aquatic organisms because of its water insolubility and lack of bioavailability. None of the CarboNRT fluid system chemical constituents was classified as a PBT chemical, and is therefore not considered to be inherently hazardous chemicals.

Comparison to Previous Assessed System Fluid

As described above, the previous stimulation fluid systems were assessed through the risk assessment processes developed in the RA Compendium. Through this assessment process, it was demonstrated that the operational controls and properties of the stimulation fluids would ensure that the chemicals were contained within the target sequences and would not exhibit long-term mobility. As detailed in the PBT assessment and the discussion presented below, the new proppant CarboNRT and the pre-existing fluid system does not introduce any new environmental risks, and has similar physical properties to the fluid systems previously assessed.

Table 2 and **Table 3** presents the drinking water guidelines and PNECs for aquatic life for the CarboNRT fluid system, **Table 4** compares the chemical constituents in the CarboNRT fluid system to the previous Halliburton fluid systems assessed as either Delta 140 or CleanStimAU. The following summarises the key findings of this comparison:

- The chemicals used in the CarboNRT fluid system are no more mobile than those assessed for Delta 140 or CleanStimAU fluid systems in the RA Compendium. Therefore, the chemicals are anticipated to be contained to the immediate vicinity of the fracture zone with many of the soluble organics (e.g., alcohols) rapidly biodegrading in the subsurface or being extracted in the flowback water.
- The CarboNRT fluid system does not contain BTEX (benzene, toluene, ethylbenzene, xylenes) or polycyclic aromatic hydrocarbons (PAHs); **Attachment 4** presents the Australian Government's National Measurement Institute (NATA) reports of analyses that document this finding.
- There were no carcinogenic chemicals identified in the CarboNRT fluid system.

Overall, the potential hazard to human health and the environment are less in the CarboNRT system fluid when compared to the previous Halliburton Delta 140 and CleanStimAU system fluid. In general, there are fewer constituents in the CarboNRT system fluid than in the previous Halliburton fluid system, including fewer solvents.

Based on the assessment presented, the potential risks to human health and the environment presented in the RA Compendium for Delta 140 and CleanStimAU would be expected to be similar or greater than the potential risks from CarboNRT, and a quantitative risk assessment is not required for CarboNRT. The existing combination of management and operational controls that were being implemented to eliminate and control the potential for exposures outlined in the quantitative risk assessment for the previous system fluids would also serve to eliminate and control any potential for

exposures from the CarboNRT system fluid. The potential risks would be within the acceptable range for implementation of management and operational controls. These include:

- Worker training and hazard identification
- Use of appropriate personal protective equipment (gloves, etc.)
- Flowback storage pond fencing to prevent entry of livestock and minimise trespassing
- Installation of dam liners and routine dam inspections to prevent releases from flowback storage ponds
- Routine operational and security patrols to prevent trespassing.

Attachment 2 Human health and environmental toxicological profiles

Human health toxicological profiles

Toxicity Profile

Acetic acid
(CAS No. 64-19-7)

Acetic acid dissociates in aqueous media to H^+ and the acetate anion ($CH_3CO_2^-$). It is naturally occurring as the acid in apple cider vinegar and other fruit-derived products. It and several of its salts are commonly used as food additives (*e.g.*, as flavor enhancers) and are listed as Generally Recognized as Safe (GRAS) by the U.S. Food and Drug Administration (FDA).

pH: 2.5 at 50 g/L and 20°C
pK_a: 4.76 @ 20°C

Acute Toxicity

The oral LD_{50} in rats is 4,950 mg/kg, and the dermal LD_{50} in rabbits is 1,060 mg/kg. The 4-hour LC_{50} in rats is 11.4 mg/L.

Irritation

In the EU, acetic acid is classified as a skin and eye irritant at concentrations <25%. At ≥25%, it is classified as corrosive to the skin.

Sensitization

No data are available.

Repeated Dose Toxicity

In an 8-month study, rats dosed with 60 mg/kg acetic acid (three times per week) developed hyperplasia in the esophagus and forestomach.

Genotoxicity

Acetic acid was not mutagenic to *Salmonella typhimurium* strains TA 98, TA 100, TA 1535, TA 1537, and TA 1538 in an *in vitro* bacterial mutation assay with or without metabolic activation. Acetic acid (in media adjusted to a pH of 8.5) was also not genotoxic in an *in vitro* chromosomal aberration test using Chinese Hamster Ovary cells with or without metabolic activation.

Carcinogenicity

No adequate carcinogenicity studies have been conducted on acetic acid.

Reproductive Toxicity

No studies could be located.

Developmental Toxicity

There were no effects on implantations or on maternal or fetal survival in mice, rats, or rabbits at doses up to 1,600 mg/kg.

Key Study/Critical Effect for Screening Criteria

There are no repeat dose toxicity studies that were considered adequate for human health risk assessment. The only study reported on the toxicity of acetic acid by oral gavage showed effects of irritation (probably due to the pH of acetic acid) at the site of contact in the gastrointestinal tract. No systemic effects were reported.

The Joint FAO/WHO Expert Committee on Food Additives (JECFA) has maintained a group ADI of "not limited" for acetic acid and its potassium and sodium salts.

The Australian drinking water guidance value for pH may apply to acetic acid.

Toxicity Profile

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyanopsis tetragonolobus*. Structurally, it is a galactomannan consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum cranges from 200,000 to 300,000 daltons (Glickman, 1969).

Guar gum is approved for use as a food additive by the U.S. Food and Drug Administration and is on the list of substances "generally recognized as safe" (CFR 1974).

Acute Toxicity

The oral LD_{50} is 8,100 mg/kg for mice and 9,400 mg/kg for rats (Bailey and Morgareidge, 1948).

Irritation

No data were found.

Sensitization

There are reports of respiratory sensitization in workers exposed occupationally to guar gum dusts (Maio, 1986).

Repeat Dose Toxicity Studies

F344 rats and $B6C3F_1$ mice were given diets containing 0, 6,300, 12,500, 25,000, 50,000 or 100,000 ppm guar gum for 13 weeks (NTP, 1982). Mean body weights were decreased in male rats (100,000 ppm group) and in female mice (50,000 and 100,000 ppm). A dose-related decrease in feed consumption was observed for male and female rats; male and female mice were comparable or higher than that of controls. There were no compound-related clinical signs or histopathological effects.

F344 rats and $B6C3F_1$ mice were given diets containing 0, 25,000 ppm or 50,000 ppm guar gum for 103 weeks (NTP, 1982). Mean body weights of the high-dose females were lower than those of the controls after week 20 for mice and week 40 for rats. No compound-

related clinical signs or adverse effects on survival were observed. Feed consumption by dosed rats and mice of either sex was lower than that of controls. There were no non-neoplastic histopathological effects in either rats or mice that were treatment-related.

Genotoxicity

Guar gum was not mutagenic to *Salmonella typhimurium* TA 1530 or G-46 when tested without metabolic activation; however, it was mutagenic to *Saccharomyces cerevisiae* D-3 (Green, 1977). Guar gum also was reported to cause chromosomal aberrations in human embryonic lung cells WI-38 (Green, 1977). No *in vivo* genotoxicity studies have been conducted on guar gum.

Carcinogenicity

F344 rats and B6C3F$_1$ mice were given diets containing 0, 25,000 ppm or 50,000 ppm guar gum for 103 weeks (NTP, 1982). There were increased incidences of adenomas of the pituitary in male rats and pheochromocytomas of the adrenal in female rats that were statistically significant, but these differences were considered to be unrelated to guar gum administration. When pituitary adenomas or carcinomas and when pheochromocytomas or malignant pheochromocytomas are combined, the statistical differences disappear. Hepatocellular carcinomas occurred in treated male mice at incidences that were significantly lower than that in controls. The combined incidence of male mice with either hepatocellular adenomas or carcinomas was also significantly lower in the high-dose group. It was concluded that under conditions of this bioassay, guar gum was not carcinogenic for F344 rats or B6C3F$_1$ mice.

Reproductive Toxicity

No data were found.

Developmental Toxicity

Female rabbits were given daily (6 hours/day) dermal administration of 0, 2, 10 and 50 mg/kg guar gum during gestational days 6 through 18 (IRDC, 1988). Mortalities included 2 deaths at 50 mg/kg and 1 death at 10 mg/kg. A single animal was killed in extremis. A dose-related increase in dermal irritation (including erythema, edema, and desquamation) was observed in animals receiving 10 and 50 mg/kg. The number of early resorptions was significantly increased and the number of viable fetuses was correspondingly decreased at 50 mg/kg/day ($p<0.05$). The frequency of fetal malformations and variations in the treated groups was comparable to that of the control group at all dose levels. The NOEL for this study is 2 mg/kg/day.

Key Study/Critical Effect for Screening Criteria

The key studies for the determination of a drinking water guidance value is the NTP two-year chronic bioassays. The LOAELs are based on decreased mean body weights in female mice and rats fed 50,000 ppm guar gum in diet for 103 weeks. The NOAELs for these studies are 25,000 ppm guar gum.

Rat: NOAEL (mg/kg/day) = 25,000 ppm * 0.05 = 1,250 mg/kg/day

Mouse: NOAEL (mg/kg/day) = 25,000 ppm * 0.13 = 3,250 mg/kg/day

Where 0.05 and 0.13 are the fraction of body weight that rats and mice, respectively, consume per day as food (U.S. EPA).

The lowest NOAEL of 1,250 mg/kg/day for the rat will be used to derive a drinking water guidance value.

Uncertainty factors: 10 (interspecies variability); 10 (intraspecies variability)

Oral RfD = 1,250/100 = 12.5 mg/kg/day

Drinking water guideline = 44 ppm

Toxicity Profile

Hemicellulase
(CAS No. 9025-56-3)

Hemicellulases are a group of enzymes that break down hemicellulose, which are polysaccharides that are present in cell walls of all terrestrial plants. These polysaccharides have a β-(1→4)-linked backbone and are composed of pentoses (xylose, arabinoses), hexoses (mannose, glucose, galactose), and sugar acids. Unlike cellulose which are polysaccharides consisting of linear chains of several hundred to over ten thousand β-(1→4) linked D-glucoses, hemicelluloses are not chemically homogeneous. The best characterized hemicellulases are the 1,4- β -D-xylanases and, in particular, those derived from fungal sources presumably because their substrates, xylans, constitute the largest proportion of hemicelluloses in pasture plants.

No toxicity information could be located on hemicellulases; however, mammalian toxicity information were found on the cellulase enzymes (HERA, 2005). Cellulases cleave the ß-1,4-glycosidic bonds in cellulose, and are used in the pulp and paper industry, the textile industry, and in detergents to remove deposits and stains.

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity. For the purposes of risk assessment, the structure of hemicellulases would be expected to be similar to that of cellulases, given that hemicellulases and cellulases are both enzyme families that hydrolyze polysaccharides, although differing in their substrates. Thus, the toxicity data on cellulases will be used as read-across to hemicellulases.

Acute Toxicity

The oral LD_{50} of a cellulase enzyme was calculated to be 8,000 mg/kg for mice and >10,000 mg/kg for rats (HERA, 2005). The inhalation LC_{50} of the same cellulase enzyme in rats was >3.48 mg/L. The mass mean diameter was 7.8 μm with a geometric standard deviation of 2.1 μm (HERA, 2005).

Irritation

Cellulase enzymes are mild to non-irritating to the skin and eyes of rabbits (HERA, 2005). However, the irritation potential is dependent on the amount of protease contamination in the enzyme test preparation, particularly with regards to eye irritation.

Sensitization

A cellulase enzyme was not a skin sensitizer to guinea pigs (HERA, 2005).

Repeated Dose Toxicity

Male and female rats were dosed by oral gavage with 0, 300, 1,000 or 3,000 mg/kg of a cellulase enzyme for 4 weeks. There were no treatment-related clinical signs, but a slight dose-related increase in body weight gain (approx. 7%) was seen in the males. No treatment-related changes were noted in the hematology or clinical chemistry. There were no gross or histopathologic changes that were considered treatment-related (HERA, 2005).

Male and female rats were given in their feed concentrations of 0, 120, 600 or 3,000 mg/kg of a cellulase enzyme for 13 weeks. There were no treatment-related clinical signs. A reduction in body weight gain was seen in both sexes at the 3,000 mg/kg level (10% in males and 20% in females). A slight reduction in food consumption was also noted for the 3,000 mg/kg rats. Alkaline phosphatase was increased in the 600 and 3,000 mg/kg females in a dose-dependent manner. There were no gross or histopathologic changes that were considered treatment-related. The NOAEL for this study is 600 mg/kg/day (HERA, 2005).

Genotoxicity

In an *in vitro* bacterial mutation assay, a cellulase enzyme was not mutagenic to *Salmonella typhimurium* strains TA 1535, TA 100, TA 1537 and TA98 in the presence or absence of metabolic activation. In an *in vivo* bone marrow micronucleus assay, a cellulase enzyme was not genotoxic when given to rats by oral gavage (HERA, 2005).

Carcinogenicity

No data were found.

Reproductive Toxicity

No data were found.

Developmental Toxicity

No data were found.

Key Study/Critical Effect for Screening Criteria

In a 13-week dietary study, there was reduced body weight gain in rats given 3,000 mg/kg of a cellulase enzyme. No other adverse effects were observed. The NOAEL for this study is 600 mg/kg-day.

Uncertainty factors: 10 (interspecies variability); 10 (intraspecies variability); 10 (subchronic to chronic)

Oral RfD = 600/1000 = 0.6 mg/kg-day

Drinking water guideline = 2 ppm

Toxicity Profile

Lactose
(CAS No. 63-42-3)

Lactose is a disaccharide sugar composed of galactose and glucose. It is naturally synthesized in the mammary gland of virtually all mammals, occurring in milk at levels between 1 and 7%. Commercially, lactose is extracted from the whey of cow's milk (whey is the residual liquid of milk following cheese and casein production) and is purified extensively to remove fats, proteins, vitamins and minerals (Baldrick and Bamford, 1997; Goodhart, 1994).

Pharmacokinetics/Metabolism

Lactose *per se* is not readily absorbed by the oral route. After dietary intake, lactose is readily hydrolyzed to galactose and glucose by the enzyme lactase (Hansen, 1974; Williams, 1986). Lactase is a β-galactosidase found in the brush border of the intestinal epithelium. Once hydrolyzed, the monosaccharides are then readily absorbed. Lactose can also be hydrolyzed by other enzymes, such as acid β-galactosidase.

Acute Toxicity

The acute oral LD_{50} in rats is >10,000 mg/kg (Baldrick and Bamford, 1997).

Irritation

No data were located.

Sensitization

No data were located.

Repeated Dose Toxicity/Carcinogenicity

Wistar rats were fed 20% lactose for 12 weeks before mating, and during pregnancy and lactation. At weaning, the animals were fed the same diet and the study was terminated at week 130. There were low body weights; increased blood alkaline phosphatase and urinary calcium; decreased pH of cecum contents; enlargement/increased weight of the cecum; pelvic nephrocalcinosis of the kidneys; increased proliferation of the bile ducts; adrenal medullary hyperplasia and pheochromocytomas; and Leydig cell tumors (Sinkeldam *et al.*, 1992a).

Similar findings were also observed in another study in which rats were fed 20% lactose in their diet for 130 weeks. Findings included loose feces (week one and two only); decreased pH of the feces; low body weights; increased food and water consumption; increased blood alkaline phosphatase and decreased bicarbonate; increased calcium concentration and excretion; reduced urinary pH; increased cecum weight; mineralization of the renal pelvis; increased incidence of basophilic cell foci in the adrenal medulla; and Leydig cell hyperplasia (De Groot *et al.*, 1995).

Genotoxicity

Lactose was negative in an *in vitro* chromosomal aberration study with cultured human lymphocytes in the presence and absence of metabolic activation (Sinkeldam *et al.*, 1992a).

Reproductive/Developmental Toxicity

In a multi-generation study, rats were fed 20% lactose over three successive generations. There were no adverse effects on fertility or reproductive performance. There was a slight decrease in the number of pups born alive, litter size at birth, viability index and pup weight for F_0 and F_1 offspring. There were signs of low body weights in the parental animals, and enlargement and increased weight of the cecum (Sinkeldam *et al.*, 1992b).

Pregnant mice were given 10,000 mg/kg lactose during gestation days 8-12. No maternal toxicity was observed and there were no effects on litter size, body weight on days 1 and 3, or neonate survival (Seidenberg *et al.*, 1986).

Key Study/Critical Effect for Screening Criteria

Many of the findings from the oral studies on lactose can be related to the fact that it is poorly absorbed from the small intestine. This results in a large proportion reaching the cecum and colon where it is readily fermented by the intestinal microflora. Consequently, there is increased production of volatile fatty acids and lactic acid, and a lowering of the pH and increased osmotic pressure. These changes facilitate calcium absorption. The adrenal tumors are thought to be secondary to increased calcium absorption from the intestine. Increased Leydig cell tumors in rats are of questionable relevance to humans.

Adverse effects were noted in rats given 20% in their diet for 130 weeks. Since there was only one dose level, a NOAEL was not identified.

LOAEL (mg/kg/day) = 20,000 ppm * 0.05 = 1,000 mg/kg/day

Where 0.05 is the fraction of body weight that is consumed per day as food for the mouse (U.S. EPA).

Uncertainty factors: 10 (interspecies variability); 10 (intraspecies variability); 10 (LOAEL to NOAEL)

Oral Reference Dose = 1,000/1,000 = 1.0 mg/kg/day

Drinking water guideline value = 3.5 ppm

Toxicity Profile

Monoethanolamine borate
(CAS No. 26038-87-9)

The toxicity profile includes toxicity data on boric acid, reaction products with ethanolamine and triethanolamine (CAS No. 68512-53-8), which is structurally similar to monoethanolamine borate.

Acute Toxicity

The acute oral LD_{50} in rats is >2,000 mg/kg, and the acute dermal LD_{50} of CAS 68512-53-8 in rats is >2,000 mg/kg.

Irritation

Monoethanolamine borate was slightly irritating and was not considered to be a skin irritant when tested on the skin of rabbits. Monoethanolamine (MEA) Polyborate 1:1 and MEA Polyborate 1:3 were tested for eye irritancy using the Bovine Corneal Opacity and Permeability test (BCOP test). Minimal to no ocular irritation was observed in both studies.

Sensitization

CAS No. 68512-53-8 was not a skin sensitizer to guinea pigs using the Buehler method.

Repeated Dose Toxicity

Groups of male and female rats received CAS No. 68512-53-8 by oral gavage at dose levels of 0, 62.5, 250 or 1,000 mg/kg body weight per day for a period of 28 days. No deaths occurred throughout the study. Behavior, state of health, body weight development and food consumption, were not affected by administration of the test substance. No treatment-related clinical signs were observed in all animals. No changes of the oral mucosa or impairment of dental growth was observed in all study groups. There were no substance related adverse findings either in hematological examinations, clinical chemistry or urine analyses throughout the study period. As a non-adverse finding, the test substance induced slightly lower total bilirubin, cholesterol and triglycerides in high dose group rats (1,000 mg/kg body weight) and possibly marginally lower hemoglobin and hematocrit content when compared to the controls at the end of the study period. These changes were at the lower range of the historical control data for this rat strain and age and hence, not considered to be of toxicological significance. The test substance did not influence any of

the neurotoxicological parameters. No test article related changes in organ weights were observed. Necropsy at terminal sacrifice revealed no gross pathology findings in the animals of all experimental groups. All microscopic findings sporadically observed in different organs of single animals were interpreted as not compound related. The NOAEL for this study is 1,000 mg/kg/day.

Genotoxicity

In an *in vitro* chromosomal aberration test using cultured peripheral human lymphocytes, MEA Polyborate 1:1 showed a clastogenic response in experiments where the pH of the treated cultures was above the pH of the solvent control. The clastogenicity was only observed in the first cytogenetic assay. Due to fact that the adjustment of the pH of the cultures treated with MEA Polyborate 1:1 did not show a clastogenic response in the third cytogenetic assay, it has to be assumed that the high pH is responsible for the detected clastogenic activity.

In an *in vitro* chromosomal aberration test using cultured peripheral human lymphocytes, MEA Polyborate 1:3 did not induce a statistically significant or biologically relevant increase in the number of cells with chromosome aberrations in the absence and presence of S9-mix, in either of the two independently repeated experiments. CAS No. 68512-53-8 did not induce gene mutations in an *in vitro* HPRT-test with V79 Chinese hamster lung fibroblast cells, either in the presence or in the absence of metabolic activation.

Carcinogenicity

No data are available.

Reproductive Toxicity

No data are available.

Developmental Toxicity

No data are available.

Key Study/Critical Effect for Screening Criteria

A 28-day oral toxicity study conducted was conducted in rats with CAS No. 68512-53-8 (Boric acid, reaction products with ethanolamine and triethanolamine). The NOAEL for this study is 1,000 mg/kg/day. Data from CAS No. 68512-53-8 is being used as read-across to monoethanolamine borate.

Uncertainty factors: 10 (interspecies variability); 10 (intraspecies variability); 10 (subacute to chronic)

Oral RfD = 1000/1000 = 1 mg/kg/day

Drinking water guideline: 3.5 ppm

Reference

ECHA REACH database: http://apps.echa.europa.eu/registered/registered-sub.aspx

Toxicity Profile

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Sodium hydroxide (NaOH) is present in the environment as sodium (Na^+) and hydroxyl ions (OH^-). Sodium is a normal constituent of the blood and an excess is excreted in the urine. A significant amount of sodium is taken up via the food because the normal uptake of sodium via food is 3.1-6.0 g per day according to Fodor *et al.* (1999). Exposure to NaOH could potentially increase the pH of the blood. However, the pH of the blood is regulated between narrow ranges to maintain homeostasis (pH of 7.4 to 7.5) by urinary excretion of bicarbonate and via exhalation of carbon dioxide.

Acute Toxicity

An oral LD_{50} of a 1-10% solution of NaOH in rabbits was reported to be 325 mg/kg (expressed as 100% NaOH). Mortality was also observed when 1% NaOH was dosed, but in this case, the applied volume was relatively high (24 mL per kg body weight).

Irritation

A NaOH solution of 8% can be considered corrosive based on animal data. Human data indicate that concentrations of 0.5 to 4% were irritating. In two different studies a concentration of 0.5% was irritating for only 55 and 61% of the volunteers, respectively. Thus, it is assumed that a concentration, which is slightly lower than 0.5%, is the non-irritating concentration.

The available animal data on eye irritation showed that the non-irritant level was 0.2-1.0 %, while the corrosive concentration was 1.2 % or >2%.

Sensitization

Male volunteers were exposed on the back to sodium hydroxide concentrations of 0.063 – 1.0% (induction). After 7 days the volunteers were challenged to a concentration of 0.125%. The irritant response correlated well with the concentration of NaOH, but an increased response was not observed when the previously patch tested sites were re-challenged. Based on this study sodium hydroxide has no skin sensitization potential.

Repeated Dose Toxicity

No animal data are available on repeated dose toxicity studies by oral, dermal, inhalation or by other routes for NaOH. It is not useful to study the repeated dose toxicity of hydroxide via an oral study because at high concentrations the substance is corrosive or irritating, while at low concentrations the hydroxide will be neutralized in the stomach by gastric juice, which has a very low pH.

Genotoxicity

Both the *in vitro* and the *in vivo* genotoxicity tests are negative.

Carcinogenicity

No carcinogenicity studies on sodium hydroxide were identified.

Reproductive Toxicity

No valid studies were identified regarding toxicity to reproduction in animals after oral, dermal or inhalation exposure to NaOH. It is not useful to study the reproduction/developmental toxicity of hydroxide via an oral study because at high concentrations the substance is corrosive or irritating, while at low concentrations the hydroxide will be neutralized in the stomach by gastric juice, which has a very low pH.

Developmental Toxicity

No valid studies were identified regarding developmental toxicity in animals after oral, dermal or inhalation exposure to NaOH. It is not useful to study the reproduction/developmental toxicity of hydroxide via an oral study because at high concentrations the substance is corrosive or irritating, while at low concentrations the hydroxide will be neutralized in the stomach by gastric juice, which has a very low pH.

Key Study/Critical Effect for Screening Criteria

The Australian drinking water guideline value for pH may apply to sodium hydroxide.

Toxicity Profile

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Limited toxicity information was located for this alkyl phosphonium salt.

Acute Toxicity

An oral LD_{50} in rats was reported to be 1,002 mg/kg. The 4-hour LC_{50} to rats is <0.9 mg/L (aerosol).

Irritation

TTPC is corrosive to the skin and eyes.

Sensitization

TTPC is not a skin sensitizer.

Repeated Dose Toxicity

No data were found.

Genotoxicity

TTPC tested negative in an Ames test.

Carcinogenicity

No data were found.

Reproductive Toxicity

No data were found.

Developmental Toxicity

No data were found.

Key Study/Critical Effect for Screening Criteria

No data are available for determining the critical effect and the LOAEL/NOAEL for an oral reference dose.

Environmental toxicological profiles

Environmental Assessment

Acetic Acid
(CAS No. 64-19-7)

Acetic acid and its salts undergo dissociation in aqueous media into the acetate anion ($H_3C_2O_2^-$) and the respective cations (H^+, NH_4^+, Ca^{2+}, Mg^{2+}, Mn^{2+}, K^+, Na^+). The toxicity of each compound is driven by acetate, with the cations playing a minor role. The pH is 2.5 at 50 g/L and 20ºC; and the pK_a is 4.76 at 20ºC.

Environmental Transport

Level I fugacity modeling predicts that about 73% of any acetic acid released to the environment would partition to water, with the remainder partitioning into the air (U.S. HPVIS database).

Biodegradation

Acetic acid and its salts readily dissociate into their respective cations and the acetate anion; the anion acetate is readily biodegraded. In aerobic conditions using adapted wastewater from domestic sewage, degradation was 96% after 20 days (Price *et al.*, 1974). It was also shown to be readily biodegradable under anaerobic conditions using activated sludge (99% after 7 days) (Kameya *et al.*, 1995).

Aquatic Toxicity

The 96-hour LC_{50} in bluegill sunfish is 75 mg/L (Price *et al.*, 1974), and the 96-hour LC_{50} in mosquito fish is 251 mg/L (Wallen *et al.*, 1957). The 96-hour LC_{50} of 60% acetic acid in *Oncorhynchus mykiss* is 108 mg/L (64.8 mg acetic acid/L) (unpublished data, ECHA). In a chronic study with *Oncorhynchus mykiss*, the 21-day LC_{50} and NOEC for 60% acetic acid were 87 mg/L and 57.2 mg/L, respectively (unpublished data, ECHA). The 21-day LC_{50} and NOEC for 100% acetic acid were 52.2 mg/L and 34.3 mg/L, respectively (unpublished data, ECHA).

The 24-hour EC_{50} to Daphnia was reported to be 95 mg/L (un-neutralized) and 6,000 mg/L (neutralized to pH 8.0) (Bringmann and Kuehn, 1982). One other study showed the 48-hour EC_{50} to be 65 mg/L (Janssen *et al.*, 1993). In a chronic Daphnia study, the 21-day NOEC for reproduction was reported to be 22.7 mg/L for 100% acetic acid (unpublished data, ECHA). In another chronic Daphnia study, the 21-day NOEC for reproduction was 31.4 mg/L for 100% acetic acid (unpublished data, ECHA).

In an algae growth inhibition study, the reported nominal ErC_{50} to *Desmodesmus subspicatus* was 810.9 mg/L for 60% acetic acid (unpublished data, ECHA). The reported

nominal ErC_{50} was 486.5 mg/L for 100% acetic acid (unpublished data, ECHA). The toxicity threshold to algae after 8 days in a growth inhibition test was reported to be 4,000 mg/L (Bringmann and Kuehn, 1980).

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (65 mg/L) and Daphnia (65 mg/L), and algae (487 mg/L). Long-term results are also available for fish (NOEC = 34 mg/L) and Daphnia (NOEC = 23 mg/L). On the basis that the data consists of short-term results from three trophic levels and two chronic study for fish and another chronic study for Daphnia, an assessment factor of 50 has been applied to the lowest NOEC of 23 mg/L for Daphnia.
The $PNEC_{aquatic}$ was calculated to be 0.5 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Thus, the determination of the $PNEC_{sediment}$ is not possible. Based on its properties, no adsorption of acetic acid to sediment is to be expected and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. Acetic acid dissociates completely in water with its environmental distribution dominated by its high water solubility. Since log Kow and Koc are only applicable to the non-ionized forms of a substance, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Thus, the determination of the $PNEC_{soil}$ is not possible. Based on its properties, no adsorption of acetic acid to soil is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

The acetate ion of acetic acid is readily biodegradable and thus it does not meet the screening criteria for persistence.

The log Kow for acetic acid is reported to be -0.17 (Verschueren, 1966). Acetate is also found in the body and is metabolized as part of the body's biochemical pathways. Thus,

acetic acid (specifically, the acetate ion) does not meet the screening criteria for bioaccumulation.

The NOECs from the chronic aquatic toxicity data on acetic acid are >0.01 mg/L. Thus, acetic acid does not meet the criteria for toxicity.

The overall conclusion is that acetic acid is not a PBT substance.

Environmental Assessment

Guar Gum
(CAS No. 9000-30-0)

Guar gum (CAS No. 9000-30-0) is the milled endosperm of the leguminous plant *Cyanopsis tetragonolobus*. Structurally, it is a galactomannan (a polysaccharide) consisting of a main chain of D-mannose with a side chain of D-galactose at approximately every second mannose unit. The mannose units are β-(l-4) linked, and the single D-galactose units are joined to the main chain by α-(1-6) linkages. The estimated molecular weight of guar gum ranges from 200,000 to 300,000 daltons (Glickman, 1969).

Biodegradation

No information was found. Guar gum, being a polysaccharide composed of galactomannan, would be expected to be readily biodegradable.

Bioaccumulation

Not expected to bioaccumulate as a polysaccharide composed of galactomannans.

Aquatic Toxicity

The 48-hour LC_{50} for *Daphnia magna* was reported to be 42 mg/L (Biesinger *et al.*, 1976).

Toxicity to Terrestrial Organisms

No data were located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for one trophic level. An acute LC_{50} value is available for the invertebrate Daphnia (42 mg/L). On the basis that the data consists of only one short-term result from one trophic level, an assessment factor of 1,000 has been applied to the reported effect concentration of 42 mg/L for Daphnia. The $PNEC_{aquatic}$ is 0.042 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition

method cannot be used to determine a $PNEC_{sediment}$ and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on soil organisms are available. The Kow and Koc of guar gum cannot be calculated using EPISUITE because the molecular weight of guar gum greatly exceeds the limit of 1,000. Thus, the equilibrium partition method cannot be used to determine a $PNEC_{soil}$ and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

No biodegradation was found on guar gum. However, guar gum is a naturally occurring polysaccharide which would be expected to readily biodegrade. Thus, it is not expected to meet the screening criteria for persistence.

The molecular weight of guar gum ranges from 200,000 to 300,000 daltons, and it is also water soluble. Thus, guar gum is not expected to meet the criteria for bioaccumulation.

The acute aquatic toxicity of guar gum is >0.1 mg/L. Thus, guar gum is not expected to meet the screening criteria for toxicity.

The overall conclusion is that guar gum is not a PBT substance.

Environmental Assessment

Hemicellulase
(CAS No. 9025-56-3)

Hemicellulases are a group of enzymes that break down hemicellulose, which are polysaccharides that are present in cell walls of all terrestrial plants. These polysaccharides have a β-(1→4)-linked backbone and are composed of pentoses (xylose, arabinoses), hexoses (mannose, glucose, galactose), and sugar acids. Unlike cellulose which are polysaccharides consisting of linear chains of several hundred to over ten thousand β-(1→4) linked D-glucoses, hemicelluloses are not chemically homogeneous. The best characterized hemicellulases are the 1,4- β -D-xylanases and, in particular, those derived from fungal sources presumably because their substrates, xylans, constitute the largest proportion of hemicelluloses in pasture plants.

No toxicity information could be located on hemicellulases; however, mammalian toxicity information were found on the cellulase enzymes (HERA report, 2005). Cellulases cleave the ß-1,4-glycosidic bonds in cellulose, and are used in the pulp and paper industry, the textile industry, and in detergents to remove deposits and stains.

Enzymes are catalytic proteins or polypeptides and consist of amino acid residues coupled via peptide bonds. They are primarily characterized by their biocatalytic or enzymatic activity. There is a broad range of detergent cellulases used both from fungal as well as from bacterial origin; all are characterized by ß-1,4-endoglucanase activity. For the purposes of risk assessment, the structure of hemicellulases would be expected to be similar to that of cellulases, given that hemicellulases and cellulases are both enzyme families that hydrolyze polysaccharides, although differing in their substrates. Thus, the toxicity data on cellulases will be used as read-across to hemicellulases.

Biodegradation

Three different cellulase enzymes were considered readily biodegradable based on the results of OECD 301C and 301E tests (HERA, 2005). In an OECD 301E test, there was 84% DOC removal of the enzyme Carezyme after 28 days. In another OECD 301E test, there was 92% DOC removal of the enzyme Clazinase® after 28 days. In an OECD 301C test, BOD/COD was 78% after 28 days. Likewise, hemicellulase is expected to be readily biodegradable.

Aquatic Toxicity

The 96-hour LC_{50} of an alkaline cellulase to zebrafish (*Brachydanio rerio*) is 330 mg aep/L (HERA, 2005). The 48-hour EC_{50} of the same alkaline cellulase to *Daphnia magna* is >1,000 mg aep/L (HERA, 2005). The same alkaline cellulase was also tested in algae (*Scenedesmus subspicatus*), with a 72-hour EC_{50} of >1000 mg aep/L (HERA, 2005).

The 24- and 48-hour EC_{50} values of an alkaline cellulase (SP 227, Celluzyme) to *Daphnia magna* are >1,000 mg aep/L and approximately 1,000 mg aep/L respectively (HERA, 2005).

Two additional acute fish toxicity studies showed findings with LC_{50} values of >100 mg aep/L, but no references were provided (HERA, 2005).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (330 mg aep/L), Daphnia (>1,000 mg aep/L), and algae (1,000 mg aep/L). Although the HERA report provides information on two acute fish studies with LC_{50} values of >100 mg aep/L, no references were provided and were therefore excluded from the determination of PNECs. On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 330 mg aep/L for fish. The $PNEC_{aquatic}$ is 0.33 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{sediment}$ was calculated to be 0.21 mg aeg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. A calculated Koc of <1.3 was reported in the HERA report, calculated according to the TGD. Using a Koc of 1.3 and a $PNEC_{aquatic}$ of 0.33 mg aep/L, the $PNEC_{soil}$ was calculated to be 0.006 mg aeg/kg.

PBT Assessment

Hemicellulase is expected to be readily biodegradable based on read-across to cellulases. Thus, hemicellulase does not meet the screening criteria for persistence.

Based on the similarity to cellulase, hemicellulase has a high molecular weight (20 to 80 kD), has hydrophilic properties (high water solubility, log Kow <0), and is readily metabolized in organisms by proteolytic enzymes or proteases. Thus, hemicellulose does not meet the screening criteria for bioaccumulation.

The acute $EC(L)_{50}$ of hemicellulase is >0.1 mg/L in fish, invertebrates and algae. Thus, hemicellulase does not meet the screening criteria for toxicity.

The overall conclusion is that hemicellulase is not a PBT substance.

Environmental Assessment

Lactose
(CAS No. 63-42-3)

Lactose is a disaccharide sugar composed of galactose and glucose. It is naturally synthesized in the mammary gland of virtually all mammals, occurring in milk at levels between 1 and 7%. Commercially, lactose is extracted from the whey of cow's milk (whey is the residual liquid of milk following cheese and casein production) and is purified extensively to remove fats, proteins, vitamins and minerals (Baldrick and Bamford, 1997; Goodhart, 1994).

Biodegradation

No biodegradation studies were found on lactose. The QSAR model BIOWIN estimates that the biodegradation of lactose would be fast, with primary degradation in hours-days and ultimate degradation in days-weeks (U.S. EPA, 2011).

Aquatic Toxicity

No aquatic toxicity studies were found on lactose.

Using ECOSAR, the 96-hour LC_{50} in fish was estimated to be 81,045 mg/L; the 48-hour LC_{50} in *Daphnia* was estimated to be 3,460,000 mg/L; and the 96-hour EC_{50} in green algae was estimated to be 583,000 mg/L (U.S. EPA, 2011).

Toxicity to Sediment Organisms

No data could be located.

Toxicity to Terrestrial Organisms

No data could be located.

Determination of PNECs

$PNEC_{aquatic}$: No experimental results are available for lactose. Acute $E(L)C_{50}$ estimates using the QSAR model ECOSAR are: fish (81,045 mg/L), Daphnia (3,460,000 mg/L), and algae (583,000 mg/L). On the basis that the data consists of short-term results from three

trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 81,045 mg/L for fish. The $PNEC_{aquatic}$ is 81 mg/L.

PBT Assessment

No experimental biodegradation data are available on lactose. The QSAR model BIOWIN predict that lactose will biodegrade fast, with primary degradation in hours-days and ultimate degradation in days-weeks. Thus, lactose does not meet the screening criteria for persistence.

The estimated log K_{ow} and BCF for lactose is -5.03 and 3.162, respectively (U.S. EPA, 2011). Thus, lactose does not meet the screening criteria for bioaccumulation.

The estimated acute $EC(L)_{50}$ values of lactose indicate that it is non-toxic to fish, invertebrates and algae. Thus, it does not meet the screening criteria for toxicity.

The overall conclusion is that lactose is not a PBT substance.

Environmental Assessment

Monoethanolamine borate
(CAS No. 26038-87-9)

Monoethanolamine borate is also known as orthoboric acid, compound with 2-aminoethanol. It is a UVCB substance with the chemical formula: $C_2H_7NO.xBH_3O_3$.

Environmental Transport

Monoethanolamine (MEA) Polyborate 1:1 and MEA Polyborate 1:3 do not significantly adsorb to soil. The experimental log Koc was determined to be approximately 1.26.

Biodegradation

MEA Polyborate 1:1 was considered readily biodegradable in a modified Sturm test (OECD 301B). Degradation was 73% after 28 days.

MEA Polyborate 1:3 was considered readily biodegradable in a modified Sturm test (OECD 301B). Degradation was 75% after 28 days.

Aquatic Toxicity

The 96-hour LC_{50} in Carp for MEA Polyborate 1:3 is 617 mg/L.

The 48-hour EC_{50}s in *Daphnia magna* for MEA Polyborate 1:3 and MEA Polyborate 1:1 are 496 and 423 mg/L, respectively.

The 72-hour ErC_{50} in fresh water algae species *Pseudokirchneriella subcapitata* for MEA Polyborate 1:1 is 26 mg/L. The 72-hr EyC_{50} (yield inhibition) is 13 mg/L. The NOEC for growth rate reduction and yield inhibition is 3.2 mg/L. The 72-hr ErC_{50} in fresh water algae species *Pseudokirchneriella subcapitata* for MEA Polyborate 1:3 is 67 mg/L.

Toxicity to Sediment Organisms

No data are available.

Toxicity to Terrestrial Organisms

No data are available.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (617 mg/L), Daphnia (423 mg/L), and algae (13 mg/L). On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 13 mg/L for algae. The $PNEC_{aquatic}$ is 0.013 mg/L.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. The equilibrium partition method was used to determine a $PNEC_{sediment}$. The Koc was experimentally determined to be approximately 18.20. Using a Koc of 18.20 and a $PNEC_{aquatic}$ of 0.013 mg/L, the $PNEC_{sediment}$ was calculated to be 0.012 mg/kg.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The equilibrium partition method was used to determine a $PNEC_{soil}$. The Koc was experimentally determined to be approximately 18.20. Using a Koc of 18.20 and a $PNEC_{aquatic}$ of 0.013 mg/L, the $PNEC_{soil}$ was calculated to be 0.003 mg/kg (3.1 µg/kg).

PBT Assessment

Monoethanolamine borate is readily biodegradable and thus it does not meet the screening criteria for persistence.

Monoethanolamine borate is a UVCB substance and a log Kow cannot be accurately determined. For monoethanolamine itself, the measured log Kow and estimated BCF from BCFBAF v.3.01 are -1.6122 and 3.16 L/kg, respectively. The borate salt of monoethanolamine would not be expected to meet the screening criteria for bioaccumulation.

No chronic aquatic toxicity studies are available for monoethanolamine borate. The acute toxicity studies in fish, invertebrates and algae are >0.1 mg/L. Thus, monoethanolamine borate does not meet the criteria for toxicity.

The overall conclusion is that monoethanolamine borate is not a PBT substance.

Environmental Assessment

Sodium hydroxide
(CAS No. 1310-73-2)

Sodium hydroxide (NaOH) has been reviewed in the OECD-SIDS program (OECD, 2002a,b).

Environmental Fate

The high water solubility and low vapor pressure indicate that sodium hydroxide (NaOH) will be found predominantly in the aquatic environment. NaOH is present in the environment as sodium (Na^+) and hydroxyl (OH^-) ions, which implies that it will not adsorb on particulate matter or surfaces and will not accumulate in living tissues.

Measured concentrations in aquatic ecosystems
The concentration of hydroxyl ions in the environment has been determined very extensively via pH measurements. The pH is a very important parameter of aquatic ecosystems and it is a standard parameter of water quality monitoring programs. The most important freshwater aquatic ecosystems of the world revealed average annual pH values between 6.5 and 8.3 but lower and higher values have been measured in other aquatic ecosystems (UNEP, 1995). In aquatic ecosystems with dissolved organic acids a pH of less than 4.0 has been measured, while in waters with a high chlorophyll content the bicarbonate assimilation can result in pH values of higher than 9.0 at midday (UNEP, 1995). The pH of an aquatic ecosystem is mainly determined by geochemical, hydrological and/or biological processes.

Also sodium has been measured extensively in aquatic ecosystems. For example UNEP (1995) reported the concentration for a total number of 75 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th –percentile, mean and 90th-percentile were 1.5, 28 and 68 mg/l, respectively.

NaOH addition and buffer capacity
An addition of NaOH to an aquatic ecosystem may increase the pH depending on the buffer capacity of the receiving water. In general the buffer capacity is regulated by the equilibria between CO_2, HCO_3^- and CO_3^{2-}:

$CO_2 + H_2O \leftrightarrow HCO_3^- + H^+$ ($pKa_1 = 6.35$)
$HCO_3^- \leftrightarrow CO_3^{2-} + H^+$ ($pKa_2 = 10.33$)

If the pH is between 7 and 9 then the bicarbonate ion is the most important species responsible for the buffer capacity of aquatic ecosystems. UNEP (1995) reported the bicarbonate concentration for a total number of 77 rivers in North-America, South-America, Asia, Africa, Europe and Oceania. The 10th– percentile, mean and 90th-percentile were 20, 106 and 195 mg/l, respectively.

Aquatic Toxicity

At concentrations reported in publications and study reports, the toxicity has been assumed to be due to hydroxide only, because at these effect concentrations the concentration of sodium is too low to explain the effects. However, it should be realized that the results of toxicity tests with NaOH depend on the buffer capacity of the test medium. In a highly buffered test medium the hydroxyl ion will be neutralized and the observed toxicity will be low, while in a poorly buffered test medium the pH will increase rapidly and therefore the observed toxicity will be relatively high. Besides the direct effects (pH change) NaOH could also have indirect effects. The pH change could influence the speciation of other chemicals and therefore increase and/or decrease the toxicity *e.g.*, NH_3 is more toxic than NH_4^+.

The 24-hour LC_{50} to *Carassius auratus* (goldfish) is 160 mg/L . At 100 mg/L, which was equivalent to a pH of 9.8, no mortality was observed. The 48-hour LC_{50} to *Leuciscus idus melanotus*, is 189 mg/L. The 96-hour LC_{50} of *Gambusia affinis* (mosquitofish) is 125 mg/L. At 84 mg/L, no effects on the fish were observed. The pH was 9 at 100 mg/L. The 48-hour LC_{50} is 40 mg/L for *Ceriodaphnia* cf. *dubia*. The toxicity threshold concentration of NaOH for *Daphnia magna* was reported to range from 40 to 240 mg/L.

No data are available on the effects of NaOH on algae.

Toxicity to Terrestrial Organisms

Toxicity tests, which determined the effects of NaOH on terrestrial organisms, are not available. Significant exposure of the terrestrial environment is not expected and for this reason there is no need to perform toxicity test with terrestrial organisms. The results of terrestrial toxicity tests will depend strongly on the buffer capacity of the soil and can probably be predicted based on the buffer capacity of the soil.

Determination of PNECs

In many cases pH, buffer capacity and/or medium composition were not discussed in the publications, although this is essential information for toxicity tests with NaOH. This is the most important reason why most of the studies, mentioned above were considered invalid. Although valid acute ecotoxicity tests and chronic ecotoxicity tests with NaOH are not available there is no need for additional testing with NaOH. A significant number of acute toxicity tests are available and the results of the tests are more or less consistent. Altogether they give a sufficient indication about acute toxicity levels of sodium hydroxide.

Furthermore acute toxicity data cannot be used to derive a PNEC or a PNEC added for sodium hydroxide. Aquatic ecosystems are characterized by an alkalinity/pH and the organisms of the ecosystem are adapted to these specific natural conditions. Based on the natural alkalinity of waters, organisms will have different optimum pH conditions, ranging from poorly buffered waters with a pH of 6 or less to very hard waters with pH values up to 9. A lot of information is available about the relationship between pH and ecosystem structure and also natural variations in pH of aquatic ecosystems have been quantified and reported extensively in ecological publications and handbooks.

Normally a PNEC or a PNEC added has to be derived from the available ecotoxicity data. A PNEC added is a PNEC which is based on added concentrations of a chemical (added risk approach). Based on the available data it is not considered useful to derive a PNEC or a PNEC added for NaOH because:

- The natural pH of aquatic ecosystems can vary significantly between aquatic ecosystems,

- Also the sensitivity of the aquatic ecosystems to a change of the pH can vary significantly between aquatic ecosystems and

- The change in pH due to an anthropogenic NaOH addition is influenced significantly by the buffer capacity of the receiving water.

Although a PNEC or a PNEC added was not calculated for NaOH there is a need to assess the environmental effect of an NaOH (alkaline) discharge. Based on the pH and buffer capacity of effluent and receiving water and the dilution factor of the effluent, the pH of the receiving water after the discharge can be calculated. Of course the pH change can be measured also very easily via a laboratory experiment or by conducting field measurements. The change in pH should be compared with the natural variation in pH of the receiving water and based on this comparison it should be assessed if the pH change is acceptable.

$PNEC_{aquatic}$: Based on the information above, a PNEC was not derived for sodium hydroxide.

$PNEC_{sediment}$: No experimental toxicity data on sediment organisms are available. Sodium hydroxide dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as sodium hydroxide. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of sodium hydroxide to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No experimental toxicity data on terrestrial organisms are available. The environmental distribution of sodium hydroxide is dominated by its water solubility. Sorption of sodium hydroxide should probably be regarded as a reversible situation, i.e.,

the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as sodium hydroxide Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, sodium hydroxide is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Sodium hydroxide is an organic salt that dissociates completely to sodium and hydroxide ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both sodium and hydroxide ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Sodium and hydroxide ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, sodium hydroxide is not expected to bioaccumulate.

No chronic toxicity data exist on sodium hydroxide; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, sodium hydroxide does not meet the screening criteria for toxicity.

The overall conclusion is that sodium hydroxide is not a PBT substance.

Environmental Assessment

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Limited information was located for TTPC, with most coming from secondary sources.

Biodegradation
TTPC was not readily biodegradable in an OECD 301 test (BuruEnergy).

In a die-away test (using activated sludge) with radiolabelled TTPC for 168 hours at 0.31 mg/L, the first-order rate constant was 0.69/hour and the half-life was 6.6 hours. After 24 and 168 hours, degradation was >81% and >98%, respectively (BuruEnergy).

TTPC was evaluation in simulation tests over a 40-day period using double ^{14}C labeled TTPC. In activated sludge, there was >40% degradation after 30 days with 50 ppb TTPC and >30% degradation after 7 days with 5 ppb TTPC. In sea water, there was >30% degradation after 35 days with 5 ppb TTPC. In river water, there was >20% after 35 days with 5 TTPC (BuruEnergy).

Environmental Fate
The soil adsorption/desorption of TTPC was tested with three soils differing in sand/silt/clay content, by running an aqueous solution of radiolabelled TTPC through a column of soil. Soil adsorption ranged from 93-96% (BuruEnergy). TTPC is freely soluble in water (BuruEnergy). It is stable in water over a wide pH range (BuruEnergy).

Bioaccumulation
The octanol-water coefficient (K_{ow}) was determined experimentally to be 2.45 from an OECD 107 test (BuruEnergy).

Aquatic Toxicity

Bellacide 350 MSDS: The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L.

U.S. EPA OPP Pesticide Ecotoxicity Database (wit study details): The 96-hour LC_{50}s in rainbow trout are 0.49 and 0.2 mg/L. The 96-hour LC_{50}s in Bluegill sunfish and common carp (*Cyprinus carpio*) are 0.06 and 0.09 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* is 0.025 mg/L.

Environmental Properties of Proposed Biocide BE-9 (Document from BuruEnergy)
The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L

and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L. The 72-hour EC_{50} in green algae *Selenastrum capricornutum* was reported to be 0.019 mg/L.

Toxicity to Sediment Organisms

No data were found.

Toxicity to Terrestrial Organisms

U.S. EPA OPP Pesticide Ecotoxicity Database: The 8-day dietary LC_{50} in Bobwhite Quail is 4,215 ppm, with a NOEL of 1,980 ppm. The 8-day dietary LC_{50} in Mallard Duck is 3,663 ppm, with a NOEL of 1,780 ppm. The 14-day oral gavage LD_{50} in Mallard Duck is 232 mg/kg, with a NOEL of 178 mg/kg.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.2 mg/L), Daphnia (0.025 mg/L), and algae (0.019 mg/L). While the lowest acute value is 0.019 mg/L, it has only been reported in summary document from BuruEnergy and needs to be substantiated. For the purposes of PNEC determination, the acute EC_{50} value for Daphnia will be used. It should be noted that the two values are very similar.

On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the effect concentration of 0.025 mg/L for Daphnia. The $PNEC_{aquatic}$ is calculated to be 2.5×10^{-5} mg/L (0.025 µg/L).

PBT Assessment

TTPC is not readily biodegradable. In a simulation test using river water, there was >20% after 35 days. Thus, TTPC appears to meet the screening criteria for persistence.

The octanol-water coefficient (K_{ow}) for TTPC is 2.45. Thus, TTPC does not meet the screening criteria for bioaccumulation.

No chronic toxicity data are available for TTPC. The lowest acute $EC(L)_{50}$ of TTPC is 0.025 mg/L in invertebrates. Since this value is <0.1 mg/L, TTPC does meet the screening criteria for toxicity.

SAFETY DATA SHEET

ACETIC ACID 55%-90%

Revision Date: 20-Aug-2018 **Revision Number:** 3

1. Product Identifier & Identity for the Chemical

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

1.1. Product Identifier

Product Name ACETIC ACID 55%-90%

Other means of Identification

Synonyms None

Hazardous Material Number: MC600186

Recommended use of the chemical and restrictions on use

Recommended Use Scale Control

Uses advised against Consumer use

Supplier's name, address and phone number

Manufacturer/Supplier Multi-Chem Mintech
1 Ward Road
East Rockingham
WA 6168
Australia

Telephone Number: 61 (08) 9419 5300
Fax Number: 61 (08) 9439 1055
Emergency Telephone Number: + 61 1 800 686 951

E-mail Address fdunexchem@halliburton.com

Emergency phone number

Police or Fire Brigade: - 000 (exchange): - 1100

2. Hazard Identification

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

Classification of the hazardous chemical

Skin Corrosion/Irritation	Category 1 - H314
Serious Eye Damage/Irritation	Category 1 - H318
Specific Target Organ Toxicity - (Single Exposure)	Category 3 - H335
Flammable liquids.	Category 3 - H226

Label elements, including precautionary statements

Hazard Pictograms

Signal Word DANGER

Hazard Statements:
H226 - Flammable liquid and vapor
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H335 - May cause respiratory irritation

Precautionary Statements

Prevention
P210 - Keep away from heat, hot surfaces, sparks, open flames and other ignition sources. No smoking.
P233 - Keep container tightly closed
P240 - Ground and bond container and receiving equipment.
P241 - Use explosion-proof electrical/ventilating/lighting/equipment
P242 - Use only non-sparking tools
P243 - Take action to prevent static discharges.
P260 - Do not breathe dust/fume/gas/mist/vapors/spray
P261 - Avoid breathing dust/fume/gas/mist/vapors/spray
P271 - Use only outdoors or in a well-ventilated area
P280 - Wear protective gloves/protective clothing/eye protection/face protection

Response
P301 + P330 + P331 - IF SWALLOWED: rinse mouth. Do NOT induce vomiting
P303 + P361 + P353 - IF ON SKIN (or hair): Take off immediately all contaminated clothing. Rinse skin with water [or shower].
P363 - Wash contaminated clothing before reuse
P304 + P340 - IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing
P305 + P351 + P338 - IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P310 - Immediately call a POISON CENTER or doctor/physician
P370 + P378 - In case of fire: Use water spray for extinction

Storage
P403 + P233 - Store in a well-ventilated place. Keep container tightly closed
P403 + P235 - Store in a well-ventilated place. Keep cool
P405 - Store locked up

Disposal
P501 - Dispose of contents/container in accordance with local/regional/national/international regulations

Contains Substances	**CAS Number**
Acetic acid	64-19-7

Other hazards which do not result in classification
This mixture contains no substance considered to be persistent, bioaccumulating nor toxic (PBT).
This mixture contains no substance considered to be very persistent nor very bioaccumulating (vPvB).

For the full text of the H-phrases mentioned in this Section, see Section 16

3. Composition/information on Ingredients

Substances	CAS Number	PERCENT (w/w)	GHS Classification - Australia
Acetic acid	64-19-7	60 - 100%	Skin Corr. 1A (H314) Eye Corr. 1 (H318) STOT SE 3 (H335) Flam. Liq. 3 (H226)

4. First aid measures

Description of necessary first aid measures

Inhalation If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Eyes In case of contact, immediately flush eyes with plenty of water for at least 30 minutes. Remove contact lenses after the first 5 minutes and continue washing. Seek immediate medical attention/advice. Suitable emergency eye wash facility should be immediately available

Skin In case of contact, immediately flush skin with plenty of soap and water for at least 30 minutes and remove contaminated clothing, shoes and leather goods immediately. Get medical attention immediately.

Ingestion Rinse mouth with water many times. Get medical attention, if symptoms occur

Symptoms caused by exposure

Causes severe skin irritation with tissue destruction. Causes severe eye irritation which may damage tissue. May cause respiratory irritation.

Medical Attention and Special Treatment

Notes to Physician Treat symptomatically

5. Fire Fighting Measures

Suitable extinguishing equipment

Suitable Extinguishing Media

Water fog, carbon dioxide, foam, dry chemical.

Extinguishing media which must not be used for safety reasons

Do NOT spray pool fires directly with water. A solid stream of water directed into hot burning liquid can cause splattering.

Specific hazards arising from the chemical

Special exposure hazards in a fire

Decomposition in fire may produce harmful gases.

Special protective equipment and precautions for fire fighters

Special protective equipment for firefighters

Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. Accidental release measures

6.1. Personal precautions, protective equipment and emergency procedures

Ensure adequate ventilation. Use appropriate protective equipment. Do not breathe dust/fume/gas/mist/vapors/spray. Remove sources of ignition. Take precautionary measures against static discharges All equipment used when handling the product must be grounded Avoid contact with skin, eyes and clothing.

6.2. Environmental precautions

Prevent from entering sewers, waterways, or low areas.

6.3. Methods and material for containment and cleaning up

Dike far ahead of liquid spill for later disposal. Soak up with inert absorbent material. Pick up and transfer to properly labeled containers. Remove ignition sources and work with non-sparking tools.

7. Handling and storage

7.1. Precautions for safe handling

Handling Precautions

Do not breathe dust/fume/gas/mist/vapors/spray. Ensure adequate ventilation. Use appropriate protective equipment. Remove sources of ignition. Ground and bond containers when transferring from one container to another. Avoid contact with eyes, skin, or clothing.

Hygiene Measures

Handle in accordance with good industrial hygiene and safety practice.

7.2. Conditions for safe storage, including any incompatibilities

Storage Information

Store in a cool well ventilated area. Keep from heat, sparks, and open flames.

Other Guidelines

No information available

8. Exposure Controls/Personal Protection

Control parameters - exposure standards, biological monitoring

Exposure Limits

Substances	CAS Number	Australia NOHSC	ACGIH TLV-TWA
Acetic acid	64-19-7	TWA: 10 ppm TWA: 25 mg/m^3 STEL: 15 ppm STEL: 37 mg/m^3	TWA: 10 ppm STEL: 15 ppm

Appropriate engineering controls

Engineering Controls Ensure adequate ventilation, especially in confined areas

Personal protective equipment (PPE)

Personal Protective Equipment If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.

Respiratory Protection If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear a NIOSH certified, European Standard EN 149, AS/NZS 1715:2009, or equivalent respirator when using this product. Selection of and instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional.

Hand Protection Use gloves which are suitable for the chemicals present in this product as well as other environmental factors in the workplace.

Skin Protection Wear impervious protective clothing, including boots, gloves, lab coat, apron, rain jacket, pants or coverall, as appropriate, to prevent skin contact.

Eye Protection None known.

Other Precautions None known.

Environmental Exposure Controls No information available

9. Physical and Chemical Properties

9.1. Information on basic physical and chemical properties

Physical State: Liquid

Color Light Amber to Dark Amber , Clear to Slightly Hazy

Odor: Pungent

Odor Threshold: No information available

Property Remarks/ - Method	Values
pH:	2.5-3.8 (10% in 1:1 IPA:H2O)
Freezing Point / Range	No data available
Melting Point / Range	No data available
Boiling Point / Range	No data available
Flash Point	> 40 °C / > 104 °F (SFCC)
Evaporation rate	No data available
Vapor Pressure	No data available
Vapor Density	No data available
Specific Gravity	1.0653-1.0903 (20 °C/68 °F)
Water Solubility	Soluble in water
Solubility in other solvents	No data available
Partition coefficient: n-octanol/water	No data available
Autoignition Temperature	No data available
Decomposition Temperature	No data available
Viscosity	No data available
Explosive Properties	No information available
Oxidizing Properties	No information available

9.2. Other information

VOC Content (%)	No data available
Liquid Density	8.88-9.09 lbs/gal
Bulk Density	1065-1090 kg/m^3

10. Stability and Reactivity

10.1. Reactivity
Not expected to be reactive.
10.2. Chemical stability
Stable
10.3. Possibility of hazardous reactions
Will Not Occur
10.4. Conditions to avoid
Keep away from heat, sparks and flame.
10.5. Incompatible materials
Strong oxidizers.
10.6. Hazardous decomposition products
Carbon oxides.

11. Toxicological Information

Information on routes of exposure
Principle Route of Exposure Skin contact. Eye contact. Inhalation.

Symptoms related to exposure
Most Important Symptoms/Effects
Causes severe skin irritation with tissue destruction. Causes severe eye irritation which may damage tissue. May cause respiratory irritation.

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Acetic acid	64-19-7	No data available	1060 mg/kg-bw (rabbit)	11.4 mg/L (rat, 4 h, vapor)

Immediate, delayed and chronic health effects from exposure
Inhalation May cause respiratory irritation.
Eye Contact Causes serious eye damage.
Skin Contact Causes severe burns.

Ingestion Causes burns of the mouth, throat and stomach.

Exposure Levels
No data available

Interactive effects
No data available

Data limitations
No data available

Substances	CAS Number	Skin corrosion/irritation
Acetic acid	64-19-7	Extremely corrosive and destructive to tissue Skin, rabbit:

Substances	CAS Number	Serious eye damage/irritation
Acetic acid	64-19-7	Eye, rabbit: Causes serious eye damage

Substances	CAS Number	Skin Sensitization
Acetic acid	64-19-7	Not regarded as a sensitizer.

Substances	CAS Number	Respiratory Sensitization
Acetic acid	64-19-7	No information available

Substances	CAS Number	Mutagenic Effects
Acetic acid	64-19-7	In vivo tests did not show mutagenic effects. In vitro tests did not show mutagenic effects.

Substances	CAS Number	Carcinogenic Effects
Acetic acid	64-19-7	Did not show carcinogenic effects in animal experiments

Substances	CAS Number	Reproductive toxicity
Acetic acid	64-19-7	Did not show teratogenic effects in animal experiments. Animal testing did not show any effects on fertility.

Substances	CAS Number	STOT - single exposure
Acetic acid	64-19-7	May cause respiratory irritation. No information available

Substances	CAS Number	STOT - repeated exposure
Acetic acid	64-19-7	No significant toxicity observed in animal studies at concentration requiring classification.

Substances	CAS Number	Aspiration hazard
Acetic acid	64-19-7	Not applicable

12. Ecological Information

Ecotoxicity
Product Ecotoxicity Data
Product is not classified as hazardous to the environment.

Substance Ecotoxicity Data

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Acetic acid	64-19-7	EC50(72 h)=55.22 mg/L (Anabaena flos-aquae)	LC50(96 h)=251 mg/L (Gambusia affinis) LC50(96 h)=75 mg/L (Lepomis macrochirus)	NOAEC (16 h) =1150 mg/L (Pseudomonas putida)	EC50(48 h)=65 mg/L (Daphnia magna)

12.2. Persistence and degradability

Substances	CAS Number	Persistence and Degradability
Acetic acid	64-19-7	Readily biodegradable (99% @ 7d)

12.3. Bioaccumulative potential

Substances	CAS Number	Bioaccumulation
Acetic acid	64-19-7	LogPow-0.17

12.4. Mobility in soil

Substances	CAS Number	Mobility
Acetic acid	64-19-7	No information available

12.6. Other adverse effects

Endocrine Disruptor Information
This product does not contain any known or suspected endocrine disruptors

13. Disposal Considerations

Safe handling and disposal methods
Disposal should be made in accordance with federal, state, and local regulations.

Disposal of any contaminated packaging
Follow all applicable national or local regulations.

Environmental regulations
Not applicable

14. Transport Information

Transportation Information

Australia ADG

UN Number UN2789
UN proper shipping name: Acetic Acid Solution
Transport Hazard Class(es): 8 (3)
Packing Group: III
Environmental Hazards: Not applicable

IMDG/IMO

UN Number UN2789
UN proper shipping name: Acetic Acid Solution
Transport Hazard Class(es): 8 (3)
Packing Group: III
Environmental Hazards: Not applicable
EMS: EmS F-E, S-C

IATA/ICAO

UN Number UN2789
UN proper shipping name: Acetic Acid Solution
Transport Hazard Class(es): 8 (3)
Packing Group: III
Environmental Hazards: Not applicable

Special precautions during transport
None

HazChem Code
•2P

15. Regulatory Information

Safety, health and environmental regulations specific for the product

International Inventories

Australian AICS Inventory	All components are listed on the AICS or are subject to a relevant exemption, permit, or assessment certificate.
New Zealand Inventory of Chemicals	All components are listed on the NZIoC or are subject to a relevant exemption, permit, or assessment certificate.
EINECS (European Inventory of Existing Chemical Substances)	This product, and all its components, complies with EINECS
US TSCA Inventory	All components listed on inventory or are exempt.
Canadian Domestic Substances List (DSL)	All components listed on inventory or are exempt.

Poisons Schedule number
S6

International Agreements

Montreal Protocol - Ozone Depleting Substances:	Does not apply.
Stockholm Convention - Persistent Organic Pollutants:	Does not apply
Rotterdam Convention - Prior Informed Consent:	Does not apply.
Basel Convention - Hazardous Waste:	Does not apply.

16. Other information

Date of preparation or review

Revision Date: 20-Aug-2018

Revision Note
Update to Format

Full text of H-Statements referred to under sections 2 and 3
H226 - Flammable liquid and vapor
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H335 - May cause respiratory irritation

Additional information For additional information on the use of this product, contact your local Halliburton representative.

For questions about the Safety Data Sheet for this or other Halliburton products, contact Chemical Stewardship at 1-580-251-4335.

Key abreviations or acronyms used
bw – body weight
CAS – Chemical Abstracts Service
EC50 – Effective Concentration 50%
LC50 – Lethal Concentration 50%
LD50 – Lethal Dose 50%

Response None

Storage None

Disposal None

Contains

Substances	**CAS Number**
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA

Other hazards which do not result in classification

This mixture contains no substance considered to be persistent, bioaccumulating nor toxic (PBT).
This mixture contains no substance considered to be very persistent nor very bioaccumulating (vPvB).

Australia Classification

For the full text of the H-phrases mentioned in this Section, see Section 16

Classification Not Classified
Risk Phrases None

3. Composition/information on Ingredients

Substances	CAS Number	PERCENT (w/w)	GHS Classification - Australia
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	60 - 100%	Not Applicable

4. First aid measures

Description of necessary first aid measures

Inhalation If inhaled, move victim to fresh air and seek medical attention.

Eyes In case of contact, or suspected contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention immediately after flushing.

Skin In case of contact, immediately flush skin with plenty of soap and water for at least 15 minutes. Get medical attention. Remove contaminated clothing and launder before reuse.

Ingestion Do NOT induce vomiting. Give nothing by mouth. Obtain immediate medical attention.

Symptoms caused by exposure

No significant hazards expected.

Medical Attention and Special Treatment

Notes to Physician Treat symptomatically

5. Fire Fighting Measures

Suitable extinguishing equipment

Suitable Extinguishing Media

Water fog, carbon dioxide, foam, dry chemical.

Extinguishing media which must not be used for safety reasons
None known.

Specific hazards arising from the chemical
Special Exposure Hazards
Decomposition in fire may produce harmful gases.

Special protective equipment and precautions for fire fighters
Special Protective Equipment for Fire-Fighters
Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. Accidental release measures

6.1. Personal precautions, protective equipment and emergency procedures
Use appropriate protective equipment. Avoid contact with skin, eyes and clothing. Avoid breathing vapors. Ensure adequate ventilation.

6.2. Environmental precautions
Prevent from entering sewers, waterways, or low areas.

6.3. Methods and material for containment and cleaning up
Isolate spill and stop leak where safe. Contain spill with sand or other inert materials. Scoop up and remove.

7. Handling and storage

7.1. Precautions for Safe Handling
Handling Precautions
Avoid contact with eyes, skin, or clothing. Avoid breathing vapors. Ensure adequate ventilation. Wash hands after use. Launder contaminated clothing before reuse. Use appropriate protective equipment.
Hygiene Measures
Handle in accordance with good industrial hygiene and safety practice.

7.2. Conditions for safe storage, including any incompatibilities
Storage Information
Store away from oxidizers. Store in a cool well ventilated area. Keep container closed when not in use. Product has a shelf life of 36 months.
Other Guidelines
No information available

8. Exposure Controls/Personal Protection

Control parameters - exposure standards, biological monitoring
Exposure Limits

Substances	CAS Number	Australia NOHSC	ACGIH TLV-TWA
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	Not applicable	Not applicable

Appropriate engineering controls
Engineering Controls Use in a well ventilated area. Local exhaust ventilation should be used in areas without good cross ventilation.

Personal protective equipment (PPE)
Respiratory Protection Not normally needed. But if significant exposures are possible then the following respirator is recommended:
Organic vapor respirator.

Hand Protection Impervious rubber gloves.
Skin Protection Rubber apron.
Eye Protection Safety glasses.

Other Precautions None known.
Environmental Exposure Controls Do not allow material to contaminate ground water system

9. Physical and Chemical Properties

9.1. Information on basic physical and chemical properties

Physical State: Liquid
Odor: Amine
Color: Blue
Odor Threshold: No information available

Property Remarks/ - Method	Values
pH:	7.9
Freezing Point/Range	No data available
Melting Point/Range	No data available
Boiling Point/Range	No data available
Flash Point	No data available
Evaporation rate	No data available
Vapor Pressure	No data available
Vapor Density	No data available
Specific Gravity	1.16
Water Solubility	Soluble in water
Solubility in other solvents	No data available
Partition coefficient: n-octanol/water	No data available
Autoignition Temperature	No data available
Decomposition Temperature	No data available
Viscosity	No data available
Explosive Properties	No information available
Oxidizing Properties	No information available

9.2. Other information

VOC Content (%)	No data available
Liquid Density	9.66 lbs/gal @ 20 C

10. Stability and Reactivity

10.1. Reactivity
Not expected to be reactive.
10.2. Chemical Stability
Stable
10.3. Possibility of Hazardous Reactions
Will Not Occur
10.4. Conditions to Avoid
None anticipated
10.5. Incompatible Materials
Strong oxidizers. Dehydrating agents.
10.6. Hazardous Decomposition Products
Toxic fumes. Carbon monoxide and carbon dioxide.

11. Toxicological Information

Information on routes of exposure
Principle Route of Exposure Eye or skin contact, inhalation.

Sympotoms related to exposure
Most Important Symptoms/Effects
No significant hazards expected.

Numerical measures of toxicity

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	No data available	No data available	No data available

Immediate, delayed and chronic health effects from exposure

Inhalation May cause mild respiratory irritation.
Eye Contact May cause mild eye irritation.
Skin Contact May cause mild skin irritation.
Ingestion None known.

Chronic Effects/Carcinogenicity No data available to indicate product or components present at greater than 0.1% are chronic health hazards.

Exposure Levels
No data available

Interactive effects
Skin disorders. Eye ailments.

Data limitations
No data available

12. Ecological Information

Ecotoxicity
Product Ecotoxicity Data
No data available

Substance Ecotoxicity Data

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	No information available	No information available	No information available	No information available

12.2. Persistence and degradability

Substances	CAS Number	Persistence and Degradability
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	No information available

12.3. Bioaccumulative potential

Substances	CAS Number	Log Pow
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	No information available

12.4. Mobility in soil

Substances	CAS Number	Mobility
Contains no hazardous substances in concentrations above cut-off values according to the competent authority	NA	No information available

12.6. Other adverse effects

Endocrine Disruptor Information

This product does not contain any known or suspected endocrine disruptors

13. Disposal Considerations

Safe handling and disposal methods

Disposal should be made in accordance with federal, state, and local regulations.

Disposal of any contaminated packaging

Follow all applicable national or local regulations.

Environmental regulations

Not applicable

14. Transport Information

HALLIBURTON

SAFETY DATA SHEET

BE-9

Revision Date: 13-Oct-2017 **Revision Number:** 20

1. Product Identifier & Identity for the Chemical

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

1.1. Product Identifier

Product Name BE-9

Other means of Identification

Synonyms None

Hazardous Material Number: HB006583

Recommended use of the chemical and restrictions on use

Recommended Use Biocide

Uses advised against No information available

Supplier's name, address and phone number

Manufacturer/Supplier Halliburton Australia Pty. Ltd.
15 Marriott Road, Jandakot, WA 6164
Australia
ACN Number: 009 000 775
Telephone Number: + 61 1 800 686 951
Fax Number: 61 (08) 9455 5300

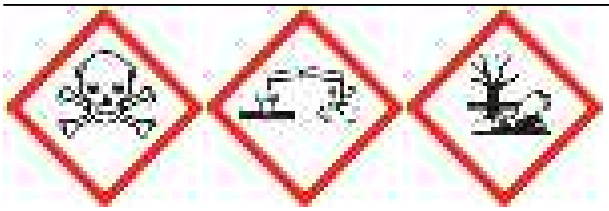
E-mail Address fdunexchem@halliburton.com

Emergency phone number

+ 61 1 800 686 951
Global Incident Response Access Code: 334305
Contract Number: 14012

Australian Poisons Information Centre
24 Hour Service: - 13 11 26
Police or Fire Brigade: - 000 (exchange): - 1100

2. Hazard Identification



Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

Classification of the hazardous chemical

Skin Corrosion/Irritation	Category 1 - H314
Serious Eye Damage/Irritation	Category 1 - H318
Acute Aquatic Toxicity	Category 1 - H400
Chronic Aquatic Toxicity	Category 2 - H411

Label elements, including precautionary statements

Hazard Pictograms

Signal Word DANGER

Hazard Statements:
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H400 - Very toxic to aquatic life
H411 - Toxic to aquatic life with long lasting effects

Precautionary Statements

Prevention
P260 - Do not breathe dust/fume/gas/mist/vapors/spray
P273 - Avoid release to the environment
P280 - Wear protective gloves/protective clothing/eye protection/face protection

Response
P301 + P330 + P331 - IF SWALLOWED: rinse mouth. Do NOT induce vomiting
P303 + P361 + P353 - IF ON SKIN (or hair): Take off immediately all contaminated clothing. Rinse skin with water [or shower].
P363 - Wash contaminated clothing before reuse
P304 + P340 - IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing
P310 - Immediately call a POISON CENTER or doctor/physician
P305 + P351 + P338 - IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P391 - Collect spillage

Storage
P405 - Store locked up

Disposal
P501 - Dispose of contents/container in accordance with local/regional/national/international regulations

Contains

Substances	**CAS Number**
Tributyl tetradecyl phosphonium chloride	81741-28-8

Other hazards which do not result in classification
None known

For the full text of the H-phrases mentioned in this Section, see Section 16

3. Composition/information on Ingredients

Substances	CAS Number	PERCENT (w/w)	GHS Classification - Australia
Tributyl tetradecyl phosphonium chloride	81741-28-8	5 - 10%	Acute Tox. 4 (H302) Acute Tox. 2 (H330) Skin Corr. 1B (H314) Eye Corr. 1 (H318) Aquatic Acute 1 (H400) Aquatic Chronic 1 (H410)

4. First aid measures

Description of necessary first aid measures

Inhalation If inhaled, move victim to fresh air and seek medical attention.

Eyes Immediately flush eyes with large amounts of water for at least 30 minutes. Seek prompt medical attention.

Skin In case of contact, immediately flush skin with plenty of soap and water for at least 30 minutes and remove contaminated clothing, shoes and leather goods immediately. Get medical attention immediately.

Ingestion Do NOT induce vomiting. Give nothing by mouth. Obtain immediate medical attention.

Symptoms caused by exposure

Causes severe eye irritation which may damage tissue. Causes severe skin irritation with tissue destruction.

Medical Attention and Special Treatment

Notes to Physician Treat symptomatically

5. Fire Fighting Measures

Suitable extinguishing equipment

Suitable Extinguishing Media

Water fog, carbon dioxide, foam, dry chemical.

Extinguishing media which must not be used for safety reasons

None known.

Specific hazards arising from the chemical

Special exposure hazards in a fire

Decomposition in fire may produce harmful gases. Do not allow runoff to enter waterways. Use water spray to cool fire exposed surfaces.

Special protective equipment and precautions for fire fighters

Special protective equipment for firefighters

Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. Accidental release measures

6.1. Personal precautions, protective equipment and emergency procedures

Use appropriate protective equipment.

6.2. Environmental precautions

Prevent from entering sewers, waterways, or low areas.

6.3. Methods and material for containment and cleaning up

Isolate spill and stop leak where safe. Contain spill with sand or other inert materials. Scoop up and remove.

7. Handling and storage

7.1. Precautions for safe handling

Handling Precautions

Avoid contact with eyes, skin, or clothing. Wash hands after use. Launder contaminated clothing before reuse. Do NOT consume food, drink, or tobacco in contaminated areas.

Hygiene Measures

Handle in accordance with good industrial hygiene and safety practice.

7.2. Conditions for safe storage, including any incompatibilities

Storage Information

Store in a cool well ventilated area. Keep container closed when not in use. Store away from direct sunlight. Store in a dry location. Store in a manner to prevent commingling with incompatible materials. Store away from alkalis. Store away from reducing agents. Store locked up.

Other Guidelines

No information available

8. Exposure Controls/Personal Protection

Control parameters - exposure standards, biological monitoring

Exposure Limits

Substances	CAS Number	Australia NOHSC	ACGIH TLV-TWA
Tributyl tetradecyl phosphonium chloride	81741-28-8	Not applicable	Not applicable

Appropriate engineering controls

Engineering Controls Use in a well ventilated area. Local exhaust ventilation should be used in areas without good cross ventilation.

Personal protective equipment (PPE)

Personal Protective Equipment If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.

Respiratory Protection If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear a NIOSH certified, European Standard EN 149, AS/NZS 1715:2009, or equivalent respirator when using this product. Selection of and instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional.
Dust/mist respirator. (N95, P2/P3)

Hand Protection Chemical-resistant protective gloves (EN 374) Suitable materials for longer, direct contact (recommended: protection index 6, corresponding to > 480 minutes permeation time as per EN 374): Neoprene gloves. (>= 0.75 mm thickness)
This information is based on literature references and on information provided by glove manufacturers, or is derived by analogy with similar substances. Please note that in practice the working life of chemical-resistant protective gloves may be considerably shorter than the permeation time determined in accordance with EN 374 as a result of the many influencing factors (e.g. temperature). If signs of wear and tear are noticed then the gloves should be replaced. Manufacturer's directions for use should be observed because of great diversity of types.

Skin Protection Wear impervious protective clothing, including boots, gloves, lab coat, apron, rain jacket, pants or coverall, as appropriate, to prevent skin contact.

Eye Protection Chemical goggles; also wear a face shield if splashing hazard exists.

Other Precautions Eyewash fountains and safety showers must be easily accessible.

Environmental Exposure Controls No information available

9. Physical and Chemical Properties

9.1. Information on basic physical and chemical properties

Physical State: Liquid
Color Clear colorless
Odor: Slight
Odor Threshold: No information available

Property Remarks/ - Method	Values
pH:	6-8
Freezing Point / Range	-8 - -10 °C
Melting Point / Range	No data available
Boiling Point / Range	100 °C / 212 °F
Flash Point	No data available
Evaporation rate	No data available
Vapor Pressure	No data available
Vapor Density	No data available
Specific Gravity	0.95 - 1.0
Water Solubility	Miscible with water
Solubility in other solvents	No data available
Partition coefficient: n-octanol/water	No data available
Autoignition Temperature	No data available
Decomposition Temperature	No data available
Viscosity	No data available
Explosive Properties	No information available
Oxidizing Properties	No information available

9.2. Other information

VOC Content (%) No data available

10. Stability and Reactivity

10.1. Reactivity

Not expected to be reactive.

10.2. Chemical stability

Stable

10.3. Possibility of hazardous reactions

Will Not Occur

10.4. Conditions to avoid

None anticipated

10.5. Incompatible materials

Reducing agents. Strong alkalis.

10.6. Hazardous decomposition products

Chlorine. Phosphorus acids. Carbon monoxide and carbon dioxide.

11. Toxicological Information

Information on routes of exposure

Principle Route of Exposure Eye or skin contact, inhalation.

Symptoms related to exposure

Most Important Symptoms/Effects

Causes severe eye irritation which may damage tissue. Causes severe skin irritation with tissue destruction.

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Tributyl tetradecyl phosphonium chloride	81741-28-8	= 611 mg/kg (rat)	No data of sufficient quality are available	> 0.908 mg/L (rat, 4hr, mist)

Immediate, delayed and chronic health effects from exposure

Inhalation May cause respiratory irritation.

Eye Contact Causes severe eye irritation which may damage tissue. May cause eye burns.

Skin Contact Causes severe skin irritation with tissue destruction.

Ingestion Irritation of the mouth, throat, and stomach. May cause abdominal pain, vomiting, nausea, and diarrhea.

Chronic Effects/Carcinogenicity No data available to indicate product or components present at greater than 0.1% are chronic health hazards.

Exposure Levels

No data available

Interactive effects

Lung disorders. Skin disorders.

Data limitations

No data available

Substances	CAS Number	Skin corrosion/irritation
Tributyl tetradecyl phosphonium chloride	81741-28-8	Causes burns (Rabbit)

Substances	CAS Number	Serious eye damage/irritation
Tributyl tetradecyl phosphonium chloride	81741-28-8	Causes severe eye irritation which may damage tissue. (Rabbit)

Substances	CAS Number	Skin Sensitization
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	Respiratory Sensitization
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	Mutagenic Effects
Tributyl tetradecyl phosphonium chloride	81741-28-8	No data of sufficient quality are available.

Substances	CAS Number	Carcinogenic Effects
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	Reproductive toxicity
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	STOT - single exposure
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	STOT - repeated exposure
Tributyl tetradecyl phosphonium chloride	81741-28-8	No data of sufficient quality are available.

Substances	CAS Number	Aspiration hazard
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

12. Ecological Information

Ecotoxicity

Substance Ecotoxicity Data

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available	LC50 (96 h) 0.46 mg/L (Oncorhynchus mykiss) LC50 (96 h) 0.06 mg/L (Lepomis macrochirus)	No information available	EC50 (48 h) 0.025 mg/L (Daphnia sp.)

12.2. Persistence and degradability

Substances	CAS Number	Persistence and Degradability
Tributyl tetradecyl phosphonium chloride	81741-28-8	(0% @ 28d)

12.3. Bioaccumulative potential

Substances	CAS Number	Log Pow
Tributyl tetradecyl phosphonium chloride	81741-28-8	< 3

12.4. Mobility in soil

Substances	CAS Number	Mobility
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

12.6. Other adverse effects

Endocrine Disruptor Information

This product does not contain any known or suspected endocrine disruptors

13. Disposal Considerations

Safe handling and disposal methods
Disposal should be made in accordance with federal, state, and local regulations. Incineration recommended in approved incinerator according to federal, state, and local regulations. Substance should NOT be deposited into a sewage facility.

Disposal of any contaminated packaging
Follow all applicable national or local regulations.

Environmental regulations
Not applicable

14. Transport Information

Transportation Information

Australia ADG

UN Number	UN2922
UN proper shipping name:	Corrosive Liquid, Toxic, N.O.S. (contains Tributyl Tetradecyl Phosphonium Chloride)
Transport Hazard Class(es):	8, (6.1)
Packing Group:	II
Environmental Hazards:	Marine Pollutant

IMDG/IMO

UN Number	UN2922
UN proper shipping name:	Corrosive Liquid, Toxic, N.O.S. (contains Tributyl Tetradecyl Phosphonium Chloride)
Transport Hazard Class(es):	8, (6.1)
Packing Group:	II
Environmental Hazards:	Marine Pollutant
EMS:	EmS F-A, S-B

IATA/ICAO

UN Number	UN2922
UN proper shipping name:	Corrosive Liquid, Toxic, N.O.S. (contains Tributyl Tetradecyl Phosphonium Chloride)
Transport Hazard Class(es):	8, (6.1)
Packing Group:	II
Environmental Hazards:	Marine Pollutant

Special precautions during transport
None

HazChem Code
2X

15. Regulatory Information

Safety, health and environmental regulations specific for the product

International Inventories

Australian AICS Inventory	All components are listed on the AICS or are subject to a relevant exemption, permit, or assessment certificate.
New Zealand Inventory of Chemicals	All components are listed on the NZIoC or are subject to a relevant exemption, permit, or assessment certificate.
EINECS (European Inventory of Existing Chemical Substances)	This product, and all its components, complies with EINECS
US TSCA Inventory	All components listed on inventory or are exempt.
Canadian Domestic Substances List (DSL)	All components listed on inventory or are exempt.

Poisons Schedule number

None Allocated

International Agreements

Montreal Protocol - Ozone Depleting Substances:	Does not apply
Stockholm Convention - Persistent Organic Pollutants:	Does not apply
Rotterdam Convention - Prior Informed Consent:	Does not apply
Basel Convention - Hazardous Waste:	Does not apply

16. Other information

Date of preparation or review

Revision Date: 13-Oct-2017

Revision Note
SDS sections updated:
2

Full text of H-Statements referred to under sections 2 and 3
H302 - Harmful if swallowed
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H330 - Fatal if inhaled
H400 - Very toxic to aquatic life
H401 - Toxic to aquatic life
H410 - Very toxic to aquatic life with long lasting effects
H411 - Toxic to aquatic life with long lasting effects

Additional information

For additional information on the use of this product, contact your local Halliburton representative.

For questions about the Safety Data Sheet for this or other Halliburton products, contact Chemical Stewardship at 1-580-251-4335.

Key abreviations or acronyms used
bw – body weight
CAS – Chemical Abstracts Service
EC50 – Effective Concentration 50%
LC50 – Lethal Concentration 50%
LD50 – Lethal Dose 50%
LL50 – Lethal Loading 50%
mg/kg – milligram/kilogram
mg/L – milligram/liter
NOEC – No Observed Effect Concentration
OEL – Occupational Exposure Limit
PBT – Persistent Bioaccumulative and Toxic
ppm – parts per million
STEL – Short Term Exposure Limit
TWA – Time-Weighted Average
vPvB – very Persistent and very Bioaccumulative
h - hour
mg/m^3 - milligram/cubic meter
mm - millimeter
mmHg - millimeter mercury
w/w - weight/weight
d - day

SAFETY DATA SHEET

Caustic Soda 30% / CAU-186

Revision Date: 29-Dec-2015 **Revision Number:** 2

1. Product Identifier & Identity for the Chemical

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

1.1. Product Identifier

Product Name Caustic Soda 30% / CAU-186

Other means of Identification

Synonyms: None

Product Code: MC600012

Recommended use of the chemical and restrictions on use

Recommended Use pH Control

Uses Advised Against No information available

Supplier's name, address and phone number

Manufacturer/Supplier Multi-Chem Mintech
1 Ward Road
East Rockingham
WA 6168
Australia

Telephone Number: 61 (08) 9419 5300
Fax Number: 61 (08) 9439 1055 Emergency Telephone Number: + 61 1 800 686 951

E-Mail address: fdunexchem@halliburton.com

Emergency phone number

+ 61 1 800 686 951

Australian Poisons Information Centre

24 Hour Service: - 13 11 26

Police or Fire Brigade: - 000 (exchange): - 1100

2. Hazard Identification

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

Classification of the hazardous chemical

Skin Corrosion / irritation	Category 1 - H314
Serious Eye Damage / Eye Irritation	Category 1 - H318
Specific Target Organ Toxicity - (Single Exposure)	Category 3 - H335
Substances/mixtures corrosive to metal.	Category 1 - H290

Label elements, including precautionary statements

Hazard Pictograms

Signal Word Danger

Hazard Statements
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H335 - May cause respiratory irritation
H290 - May be corrosive to metals

Precautionary Statements

Prevention
P234 - Keep only in original container
P260 - Do not breathe dust/fume/gas/mist/vapors/spray
P264 - Wash face, hands and any exposed skin thoroughly after handling
P280 - Wear protective gloves/eye protection/face protection

Response
P301+ P330 + P331 - IF SWALLOWED: Rinse mouth. Do NOT induce vomiting
P303 + P361 + P353 - IF ON SKIN (or hair): Take off immediately all contaminated clothing. Rinse skin with water/shower
P363 - Wash contaminated clothing before reuse
P304 + P340 - IF INHALED: Remove to fresh air and keep at rest in a position comfortable for breathing
P310 - Immediately call a POISON CENTER or doctor/physician
P305 + P351 + P338 - IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P390 - Absorb spillage to prevent material damage

Storage
P403 + P233 - Store in a well-ventilated place. Keep container tightly closed
P405 - Store locked up

Disposal
P501 - Dispose of contents/container in accordance with local/regional/national/international regulations

Contains Substances	**CAS Number**
Sodium hydroxide	1310-73-2

Other hazards which do not result in classification
None known

Australia Classification
For the full text of the H-phrases mentioned in this Section, see Section 16

Classification C - Corrosive.

Risk Phrases
R35 Causes severe burns.
R37 Irritating to respiratory system.

3. Composition/information on Ingredients

Substances	CAS Number	PERCENT (w/w)	GHS Classification - Australia

Sodium hydroxide	1310-73-2	30 - 60%	Skin Corr. 1A (H314) Eye Corr. 1 (H318) STOT SE 3 (H335) Met. Corr. 1 (H290)

4. First aid measures

Description of necessary first aid measures

Inhalation If inhaled, move victim to fresh air and seek medical attention.

Eyes In case of contact, or suspected contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention immediately after flushing.

Skin In case of contact, immediately flush skin with plenty of soap and water for at least 15 minutes. Get medical attention. Remove contaminated clothing and launder before reuse. Destroy or properly dispose of contaminated shoes.

Ingestion Do NOT induce vomiting. Give nothing by mouth. Obtain immediate medical attention.

Symptoms caused by exposure

Causes severe eye irritation which may damage tissue. Causes severe skin irritation with tissue destruction. May cause respiratory irritation.

Medical Attention and Special Treatment

Notes to Physician Treat symptomatically

5. Fire Fighting Measures

Suitable extinguishing equipment

Suitable Extinguishing Media

All standard fire fighting media

Extinguishing media which must not be used for safety reasons

None known.

Specific hazards arising from the chemical

Special Exposure Hazards

May form explosive mixtures with strong acids. Reaction with steel and certain other metals generates flammable hydrogen gas.

Special protective equipment and precautions for fire fighters

Special Protective Equipment for Fire-Fighters

Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. Accidental release measures

6.1. Personal precautions, protective equipment and emergency procedures

Use appropriate protective equipment.

6.2. Environmental precautions

Prevent from entering sewers, waterways, or low areas.

6.3. Methods and material for containment and cleaning up

Isolate spill and stop leak where safe. Contain spill with sand or other inert materials. Neutralize to pH of 6-8. Scoop up and remove.

7. Handling and storage

7.1. Precautions for Safe Handling

Handling Precautions

Avoid contact with eyes, skin, or clothing. Avoid breathing vapors. Wash hands after use. Launder contaminated clothing before reuse.

Hygiene Measures
Handle in accordance with good industrial hygiene and safety practice.

7.2. Conditions for safe storage, including any incompatibilities
Storage Information
Store away from acids. Store in a cool well ventilated area. Keep container closed when not in use. Product has a shelf life of 12 months. Store locked up.
Other Guidelines
No information available

8. Exposure Controls/Personal Protection

Control parameters - exposure standards, biological monitoring
Exposure Limits

Substances	CAS Number	Australia NOHSC	ACGIH TLV-TWA
Sodium hydroxide	1310-73-2	2 mg/m^3	2 mg/M3

Appropriate engineering controls
Engineering Controls Use in a well ventilated area. Local exhaust ventilation should be used in areas without good cross ventilation.

Personal protective equipment (PPE)
Personal Protective Equipment If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.
Respiratory Protection Dust/mist respirator. (N95, P2/P3)
Hand Protection Impervious rubber gloves.
Skin Protection Full protective chemical resistant clothing.
Eye Protection Chemical goggles; also wear a face shield if splashing hazard exists.
Other Precautions Eyewash fountains and safety showers must be easily accessible.
Environmental Exposure Controls No information available

9. Physical and Chemical Properties

9.1. Information on basic physical and chemical properties
Physical State: Liquid **Color:** Clear colorless
Odor: Odorless **Odor Threshold:** No information available

Property	Values	Remarks/ - Method
pH:	14	
Freezing Point/Range	No data available	
Melting Point/Range	No data available	
Boiling Point/Range	144 °C / 291 °F	
Flash Point	No data available	
Evaporation rate	No data available	
Vapor Pressure	No data available	
Vapor Density	No data available	
Specific Gravity	1.52	
Water Solubility	Miscible with water	
Solubility in other solvents	No data available	
Partition coefficient: n-octanol/water	No data available	
Autoignition Temperature	No data available	
Decomposition Temperature	No data available	
Viscosity	No data available	
Explosive Properties	No information available	
Oxidizing Properties	No information available	

9.2. Other information
Molecular Weight 40

VOC Content (%) No data available

10. Stability and Reactivity

10.1. Reactivity
Not expected to be reactive.
10.2. Chemical Stability
Stable
10.3. Possibility of Hazardous Reactions
Will Not Occur
10.4. Conditions to Avoid
None anticipated
10.5. Incompatible Materials
Strong acids. Peroxides. Halogenated compounds. Amphoteric metals such as aluminum, magnesium, lead, tin, or zinc.
10.6. Hazardous Decomposition Products
None known.

11. Toxicological Information

Information on routes of exposure
Principle Route of Exposure Eye or skin contact, inhalation.

Symptoms related to exposure
Most Important Symptoms/Effects
Causes severe eye irritation which may damage tissue. Causes severe skin irritation with tissue destruction. May cause respiratory irritation.

Numerical measures of toxicity

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Sodium hydroxide	1310-73-2	No data available	1350 mg/kg (Rabbit)	No data available

Immediate, delayed and chronic health effects from exposure
Inhalation Causes severe respiratory burns.
Eye Contact Causes severe eye burns.
Skin Contact Causes severe burns.
Ingestion Causes burns of the mouth, throat and stomach.

Chronic Effects/Carcinogenicity Prolonged, excessive exposure may cause erosion of the teeth.

Exposure Levels
No data available

Interactive effects
Skin disorders.

Data limitations
No data available

Substances	CAS Number	Skin corrosion/irritation
Sodium hydroxide	1310-73-2	Causes severe burns

Substances	CAS Number	Eye damage/irritation
Sodium hydroxide	1310-73-2	Causes severe eye burns (Rabbit)

Substances	CAS Number	Skin Sensitization
Sodium hydroxide	1310-73-2	Did not cause sensitization on laboratory animals (guinea pig)

Substances	CAS Number	Respiratory Sensitization
Sodium hydroxide	1310-73-2	No information available

Substances	CAS Number	Mutagenic Effects
Sodium hydroxide	1310-73-2	Did not show mutagenic effects in animal experiments In vitro tests did not show mutagenic effects

Substances	CAS Number	Carcinogenic Effects
Sodium hydroxide	1310-73-2	No data of sufficient quality are available.

Substances	CAS Number	Reproductive toxicity
Sodium hydroxide	1310-73-2	No information available

Substances	CAS Number	STOT - single exposure
Sodium hydroxide	1310-73-2	May cause respiratory irritation.

Substances	CAS Number	STOT - repeated exposure
Sodium hydroxide	1310-73-2	No significant toxicity observed in animal studies at concentration requiring classification. Not applicable due to corrosivity of the substance.

Substances	CAS Number	Aspiration hazard
Sodium hydroxide	1310-73-2	Not applicable

12. Ecological Information

Ecotoxicity

Product Ecotoxicity Data

No data available

Substance Ecotoxicity Data

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Sodium hydroxide	1310-73-2	No information available	LC50 (96h) 125 mg/L (Gambusia affinis) LC50 (48h) 189 mg/L (Leuciscus melanotus) LC50 (24h) 145 mg/L (Poecilia reticulate)	No information available	EC50 (48h) 40.4 mg/L (Ceriodaphnia sp.)

12.2. Persistence and degradability

The methods for determining biodegradability are not applicable to inorganic substances.

Substances	CAS Number	Persistence and Degradability
Sodium hydroxide	1310-73-2	The methods for determining biodegradability are not applicable to inorganic substances.

12.3. Bioaccumulative potential

Does not bioaccumulate.

Substances	CAS Number	Log Pow
Sodium hydroxide	1310-73-2	No information available

12.4. Mobility in soil

Substances	CAS Number	Mobility
Sodium hydroxide	1310-73-2	No information available

12.6. Other adverse effects

Endocrine Disruptor Information

This product does not contain any known or suspected endocrine disruptors

13. Disposal Considerations

Safe handling and disposal methods

Disposal should be made in accordance with federal, state, and local regulations. Substance should NOT be deposited into a sewage facility.

Disposal of any contaminated packaging
Follow all applicable national or local regulations. Contaminated packaging may be disposed of by: rendering packaging incapable of containing any substance, or treating packaging to remove residual contents, or treating packaging to make sure the residual contents are no longer hazardous, or by disposing of packaging into commercial waste collection.

Environmental regulations
Not applicable

14. Transport Information

Transportation Information

R35 Causes severe burns.
R37 Irritating to respiratory system.

Full text of H-Statements referred to under sections 2 and 3
H290 - May be corrosive to metals
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H335 - May cause respiratory irritation

Additional information

For additional information on the use of this product, contact your local Halliburton representative.

For questions about the Safety Data Sheet for this or other Halliburton products, contact Chemical Stewardship at 1-580-251-4335.

Key abreviations or acronyms used

bw – body weight
CAS – Chemical Abstracts Service
EC50 – Effective Concentration 50%
LC50 – Lethal Concentration 50%
LD50 – Lethal Dose 50%
LL50 – Lethal Loading 50%
mg/kg – milligram/kilogram
mg/L – milligram/liter
NOEC – No Observed Effect Concentration
OEL – Occupational Exposure Limit
PBT – Persistent Bioaccumulative and Toxic
ppm – parts per million
STEL – Short Term Exposure Limit
TWA – Time-Weighted Average
vPvB – very Persistent and very Bioaccumulative
h - hour
mg/m^3 - milligram/cubic meter
mm - millimeter
mmHg - millimeter mercury
w/w - weight/weight
d - day

End of Safety Data Sheet

HALLIBURTON

MATERIAL SAFETY DATA SHEET

Product Trade Name: **CLBEAU196**

Revision Date: 27-Aug-2013

1. IDENTIFICATION OF THE SUBSTANCE/PREPARATION AND OF THE COMPANY/UNDERTAKING

Statement of Hazardous Nature Hazardous according to the criteria of NOHSC, Non-Dangerous Goods according to the criteria of ADG.

Manufacturer/Supplier

Halliburton Australia Pty. Ltd.
15 Marriott Road
Jandakot
WA 6164
Australia

ACN Number: 009 000 775
Telephone Number: 61 (08) 9455 8300
Fax Number: 61 (08) 9455 5300

Product Emergency Telephone
Australia: 08-64244950
Papua New Guinea: 05 1 281 575 5000
NewZealand: 06-7559274

Fire, Police & Ambulance - Emergency Telephone
Australia: 000
Papua New Guinea: 000
New Zealand: 111

Identification of Substances or Preparation

Product Trade Name: CLBEAU196
Synonyms: None
Chemical Family: Polysaccharide
UN Number: None
Dangerous Goods Class: None
Subsidiary Risk: None
Hazchem Code: None Allocated
Poisons Schedule: None Allocated
Application: Breaker

Prepared By

Chemical Compliance
Telephone: 1-580-251-4335
e-mail: fdunexchem@halliburton.com

2. COMPOSITION/INFORMATION ON INGREDIENTS

Substances	CAS Number	PERCENT (w/w)	Australia NOHSC	New Zealand WES	ACGIH TLV-TWA
Hemicellulase enzyme	9012-54-8	1 - 5%	Not applicable	Not applicable	Not applicable

Non-Hazardous Substance to Total of 100%

3. HAZARDS IDENTIFICATION

Hazard Overview Airborne dust may be explosive. May cause allergic respiratory reaction. May cause eye and respiratory irritation.

Risk Phrases R42 May cause sensitization by inhalation.

HSNO Classification 6.5A Respiratory sensitisers

4. FIRST AID MEASURES

Inhalation If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Skin Wash with soap and water. Get medical attention if irritation persists.

Eyes In case of contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention if irritation persists.

Ingestion Under normal conditions, first aid procedures are not required.

Notes to Physician Not Applicable

5. FIRE FIGHTING MEASURES

Suitable Extinguishing Media
All standard fire fighting media

Extinguishing media which must not be used for safety reasons
None known.

Special Exposure Hazards Organic dust in the presence of an ignition source can be explosive in high concentrations. Good housekeeping practices are required to minimize this potential.

Special Protective Equipment for Fire-Fighters Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. ACCIDENTAL RELEASE MEASURES

Personal Precautionary Measures Use appropriate protective equipment. Avoid creating and breathing dust.

Environmental Precautionary Measures Prevent from entering sewers, waterways, or low areas.

Procedure for Cleaning / Absorption Scoop up and remove.

7. HANDLING AND STORAGE

Handling Precautions Avoid creating or inhaling dust. Slippery when wet.

Storage Information Store away from oxidizers. Store in a cool, dry location. Product has a shelf life of 18 months.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls	Use in a well ventilated area.
Personal Protective Equipment	If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.
Respiratory Protection	Not normally needed. But if significant exposures are possible then the following respirator is recommended: Dust/mist respirator. (N95, P2/P3)
Hand Protection	Impervious rubber gloves.
Skin Protection	Normal work coveralls.
Eye Protection	Wear safety glasses or goggles to protect against exposure.
Other Precautions	None known.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical State:	Powder
Color:	White to Tan
Odor:	Characteristic
pH:	3.8-8 (1%)
Specific Gravity @ 20 C (Water=1):	Not Determined
Density @ 20 C (kg/l):	Not Determined
Bulk Density @ 20 C (kg/M3):	Not Determined
Boiling Point/Range (C):	Not Determined
Freezing Point/Range (C):	Not Determined
Pour Point/Range (C):	Not Determined
Flash Point/Range (C):	Not Determined **Min:** > 93
Flash Point Method:	Not Determined
Autoignition Temperature (C):	Not Determined
Flammability Limits in Air - Lower (g/m^3):	Not Determined
Flammability Limits in Air - Lower (%):	Not Determined
Flammability Limits in Air - Upper (g/m^3):	Not Determined
Flammability Limits in Air - Upper (%):	Not Determined
Vapor Pressure @ 20 C (mmHg):	Not Determined
Vapor Density (Air=1):	Not Determined
Percent Volatiles:	Not Determined
Evaporation Rate (Butyl Acetate=1):	Not Determined
Solubility in Water (g/100ml):	Disperses
Solubility in Solvents (g/100ml):	Not Determined
VOCs (g/l):	Not Determined
Viscosity, Dynamic @ 20 C (centipoise):	Not Determined
Viscosity, Kinematic @ 20 C (centistokes):	Not Determined
Partition Coefficient/n-Octanol/Water:	Not Determined
Molecular Weight (g/mole):	Not Determined
Decomposition Temperature (C):	Not Determined

10. STABILITY AND REACTIVITY

Stability Data: Stable

Hazardous Polymerization: Will Not Occur

Conditions to Avoid None anticipated

Incompatibility (Materials to Avoid) Strong oxidizers.

Hazardous Decomposition Products Carbon monoxide and carbon dioxide.

Additional Guidelines Not Applicable

11. TOXICOLOGICAL INFORMATION

Principle Route of Exposure Eye or skin contact, inhalation.

Sympotoms related to exposure

Acute Toxicity

Inhalation May cause allergic respiratory reaction. May cause mild respiratory irritation.

Eye Contact May cause mild eye irritation.

Skin Contact None known.

Ingestion None known

Chronic Effects/Carcinogenicity No data available to indicate product or components present at greater than 1% are chronic health hazards.

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Hemicellulase enzyme	9012-54-8	> 2000 mg/kg (Rat)	No data available	No data available

12. ECOLOGICAL INFORMATION

Ecotoxicological Information

Ecotoxicity Product

Acute Fish Toxicity: Not determined

Acute Crustaceans Toxicity: Not determined

Acute Algae Toxicity: Not determined

Ecotoxicity Substance

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Daphnia Magna (Water Flea)
Hemicellulase enzyme	9012-54-8	No information available	No information available	No information available	EC50: > 39.5 mg/L (Daphnia magna)

Persistence and degradability

Readily biodegradable

Bioaccumulative potential

Does not bioaccumulate

Mobility in soil

No information available

Results of PBT and vPvB assessment

No information available.

Other adverse effects

13. DISPOSAL CONSIDERATIONS

Disposal Method Bury in a licensed landfill according to federal, state, and local regulations.

Contaminated Packaging Follow all applicable national or local regulations.

14. TRANSPORT INFORMATION

Land Transportation

ADR
Not restricted

Air Transportation

ICAO/IATA
Not restricted

Sea Transportation

IMDG
Not restricted

Other Transportation Information

Labels: None

15. REGULATORY INFORMATION

Chemical Inventories

Australian AICS Inventory	All components listed on inventory or are exempt.
New Zealand Inventory of Chemicals	All components listed on inventory or are exempt.
US TSCA Inventory	All components listed on inventory or are exempt.
EINECS Inventory	This product, and all its components, complies with EINECS
Classification	Xn - Harmful.
Risk Phrases	R42 May cause sensitization by inhalation.
Safety Phrases	S2 Keep out of reach of children. S22 Do not breathe dust. S24 Avoid contact with skin. S36/37 Wear suitable protective clothing and gloves.

16. OTHER INFORMATION

The following sections have been revised since the last issue of this SDS
Not applicable

HALLIBURTON

MATERIAL SAFETY DATA SHEET

Product Trade Name: **CLWGAU421**

Revision Date: 05-Sep-2012

1. IDENTIFICATION OF THE SUBSTANCE/PREPARATION AND OF THE COMPANY/UNDERTAKING

Statement of Hazardous Nature Non-Hazardous according to the criteria of NOHSC, Non-Dangerous Goods according to the criteria of ADG.

Manufacturer/Supplier

Halliburton/Baroid Australia Pty. Ltd.
15 Marriott Road
Jandakot
WA 6164
Australia

ACN Number: 009 000 775
Telephone Number: 61 (08) 9455 8300
Fax Number: 61 (08) 9455 5300

Product Emergency Telephone
Australia: 08-64244950
Papua New Guinea: 05 1 281 575 5000
New Zealand: 06-7559274

Fire, Police & Ambulance - Emergency Telephone
Australia: 000
Papua New Guinea: 000
New Zealand: 111

Identification of Substances or Preparation

Product Trade Name: CLWGAU421
Synonyms: None
Chemical Family: Carbohydrate
UN Number: None
Dangerous Goods Class: None
Subsidiary Risk: None
Hazchem Code: None Allocated
Poisons Schedule: None Allocated
Application: Gelling Agent

Prepared By

Chemical Compliance
Telephone: 1-580-251-4335
e-mail: fdunexchem@halliburton.com

2. COMPOSITION/INFORMATION ON INGREDIENTS

Substances	CAS Number	PERCENT	Australia NOHSC	New Zealand WES	ACGIH TLV-TWA
Polysaccharide	Proprietary	60 - 100%	Not applicable	Not applicable	Not applicable

Non-Hazardous Substance to Total of 100%

3. HAZARDS IDENTIFICATION

Hazard Overview	May cause eye, skin, and respiratory irritation. Airborne dust may be explosive.
Risk Phrases	None
HSNO Classification	9.1C Harmful in the aquatic environment

4. FIRST AID MEASURES

Inhalation	If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.
Skin	Wash with soap and water. Get medical attention if irritation persists.
Eyes	In case of contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention if irritation persists.
Ingestion	Do NOT induce vomiting. Give nothing by mouth. Obtain immediate medical attention.
Notes to Physician	Not Applicable

5. FIRE FIGHTING MEASURES

Suitable Extinguishing Media	Water fog, carbon dioxide, foam, dry chemical.
Extinguishing media which must not be used for safety reasons	None known.
Special Exposure Hazards	Organic dust in the presence of an ignition source can be explosive in high concentrations. Good housekeeping practices are required to minimize this potential.
Special Protective Equipment for Fire-Fighters	Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. ACCIDENTAL RELEASE MEASURES

Personal Precautionary Measures	Avoid creating and breathing dust. Slippery when wet.
Environmental Precautionary Measures	None known.
Procedure for Cleaning / Absorption	Scoop up and remove.

7. HANDLING AND STORAGE

Handling Precautions	Wash hands after use. Launder contaminated clothing before reuse. Avoid contact with eyes, skin, or clothing. Avoid creating or inhaling dust. Avoid dust accumulations. Slippery when wet. Ground and bond containers when transferring from one container to another.

Storage Information Store in a well ventilated area. Store away from oxidizers. Keep container closed when not in use. Store in a cool, dry location. Keep from heat, sparks, and open flames. Product has a shelf life of 24 months.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls A well ventilated area to control dust levels. Local exhaust ventilation should be used in areas without good cross ventilation.

Respiratory Protection If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear a NIOSH certified, European Standard EN 149, or equivalent respirator when using this product. Selection of and instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional.

Not normally needed. But if significant exposures are possible then the following respirator is recommended:
Dust/mist respirator. (N95, P2/P3)

Hand Protection Normal work gloves.

Skin Protection Normal work coveralls.

Eye Protection Wear safety glasses or goggles to protect against exposure.

Other Precautions Eyewash fountains and safety showers must be easily accessible.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical State:	Powder
Color:	White to off white
Odor:	Odorless
pH:	6.5-8 (1%)
Specific Gravity @ 20 C (Water=1):	1.6
Density @ 20 C (kg/l):	Not Determined
Bulk Density @ 20 C (kg/m^3):	750
Boiling Point/Range (C):	Not Determined
Freezing Point/Range (C):	Not Determined
Pour Point/Range (C):	Not Determined
Flash Point/Range (C):	Not Determined
Flash Point Method:	Not Determined
Autoignition Temperature (C):	> 370
Flammability Limits in Air - Lower (g/m^3):	Not Determined
Flammability Limits in Air - Lower (%):	Not Determined
Flammability Limits in Air - Upper (g/m^3):	Not Determined
Flammability Limits in Air - Upper (%):	Not Determined
Vapor Pressure @ 20 C (mmHg):	Not Determined
Vapor Density (Air=1):	Not Determined
Percent Volatiles:	Not Determined
Evaporation Rate (Butyl Acetate=1):	Not Determined
Solubility in Water (g/100ml):	Forms gel
Solubility in Solvents (g/100ml):	Not Determined
VOCs (g/l):	Not Determined
Viscosity, Dynamic @ 20 C (centipoise):	Not Determined
Viscosity, Kinematic @ 20 C (centistokes):	Not Determined
Partition Coefficient/n-Octanol/Water:	Not Determined
Molecular Weight (g/mole):	Not Determined
Decomposition Temperature (C):	Not Determined

10. STABILITY AND REACTIVITY

Stability Data:	Stable
Hazardous Polymerization:	Will Not Occur
Conditions to Avoid	None known.
Incompatibility (Materials to Avoid)	Strong oxidizers.
Hazardous Decomposition Products	Carbon monoxide and carbon dioxide.
Additional Guidelines	Not Applicable

11. TOXICOLOGICAL INFORMATION

Principle Route of Exposure	Eye or skin contact, inhalation.

Sympotoms related to exposure

Inhalation	May cause mild respiratory irritation. In high air concentrations: May impede respiration.
Skin Contact	May cause an allergic skin reaction. Prolonged or repeated contact may cause skin irritation.
Eye Contact	May cause mild eye irritation.
Ingestion	May cause allergic reaction.
Aggravated Medical Conditions	None known.
Chronic Effects/Carcinogenicity	No data available to indicate product or components present at greater than 1% are chronic health hazards.
Other Information	None known.

Toxicity Tests

Oral Toxicity:	Not determined
Dermal Toxicity:	Not determined
Inhalation Toxicity:	Not determined
Primary Irritation Effect:	Not determined
Carcinogenicity	Not determined
Genotoxicity:	Not determined
Reproductive / Developmental Toxicity:	Not determined

12. ECOLOGICAL INFORMATION

Mobility (Water/Soil/Air)	Not determined
Persistence/Degradability	Readily biodegradable

Bio-accumulation Not determined

Ecotoxicological Information

Acute Fish Toxicity: Not determined
Acute Crustaceans Toxicity: Not determined
Acute Algae Toxicity: Not determined

Chemical Fate Information Not determined

Other Information Not applicable

13. DISPOSAL CONSIDERATIONS

Disposal Method Bury in a licensed landfill according to federal, state, and local regulations.

Contaminated Packaging Follow all applicable national or local regulations.

14. TRANSPORT INFORMATION

Land Transportation

ADR
Not restricted

Air Transportation

ICAO/IATA
Not restricted

Sea Transportation

IMDG
Not restricted

Other Transportation Information

Labels: None

15. REGULATORY INFORMATION

Chemical Inventories

Australian AICS Inventory All components listed on inventory or are exempt.
New Zealand Inventory of Chemicals All components listed on inventory or are exempt.
US TSCA Inventory All components listed on inventory or are exempt.
EINECS Inventory This product, and all its components, complies with EINECS

Classification Not Classified

Risk Phrases None

Safety Phrases None

2. HAZARDS IDENTIFICATION

Statement of Hazardous Nature Non-Hazardous according to the criteria of NOHSC, Non-Dangerous Goods according to the criteria of ADG.

Hazard Overview May cause mild eye, skin, and respiratory irritation. Organic dust in the presence of an ignition source can be explosive in high concentrations. Good housekeeping practices are required to minimize this potential.

Classification None

Risk Phrases None

Safety Phrases None

HSNO Classification
6.3B Mildly irritating to the skin
6.5A Respiratory sensitisers
6.5B Contact sensitisers
9.1D Slightly harmful in the aquatic environment

3. COMPOSITION/INFORMATION ON INGREDIENTS

Substances	CAS Number	PERCENT (w/w)	Australia NOHSC	New Zealand WES	ACGIH TLV-TWA
Contains no hazardous substances	Mixture	60 - 100%	Not applicable	Not applicable	Not applicable

Non-Hazardous Substance to Total of 100%

4. FIRST AID MEASURES

Inhalation If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Skin Wash with soap and water. Get medical attention if irritation persists.

Eyes In case of contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention if irritation persists.

Ingestion Under normal conditions, first aid procedures are not required.

Notes to Physician Not Applicable

5. FIRE FIGHTING MEASURES

Suitable Extinguishing Media
Water fog, carbon dioxide, foam, dry chemical.

Extinguishing media which must not be used for safety reasons
None known.

Special Exposure Hazards Decomposition in fire may produce toxic gases. Organic dust in the presence of an ignition source can be explosive in high concentrations. Good housekeeping practices are required to minimize this potential.

Special Protective Equipment for Fire-Fighters Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. ACCIDENTAL RELEASE MEASURES

Personal Precautionary Measures Use appropriate protective equipment. Avoid creating and breathing dust.

Environmental Precautionary Measures	Prevent from entering sewers, waterways, or low areas.
Procedure for Cleaning / Absorption	Scoop up and remove.

7. HANDLING AND STORAGE

Handling Precautions	Avoid contact with eyes, skin, or clothing. Avoid creating or inhaling dust.
Storage Information	Store away from oxidizers. Store in a cool, dry location. Product has a shelf life of 24 months.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls	Use in a well ventilated area.
Respiratory Protection	Not normally needed. But if significant exposures are possible then the following respirator is recommended: Dust/mist respirator. (N95, P2/P3)
Hand Protection	Normal work gloves.
Skin Protection	Normal work coveralls.
Eye Protection	Wear safety glasses or goggles to protect against exposure.
Other Precautions	None known.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical State:	Solid
Color:	Off white
Odor:	Bean
pH:	6.5-7.5
Specific Gravity @ 20 C (Water=1):	1.42 -1.47
Density @ 20 C (kg/l):	Not Determined
Bulk Density @ 20 C (kg/M3):	Not Determined
Boiling Point/Range (C):	Not Determined
Freezing Point/Range (C):	Not Determined
Pour Point/Range (C):	Not Determined

SAFETY DATA SHEET

GBW-30 BREAKER

Revision Date: 20-Jun-2016 **Revision Number:** 30

1. Product Identifier & Identity for the Chemical

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Non-Dangerous Goods according to the criteria of ADG.

1.1. Product Identifier

Product Name GBW-30 BREAKER

Other means of Identification

Synonyms None

Hazardous Material Number: HM000762

Recommended use of the chemical and restrictions on use

Recommended Use Breaker

Uses advised against No information available

Supplier's name, address and phone number

Manufacturer/Supplier

Halliburton Australia Pty. Ltd.
15 Marriott Road
Jandakot
WA 6164
Australia

ACN Number: 009 000 775
Telephone Number: + 61 1 800 686 951
Fax Number: 61 (08) 9455 5300

E-mail Address fdunexchem@halliburton.com

Emergency phone number

+ 61 1 800 686 951

Australian Poisons Information Centre

24 Hour Service: - 13 11 26

Police or Fire Brigade: - 000 (exchange): - 1100

2. Hazard Identification

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Non-Dangerous Goods according to the criteria of ADG.

Classification of the hazardous chemical

Respiratory Sensitization	Category 1 - H334

Label elements, including precautionary statements

Hazard pictograms

Signal Word Danger

Hazard Statements: H334 - May cause allergy or asthma symptoms or breathing difficulties if inhaled

Precautionary Statements

Prevention P261 - Avoid breathing dust/fume/gas/mist/vapors/spray
P285 - In case of inadequate ventilation wear respiratory protection

Response P304 + P341 - IF INHALED: If breathing is difficult, remove to fresh air and keep at rest in a position comfortable for breathing
P342 + P311 - If experiencing respiratory symptoms: Call a POISON CENTER or doctor/physician

Storage None

Disposal P501 - Dispose of contents/container in accordance with local/regional/national/international regulations

Contains

Substances	**CAS Number**
Hemicellulase enzyme	9012-54-8

Other hazards which do not result in classification
This mixture contains no substance considered to be persistent, bioaccumulating nor toxic (PBT).
This mixture contains no substance considered to be very persistent nor very bioaccumulating (vPvB).

For the full text of the H-phrases mentioned in this Section, see Section 16

3. Composition/information on Ingredients

Substances	CAS Number	PERCENT (w/w)	GHS Classification - Australia
Hemicellulase enzyme	9012-54-8	10 - 30%	Resp. Sens. 1 (H334)

4. First aid measures

Description of necessary first aid measures

Inhalation If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Eyes In case of contact, immediately flush eyes with plenty of water for at least 15 minutes and get medical attention if irritation persists.

Skin Wash with soap and water. Get medical attention if irritation persists.

Ingestion Under normal conditions, first aid procedures are not required.

Symptoms caused by exposure
May cause allergic respiratory reaction.

Medical Attention and Special Treatment

Notes to Physician Treat symptomatically

5. Fire Fighting Measures

Suitable extinguishing equipment
Suitable Extinguishing Media
All standard fire fighting media
Extinguishing media which must not be used for safety reasons
None known.

Specific hazards arising from the chemical
Special exposure hazards in a fire
Organic dust in the presence of an ignition source can be explosive in high concentrations. Good housekeeping practices are required to minimize this potential.

Special protective equipment and precautions for fire fighters
Special protective equipment for firefighters
Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. Accidental release measures

6.1. Personal precautions, protective equipment and emergency procedures
Use appropriate protective equipment. Avoid creating and breathing dust. Avoid contact with skin, eyes and clothing. Ensure adequate ventilation. Evacuate all persons from the area.

6.2. Environmental precautions
Prevent from entering sewers, waterways, or low areas.

6.3. Methods and material for containment and cleaning up
Scoop up and remove.

7. Handling and storage

7.1. Precautions for safe handling
Handling Precautions
Avoid creating or inhaling dust. Ensure adequate ventilation. Avoid contact with eyes, skin, or clothing. Wash hands after use. Launder contaminated clothing before reuse. Use appropriate protective equipment.
Hygiene Measures
Handle in accordance with good industrial hygiene and safety practice.

7.2. Conditions for safe storage, including any incompatibilities
Storage Information
Store away from oxidizers. Store in a cool, dry location. Product has a shelf life of 12 months.
Other Guidelines
No information available

8. Exposure Controls/Personal Protection

Control parameters - exposure standards, biological monitoring
Exposure Limits

Substances	CAS Number	Australia NOHSC	ACGIH TLV-TWA
Hemicellulase enzyme	9012-54-8	Not applicable	Not applicable

Appropriate engineering controls
Engineering Controls Use in a well ventilated area.

Personal protective equipment (PPE)
Personal Protective Equipment If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.

Respiratory Protection	If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear a NIOSH certified, European Standard EN 149, AS/NZS 1715:2009, or equivalent respirator when using this product. Selection of and instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional. Dust/mist respirator. (N95, P2/P3)
Hand Protection	Normal work gloves.
Skin Protection	Normal work coveralls.
Eye Protection	Wear safety glasses or goggles to protect against exposure.
Other Precautions	None known.
Environmental Exposure Controls	Do not allow material to contaminate ground water system

9. Physical and Chemical Properties

9.1. Information on basic physical and chemical properties

Physical State:	Powder	**Color**	White
Odor:	Odorless	**Odor Threshold:**	No information available

Property Remarks/ - Method	Values
pH:	7
Freezing Point / Range	No data available
Melting Point / Range	No data available
Boiling Point / Range	No data available
Flash Point	No data available
Evaporation rate	No data available
Vapor Pressure	No data available
Vapor Density	No data available
Specific Gravity	1.5
Water Solubility	Soluble in water
Solubility in other solvents	No data available
Partition coefficient: n-octanol/water	No data available
Autoignition Temperature	No data available
Decomposition Temperature	No data available
Viscosity	No data available
Explosive Properties	No information available
Oxidizing Properties	No information available

9.2. Other information

VOC Content (%)	No data available

10. Stability and Reactivity

10.1. Reactivity
Not expected to be reactive.
10.2. Chemical stability
Stable
10.3. Possibility of hazardous reactions
Will Not Occur
10.4. Conditions to avoid
None anticipated
10.5. Incompatible materials
Strong oxidizers.
10.6. Hazardous decomposition products
Carbon monoxide and carbon dioxide.

11. Toxicological Information

Information on routes of exposure

Principle Route of Exposure	Eye or skin contact, inhalation.

Symptoms related to exposure

Most Important Symptoms/Effects

May cause allergic respiratory reaction.

Numerical measures of toxicity

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Hemicellulase enzyme	9012-54-8	> 2000 mg/kg (Rat) (Similar substance) > 10000 mg/kg (Rat) > 8000 mg/kg (Mouse) > 2880 mg/kg (Rat)	No data available	> 3.5 mg/L (Rat) 4h > 4.86 mg/L (Rat) 4h

Immediate, delayed and chronic health effects from exposure

Inhalation May cause allergic respiratory reaction. May cause mild respiratory irritation.

Eye Contact May cause mild eye irritation.

Skin Contact None known.

Ingestion None known.

Chronic Effects/Carcinogenicity No data available to indicate product or components present at greater than 0.1% are chronic health hazards.

Exposure Levels

No data available

Interactive effects

None known.

Data limitations

No data available

Substances	CAS Number	Skin corrosion/irritation
Hemicellulase enzyme	9012-54-8	Non-irritating to the skin (Rabbit)

Substances	CAS Number	Serious eye damage/irritation
Hemicellulase enzyme	9012-54-8	Non-irritating to the eye (Rabbit)

Substances	CAS Number	Skin Sensitization
Hemicellulase enzyme	9012-54-8	No information available

Substances	CAS Number	Respiratory Sensitization
Hemicellulase enzyme	9012-54-8	May cause sensitization by inhalation

Substances	CAS Number	Mutagenic Effects
Hemicellulase enzyme	9012-54-8	In vitro tests did not show mutagenic effects.

Substances	CAS Number	Carcinogenic Effects
Hemicellulase enzyme	9012-54-8	No information available

Substances	CAS Number	Reproductive toxicity
Hemicellulase enzyme	9012-54-8	No information available

Substances	CAS Number	STOT - single exposure
Hemicellulase enzyme	9012-54-8	No significant toxicity observed in animal studies at concentration requiring classification.

Substances	CAS Number	STOT - repeated exposure
Hemicellulase enzyme	9012-54-8	No significant toxicity observed in animal studies at concentration requiring classification.

Substances	CAS Number	Aspiration hazard
Hemicellulase enzyme	9012-54-8	Not applicable

12. Ecological Information

Ecotoxicity

Product Ecotoxicity Data

No data available

Substance Ecotoxicity Data

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Hemicellulase enzyme	9012-54-8	EC50 (72h) > 99 mg/L (Pseudokirchnerella subcapitata) EC50 (72h) > 52.1 mg/L (Pseudokirchneriella subcapitata)	LC50 (96h) > 100 mg/L (Oncorhynchus mykiss) LC50 (96h) > 52.1 mg/L (Oncorhynchus mykiss)	No information available	EC50 (48h) > 39.5 mg/L (Daphnia magna) EC50 (48h) > 99 mg/L (Daphnia magna) EC50 (48h) > 52.1 mg/L (Daphnia magna)

12.2. Persistence and degradability

Substances	CAS Number	Persistence and Degradability
Hemicellulase enzyme	9012-54-8	Readily biodegradable (129% @ 28d)

12.3. Bioaccumulative potential

Does not bioaccumulate.

Substances	CAS Number	Log Pow
Hemicellulase enzyme	9012-54-8	-2.95 (Similar substance)

12.4. Mobility in soil

Substances	CAS Number	Mobility
Hemicellulase enzyme	9012-54-8	No information available

12.6. Other adverse effects

Endocrine Disruptor Information

This product does not contain any known or suspected endocrine disruptors

13. Disposal Considerations

Safe handling and disposal methods

Bury in a licensed landfill according to federal, state, and local regulations.

Disposal of any contaminated packaging

Follow all applicable national or local regulations.

Environmental regulations

Not applicable

14. Transport Information

Transportation Information

UN Number Not restricted
UN proper shipping name: Not restricted
Transport Hazard Class(es): Not applicable
Packing Group: Not applicable
Environmental Hazards: Not applicable

Special precautions during transport

None

HazChem Code

None Allocated

15. Regulatory Information

Safety, health and environmental regulations specific for the product

International Inventories

Australian AICS Inventory	All components are listed on the AICS or are subject to a relevant exemption, permit, or assessment certificate.
New Zealand Inventory of Chemicals	All components are listed on the NZIoC or are subject to a relevant exemption, permit, or assessment certificate.
EINECS (European Inventory of Existing Chemical Substances)	This product, and all its components, complies with EINECS
US TSCA Inventory	All components listed on inventory or are exempt.
Canadian Domestic Substances List (DSL)	All components listed on inventory or are exempt.

Poisons Schedule number

APPENDIX H.6 RISK ASSESSMENT – SCOTIA BE-9 ALGACIDE AND KCL SYSTEM

1.0 Introduction

Consistent with the risk assessment methodology utilised in Hydraulic Fracturing Risk Assessment Compendium (RA Compendium), Santos Ltd. (Santos) – refer Section 5, EHS Support LLC has used a weight-of-evidence approach to evaluate the potential for human health and environmental (e.g., ecological) risks as a result of use of production water potentially containing hydraulic fracturing chemicals. It is proposed that production water from the Scotia fields (potentially containing hydraulic fracturing chemicals) will be blended with groundwater to facilitate irrigation to land without treatment. A low toxicity hydraulic fracturing fluid system has been selected for use in the Scotia comprising KCL and a biocide (comprising either BE-9 or Algacide).

The methodology used in the Quantitative Risk Assessment (QRA) was designed to meet Conditions 49e and 49f of the 2 October 2011 approval under the *Environmental Protection and Biodiversity Conservation Act 1999* (EPBC 2008/4059) and the Environmental Amendment (EA) conditions to assess the toxicity of the mixtures.

GLNG is a Santos PETRONAS Total KOGAS project.
Santos | PETRONAS | TOTAL | KOGAS

2.0 Qualitative Risk Assessment and Evaluation

2.1 Chemicals Evaluated

The Scotia BE-9 Algacide and KCL System was assessed. The list of individual chemicals is presented in **Table 1** below. A mass balance of the chemicals is provided as **Appendix 1**.

Material Safety Data Sheets (MSDSs) for each of the hydraulic fluid chemicals are included in **Appendix 2** of this report. Information regarding the chemical and physical properties of the individual chemicals listed below as well as the approximate percentage present in the hydraulic fracturing system can be found on the MSDSs.

While none of the fracturing fluid chemicals identified contain benzene, toluene, ethylbenzene, xylenes (BTEX) or polycyclic aromatic hydrocarbons (PAHs), PAHs occur naturally in coal and it is possible that certain PAHs may naturally be present in the coal seam groundwater used in the hydraulic fracturing process.

Table 1: Hydraulic Fracturing Chemicals

Chemical	CAS Number
Glutaraldehyde	111-30-8
Tributyl Tetradecyl Phosphonium Chloride	81741-28-8
Potassium chloride	7447-40-7

2.2 Risk Assessment Framework and Findings

As outlined in **Section 5.0** of the RA Compendium, a systematic weight of evidence approach has been used for the assessment of risks associated with hydraulic fracturing chemicals. This same methodology has been utilised to complete the RA for the Scotia BE-9 Algacide and KCL System and the proposed land irrigation activities. A detailed discussion of the methodologies and approach is contained within the RA Compendum and for consistency with the risk assessment methodology (and to streamline the text in this document) the key sections are referenced below. The assessment including the following evaluations:

Qualitative Assessment Methodologies

- Exposure Assessment
- Mass Balance of Fluid System

Quantitative Risk Assessment Methodologies

- Quantitative Human Health Risk Assessment (HHRA)
- Quantitative Ecological Risk Assessment for Terrestrial and Aquatic Receptors.

2.3 Exposure Assessment

As discussed in **Section 7.0** of the RA Compendium, the exposure assessment identified receptors potentially exposed to chemicals of potential concern (COPC) identified for the study, and outlines the exposure pathways by which the receptors may come in to contact with the COPCs. A detailed exposure assessment was not conducted in the qualitative RA.

2.4 Mass Balance of Fluid System

A quantitative mass balance calculation was undertaken to identify the amount of each chemical additive of the hydraulic fracturing fluid system. The results of the mass balance calculations are presented in **Appendix 1**.

2.5 Quantitative Risk Assessment

In accordance with the methodologies presented in **Section 8.0**, a QRA was conducted on theoretical datasets for those chemicals identified in the Scotia BE-9/Algacide and KCL System. The QRA approach evaluates the toxicity of the individual substances, and characterises the cumulative risks of the total effluent toxicity and ecotoxicity.

Generally, this methodology includes the identification of the hazards posed by constituents in the flowback water, compilation of the toxicity criteria for each constituent, development of exposure models to estimate the daily intake of the constituents, and calculations of individual constituent hazard quotients (daily intake divided by the toxicity criteria) and a cumulative constituent hazard index (HI) for each potentially complete exposure pathway for each human or terrestrial receptor.

Potential complete exposure pathways to the storage and land application of flowback/production water from hydraulically stimulated wells potential risks to humans, terrestrial and aquatic receptors from the potential storage and accidental releases are evaluated in the QRA.

The QRA considered the following specific exposure pathways:

1. Exposure of worker to flowback water contained within flowback storage tank.
2. Exposure of worker to flowback water used in the irrigation area.
3. Exposure of terrestrial receptors (e.g., livestock and wildlife) to flowback water contained within the flowback storage tank.
4. Exposure of aquatic receptors to flowback water in the situation of an accidental release, such as from piping or a release from the flowback storage tank. These potential releases could include a failure of containment systems, overtopping of the dam or in an extreme situation (considered highly unlikely) structural failure of the dam itself.

3.1 Exposure Assessment

The purpose of the exposure assessment in the QRA was to predict the magnitude and frequency of potential human exposure to each COPC following the methodologies presented in **Section 8.1**. A conceptual site model (CSM) was developed which describes the potential receptors and exposure scenarios for the flowback water used in this exposure assessment. The potential exposures to receptors were evaluated based on the potential for a complete exposure pathway.

As discussed in **Section 8.2**, exposure point concentrations (EPCs) were derived for the theoretical assessment; empirical data were not available for evaluation. The EPCs for the theoretical assessment were calculated by estimating the mass and discharge flow of the COPCs in the flowback water.

3.2 Human Health QRA

A human health hazard assessment was conducted according to the methodologies presented in **Section 8.4**. The purpose of the hazard assessment process was to summarise the environmental data, and to address the toxicological assessment of the COPCs that will be evaluated further in the RA process.

Exposure assumptions for the worker scenario were developed based on default or site-specific assumptions (**Section 8.4**). This receptor exposure pathway includes an adult worker, either exposed at the well pad tank or in the irrigation field, that may come in contact with the flowback water exposure scenarios. For the well pad worker, exposure may occur for approximately 1 hour/day, 250 days/year, for 3 years with potential incidental ingestion [of 50 millilitres (ML) of water] and dermal contact (e.g., water contact of arms and head). This is based on the expected operational period for a typical well pad. For the irrigation worker, exposure may occur for approximately 4 hours/day, 250 days/year, for 20 years with potential incidental ingestion [of 50 ML of water] and dermal contact (e.g., water contact of arms and head). This is based on the expected use of an irrigation field from multiple well pad tansk. The exposure parameters used in the QRA are presented on **Tables 2** and **3**.

Calculation of intake of COPCs was performed using the equations presented below:

Ingestion of water:

$$Intake\ (mg/kg-day)\ =\ (CW\ x\ IR\ X\ EF\ X\ ED)\ /\ (BW\ x\ AT)$$

Dermal contact with water:

$$Absorbed\ dose\ (mg/kg-day)\ =\ (CW\ x\ SA\ x\ DP\ x\ ET\ x\ EF\ x\ ED\ x\ CF)\ /\ (BW\ x\ AT)$$

Where:

CW = concentration in water (mg/l)
ET = exposure time (hr/day or hours/hours)
EF = exposure frequency (day/year)
ED = exposure duration (years)
CF = correction factor (1 x 10-3 l/cm3)
AT = averaging time (days)
IR = ingestion rate (l/hr)
BW = body weight (kg)
SA = skin surface area available for contact (cm2/d)
DP = dermal permeability factor (Kp – cm/hr).

3.3 Toxicity Assessment

A toxicity assessment was conducted to determine the relationship between the dose of a COPC taken into the body, and the probability that an adverse effect will result from that dose. Quantitative estimates of the potency of COPCs include two sets of toxicity values, one for genotoxic carcinogens and one for other non-genotoxic carcinogens and non-carcinogenic effects. Detailed toxicological profiles are included as **Appendix 3**. The derivation of Oral Reference Dose and Drinking Water Guideline Values are presented in **Table 4**.

3.4 Exposure Point Concentration

As presented above, the exposure scenarios are based on anticipated conditions, and the potential for exposure to the theoretical estimate of exposure. EPCs for the exposure assessment were calculated using the results of theoretical fate and transport modelling calculations and the existing environmental conditions within the fracturing fluids flowback storage ponds, and the flowback used in the irrigation fields.

To assess the potential flux of hydraulic fracturing chemicals to the environment, vendor disclosures for the hydraulic fracturing fluid systems were reviewed, and the chemical concentrations of key inputs were determined. It should be noted that two potential biocides (only one will be used at a time) have

been identified and the maximum and minimum concentrations of these chemicals with the following Scenarios used to estimate the EPCs:

- Scenario 1: a highly conservative base case where production water concentrations are equal to the concentrations in the hydraulic fracturing fluid system; and,

- Scenario 2: likely conditions where down well losses and dilution from other wells will lead to a production water quality with concentrations 50% reduced from the hydraulic fracturing fluid system. The losses accounting for this reduction, include dilution, ion exchange, sorption and bio-decay in the subsurface.

For the theoretical calculations, the estimated chemical concentrations of the COPCs in the Scotia BE-9/Algacide and KCL System, as presented in **Appendix 1**, were used to estimate the potential concentrations in water within the fracturing fluids flowback storage ponds and the irrigation fields.

The flowback water will be contained within production waterstorage tank and then blended with groundwater. The storage time in tanks is anticipated to be between 3 and 30 days where biological degradation of some constituent will occur. Water will be pumped from the tank for a range of beneficial uses including transfer to the irrigation area on an as needed basis. Therefore, the concentration of COPCs in the flowback storage tank was adjusted, where applicable, to account for the biodegradation of constituents over time. The biodegradation information was obtained from the Organisation for Economic Cooperation and Development (OECD) ready tests (OECD, 1992) that were developed as a first tier testing scheme to provide preliminary screening of organic chemicals. The ready tests are stringent screening tests that are conducted under aerobic conditions in which a high concentration of the test substance is used, and biodegradation is measured by non-specific parameters including dissolved organic carbon, biochemical oxygen demand and carbon dioxide production. **Table 5** presents the environmental fate information that was used to assess biodegradation of COPCs, and that was applied at the time periods of 0, 30, 150 and 300 days from initial flowback.

The water quality data derived using these assumptions for the theoretical COPCs are presented in **Appendix 1**.

The theoretical EPCs for the four exposure time periods (0, 30, 150 and 300 days) were compared to human health toxicity-based screening levels, and the results of this comparison, including the ratio of exceedance of screening levels, is presented in **Appendix 4**.

3.5 Risk Estimation

Risk estimation was performed in accordance with the methodologies outlined in **Section 8.4**. The total target risk range for carcinogens was 1×10^{-4} to 1×10^{-6}; the target HI for non-threshold effects is less than or equal to 1.0.

No carcinogenic compounds are present in the stimulation fluids injected into the subsurface and as a result, only non-carcinogenic risks were calculated.

The results of the theoretical assessments for Scotia BE-9/Algacide and KCL System for the two worker exposure scenarios (day 0 and day 150, Scotia BE-9 Algacide and KCL System events) are summarized in **Tables 6 through 9**. As discussed above, the theoretical assessment was conducted at the well pad sites and the irrigation fields.

The exposure scenarios include the Scotia BE-9 Algacide and KCL System event, as presented in **Appendix 1** for day 0 and day 150 from the production water storage tank. The absence of appreciable biodegradation of select constituents of concern did not result in appreciable declines in Hazard Indices (HI) over time. The operations worker (working at the well pad, gathering lines and tanks) had potential

unacceptable risks for the Scotia BE-9 Algacide and KCL System at Day 0 (HI=1.2, **Table 6**), and for day 150 (HI=1.2, **Table 7**). The irrigation field worker for day 0 had unacceptable risks for the Scotia BE-9 Algacide and KCL System (HI=1.2, **Table 8**), and for day 150 (HI=1.2, **Table 9**). All unacceptable risks were only associated with the ingestion of TTPC for the maximum concentration in the base case. Based on the likely operational conditions (with down well dilution and attenuation and blending in the water storage tank) no unacceptable risks were present (HI < 1).

On this basis and using the theoretical concentrations, no adverse effects are predicted on the workers in both exposure groups except under maximum conservative conditions for the estimated EPC.

3.6 Ecological Risk Assessment

As discussed in **Section 8.5**, a screening level ecological risk assessment (ERA) was conducted to evaluate the potential for adverse ecological effects to terrestrial and aquatic ecological receptors that may be exposed to residual levels of hydraulic fracturing chemicals in water stored, irrigated or potentially released to the environment.

3.7 Exposure Assessment

Terrestrial receptors evaluated in the ERA include domesticated livestock, large mammalian wildlife and small mammalian wildlife. Beef cattle were used to evaluate domesticated livestock, kangaroos evaluated for large mammalian wildlife, and dingos for small mammalian wildlife. Aquatic receptors evaluated included invertebrates and fishes.

The estimate for dose-based or intake rates for the assessment endpoints for wildlife representing domestic livestock and native mammalian species used the following general equation:

TI = Cwater x IRwater x EF x ED / BW x ED x 365 days/year

Where:

TI = Total intake of COPC (mg/kg/day)

Cwater = Concentration of COPC in water (mg/l)

IRwater = Ingestion rate (litres/day)

EF = Exposure frequency (days/year)

ED = Exposure duration (years)

BW = Body weight (kg).

Tables 10 through 12 provide the lift-history input values for ingestion rates, exposure frequency, exposure duration and BW.

3.8 Toxicity Assessment

To evaluate the potential for adverse ecological effects, toxicity reference values (TRVs) are selected as measurement endpoints for the ERA that will be used in the risk analysis. Detailed environmental profiles are included as **Appendix 5**. The TRVs are based on COPC levels that imply no adverse effects or levels that represent the lowest concentration at which adverse effects may occur. The ERA used two types of TRVs. The first TRV is a concentration-based TRV to evaluate the concentration of the selected COPC in the surface water and direct exposure by the aquatic ecological receptor. The determination of TRVs for freshwater was conducted according to the predicted no-effects concentration (PNEC) guidance in the Environmental Risk Assessment Guidance Manual for Industrial

Chemicals prepared by the Australian Environmental Agency (AEA, 2009). **Table 13** presents the COPC, the endpoint, NOEC [milligrams per litre (mg/L)], assessment factor and the aquatic PNEC (mg/L). The second TRV is a dose-based TRV to evaluate the intake dose of the selected COPC from exposure to surface water by ingestion. The calculated TRVs for each of the mammalian ecological receptors evaluated in the ERA are presented in the species-specific ecological risk models.

3.9 Exposure Point Concentration

EPCs for the exposure assessment were calculated using the results of theoretical fate and transport modelling calculations. The potentially affected flowback water that represents complete exposure pathways for the ecological receptors includes the surface water systems that were used to estimate the EPCs for the human health receptors. The EPCs for the ecological receptors were estimated assuming the same Scenarios, with exposure occurring in the irrigation area where irrigation water may pool and wildlife may drink from the standing water. **Appendix 1** presents the calculated EPCs for the ecological receptor exposure scenarios. The theoretical EPCs for the four exposure time periods (0, 30, 150, and 300 days) were compared to ecological based toxicity-based screening levels, and the results of this comparison, including the ratio of exceedance of screening levels, is presented in **Appenidix 6**.

Risks were characterised in accordance with the methodologies discussed in **Section 8.5.6**. The resulting ecological hazard quotient must be less than or equal to 1.0 for risks to be considered acceptable.

3.10 Estimation of Risk

The HI calculated for flowback water for aquatic risk were elevated above the acceptable level for the majority of COPCs evaluated (**Appendix 6**). Where large discharges of flowback water occur to surface water and/or flux dilution within the surface-water was insufficient, potential impacts on aquatic receptors could occur. As noted in the toxicity assessment section above, the lack of a robust aquatic toxicological database resulted in highly conservative aquatic screening values for the theoretical exposure scenario COPCs to be conservatively very low.

The results of the theoretical assessments for Scotia BE-9 Algacide and KCL System for the livestock cattle, kangaroo and dingo are summarized in **Tables 14 through 19**. The exposure scenarios include the Scotia BE-9 Algacide and KCL System EPCs presented in **Appendix 1** for day 0 and day 150 from the fracturing fluid well flowback. The modelled risks from Scotia BE-9/Algacide and KCL System chemicals in the flowback water were acceptable for the livestock cattle, kangaroo, and dingo for all exposure scenarios.

3.0 Summary of QRA Findings

An assessment was conducted using highly conservative theoretical calculations based on the chemicals utilised by in the hydraulic fracturing fluid system. This assessment assumed that a range of theoretical concentrations of injected chemicals would be present in the flowback/production water considering biodegradation rates, where applicable.

Consistent with the detailed Risk Assessments conducted for Hydraulic Fracturing no potentially complete exposure pathways were identified for groundwater. Potential exposures are limited to the aboveground storage and handling of flowback/production water and the proposed irrigation of water to land.

The two exposure scenarios modelled for the QRA were for an operations worker (well pad, gathering systems and water storage) and an irrigation worker (working in the irrigation area) being exposed to flowback water under various EPC Scenarios. Based on quantitative risk calculations, all potential risks for the various scenarios were acceptable except for the unacceptable risks that were associated with the ingestion of TTPC at the maximum concentration base case scenario. Considering the likely attenuation that will occur downhole (through sorption, dilution etc), the less conservative estimate is considered more representative of likely conditions within the irrigation area. Based on the chemicals proposed for use in the hydraulic fracturing fluid system no carcinogenic risks identified.

The modelled risks from Scotia BE-9 Algacide and KCL System chemicals in the flowback water were acceptable for the livestock cattle, kangaroo, and dingo for all EPC exposure scenarios. However, potential impacts could occur if releases of flowback water were to occur to aquatic environments. The presence of elevated salinity as well as biocides are key aquatic ecology stressors and would require high levels of dilution before adverse impacts could be prevented. The absence of watercourses in the immediate vicinity of the irrigation area, mitigation of potential impacts on aquatic systems will be managed through operational controls that minimize the potential for releases and manage irrigation rates to limit the potential for large-scale runoff.

A combination of management and operational controls will be implemented to eliminate and control the potential for exposures. These include:

- Worker training and hazard identification
- Use of appropriate personal protective equipment (gloves, etc.)
- Storage of production water in specifically designed tanks
- Management of irrigation rates to prevent ponding and runoff
- Routine operational and security patrols to prevent trespassing.

4.0 Conclusions

A weight-of-evidence evaluation of potential risks was performed for the Scotia BE-9/Algacide and KCL System. Based on the qualitative and quantitative risk characterisations, the overall risk to human health and the environment is low. Existing operational control activities employed by Santos are in place that will limit the potential risks to human health and the environment. These measures include:

- Occupational health and safety procedures implemented during hydraulic fracturing operations to prevent workers from direct contact with chemicals during spills and when handling flowback water or sediments;
- Construction of the irrigation areas away from sensitive receptors and watercourses to mitigate potential risks to aquatic receptors;
- Implementation of spill containment procedures during operations to prevent migration of and exposure to chemicals;
- Storage and management of production water within specially designed tanks; and
- Design and management of irrigation rates to prevent runoff and overland flow.

Identification of Substances or Preparation

Product Trade Name:	ALDACIDE® G ANTIMICROBIAL
Synonyms:	None
Chemical Family:	Aldehyde
UN Number:	UN3265
Dangerous Goods Class:	8
Subsidiary Risk:	None
Hazchem Code:	None Allocated
Poisons Schedule:	S6
Application:	Biocide

2. HAZARDS IDENTIFICATION

Statement of Hazardous Nature Hazardous according to the criteria of NOHSC, Dangerous Goods according to the criteria of ADG.

Hazard Overview

Keep out of reach of children May cause eye burns. May cause irreversible eye damage. May cause severe skin irritation. May be harmful if swallowed. May be harmful if inhaled May cause allergic skin reaction.

Classification

C - Corrosive.
Xn - Harmful.
N - Dangerous For The Environment.

Risk Phrases

R34 Causes burns.
R20/22 Harmful by inhalation and if swallowed.
R42/43 May cause sensitization by inhalation and skin contact.
R50/53 Very toxic to aquatic organisms, may cause long-term adverse effects in the aquatic environment.

Safety Phrases

S23 Do not breathe gas, fumes, vapour or spray.

S26 In case of contact with eyes, rinse immediately with plenty of water and seek medical advice.

S45 In case of accident or if you feel unwell, seek medical advice immediately.
S1/2 Keep locked up and out of reach of children.

S36/37/39 Wear suitable protective clothing, gloves and eye/face protection.

HSNO Classification

6.1A (Inhalation) Acutely Toxic Substances
6.5A Respiratory sensitisers
6.5B Contact sensitisers
6.9B Harmful to human target organs or systems
8.2B Corrosive to dermal tissue if exposed for greater than 3 mins
8.3A Corrosive to ocular tissue
9.1D Slightly harmful in the aquatic environment
9.2B Ecotoxic in the soil environment
9.3B Ecotoxic to terrestrial invertebrates

3. COMPOSITION/INFORMATION ON INGREDIENTS

Substances	CAS Number	PERCENT (w/w)	Australia NOHSC	New Zealand WES	ACGIH TLV-TWA
Glutaraldehyde	111-30-8	10 - 30%	0.1 ppm	STEL: 0.05 ppm	0.05 ppm

Non-Hazardous Substance to Total of 100%

4. FIRST AID MEASURES

Inhalation

If inhaled, remove from area to fresh air. Get medical attention if respiratory irritation develops or if breathing becomes difficult.

Skin

In case of contact, immediately flush skin with plenty of soap and water for at least 15 minutes. Get medical attention. Remove contaminated clothing and discard.

Eyes

Immediately flush eyes with large amounts of water for at least 30 minutes. Seek prompt medical attention.

Ingestion

Do NOT induce vomiting. Give nothing by mouth. Obtain immediate medical attention.

Notes to Physician	Probable mucosal damage may contraindicate the use of gastric lavage. No specific antidote. Treat symptomatically.

5. FIRE FIGHTING MEASURES

Suitable Extinguishing Media
Water fog, carbon dioxide, foam, dry chemical.

Extinguishing media which must not be used for safety reasons
None known.

Special Exposure Hazards	Decomposition in fire may produce toxic gases.
Special Protective Equipment for Fire-Fighters	Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. ACCIDENTAL RELEASE MEASURES

Personal Precautionary Measures	Use appropriate protective equipment. Use only competent persons for cleanup.
Environmental Precautionary Measures	Prevent from entering sewers, waterways, or low areas.
Procedure for Cleaning / Absorption	Isolate spill and stop leak where safe. Contain spill with sand or other inert materials. Scoop up and remove.

7. HANDLING AND STORAGE

Handling Precautions	Avoid contact with eyes, skin, or clothing. Avoid breathing vapors. Avoid breathing mist. Do not swallow. Wash hands after use. Launder contaminated clothing before reuse.
Storage Information	Store away from acids. Store away from alkalis. Keep container closed when not in use. Product has a shelf life of 36 months.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Engineering Controls	Use in a well ventilated area. Local exhaust ventilation should be used in areas without good cross ventilation. If vapors are strong enough to be irritating to the nose or eyes, the TLV is probably being exceeded and special ventilation or respiratory protection maybe required.
Respiratory Protection	If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear a NIOSH certified, European Standard EN 149, AS/NZS 1715:2009, or equivalent respirator when using this product. Selection of and instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional. Full Facepiece Respirator with Organic vapor cartridge with particulate prefilter.

Hand Protection	Chemical-resistant protective gloves (EN 374) Suitable materials for longer, direct contact (recommended: protection index 6, corresponding to > 480 minutes permeation time as per EN 374): Butyl rubber gloves. (>= 0.7 mm thickness) This information is based on literature references and on information provided by glove manufacturers, or is derived by analogy with similar substances. Please note that in practice the working life of chemical-resistant protective gloves may be considerably shorter than the permeation time determined in accordance with EN 374 as a result of the many influencing factors (e.g. temperature). If signs of wear and tear are noticed then the gloves should be replaced. Manufacturer's directions for use should be observed because of great diversity of types.
Skin Protection	Butyl coated apron or clothing.
Eye Protection	Splashproof chemical monogoggles or safety glasses with side shields in conjunction with a face shield. Do NOT wear contact lenses.
Other Precautions	Eyewash fountains and safety showers must be easily accessible.

9. PHYSICAL AND CHEMICAL PROPERTIES

Physical State:	Liquid
Color:	Clear light yellow
Odor:	Sharp
pH:	3.1-4.5
Specific Gravity @ 20 C (Water=1):	1.064
Density @ 20 C (kg/l):	1.064
Bulk Density @ 20 C (kg/M3):	Not Determined
Boiling Point/Range (C):	100.5
Freezing Point/Range (C):	-5 / -10
Pour Point/Range (C):	Not Determined
Flash Point/Range (C):	Not Determined
Flash Point Method:	Not Determined
Autoignition Temperature (C):	> 275
Flammability Limits in Air - Lower (g/m^3):	Not Determined
Flammability Limits in Air - Lower (%):	Not Determined
Flammability Limits in Air - Upper (g/m^3):	Not Determined
Flammability Limits in Air - Upper (%):	Not Determined
Vapor Pressure @ 20 C (mmHg):	0.2
Vapor Density (Air=1):	0.8
Percent Volatiles:	100
Evaporation Rate (Butyl Acetate=1):	0.9
Solubility in Water (g/100ml):	Soluble
Solubility in Solvents (g/100ml):	Not Determined
VOCs (g/l):	Not Determined
Viscosity, Dynamic @ 20 C (centipoise):	Not Determined
Viscosity, Kinematic @ 20 C (centistokes):	Not Determined
Partition Coefficient/n-Octanol/Water:	-0.333
Molecular Weight (g/mole):	Not Determined
Decomposition Temperature (C):	Not Determined

10. STABILITY AND REACTIVITY

Stability Data:	Stable
Hazardous Polymerization:	Will Not Occur
Conditions to Avoid	Keep away from heat, sparks and flame.

Incompatibility (Materials to Avoid) Strong acids. Strong alkalis.

Hazardous Decomposition Products Carbon monoxide and carbon dioxide.

Additional Guidelines Not Applicable

11. TOXICOLOGICAL INFORMATION

Principle Route of Exposure Eye or skin contact, inhalation.

Sympotoms related to exposure

Acute Toxicity

Inhalation Harmful if inhaled. Causes severe respiratory irritation. Vapors given off by heated product may be harmful. May cause allergic respiratory reaction. Inhalation of vapors may result in skin sensitization.

Eye Contact May cause eye burns. May cause permanent eye damage. High vapor concentration will cause irritation.

Skin Contact May cause skin burns. This product contains ingredients which may produce an allergic skin reaction. It should be treated as a skin sensitizer.

Ingestion Causes burns of the mouth, throat and stomach. Harmful if swallowed. Aspiration into the lungs may cause chemical pneumonitis including coughing, difficulty breathing, wheezing, coughing up blood and pneumonia, which can be fatal.

Chronic Effects/Carcinogenicity No data available to indicate product or components present at greater than 1% are chronic health hazards.

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Glutaraldehyde	111-30-8	252 mg/kg (Rat) 316 mg/kg (Rat)	> 2000 mg/kg (Rat) 560 µL/kg (Rabbit)	0.48 mg/L (Rat, 4h)

12. ECOLOGICAL INFORMATION

Ecotoxicological Information

Ecotoxicity Product

Acute Fish Toxicity: May be highly toxic to aquatic life.
LC50: (96 hour) 13 mg/l (Lepomis macrochirus)

Acute Crustaceans Toxicity: TLM48: 0.11 mg/l (Acartia tonsa)
TLM48: 29.73 mg/l (Daphnia magna)

Acute Algae Toxicity: EC50: 8.1 mg/l (Skeletonema costatum)

Ecotoxicity Substance

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Glutaraldehyde	111-30-8	EC50(72h): 0.61 mg/L (Desmodesmus subspicatus)	LC50: 7.8-22 mg/L (Lepomis macrochirus); LC50: 7.8-13 mg/L (Oncorhynchus mykiss); LC50: 5.4 mg/L (Pimephales promelas)	No information available	EC50(48h): 0.56 - 1.0 mg/L (Daphnia magna)

12.2. Persistence and degradability

Readily biodegradable

Substances	CAS Number	Persistence and Degradability

Glutaraldehyde	111-30-8	Readily biodegradable (90-100% @ 28d)

12.3. Bioaccumulative potential

Does not bioaccumulate

Substances	CAS Number	Log Pow
Glutaraldehyde	111-30-8	0.22

12.4. Mobility in soil

No information available

12.5. Results of PBT and vPvB assessment

No information available.

12.6. Other adverse effects

13. DISPOSAL CONSIDERATIONS

Disposal Method Disposal should be made in accordance with federal, state, and local regulations.

Contaminated Packaging Follow all applicable national or local regulations.

14. TRANSPORT INFORMATION

Australia Dangerous Goods

UN Number: UN3265
UN Proper Shipping Name: Corrosive Liquid, Acidic, Organic, N.O.S. (Contains Glutaraldehyde)
Transport Hazard Class(es): 8
Packing Group: III

IMDG/IMO

UN Number: UN3265
UN Proper Shipping Name: Corrosive Liquid, Acidic, Organic, N.O.S. (Contains Glutaraldehyde)
Transport Hazard Class(es): 8
Packing Group: III
Environmental Hazards: Not applicable
EMS: EmS F-A, S-B

IATA/ICAO

UN Number: UN3265
UN Proper Shipping Name: Corrosive Liquid, Acidic, Organic, N.O.S. (Contains Glutaraldehyde)
Transport Hazard Class(es): 8
Packing Group: III

Special Precautions for User: None

Transport in bulk according to Annex II of MARPOL 73/78 and the IBC Code: Not applicable

15. REGULATORY INFORMATION

Chemical Inventories

Australian AICS Inventory All components listed on inventory or are exempt.
New Zealand Inventory of Chemicals All components listed on inventory or are exempt.
US TSCA Inventory All components listed on inventory or are exempt.
EINECS Inventory This product, and all its components, complies with EINECS

Classification	C - Corrosive. Xn - Harmful. N - Dangerous For The Environment.
Risk Phrases	R34 Causes burns. R20/22 Harmful by inhalation and if swallowed. R42/43 May cause sensitization by inhalation and skin contact. R50/53 Very toxic to aquatic organisms, may cause long-term adverse effects in the aquatic environment.
Safety Phrases	S23 Do not breathe gas, fumes, vapour or spray. S26 In case of contact with eyes, rinse immediately with plenty of water and seek medical advice. S45 In case of accident or if you feel unwell, seek medical advice immediately. S1/2 Keep locked up and out of reach of children. S36/37/39 Wear suitable protective clothing, gloves and eye/face protection.

HALLIBURTON

SAFETY DATA SHEET

BE-9

Revision Date: 13-Oct-2017 **Revision Number:** 20

1. Product Identifier & Identity for the Chemical

Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

1.1. Product Identifier

Product Name BE-9

Other means of Identification

Synonyms None

Hazardous Material Number: HB006583

Recommended use of the chemical and restrictions on use

Recommended Use Biocide

Uses advised against No information available

Supplier's name, address and phone number

Manufacturer/Supplier Halliburton Australia Pty. Ltd.
15 Marriott Road, Jandakot, WA 6164
Australia
ACN Number: 009 000 775
Telephone Number: + 61 1 800 686 951
Fax Number: 61 (08) 9455 5300

E-mail Address fdunexchem@halliburton.com

Emergency phone number

+ 61 1 800 686 951

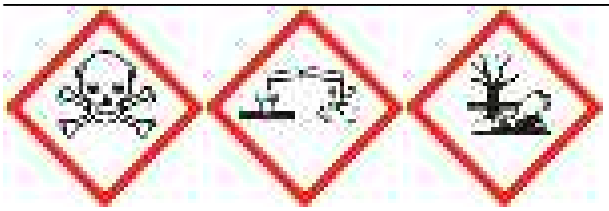
Contract Number: 14012

Australian Poisons Information Centre
24 Hour Service: - 13 11 26
Police or Fire Brigade: - 000 (exchange): - 1100

2. Hazard Identification



Statement of Hazardous Nature Hazardous according to the criteria of the 3rd Revised Edition of the Globally Harmonised System of Classification and Labelling of Chemicals (GHS), Dangerous Goods according to the criteria of ADG.

Classification of the hazardous chemical

Skin Corrosion/Irritation	Category 1 - H314
Serious Eye Damage/Irritation	Category 1 - H318
Acute Aquatic Toxicity	Category 1 - H400
Chronic Aquatic Toxicity	Category 2 - H411

Label elements, including precautionary statements

Hazard Pictograms

Signal Word DANGER

Hazard Statements:
H314 - Causes severe skin burns and eye damage
H318 - Causes serious eye damage
H400 - Very toxic to aquatic life
H411 - Toxic to aquatic life with long lasting effects

Precautionary Statements

Prevention
P260 - Do not breathe dust/fume/gas/mist/vapors/spray
P273 - Avoid release to the environment
P280 - Wear protective gloves/protective clothing/eye protection/face protection

Response
P301 + P330 + P331 - IF SWALLOWED: rinse mouth. Do NOT induce vomiting
P303 + P361 + P353 - IF ON SKIN (or hair): Take off immediately all contaminated clothing. Rinse skin with water [or shower].
P363 - Wash contaminated clothing before reuse
P304 + P340 - IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing
P310 - Immediately call a POISON CENTER or doctor/physician
P305 + P351 + P338 - IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing
P391 - Collect spillage

Storage
P405 - Store locked up

Disposal
P501 - Dispose of contents/container in accordance with local/regional/national/international regulations

Contains

Substances	**CAS Number**
Tributyl tetradecyl phosphonium chloride	81741-28-8

Other hazards which do not result in classification
None known

For the full text of the H-phrases mentioned in this Section, see Section 16

3. Composition/information on Ingredients

Substances	CAS Number	PERCENT (w/w)	GHS Classification - Australia
Tributyl tetradecyl phosphonium chloride	81741-28-8	5 - 10%	Acute Tox. 4 (H302) Acute Tox. 2 (H330) Skin Corr. 1B (H314) Eye Corr. 1 (H318) Aquatic Acute 1 (H400) Aquatic Chronic 1 (H410)

4. First aid measures

Description of necessary first aid measures

Inhalation If inhaled, move victim to fresh air and seek medical attention.

Eyes Immediately flush eyes with large amounts of water for at least 30 minutes. Seek prompt medical attention.

Skin In case of contact, immediately flush skin with plenty of soap and water for at least 30 minutes and remove contaminated clothing, shoes and leather goods immediately. Get medical attention immediately.

Ingestion Do NOT induce vomiting. Give nothing by mouth. Obtain immediate medical attention.

Symptoms caused by exposure

Causes severe eye irritation which may damage tissue. Causes severe skin irritation with tissue destruction.

Medical Attention and Special Treatment

Notes to Physician Treat symptomatically

5. Fire Fighting Measures

Suitable extinguishing equipment

Suitable Extinguishing Media

Water fog, carbon dioxide, foam, dry chemical.

Extinguishing media which must not be used for safety reasons

None known.

Specific hazards arising from the chemical

Special exposure hazards in a fire

Decomposition in fire may produce harmful gases. Do not allow runoff to enter waterways. Use water spray to cool fire exposed surfaces.

Special protective equipment and precautions for fire fighters

Special protective equipment for firefighters

Full protective clothing and approved self-contained breathing apparatus required for fire fighting personnel.

6. Accidental release measures

6.1. Personal precautions, protective equipment and emergency procedures

Use appropriate protective equipment.

6.2. Environmental precautions

Prevent from entering sewers, waterways, or low areas.

6.3. Methods and material for containment and cleaning up

Isolate spill and stop leak where safe. Contain spill with sand or other inert materials. Scoop up and remove.

7. Handling and storage

7.1. Precautions for safe handling

Handling Precautions

Avoid contact with eyes, skin, or clothing. Wash hands after use. Launder contaminated clothing before reuse. Do NOT consume food, drink, or tobacco in contaminated areas.

Hygiene Measures

Handle in accordance with good industrial hygiene and safety practice.

7.2. Conditions for safe storage, including any incompatibilities

Storage Information

Store in a cool well ventilated area. Keep container closed when not in use. Store away from direct sunlight. Store in a dry location. Store in a manner to prevent commingling with incompatible materials. Store away from alkalis. Store away from reducing agents. Store locked up.

Other Guidelines

No information available

8. Exposure Controls/Personal Protection

Control parameters - exposure standards, biological monitoring

Exposure Limits

Substances	CAS Number	Australia NOHSC	ACGIH TLV-TWA
Tributyl tetradecyl phosphonium chloride	81741-28-8	Not applicable	Not applicable

Appropriate engineering controls

Engineering Controls Use in a well ventilated area. Local exhaust ventilation should be used in areas without good cross ventilation.

Personal protective equipment (PPE)

Personal Protective Equipment If engineering controls and work practices cannot prevent excessive exposures, the selection and proper use of personal protective equipment should be determined by an industrial hygienist or other qualified professional based on the specific application of this product.

Respiratory Protection If engineering controls and work practices cannot keep exposure below occupational exposure limits or if exposure is unknown, wear a NIOSH certified, European Standard EN 149, AS/NZS 1715:2009, or equivalent respirator when using this product. Selection of and instruction on using all personal protective equipment, including respirators, should be performed by an Industrial Hygienist or other qualified professional.
Dust/mist respirator. (N95, P2/P3)

Hand Protection Chemical-resistant protective gloves (EN 374) Suitable materials for longer, direct contact (recommended: protection index 6, corresponding to > 480 minutes permeation time as per EN 374): Neoprene gloves. (>= 0.75 mm thickness)
This information is based on literature references and on information provided by glove manufacturers, or is derived by analogy with similar substances. Please note that in practice the working life of chemical-resistant protective gloves may be considerably shorter than the permeation time determined in accordance with EN 374 as a result of the many influencing factors (e.g. temperature). If signs of wear and tear are noticed then the gloves should be replaced. Manufacturer's directions for use should be observed because of great diversity of types.

Skin Protection Wear impervious protective clothing, including boots, gloves, lab coat, apron, rain jacket, pants or coverall, as appropriate, to prevent skin contact.

Eye Protection Chemical goggles; also wear a face shield if splashing hazard exists.

Other Precautions Eyewash fountains and safety showers must be easily accessible.

Environmental Exposure Controls No information available

9. Physical and Chemical Properties

9.1. Information on basic physical and chemical properties

Physical State: Liquid
Color Clear colorless
Odor: Slight
Odor Threshold: No information available

Property Remarks/ - Method	Values
pH:	6-8
Freezing Point / Range	-8 - -10 °C
Melting Point / Range	No data available
Boiling Point / Range	100 °C / 212 °F
Flash Point	No data available
Evaporation rate	No data available
Vapor Pressure	No data available
Vapor Density	No data available
Specific Gravity	0.95 - 1.0
Water Solubility	Miscible with water
Solubility in other solvents	No data available
Partition coefficient: n-octanol/water	No data available
Autoignition Temperature	No data available
Decomposition Temperature	No data available
Viscosity	No data available
Explosive Properties	No information available
Oxidizing Properties	No information available

9.2. Other information

VOC Content (%) No data available

10. Stability and Reactivity

10.1. Reactivity

Not expected to be reactive.

10.2. Chemical stability

Stable

10.3. Possibility of hazardous reactions

Will Not Occur

10.4. Conditions to avoid

None anticipated

10.5. Incompatible materials

Reducing agents. Strong alkalis.

10.6. Hazardous decomposition products

Chlorine. Phosphorus acids. Carbon monoxide and carbon dioxide.

11. Toxicological Information

Information on routes of exposure

Principle Route of Exposure Eye or skin contact, inhalation.

Symptoms related to exposure

Most Important Symptoms/Effects

Causes severe eye irritation which may damage tissue. Causes severe skin irritation with tissue destruction.

Toxicology data for the components

Substances	CAS Number	LD50 Oral	LD50 Dermal	LC50 Inhalation
Tributyl tetradecyl phosphonium chloride	81741-28-8	= 611 mg/kg (rat)	No data of sufficient quality are available	> 0.908 mg/L (rat, 4hr, mist)

Immediate, delayed and chronic health effects from exposure

Inhalation May cause respiratory irritation.

Eye Contact Causes severe eye irritation which may damage tissue. May cause eye burns.

Skin Contact Causes severe skin irritation with tissue destruction.

Ingestion Irritation of the mouth, throat, and stomach. May cause abdominal pain, vomiting, nausea, and diarrhea.

Chronic Effects/Carcinogenicity No data available to indicate product or components present at greater than 0.1% are chronic health hazards.

Exposure Levels

No data available

Interactive effects

Lung disorders. Skin disorders.

Data limitations

No data available

Substances	CAS Number	Skin corrosion/irritation
Tributyl tetradecyl phosphonium chloride	81741-28-8	Causes burns (Rabbit)

Substances	CAS Number	Serious eye damage/irritation
Tributyl tetradecyl phosphonium chloride	81741-28-8	Causes severe eye irritation which may damage tissue. (Rabbit)

Substances	CAS Number	Skin Sensitization
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	STOT - single exposure
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

Substances	CAS Number	STOT - repeated exposure
Tributyl tetradecyl phosphonium chloride	81741-28-8	No data of sufficient quality are available.

Substances	CAS Number	Aspiration hazard
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

12. Ecological Information

Ecotoxicity

Substance Ecotoxicity Data

Substances	CAS Number	Toxicity to Algae	Toxicity to Fish	Toxicity to Microorganisms	Toxicity to Invertebrates
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available	LC50 (96 h) 0.46 mg/L (Oncorhynchus mykiss) LC50 (96 h) 0.06 mg/L (Lepomis macrochirus)	No information available	EC50 (48 h) 0.025 mg/L (Daphnia sp.)

12.2. Persistence and degradability

Substances	CAS Number	Persistence and Degradability
Tributyl tetradecyl phosphonium chloride	81741-28-8	(0% @ 28d)

12.3. Bioaccumulative potential

Substances	CAS Number	Log Pow
Tributyl tetradecyl phosphonium chloride	81741-28-8	< 3

12.4. Mobility in soil

Substances	CAS Number	Mobility
Tributyl tetradecyl phosphonium chloride	81741-28-8	No information available

12.6. Other adverse effects

Endocrine Disruptor Information

This product does not contain any known or suspected endocrine disruptors

13. Disposal Considerations

Safe handling and disposal methods
Disposal should be made in accordance with federal, state, and local regulations. Incineration recommended in approved incinerator according to federal, state, and local regulations. Substance should NOT be deposited into a sewage facility.

Disposal of any contaminated packaging
Follow all applicable national or local regulations.

Environmental regulations
Not applicable

14. Transport Information

Transportation Information

End of Safety Data Sheet

Appendix 3

Toxicity Profile

Glutaraldehyde
(CAS No. 111-30-8)

Acute Toxicity

The oral LD_{50} values are: 134 to 820 mg/kg in rats; 100 to 350 mg/kg in mice; and 50 mg/kg in guinea pigs (OECD 1995). The dermal LD_{50} values are: 640 to 2,000 mg/kg in rabbits; and >2,500 mg/kg in rats and mice (OECD 1995). The inhalation 4-hour LC_{50} values have been reported to be 23.5 and 40.1 ppm for male and female rats, respectively (NICNAS 1994).

Irritation

Glutaraldehyde is corrosive to the skin and eyes of rabbits (NICNAS 1994). Signs of irritation occur at a concentration of 2% for skin and 0.2% for eyes (NICNAS 1994). Nasal irritation and respiratory difficulty in rats occurred from inhalation to glutaraldehyde vapors (NICNAS 1994).

Sensitization

Glutaraldehyde is a skin sensitizer to guinea pigs and humans (NICNAS 1994).

Repeated Dose Toxicity

Oral

Male and female Wistar rat were given in their drinking water 0, 100, 500 or 2,000 ppm glutaraldehyde for 90 days. The approximate daily intakes were 0, 3, 15 or 53 mg/kg-day for males, and 0, 4, 19 or 72 mg/kg-day for females. There were no signs of neurotoxicity at any dose level. There was slight impairment of food consumption in the 2,000 ppm animals, as well as slight impairment of body weight and body weight gain. Impaired water consumption was seen in the 100 and 500 ppm females. The NOAEL for both males and females is 100 ppm, since the impaired water consumption in the 100 ppm females was considered a palatability problem and not an adverse effect (ECHA).

Male and female Wistar rats were given in their drinking water 0, 100, 500 or 2000 ppm glutaraldehyde for 12 months. The approximate daily intakes were 0, 6.4, 30.5 or 116.6 mg/kg-day for males, and 0. 9.6, 46 or 153 mg/kg-day for females. There was no treatment-related mortality. At 2,000 ppm, treatment-related effects included respiratory sounds (both sexes), decrease in body weight (males), decrease in body weight gain (both sexes), decrease in food consumption (both sexes), reduced water consumption (both

sexes), lesions within the glandular stomach (both sexes showed erosion/ulceration of the glandular stomach), increased incidence of clear cell foci in the liver (males), and a single case of slight diffuse squamous metaplasia in the epithelium of the larynx (male). At 500 ppm, water consumption was reduced in males which was considered to be a palatability (bad taste) problem and not an adverse effect. No treatment-related effects were seen in the 100 ppm animals (ECHA).

Male and female F344 rats were given in their drinking water 0, 50, 250 or 1,000 ppm glutaraldehyde for 13 weeks. Additional groups of animals were given in their drinking water 0 or 1000 ppm glutaraldehyde for 13 weeks followed by a 4-week recovery period. The approximate daily intakes were 0, 5, 25 or 100 mg/kg-day for males, and 0, 7, 35 or 120 mg/kg-day for females. Water consumption was reduced in a dose-dependent manner in the $\geq$250 ppm males and 1,000 ppm females, which was attributed to an aversion to the taste and/or odor of glutaraldehyde in the water. There was also a reduction in food consumption in the 1,000 ppm animals with a parallel reduction in body weights. It is unclear whether the reduction in food consumption was related to the decreased water consumption. Urine volume was decreased with an increase in specific gravity, along with a slight increase in protein and ketone concentration, in the $\geq$250 ppm animals, which was probably related to the decreased water consumption. There were no treatment-related changes in the hematology parameters measured. Blood urea nitrogen was increased in a dose-related manner in the $\geq$250 ppm females at the 6-week time point, but at the 13-week or 17-week time points. Relative kidney weights were increased in a dose-related manner in the $\geq$250 ppm males and females, and increased absolute kidney weights in the females. Histopathological examination showed no treatment-related effects. The NOAEL is 50 ppm (5 and 7 mg/kg-day for males and females, respectively) based on dose-related increase in kidney weights at $\geq$250 ppm (NICNAS 1994).

Male and female Fischer 344 rats were given in their drinking water 0, 50, 250 or 1000 ppm glutaraldehyde for 104 weeks. The mean glutaraldehyde consumption was 0, 4, 17 and 64 mg/kg-day for males and 0, 6, 25 and 86 mg/kg-day for females. There were no treatment-related mortalities or clinical symptoms of toxicity. In the 250 and 1,000 ppm groups, there was reduction in body weight and body weight gain; reduction in food and water consumption; increased statistically significant incidence of nucleated erythrocytes and of large monocytes; decreases in alanine aminotransferase (ALT), aspartate aminotransferase (AST), and glutamate dehydrogenase; dose-related decrease in urine volume accompanied by a dose-related increase in osmolality; changes in absolute and relative kidney weight; gastric irritation; increases in bone marrow hyperplasia; and increased incidence of renal tubular pigmentation. The decreased water consumption was considered to be due to the bad taste , smell and/or irritancy of the test substance in the drinking water; thus, it is of no toxicological relevance. As a result of reduced water intake, there are renal physiological adaptation ,such as decreased urine, increased osmolality and changes in kidney weight. The hematological and clinical chemistry parameter changes were marginal and were considered to be of not toxicological relevance. The main hematological finding seen at the end of the study and which consisted of the appearance of nucleated erythrocytes and large monocytes in all treated groups (statistically significant for the $\geq$250 ppm males) was related to the incidence of

large granular lymphocytic leukemia (LGLL) in the spleen. The bone marrow hyperplasia and renal tubular pigmentation are related to the occurrence/incidence of large granular lymphocytic leukemia (LGLL), and were considered by the authors of the study as being secondary to a low grade hemolytic anemia in animals with LGLL. The NOAEL for this study is 50 ppm which corresponds to 4 and 6 mg/kg-day for males and females, respectively (Van Miller *et al.* 2002).

Inhalation

Male and female F344 rats were exposed by inhalation to 0, 0.0625, 0.125, 0.25, 0.5 or 1.0 ppm glutaraldehyde for 6.5 hours/day, 5 days/week for 13 weeks. The study focused on the respiratory tract, using histopathology and epithelial cell labeling index as end points. Histopathological lesions in the nasal passages and turbinates were seen at $\geq$0.25 ppm. Treatment-related effects were primarily the respiratory mucosa (nasal cavity and tips of the turbinates) and the olfactory epithelium (dorsal meatus). Hyperplasia, squamous metaplasia, olfactory degeneration, squamous exfoliation (accumulation of keratin, cell debris and bacteria in the lumen of the nasal vestibule) and focal erosions were reported for both sexes, and the severity and incidence of the findings increased with increasing concentration of glutaraldehyde. The NOAEL for this study is 0.125 ppm (Gross *et al.* 1994).

Male and female B6C3F$_1$ mice were exposed by inhalation to 0, 0.0625, 0.125, 0.25, 0.5 or 1.0 ppm glutaraldehyde for 6.5 hours/day, 5 days/week for 13 weeks. The study focused on the respiratory tract, using histopathology and epithelial cell labeling index as end points. Histopathologic lesions in the nasal passages and turbinates were seen at all exposure concentrations ($\geq$0.0625 ppm). Treatment-related lesions were primarily the respiratory mucosa (nasal cavity and tips of the turbinates) and the olfactory epithelium (dorsal meatus). Hyperplasia, squamous metaplasia, olfactory degeneration, squamous exfoliation (accumulation of keratin, cell debris and bacteria in the lumen of the nasal vestibule) and focal erosions were reported for both sexes, and the severity and incidence of the findings increased with increasing test concentration. Furthermore, neutrophilic inflammation was seen at $\geq$0.062 ppm, and squamous metaplasia as well as necrosis were seen in the larynx at 1 ppm). The LOAEL for this study is 0.0625 ppm; a NOAEL was not established (Gross *et al.* 1994).

Male and female B6C3F$_1$ mice were exposed by inhalation to 0 or 0.1 ppm glutaraldehyde for 6 hours/day, 5 days/week for 52 and 78 weeks. Survival was similar between treated and control groups. Hyperplasia of the squamous epithelium lining of the dorsal wall of the nasal passages and the lateral aspect of the atrioturbinate was seen in a greater number of exposed females than in controls. Epidermal erosion and ulceration as well as squamous and inflammatory exfoliation were also seen in the nasal lumens. All of these changes were dependent on the length of glutaraldehyde exposure. The authors concluded that, since the induced lesions occurred at the more anterior part of the nasal passages, that they were likely the result of an irritation mechanism (Zissu *et al.* 1998).

Male and female Fischer 344 rats were exposed by inhalation to 0, 0.25, 0.5, or 0.75 ppm glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival in the mid- and high-dose females was statistically significantly decreased compared to controls. Mean body weights of all exposed males and the mid- and high-dose females were generally less than those of the controls. Non-neoplastic lesions were limited primarily to the most anterior region of the nasal cavity. Effects included hyperplasia and inflammation of the squamous epithelium; hyperplasia, goblet cell hyperplasia, inflammation, and squamous metaplasia of the respiratory epithelium; and hyaline degeneration of the olfactory epithelium. The LOAEL for this study is 0.25 ppm based on hyperplasia and inflammation of the squamous epithelium of the nose in both sexes. A NOAEL was not established (van Birgelen *et al.* 2000).

Male and female $B6C3F_1$ mice were exposed by inhalation to 0, 0.0625, 0.125, or 0.25 ppm glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival of the treated animals was similar to controls. Mean body weights of the high-dose females were generally lower than the controls. Non-neoplastic lesions were limited primarily to the anterior region of the nasal cavity; the effects were qualitatively similar to those seen in the rats (see accompanying summary on the two-year rat study by van Birgelen *et al.* 2000). Squamous metaplasia of the respiratory epithelium was observed in both sexes of mice while female mice also had inflammation and hyaline degeneration of the respiratory epithelium. The incidence and severity grade (in parentheses) of the hyaline degeneration were: 16/50 (1.4), 35/49 (1.4), 32/50 (1.3), and 30/50 (1.1) for the 0, 0.0625, 0.125, and 0.25 ppm dose groups, respectively. The LOAEL for this study is 0.0625 ppm based on hyaline degeneration of the respiratory epithelium in female mice. A NOAEL was not established (van Birgelen *et al.* 2000).

Genotoxicity

Glutaraldehyde has been shown to be mutagenic in some, but not all, *in vitro* bacterial mutation assays with or without metabolic activation. Glutaraldehyde has also been shown to produce mutations, sister chromatid exchanges and chromosomal aberrations in mammalian cells *in vitro*, with and without metabolic activation (NICNAS 1994).

Glutaraldehyde did not induce micronuclei in peripheral blood of mice given a single dose of a 50% w/w aqueous solution of glutaraldehyde up to 250 mg/kg (NICNAS 1994). Sprague-Dawley rats were given a single oral gavage dose of a 50% w/w aqueous solution of glutaraldehyde. The dose levels were 25, 60 and 120 mg/kg for males, and 15, 40 and 80 mg/kg for females. There were no increases in chromosomal aberrations in bone marrow cells in either sex at any dose level (NICNAS 1994). Glutaraldehyde was inactive in a sex-linked recessive lethal mutation assay of germ cells of *Drosophila melanogaster* (NICNAS 1994).

Carcinogenicity

Oral

Male and female Fischer 344 rats were given in their drinking water 0, 50, 250 or 1,000 ppm glutaraldehyde for 104 weeks. The mean glutaraldehyde consumption was 0, 4, 17 and 64 mg/kg-day for males and 0, 6, 25 and 86 mg/kg-day for females. Mortality rates were 25-30% and 19-23% for males and females, respectively, with no dose-related increase. The major cause of death in all dose groups including the controls was large granular cell lymphatic leukemia (LGLL). There was an increased incidence of LGLL in the liver and spleen in all treated females ($\geq$50 ppm). No other treatment-related increased incidence of tumors were seen (Van Miller *et al.* 2002).

Male and female Wistar rats were given in their drinking water 0, 100, 500 or 2,000 ppm glutaraldehyde for two years. The mean glutaraldehyde consumption was 0, 6.1, 31.9, and 120.7 mg/kg-day for males and 0, 10.5, 48.5 and 176.4 mg/kg-day for females. In the high-dose animals, there was mortality (2 males and 9 females) from asphyxia and mean terminal body weights were significantly decreased compared to the controls. There were no treatment-related neoplastic effects (ECHA).

Inhalation

Male and female B6C3F_1 mice were exposed by inhalation to 0 or 0.1 ppm glutaraldehyde for 6 hours/day, 5 days/week for 52 and 78 weeks. No exposure-related neoplastic lesions were observed in either males or females (Zissu *et al.* 1998).

Male and female Fischer 344 rats were exposed by inhalation to 0, 0.25, 0.5, or 0.75 ppm glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival in the mid- and high-dose females was statistically significantly decreased compared to controls. Survival of the treated males was similar to controls. No exposure-related neoplastic lesions were observed in either males or females (van Birgelen *et al.* 2000).

Male and female B6C3F_1 mice were exposed by inhalation to 0, 0.0625, 0.125, or 0.25 ppm glutaraldehyde for 6 hours/day, 5 days/week for two years. Survival of the treated animals was similar to controls. No exposure-related neoplastic lesions were observed in either males or females (van Birgelen *et al.* 2000).

Reproductive Toxicity

A two-generation reproductive toxicity study was conducted in Wistar rats given 0, 100, 500 and 2000 ppm glutaraldehyde in their drinking water. The approximately mean daily intake is 0, 12, 58 and 199 mg/kg-day for the parental males and females of the F_0 and F_1 generation during premating. There were no adverse effects on reproductive performance or fertility. Estrous cycle data, mating behavior, conception, gestation, parturition, lactation and weaning as well as sperm parameters, sexual organ weights, gross and histopathological findings of these organs were similar between treated and control groups. In the high-dose animals, there was decreased water and/or food consumption;

and decreased body weights and/or reduced body weight gains during the premating periods in the F_0 and F_1 parental females during premating, gestation and/or lactation. The high-dose F_1 parental females also had increased number of erosions/ulcers with microscopic erosion(s) or inflammatory edema in the mucosa/submucosa of the glandular stomach. There were no adverse effects in the 500 ppm animals except for slight decreases in water consumption due to a palatability (bad taste) problem. Treatment-related signs of developmental toxicity were seen in the progeny of the high-dose F_0 and F_1 parental generation, and included impairment in body weight and consequently in organ weights in the respective F1 and F2 pups. The NOAEL for reproductive toxicity is 2,000 ppm, the highest dose tested. The NOAEL for parental system toxicity is 500 ppm. The NOAEL for developmental toxicity is 500 ppm (ECHA).

A two-generation reproductive toxicity study was conducted in Crj: CD(SD) rats given 0, 50, 250 and 1,000 ppm glutaraldhyde in their drinking water. Parental body weights and body weight gains were significantly reduced at 1,000 ppm at some periods, particularly during pre-mating. Food consumption was significantly reduced at 1,000 ppm for the F_0 and F_1 parental animals during pre-mating and gestation, and F_1 females during lactation. Water consumption was reduced throughout the pre-mating period for the F_0 and F_1 250 and 1,000 ppm parental animals. There was no indication of adverse effects on reproductive performance or fertility at any dose level. For the F_1 1,000 ppm offspring, body weights were reduced from lactation days 21-28. The NOAEL for reproductive toxicity is 1,000 ppm, the highest dose tested. The NOAEL for parental systemic toxicity is 50 ppm. The NOAEL for developmental toxicity is 250 ppm (Neeper-Bradley and Ballantyne 2000).

Developmental Toxicity

Pregnant Wistar rats were given in their drinking water 0, 50, 250 or 750 ppm (0, 5, 26 or 68 mg/kg) glutaraldehyde from GD 6 to 16. Water consumption was reduced in a dose-related manner in the $\geq$26 mg/kg dams, and was considered to be a toxic response but due to the palatability (bad taste) of the drinking test solution. No other maternal effects were seen in the study. There were no significant differences between treated and controls in the sex distribution, placental weights, fetal weights, malformations or variations. The NOELs for maternal and developmental toxicity are 5 and 68 mg/kg-day, respectively (NICNAS 1994).

Pregnant Himalayan rabbits were dosed by oral gavage with 0, 5, 15 or 45 mg/kg glutaraldehyde on GD 7 to 19. In the high-dose group, 5/15 died on GD 9-11. Food consumption and body weight gain were also significantly reduced in the high-dose group. Clinical observations in 12/15 high-dose does included soft feces, diarrhea, an blood in the bedding. At necropsy, gastrointestinal irritation was observed and uterus weight was significantly reduced. 9/10 of the remaining high-dose does did not produce live fetuses. There were reduced placental and fetal body weights in the only four fetuses. No significant maternal or developmental effects were seen in the mid- and low-dose

groups. The NOAELs for maternal and developmental toxicity are 15 mg/kg-day (NICNAS 1994).

Pregnant Charles River albino rats were dosed by oral gavage with a 25% glutaraldehyde solution on GD 6 to 15. The dose levels were 0, 25 or 50 mg/kg glutaraldehyde. One 25 mg/kg dam died during the study from injury. Body weight gain was significantly reduced in the 50 mg/kg dams. The number of corpora lutea, implantation sites, resorption sites and fetuses were similar between treated and control groups. There was no treatment-related effects on fetal body weights or skeletal or internal development of the fetuses. The NOAELs for maternal and developmental toxicity were 25 and 50 mg/kg-day, respectively (NICNAS 1994).

Key Study/Critical Effect for Screening Criteria

Oral

The NOAEL from the two-year drinking water study in rats (Van Miller *et al.* 2002) is 50 ppm, which corresponds to 4 and 6 mg/kg-day for males and females, respectively .

Uncertainty factors: 10 (interspecies variability); 10 (intraspecies variability)

Oral RfD = 4/100 = 0.04 mg/kg-day

Drinking water guidance value = 0.14 ppm

Inhalation

The LOAEL from the two-year inhalation study in mice (van Birgelen *et al.* 2000) is 0.0625 ppm or 62.5 ppb. Exposures were for 6 hours/day, 5 days/week and the critical effect is hyaline degeneration of the respiratory epithelium in female mice. This effect is considered a result of direct irritation of nasal cavity from glutaraldehyde exposure.

For a worker exposed for an 8-hour work day, the LOAEL from the mouse study is converted to 46.9 ppb.

For the general public exposed continuously, the LOAEL from the mouse study is converted to 11.2 ppb.

Uncertainty factors: 1 (interspecies variability); 1 (intraspecies variability); 10 (LOAEL to NOAEL)

Worker [8-hour exposure] RfC = 46.9/10 = 4.7 ppb
General population [continuous exposure] = 11.2/10 = 1.1 ppb

Potassium chloride
(CAS No. 7447-40-7)

Potassium chloride (KCl) has been reviewed in the OECD-SIDS program (OECD, 2001).

Potassium chloride (KCl) is an inorganic salt that readily dissociates in aqueous media to K^+ and Cl^-.

Acute Toxicity

The oral LD_{50} in rats has been reported to be 3,020 mg/kg (Boyd and Shanas, 1961).

Irritation

Potassium chloride did not produce an irritant response in an *in vitro* skin irritation OECD 439 test or an *in vitro* eye irritation test (ECHA).

Repeated Dose Toxicity

Fourteen female rats were given KCl in their drinking water (approximately 5,250 mg/kg/day) for 105 days. Ten rats were sacrificed after 105 days of exposure for examination of the heart, kidneys and the adrenals; four rats (recovery group) were kept for an additional month. KCl exposure resulted in decreased heart weight, increased kidney weight, and enlargement of part of the adrenals. All changes were reversible within one month of exposure (Bacchus, 1951).

F344/Slc male rats were given 0, 110, 450 or 1,820 mg/kg/day KCl in feed for two years. At the end of the study, survival rates were 48%, 64%, 58% and 84% in the controls, 110, 45 and 1,820 mg/kg/day groups. Nephritis was reported to be predominant in all groups, including the controls. The only treatment-related effect observed was gastritis (inflammation of the stomach lining). The incidence of gastritis and ulcers were 6%, 18%, 18% and 30% in the controls, 110, 450 and 1,820 mg/kg/day groups (Imai *et al.*, 1968).

Male and female Wistar rats were fed diets containing 0 or 3% KCl over a total period of 30 months: Examination after 13 weeks (10 rats/sex/group), after 18 months (15 rats/sex/group) and after 30 months (50 rats/sex /group). Due to the reduction of feed intake the mean test substance intake and mean body weight decreased in time. After 30 months of treatment, there was hypertrophy of the zona glomerulosa in the adrenals (24/50 treated rats versus 4/50 in controls); and cystitis in the urinary bladder (males: 3/59; females 3/50) and single epithelial hyperplasia of the bladder (males 3/50; females

2/50) (Lina *et al.*, 1994; Lina and Kuijpers, 2004)**.**

Genotoxicity

Potassium chloride was not mutagenic to *Salmonella typhimurium* strains TA100, TA 1535, TA 1537 and TA 98 strains in an *in vitro* bacterial mutation assay in the presence or absence of metabolic activation (Mortelmans *et al.*, 1986). KCl was also not mutagenic to *E. coli* in a SOS chromotest (Olivier and Marzin, 1987).

In two different studies, KCl was found to be weakly mutagenic to mouse lymphoma L5178Y cells at high concentrations (Myhr and Caspary, 1988; Mitchell *et al.*, 1988).

Potassium chloride induced a significant increase in chromosomal aberrations in Chinese Hamster lung fibroblasts (V79) cells only at the highest test dose (12,000 µg/ml) in the absence of a metabolic activation system. Measurements of the osmotic pressure of the medium revealed a two-fold increase at this test compound concentration when compared to the normal medium (530 mOsmol/ kg versus 253 mOsmol/kg (Hasegawa *et al.*, 1984). There are two other reports on the effect of KCl on formation of chromosome aberrations in Chinese hamster ovary cells (CHO). In these studies KCl concentrations of 75 and 80 mM (approximately 5500 and 6000 µg/ml) resulted in 19% and 28% aberrant cells respectively. Increased number of chromosome aberrations was observed with KCl concentrations that reduced cell survival 40% and more. It is reasonable to conclude that the increases in mutagenicity and chromosome aberrations observed in these studies are related to cytotoxicity resulting from the high KCl concentrations used. This argument is supported by the studies on the effect of increased osmolarity on genotoxicity in cultured mammalian cells.

The reported mutagenic effect of KCl most probably results from a disruption of osmotic balance of cells with a subsequent interference with chromosomal stability. This may result in the clastogenic effects (DNA breakage and chromosome structural instability) due to K^{+} effects on sequestering of Mg^{++} ions required for normal maintenance of chromatin integrity. Other chemicals may also exert such effect (*e.g.*, NaCl, sucrose).

Carcinogenicity

F344/Slc male rats were given 0, 110, 450 or 1,820 mg/kg/day KCl in feed for two years. At the end of the study, survival rates were 48%, 64%, 58% and 84% in the controls, 110, 45 and 1,820 mg/kg/day groups. There was no increased incidence of tumors that were considered to be treatment-related (Imai *et al.*, 1968).

Reproductive/Developmental Toxicity

Pregnant female Wistar rats were given by oral gavage 3.1 to 310 mg/kg KCl during gestation days 5 through 15, and sacrificed on gestation day 20. There were no effects on

survival, total number of corpora lutea, implant sites, resorptions, soft tissue observations (urogenital tract), or live offspring. No treatment-related effects were seen in the offspring with regards to survival, sex ratio, average offspring weight, external congenital abnormalities, soft tissue or skeletal defects. The maternal and developmental NOAELs were 310 mg/kg/day (FDRL, 1975).

Female CD-1 mice were given by oral gavage 2.35 to 235 mg/kg KCL during gestation days 5 through 15, and sacrificed on gestation day 17. There were no effects on survival, total number of corpora lutea, implant sites, resorptions, soft tissue observations (urogenital tract), or live offspring. No treatment-related effects were seen in the offspring with regards to survival, sex ratio, average offspring weight, external congenital abnormalities, soft tissue or skeletal defects. The maternal and developmental NOAELs were 235 mg/kg/day (FDRL, 1975).

Key Study/Critical Effect for Screening Criteria

In a two-year rat feeding study, there was an increased incidence of gastritis and ulcers at dose levels of ≥110 mg/kg/day (Imai *et al.*, 1968). There was no NOAEL. Thus, the LOAEL for this study is 110 mg/kgday. Since the gastritis and ulcers are the result of a localized irritation effect of the test substance (site of contact) in the gastrointestinal tract, an uncertainty factor for interspecies variability is deemed unnecessary.

For systemic effects, the NOAEL for the two-year rat feeding study is considered to be 1,820 mg/kg/day, the highest dose tested.

Uncertainty factors: 10 (intraspecies variability); 10 (interspecies variability); 1 (intraspecies variability)

Oral Reference Dose = 1,820/100 = 18.2 mg/kg/day

Drinking water guideline: 64 ppm

Toxicity Profile

Shellac, Ammonium salt
(CAS No. 68308-35-8)

Lac is the hardened resinous secretion of the insesct *Kerria lacca* (Douglas, 1971; CIR, 1986). The secreted lac or sticklac contains lac resin, erythrolaccin, wax, inset debris, wood materials, sand, dust and water-soluble impurities. The semirefined seedlac of commerce is the yellowish granular material obtained from the processing of sticklac (Douglas, 1971; Misra and Sengupta, 1970; CIR, 1986).

Unrefined shellac can contain shellac wax and erythrolaccin (the yellow material), which both comprise about 6% of Shellac (CIR, 1986). The removal of these constituents yields lac resin that has a soft (30%) and hard (70%) components (CIR, 1986). Mild alkaline hydrolysis of this resin results in a complex mixture of hydroxyaliphatic and alicyclic acids and their polyesters. The composition of the mixture varies with the lac source and the time of collection (CIR, 1986).

The major component of the aliphatic fraction is aleuritic acid. The alicyclic fraction consists of sesquiterpenic acids, primarily jalaric acid and its derivatives. The native form of the pure lac resin molecule has a molecular weight of 2,095, which contains four terpene acids (mostly jalaric acid) and four aleuritic acid units in repeating ester linkage (Singh *et al.*, 1974). The proposed structure for lac resin respresents an average situation since the molecule may not always be homogenous with respect to sequence or ratio of jalaric acid to other sesquiterpenic acid substitutes (Singh *et al.*, 1974). The sesquiterpenic acids in lac resin are jalaric acid, shellolic acid, epishellolic acid, laksholic acid, and epilaksholic acid.

Aqueous shellac solutions can be prepared by neutralization with ethanolamines, alkalies, or borax (CIR, 1986).

Acute Toxicity

The acute oral LD_{50} in rats is >5,000 mg/kg (CIR, 1986).

Irritation

No data were located.

Sensitization

No data were located.

Toxicity Profile

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Acute Toxicity

An oral LD_{50} in rats was reported to be 1,002 mg/kg. The 4-hour LC_{50} to rats is <0.9 mg/L (aerosol) (MSDS for Bellecide 350).

Irritation

TTPC is corrosive to the skin and eyes (MSDS for Bellecide 350).

Sensitization

TTPC is not a skin sensitizer (MSDS for Bellecide 350).

Repeated Dose Toxicity

A 90-day rat drinking water study has been conducted on a product containing TTPC. The LOAEL for the active ingredient (TTPC) is 27.2 and 32.3 mg/kg-day in males and females, respectively, based on various clinical signs and significantly reduced body weights, feed and water consumption. The NOAEL for TTPC is 8.66 mg/kg-day (EPA 2006).

Genotoxicity

TTPC tested negative in an Ames test (MSDS for Bellecide 350).

Carcinogenicity

No data were found.

Reproductive Toxicity

No data were found.

Developmental Toxicity

Female Tif:RAIf(SPF) rats were dosed by oral gavage with 0, 20, 60, or 120 mg/kg Belclene® [50% active ingredient: TTPC] during gestational days (GD) 6 through 15. In the high-dose dams, there were two possible treatment-related spontaneous deaths (GD 9 and 14) and another death on GD 15 due to an intubation error. Clinical signs included dyspnea in one mid-dose and 4 high-dose animals, and vaginal bleeding in one mid-dose female on GD 15. In the high-dose dams, maternal body weight gain was significantly lower during the treatment period (GD 6-15) and throughout the gestational period (GD 0-20). Mean food consumption was significantly reduced during GD 6-11 for both the mid- and high-dose animals. The number of females with implantations and the number of implantations/females were similar across all groups. Embryonic and fetal deaths were similar between treated and control groups. There were no soft tissue changes. There was an increased incidence of incomplete ossification of the 5th sternebra in the mid- and high-dose groups. The NOAELs for maternal and developmental toxicity for the active ingredient TTPC in this study is 30 and 10 mg/kg-day (EPA 2006).

Female chinchilla rabbits were dosed by oral gavage with 0, 7.5, 22.5, or 45 mg/kg Belclene® [50% active ingredient: TTPC] during gestational days (GD) 6 through 18. In the mid- and high-dose groups, body weight gain was significantly reduced during GD 6-18 and feed consumption was reduced during GD 6-11. Fetal body weights were significantly reduced in the mid-(males only) and high-dose dose groups. There was also an increased incidence of delayed ossification of the hindlimb phalangeal nuclei in the mid- and high-dose groups. The NOAELs for maternal and developmental toxicity for the active ingredient TTPC in this study are 3.75 mg/kg-day (EPA 2006).

Key Study/Critical Effect for Screening Criteria

The NOAEL from the rat 90-day drinking water study with TTPC as the active ingredient is 8.66 mg/kg-day.

Oral

Uncertainty factors: 10 (interspecies variability); 10 (intraspecies variability); 10 (subchronic to chronic)

Oral RfD = 8.66/1000 = 0.009 mg/kg-day

Drinking water guidance value = 0.03 ppm

Inhalation

For a worker exposed for an 8-hour work day, the ventilation rate for heavy (male) workers, *i.e.*, farm workers, is 13.5 m^3/8-hour work day; the average lifetime adult body

weight is 70 kg (Commonwealth of Australia 2012). It is also assumed that inhalation absorption is 100%.

Note that this equation is for a heavy worker exposed continuously:
$NOAEC_{worker\ cont.}$ [mg/m^3] = $NOAEL_{oral\ rat}$ x human body weight x (1/ventilation rate) x 8/24

$NOAEC_{worker\ cont.}$ = 8.66 x 70 x 1/13.5 x 8/24 = 15 mg/m^3 or 0.84 ppm

[molecular weight of TTPC: 435.13]

Inhalation RfC for a continuously exposed heavy worker = 0.84 ppm/1000 = 0.00084 ppm or 0.84 ppb

Environmental Assessment

Potassium chloride
(CAS No. 7447-40-7)

Potassium chloride (KCl) has been reviewed in the OECD-SIDS program (OECD, 2001a,b).

Environmental Fate

KCl is a solid inorganic salt that is highly soluble in water (342 g/L at 20° C). Potassium chloride fully dissociates in aqueous solutions to K^+ and Cl^- ions.

KCl, either as an inorganic salt or as K^+ and Cl^- ions, is ubiquitous in the environment. There is no potential for bioaccumulation or bioconcentration. Potassium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated.

Aquatic Toxicity

In a guideline study, the 96-hour LC_{50} in *Pimephales promelas* was reported to be 880 mg/L (Mount *et al.*, 1997). The 48-hour LC_{50} values from two studies on *Lepomis macrochirus* (Patrick *et al.*, 1968; Trama, 1954), and one study each on *Oncorhyncus mykiss* and *Ictalurus punctatus* (Waller *et al.*, 1993) ranged from 720 to 2,010 mg/L.

In a guideline study, the 48-hour EC_{50}s in *Daphnia magna* and *Ceriodaphnia dubia* were 660 and 630 mg/L, respectively (Mount *et al.*, 1997; ECHA REACH database). The 48-hour EC_{50} in *Daphnia magna* in another study was also reported to be 177 mg/L (Biesinger and Christensen, 1972).

The toxicity of KCl has been investigated in one algae species (*Nitzschia linearis*), showing 120 hour-EC_{50} (growth rate) of 1,337 mg/L (Patrick *et al.*, 1968). The 72-hour EC_{50} to *Scenedesmus subspicatus* is >100 mg/L (growth rate), with a NOEC of $\geq$100 mg/L (ECHA REACH database).

In a fish early-life-stage test with the fathead minnow (*Pimephales promelas*), the 7-day NOEC is 500 mg/L (ECHA REACH database). A long term (21-day) study has been performed on *Daphnia magna* where effects on reproduction were investigated for several metals. A 16% impairment of reproduction (LOEC) was observed at a concentration of 53 mg/L of K +, equal to KCl concentration of 101 mg/L (Biesinger and Christensen, 1972).

Toxicity to Terrestrial Organisms

Potassium is one of the three major nutrients and chloride is an essential micronutrient for plants. No data could be located on the toxicity to terrestrial organisms.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (720 mg/L), Daphnia (177 mg/L), and algae (>100 mg/L). Although chronic studies has been conducted on fish and invertebrates, these tests are not valid for deriving PNECs (ECHA REACH database). On the basis of the short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the lowest reported effect concentration of 100 mg/L for algae. The $PNEC_{aquatic}$ is determined to be 0.1 mg/L.

$PNEC_{sediment}$: No reliable experimental toxicity data on sediment organisms are available. Potassium chloride dissociates completely in water with its environmental distribution is dominated by its high water solubility. Kow and Koc parameters do not readily apply to inorganics, such as potassium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{sediment}$. Based on the its properties, no adsorption of potassium chloride to sediment is to be expected, and the assessment of this compartment will be covered by the aquatic assessment.

$PNEC_{soil}$: No reliable experimental toxicity data on terrestrial organisms are available. The environmental distribution of potassium chloride is dominated by its water solubility. Sorption of potassium chloride should probably be regarded as a reversible situation, *i.e.*, the substance is not tightly nor permanently bound. Koc and Kow parameters do not readily apply to inorganics, such as potassium chloride. Thus, the equilibrium partitioning method cannot be used to calculate the $PNEC_{soil}$. Based on the its properties, potassium chloride is not expected to significantly adsorb to soil, and the assessment of this compartment will be covered by the aquatic assessment.

PBT Assessment

Potassium chloride is an organic salt that dissociates completely to potassium and chloride ions in aqueous solutions. Biodegradation is not applicable to these inorganic ions; both potassium and chloride ions are also ubiquitous and are present in most water, soil and sediment. For the purposes of this PBT assessment, the persistent criteria is not considered applicable to this inorganic salt.

Potassium and chloride ions are essential to all living organisms and their intracellular and extracellular concentrations are actively regulated. Thus, potassium chloride is not expected to bioaccumulate.

No chronic toxicity data exist on potassium chloride; however, the acute $EC(L)_{50}$s are >0.1 mg/L in fish, invertebrates and algae. Thus, potassium chloride does not meet the screening criteria for toxicity.

The overall conclusion is that potassium chloride is not a PBT substance.

Environmental Assessment

Shellac, Ammonium salt
(CAS No. 68308-35-8)

Lac is the hardened resinous secretion of the insesct *Kerria lacca* (Douglas, 1971; CIR, 1986). The secreted lac or sticklac contains lac resin, erythrolaccin, wax, inset debris, wood materials, sand, dust and water-soluble impurities. The semirefined seedlac of commerce is the yellowish granular material obtained from the processing of sticklac (Douglas, 1971; Misra and Sengupta, 1970; CIR, 1986).

Unrefined shellac can contain shellac wax and erythrolaccin (the yellow material), which both comprise about 6% of Shellac (CIR, 1986). The removal of these constituents yields lac resin that has a soft (30%) and hard (70%) components (CIR, 1986). Mild alkaline hydrolysis of this resin results in a complex mixture of hydroxyaliphatic and alicyclic acids and their polyesters. The composition of the mixture varies with the lac source and the time of collection (CIR, 1986).

The major component of the aliphatic fraction is aleuritic acid. The alicyclic fraction consists of sesquiterpenic acids, primarily jalaric acid and its derivatives. The native form of the pure lac resin molecule has a molecular weight of 2,095, which contains four terpene acids (mostly jalaric acid) and four aleuritic acid units in repeating ester linkage (Singh *et al.*, 1974). The proposed structure for lac resin respresents an average situation since the molecule may not always be homogenous with respect to sequence or ratio of jalaric acid to other sesquiterpenic acid substitutes (Singh *et al.*, 1974). The sesquiterpenic acids in lac resin are jalaric acid, shellolic acid, epishellolic acid, laksholic acid, and epilaksholic acid.

Aqueous shellac solutions can be prepared by neutralization with ethanolamines, alkalies, or borax (CIR, 1986).

Biodegradation

No data were found. As a natural resin, it is expected to be resistant to biodegradation.

Aquatic Toxicity

No data were found. Given that the molecular weight of the pure lac resin molecule is on average ~2,000 and that it is insoluble in water at environmentally relevant pHs, it is not expected to be bioavailable; this resin is thus expected to be non-toxic to aquatic organisms.

Environmental Assessment

Glutaraldehyde
(CAS No. 111-30-8)

Hydrolysis

In an OECD TG 111 test (hydrolysis as a function of pH), glutaraldehyde was found to be hydrolytically stable at pH 4 and pH 7, but decomposed at pH 9 (ECHA).

Phototransformation in Water

Glutaraldehyde was tested in photodegradation studies in water using EPA Guideline Subdivision N pesticide guideline161-2. Under sensitized conditions equivalent to 36 days of natural sunlight (12 hours/day; sensitized acetone system) and to 34 of natural sunlight (12 hours/day; sensitized acetonitrile system), glutaraldehyde was subjected to photolytic degradation with a half-life of 18 and 49 days, respectively. No photodegradation of glutaraldehyde occurred under darkness, and no photodegradation occurred under non-sensitized conditions (ECHA).

Biodegradation

Glutaraldehyde was considered readily biodegradable in a OECD 301A (DOC die away test). Degradation was 90-100% in 28 days (ECHA). The results of the ready biodegradation test on glutaraldehyde indicate that its half-life in water can be estimated to be 15 days (AEA 2009).

In an simulation test involving aerobic sewage treatment [activated sludge units] (OECD TG 303), glutaraldehyde degraded 97% after 73 days based on DOC removal (ECHA).

Glutaraldehyde was evaluated in an aerobic aquatic metabolism test using EPA Subdivision N pesticide guideline 162-3. The total ^{14}C residues from [^{14}C]-glutaraldehyde in pond water declined in a logarithmic fashion from about 103% (day 0) to about 9% over the complete test period of 30 days. Most of the radioactivity in the sediment was bound, with extractable ^{14}C residues being 3%. There was a major capture of radioactivity in the KOH solutions, especially for the first KOH solution, indicating$^{14}CO_2$ production; peaks in radioactivity were seen after 7 and 16 days. The total mass balance accountability decreased over the complete period, reaching about 48% of the initial dose on day 30. A half-life of 8.4 days was calculated for the decline of total radioactivity in pond water. The half-life of the degradation of [^{14}C]-glutaraldehyde was determined to be 0.5 days (ECHA).

Glutaraldehyde was evaluated in an anaerobic aquatic metabolism test using EPA Subdivision N pesticide guideline 162-3. The total ^{14}C residues from [^{14}C]-glutaraldehyde in pond water declined from about 92% to about 16% over the complete test period of 90 days. A thin layer chromatograph (TLC) of pond water samples showed that the parent compound had already disappeared on day 0. An increase in ^{14}C residues was observed in the sediment during the three first days (31%) of the test, which was followed by a decrease (13% on day 7). Most of the radioactivity in the sediment was bound, with extractable ^{14}C residues being 3%. A total of 7.12% of the initial ^{14}C dose was recovered in the trapping solutions, with 7.11% having been trapped in the first KOH trap, indicating $^{14}CO_2$ production. The ^{14}C residue half-life was reported to be 5.6 days (ECHA).

Glutaraldehyde was evaluated in an aerobic soil metabolism test using EPA Subdivision N pesticide guideline 162-1. The total ^{14}C residues from [^{14}C]-glutaraldehyde in soil decreased exponentially from day 0 to day 21, reaching 40% of the initial dose. The ^{14}C residues were constant at 40% from day 21 until the end of the experimental period on day 120. The extractable ^{14}C residues were 25% of the initial dose on day 0 and decreased to 2% by day 3 to 7; these residues remained <2% until the end of the study. The bound ^{14}C residues ranged from 76 to 121% of total ^{14}C residues throughout the study period. Thin layer chromatographs (TLC) showed that about 20% of the extracted radioactivity at day 0 was due to the parent compound glutaraldehyde. Up to day 3, no parent compound could be identified; but, on day 7 the TLC showed that about 20% of extracted radioactivity was due to the parent compound. The half-life of the degradation of [^{14}C]-glutaraldehyde was calculated to be 1.7 days (ECHA).

Bioaccumulation

Glutaraldehyde is not expected to bioaccumulate. The measured log Kow at pH 5, 7 and 9 are -0.41, -0.36 and -0.80, respectively (ECHA).

Aquatic Toxicity

The 96-hour LC_{50} values to bluegill sunfish and *Oncorhynchus mykiss* are 13 and 10 mg/L, respectively (ECHA). The 48-hour LC_{50} values to *Daphnia magna* from two different studies are 14.87 and 14 mg/L (ECHA).

The 72-hour EC_{50} values to algae *Scenedesmus subspicatus* are 0.375 mg/L [biomass] and 0.6 mg/L [growth rate]; the NOEC based on growth rate is 0.025 mg/L (ECHA). In another study, the 72-hour EC_{50} value to algae *Scenedesmus subspicatus* was reported to be 0.6 mg/L based on growth rate (ECHA).

A 97-day fish, early-life stage toxicity test has been conducted with *Oncorhynchus mykiss*. The LOEC and NOEC from this study are 5 and 1.6 mg/L, respectively (ECHA). The NOEC from a 21-day *Daphnia magna* reproduction study is 5 mg/L (ECHA).

Terrestrial Toxicity

In an acute toxicity study on earthworm *Eisenia fetida* (OECD TG 207), the 14-day LC_{50} value for glutaraldehyde is >500 mg/kg (ECHA).

Glutaraldehyde has been evaluated in a terrestrial plants test: seedling emergence and seedling growth test (OECD TG 208). The test material contained 48.9% glutaraldehyde. The 19-day EC_{50} value is >1,000 mg/kg soil dry weight for *Avena sativa* (oats) based on emergence rate, dry weight and shoot length. The 19-day EC_{50} for *Brassica napus* (rapeseed oil) is >1,000 mg/kg soil dry weight based on emergence rate and shoot length and 994 mg/kg soil dry weight based on dry weight. The 19-day EC_{50} for *Vicia sativa* (vetch) is >1,000 mg/kg soil dry weight based on emergence rate and shoot length and 901 mg/kg soil dry weight based on dry weight. The NOECs for *Avena sativa* (oats) were $\geq$1,000 mg/kg dry weight on all three parameters tested. The NOECs for *Brassica napus* (rapeseed oil) were $\geq$1,000, 500, and 250 mg/kg soil dry weight for emergence rate, dry matter, and shoot length, respectively. The NOECs for *Vicia sativa* (vetch) were $\geq$1,000, 125, and 125 mg/kg soil dry weight for emergence rate, dry matter, and shoot length, respectively (ECHA).

The 28-day EC_{50} value of glutaraldehyde to soil microorganisms in a nitrogen transformation test (OECD TG 216) was reported to be 360 mg/kg soil dry weight (ECHA).

The 28-day EC_{50} value of glutaraldehyde to soil microorganisms in a carbon transformation test (OECD TG 217) is >593 mg/kg soil dry weight (ECHA).

The 14-day LD_{50} value of glutaraldehyde to mallard ducks (*Anas platyrhynchos)* is 206 mg/kg (ECHA). The 5-day LC_{50} to (*Anas platyrhynchos)* was reported to be >2,500 ppm in feed; there was no mortality (ECHA).

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (10 mg/L), Daphnia (14 mg/L), and algae (0.375 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC being 0.025 mg/L for algae. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported long-term NOEC of 0.025 mg/L for algae. The $PNEC_{aquatic}$ is 0.0025 mg/L.

PBT Assessment

Glutaraldehyde is readily biodegradable and thus does not meet the screening criteria for persistence.

The log Pow for glutaraldehyde at different pH values ranges from -0.36 to -0.80. Thus, glutaraldehyde does not meet the screening criteria for bioaccumulation.

Chronic NOECs for fish, daphnia and algae are available for glutaraldehyde and the NOEC values are >0.01 mg/L. Thus, glutaraldehyde does not meet the screening criteria for toxic.

The overall conclusion is that glutaraldehyde is not a PBT substance.

Environmental Assessment

Tributyl Tetradecyl Phosphonium Chloride [TTPC]
(CAS No. 81741-28-8)

Limited information was located for this alkyl phosphonium salt.

Hydrolysis
TTPC is stable in water over a wide range of pH values (BuruEnergy).

Photolysis
TTPC is not susceptible to photolysis (BuruEnergy).

Biodegradation
TTPC was not readily biodegradable in an OECD 301 test (BuruEnergy).

In a die-away [simulation] test (using activated sludge) with radiolabelled TTPC for 168 hours at 0.31 mg/L, the first-order rate constant was 0.69/hour and the half-life was 6.6 hours. After 24 and 168 hours, degradation was >81% and >98%, respectively (BuruEnergy).

TTPC was evaluation in simulation tests over a 40-day period using double ^{14}C labeled TTPC. In activated sludge, there was >40% degradation after 30 days with 50 ppb TTPC and >30% degradation after 7 days with 5 ppb TTPC. In river water, there was >20% after 35 days with 5 ppb TTPC. In sea water, there was >30% degradation after 35 days with 5 ppb TTPC (BuruEnergy).

Adsorption/Desorption
The soil adsorption/desorption of TTPC was tested with three soils differing in sand/silt/clay content, by running an aqueous solution of radiolabelled TTPC through a column of soil. Soil adsorption ranged from 93-96% (BuruEnergy).

Bioaccumulation
The octanol-water coefficient (K_{ow}) was determined experimentally to be 2.45 from an OECD 107 test (BuruEnergy).

Aquatic Toxicity

Bellacide 350 MSDS: The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L.

U.S. EPA OPP Pesticide Ecotoxicity Database (wit study details): The 96-hour LC_{50}s in

rainbow trout are 0.49 and 0.2 mg/L. The 96-hour LC_{50}s in Bluegill sunfish and common carp (*Cyprinus carpio*) are 0.06 and 0.09 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* is 0.025 mg/L.

Environmental Properties of Proposed Biocide BE-9 (Document from BuruEnergy)
The 96-hour LC_{50}s in rainbow trout and Bluegill sunfish were reported to be 0.46 mg/L and 0.06 mg/L, respectively. The 48-hour EC_{50} in *Daphnia* was reported to be 0.025 mg/L. The 72-hour EC_{50} in green algae *Selenastrum capricornutum* was reported to be 0.019 mg/L.

Toxicity to Sediment Organisms

No data were found.

Toxicity to Terrestrial Organisms

U.S. EPA OPP Pesticide Ecotoxicity Database: The 8-day dietary LC_{50} in Bobwhite Quail is 4,215 ppm, with a NOEL of 1,980 ppm. The 8-day dietary LC_{50} in Mallard Duck is 3,663 ppm, with a NOEL of 1,780 ppm. The 14-day oral gavage LD_{50} in Mallard Duck is 232 mg/kg, with a NOEL of 178 mg/kg.

Determination of PNECs

$PNEC_{aquatic}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.2 mg/L), Daphnia (0.025 mg/L), and algae (0.019 mg/L). While the lowest acute value is 0.019 mg/L, it has only been reported in summary document from BuruEnergy and needs to be substantiated. For the purposes of PNEC determination, the acute EC_{50} value for Daphnia will be used. It should be noted that the two values are very similar.

On the basis that the data consists of short-term results from three trophic levels, an assessment factor of 1,000 has been applied to the effect concentration of 0.025 mg/L for *Daphnia*. The $PNEC_{aquatic}$ is calculated to be 2.5×10^{-5} mg/L (0.025 μg/L).

PBT Assessment

TTPC is not readily biodegradable. In a simulation test using river water, there was >20% after 35 days. Thus, TTPC appears to meet the screening criteria for persistence.

The octanol-water coefficient (K_{ow}) for TTPC is 2.45. Thus, TTPC does not meet the screening criteria for bioaccumulation.

No chronic toxicity data are available for TTPC. The lowest acute $EC(L)_{50}$ of TTPC is 0.025 mg/L in invertebrates. Since this value is <0.1 mg/L, TTPC does meet the screening criteria for toxicity.

APPENDIX H.7 CHEMICAL FRACTURING TRACERS (CFTS) TRACER ADDITIVE PBT ASSESSMENT AND SCREENING EVALUATION

MEMO

To: Santos GLNG

From: Tom Biksey and Chris Bevan

CC: Nigel Goulding

Date: October 26, 2016

Re: **Chemical Fracturing Tracers (CFTs) Tracer Additive PBT Assessment and Screening Evaluation**

Introduction

Santos GLNG (Santos) is looking to use new water soluble tracer additives in their hydraulic fracturing process. The use of Chemical Fracturing Tracers (CFTs), is being proposed to evaluate produced water profiles and water movement within the gas reservoir. A unique CFT tracer is injected into each fracturing stage. Following the completion when the well is put on production, water samples are collected and analysed for the presence and concentration of the CFTs in each sample. The injection technique used in the field for all of the tracers is very similar. The injection of the tracers requires an electric pump, and the tracers can be injected at any suitable point on the low pressure treatment line, normally at the suction side of the high pressure fracturing pumps. Expected tracer concentration injected is expected to be 1.5 ppm. **Attachment 1** includes the Safety Data Sheets for the CFTs.

For the environmental hazard assessment, a PBT (persistence, bioaccumulative, toxic) assessment was conducted in accordance with the guidance developed by DEWHA (2009), as presented in the RA Compendium. The PBT assessment is conducted because of specific concerns for substances that can be shown to persist for long periods in the environment, to bioaccumulate in food chains, and can give rise to toxic effects after a longer time and over a greater spatial scale than chemicals without these properties. These effects may be difficult to detect at an early stage because of long-term exposures at normally low concentration levels and long life-cycles of species at the top of the food chain.

In addition, where applicable, the tracers will be assessed based on risk-based screening values for comparison to the sample analyses of the tracers. The risk-based screening values will be based on the availability of toxicological data; there is a paucity of experimental data on the 16 new chemicals, therefore, toxicological modeling will be used including EPI SUITE™ or similar QSAR modeling software (e.g., OECD); the SMILES notation will be obtained from TOXNET database. Where appropriate, surrogates may be used for human health and ecological toxicological endpoints.

PBT Assessment

The QSAR Modelling (EPISUITE) data for the PBT assessment are presented in **Tables 1** and **2**. The results of the PBT assessment for the chemical constituents in the CRT tracers are summarised in **Table 3**. There were no tracers that were considered at PBTs.

Comparison to Risk-Based Screening Criteria

The determination of risk-based screening criteria will be conducted according to the predicted no-effects concentration (PNEC) guidance in the Environmental Risk Assessment Guidance Manual for Industrial Chemicals prepared by the Australian Environmental Agency (AEA, 2009).

The PNECs are determined by dividing the lowest toxicity value from a laboratory test by the relevant assessment factor. Results of long-term tests (expressed as the 10 percent effective concentration [EC10] or no observable effects concentration [NOEC]) are preferred to those of short-term tests (50 percent effective concentration/lethal concentration [EC/LC50]) because the results give a more realistic picture of effects on the organisms during their entire life cycle.

It is preferable to use actual measured data in effects assessment and in estimation of PNECs. However, when limited or no data were available (e.g. data for only one test species) or when the measured data for a species were unacceptable, then estimation using QSARs was considered. With the exception of the $PNEC_{aquatic}$ value for nitrate (used for magnesium nitrate), the aquatic toxicity data sets for the chemicals were insufficient for using the species sensitivity distribution approach. In the case of nitrate, the ANZECC water quality guideline of 700 µg/L was used for the $PNEC_{aquatic}$; this value had been derived using the statistical distribution method.

Note that there was no human health toxicity information located on the fluorobenzoic acid compounds or on similar compounds. Therefore, no oral reference dose (RfD) or drinking water guidance values were derived.

Based on stimulation flow back monitoring conducted by Santos and the Quantitative Risk Assessment completed for the Schlumberger Fluid Systems (Appendix C of the RA Compendium), 20 percent of the total mass of constituents injected is assumed to be recovered in the flowback water. This mass is diluted within 150 percent of the injected volume (the minimum volume that must be flowed back) to establish an "estimated" concentration (i.e., concentration expected due to full dilution of the back flow water) within the flowback storage ponds. Assessment of the flowback to the CRT tracer PNEC concentrations was based on the concentration of the tracer 1.5 mg/l, divided by 1.5 factor (150 percent of injected fluid volume per coal seam) times 0.2 factor (20 percent mass returned). This results in an exposure point concentration (EPC) of 0.2 mg/l.

Comparing the EPC concentration to the calculated $PNECa_{quatic}$ values in **Table 4**, two tracers, 3-(Trifluoromethyl) benzoic acid and 4-(Trifluoromethyl) benzoic acid, had $PNEC_{aquatic}$ values less than the estimated EPC of 0.2 mg/l used for all the tracer EPCs. The order of magnitude of this exceedance is less than one, indicating that the estimated potential risk to exposed aquatic receptors is within the acceptable range based on the overall conservatism in the $PNEC_{aquatic}$ value derivation.

ATTACHMENT 1 - SAFETY DATA SHEETS

SAFETY DATA SHEET

Date-Issued: 05-2015
SDS Ref. No: CFT
Date-Revised: 5/26/2016
Revision No:002

1. PRODUCT AND COMPANY IDENTIFICATION

1.1 Product Identifiers

Product name	:	2,3-Difluorobenzoic acid
Generic name	:	23-DFBA

1.2 Relevant identified used of the substance or mixture and uses advised against

Identified uses	:	Diagnostic
Uses advised against	:	Not available

1.3 Details of the supplier of the safety data sheet

Importer	:	ProTechnics International Division of Core Laboratories 31-35 George St. Thebarton, SA, AUSTRALIA 5031
Telephone	:	(08) 8152 0244

1.4 Emergency telephone number

Poisons Information Centre	:	13 11 26 (24 hour)
Ambulance, Fire, Police	:	000

2. HAZARDS IDENTIFICATION

2.1 Classification of the substance or mixture

GHS classification in accordance with 29 CFR 1910 (OSHA HCS)
Skin irritation (Category 2), H315
Eye irritation (Category 2), H319
Specific target organ toxicity – single exposure (Category 3), Respiratory system, H335

2.2 GHS Label elements, including precautionary statements

Pictogram

Signal word Warning

Hazard statement(s)

H315	Causes skin irritation.
H319	Causes serious eye irritation.
H335	May cause respiratory irritation.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P264	Wash skin thoroughly after handling.
P280	Wear protective gloves.
P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
P304 + P340	IF INHALED: Remove affected person into fresh air and keep at rest in a position comfortable for breathing.
P332 + P313	If skin irritation occurs: Get medical advice/ attention.

2.3 Hazards not otherwise classified (HNOC) or not covered by GHS - none

---

3. COMPOSITION / INFORMATION ON INGREDIENTS

3.1 Substances

Substance/ mixture Mixture

Ingredient	CAS/Exempt No	Percent	Hazardous
2,3-Difluorobenzoic acid	4519-39-5	10	No
Water	7732-18-5	90	No

---

4. FIRST AID MEASURES

4.1 Description of first aid measures

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance. Move out of dangerous area.

If inhaled
Move person into fresh air. If cough or other symptoms develop, consult a physician.

In case of skin contact
Remove contaminated clothing including shoes and immediately wash affected area with plenty of soap and water. If irritation continues, consult a physician. Wash contaminated clothing and shoes before reuse.

In case of eye contact
Immediately flush eyes with plenty of water for two to three minutes. Remove any contact lenses and continue flushing for 15 minutes. If irritation continues, consult a physician.

If swallowed
Wash out mouth with water and keep at rest. Consult a physician.

4.2 Most important symptoms and effects, both acute and delayed

The most important known symptoms and effects are described in the labeling (see Section 2.2) and/or in Section 11.

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

---

9. PHYSICAL AND CHEMICAL PROPERTIES

9.1 Information on basic physical and chemical properties

a)	Appearance	Form: aqueous liquid Color: translucent
b)	Odor Boiling	Odorless
c)	point Freeze	Approximately 100°C
d)	point	0°C
e)	Density	1.05 g/mL
f)	Flash point	Not flammable
g)	pH	Approximately 9
h)	Evaporation factor	Not determined
i)	Solubility	Soluble in water
j)	Vapor pressure	Not determined
k)	Oxidizing properties	Not determined
l)	Vapor density	Not determined
m)	Viscosity	Not determined

9.2 Other safety information

No data available.

---

10. STABILITY AND REACTIVITY

10.1 Reactivity

Strong acids. Oxidizing materials.

10.2 Chemical stability

The product is stable under normal ambient conditions of temperature and pressure.

10.3 Possibility of hazardous reactions

Will not polymerize.

10.4 Conditions to avoid

Extreme cold.

10.5 Incompatible materials

Strong acids. Oxidizing materials.

10.6 Hazardous decomposition products

None.

---

11. . TOXICOLOGICAL INFORMATION

11.1 Information on toxicological effects

Acute toxicity – oral
Based on available data the classification criteria are not met.

Acute toxicity – dermal
Based on available data the classification criteria are not met.

Acute toxicity – inhalation
Based on available data the classification criteria are not met.

Skin corrosion/irritation
Skin irritant 2 – H315 Causes skin irritation.

Serious eye damage/irritation
Eye irritant 2 – H319 May cause severe eye irritation.

Respiratory sensitization
Based on available data the classification criteria are not met.

Skin sensitization
Based on available data the classification criteria are not met.

Germ cell mutagenicity

Genotoxicity – in vitro
Based on available data the classification criteria are not met.

Genotoxicity- in vivo
Based on available data the classification criteria are not met.

Carcinogenicity

IARC: No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible, or confirmed human carcinogen by IARC.

ACGIH: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

NTP: No component of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP

OSHA: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA.

Reproductive toxicity

Reproductive toxicity – fertility
Based on available data the classification criteria are not met.

Reproductive toxicity – development
Based on available data the classification criteria are not met.

Specific target organ toxicity – single exposure
STOT SE 3 – H335 May cause respiratory irritation.

Specific target organ toxicity – repeated exposure
Based on available data the classification criteria are not met.

Aspiration hazard
Not anticipated to present an aspiration hazard, based on chemical structure.

Additional information
RTECS: Not available.

To the best of our knowledge, the chemical, physical, and toxicological properties have not been thoroughly investigated.

12. ECOLOGICAL INFORMATION

12.1 Toxicity

No data available.

12.2 Persistence and degradability

Presumed to be persistent.

12.3 Bioaccumulative potential

No data available.

12.4 Mobility in soil

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

16. OTHER INFORMATION

HMIS Rating

Health Hazard:	1
Chronic Health Hazard:	
Flammability:	0
Physical Hazard:	0

NFPA Rating

Health Hazard:	1
Fire Hazard:	0
Reactivity Hazard:	0

MANUFACTURER DISCLAIMER: Information given herein is offered in good faith as accurate, but without guarantee. Conditions of use and suitability of the product for particular uses are beyond our control; all risks of use of the product are therefore assumed by the user. Nothing is intended as a recommendation for uses which infringe valid patents or as extending license under valid patents. Appropriate warnings and safe handling procedures should be provided to handlers and users.

9.2 Other safety information

No data available.

---

10. STABILITY AND REACTIVITY

10.1 Reactivity

Strong acids. Oxidizing materials.

10.2 Chemical stability

The product is stable under normal ambient conditions of temperature and pressure.

10.3 Possibility of hazardous reactions

Will not polymerize.

10.4 Conditions to avoid

Extreme cold.

10.5 Incompatible materials

Strong acids. Oxidizing materials.

10.6 Hazardous decomposition products

None.

---

11. . TOXICOLOGICAL INFORMATION

11.1 Information on toxicological effects

Acute toxicity – oral
Based on available data the classification criteria are not met.

Acute toxicity – dermal
Based on available data the classification criteria are not met.

Acute toxicity – inhalation
Based on available data the classification criteria are not met.

Skin corrosion/irritation
Skin irritant 2 – H315 Causes skin irritation.

Serious eye damage/irritation
Eye irritant 2 – H319 May cause severe eye irritation.

Respiratory sensitization
Based on available data the classification criteria are not met.

Skin sensitization
Based on available data the classification criteria are not met.

Germ cell mutagenicity

Genotoxicity – in vitro
Based on available data the classification criteria are not met.

Genotoxicity- in vivo
Based on available data the classification criteria are not met.

Carcinogenicity

IARC: No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible, or confirmed human carcinogen by IARC.

ACGIH: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

NTP: No component of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP

OSHA: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA.

Reproductive toxicity

Reproductive toxicity – fertility
Based on available data the classification criteria are not met.

Reproductive toxicity – development
Based on available data the classification criteria are not met.

Specific target organ toxicity – single exposure
STOT SE 3 – H335 May cause respiratory irritation.

Specific target organ toxicity – repeated exposure
Based on available data the classification criteria are not met.

Aspiration hazard
Not anticipated to present an aspiration hazard, based on chemical structure.

Additional information
RTECS: Not available.

To the best of our knowledge, the chemical, physical, and toxicological properties have not been thoroughly investigated.

12. ECOLOGICAL INFORMATION

12.1 Toxicity

No data available.

12.2 Persistence and degradability

Presumed to be persistent.

12.3 Bioaccumulative potential

No data available.

12.4 Mobility in soil

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

16. OTHER INFORMATION

SAFETY DATA SHEET

Date-Issued: 05-2015
SDS Ref. No: CFT
Date-Revised: 5/26/2016
Revision No:002

1. PRODUCT AND COMPANY IDENTIFICATION

1.1 Product Identifiers

Product name	:	2,4,5-Trifluorobenzoic acid
Generic name	:	245-TFBA

1.2 Relevant identified used of the substance or mixture and uses advised against

Identified uses	:	Diagnostic
Uses advised against	:	Not available

1.3 Details of the supplier of the safety data sheet

Importer	:	ProTechnics International Division of Core Laboratories 31-35 George St. Thebarton, SA, AUSTRALIA 5031
Telephone	:	(08) 8152 0244

1.4 Emergency telephone number

Poisons Information Centre	:	13 11 26 (24 hour)
Ambulance, Fire, Police	:	000

2. HAZARDS IDENTIFICATION

2.1 Classification of the substance or mixture

GHS classification in accordance with 29 CFR 1910 (OSHA HCS)
Skin irritation (Category 2), H315
Eye irritation (Category 2), H319
Specific target organ toxicity – single exposure (Category 3), Respiratory system, H335

2.2 GHS Label elements, including precautionary statements

Pictogram

Signal word Warning

Hazard statement(s)

H315	Causes skin irritation.
H319	Causes serious eye irritation.
H335	May cause respiratory irritation.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P264	Wash skin thoroughly after handling.
P280	Wear protective gloves.
P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
P304 + P340	IF INHALED: Remove affected person into fresh air and keep at rest in a position comfortable for breathing.
P332 + P313	If skin irritation occurs: Get medical advice/ attention.

2.3 Hazards not otherwise classified (HNOC) or not covered by GHS - none

---

3. COMPOSITION / INFORMATION ON INGREDIENTS

3.1 Substances

Substance/ mixture Mixture

Ingredient	CAS/Exempt No	Percent	Hazardous
2,4,5-Trifluorobenzoic acid	446-17-3	10	No
Water	7732-18-5	90	No

---

4. FIRST AID MEASURES

4.1 Description of first aid measures

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance. Move out of dangerous area.

If inhaled
Move person into fresh air. If cough or other symptoms develop, consult a physician.

In case of skin contact
Remove contaminated clothing including shoes and immediately wash affected area with plenty of soap and water. If irritation continues, consult a physician. Wash contaminated clothing and shoes before reuse.

In case of eye contact
Immediately flush eyes with plenty of water for two to three minutes. Remove any contact lenses and continue flushing for 15 minutes. If irritation continues, consult a physician.

If swallowed
Wash out mouth with water and keep at rest. Consult a physician.

4.2 Most important symptoms and effects, both acute and delayed

The most important known symptoms and effects are described in the labeling (see Section 2.2) and/or in Section 11.

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

---

9. PHYSICAL AND CHEMICAL PROPERTIES

9.1 Information on basic physical and chemical properties

a)	Appearance	Form: aqueous liquid Color: translucent
b)	Odor Boiling	Odorless
c)	point Freeze	Approximately 100°C
d)	point	0°C
e)	Density	1.05 g/mL
f)	Flash point	Not flammable
g)	pH	Approximately 9
h)	Evaporation factor	Not determined
i)	Solubility	Soluble in water
j)	Vapor pressure	Not determined
k)	Oxidizing properties	Not determined
l)	Vapor density	Not determined
m)	Viscosity	Not determined

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

---

9. PHYSICAL AND CHEMICAL PROPERTIES

9.1 Information on basic physical and chemical properties

a)	Appearance	Form: aqueous liquid Color: translucent
b)	Odor Boiling	Odorless
c)	point Freeze	Approximately 100°C
d)	point	0°C
e)	Density	1.05 g/mL
f)	Flash point	Not flammable
g)	pH	Approximately 9
h)	Evaporation factor	Not determined
i)	Solubility	Soluble in water
j)	Vapor pressure	Not determined
k)	Oxidizing properties	Not determined
l)	Vapor density	Not determined
m)	Viscosity	Not determined

9.2 Other safety information

No data available.

---

10. STABILITY AND REACTIVITY

10.1 Reactivity

Strong acids. Oxidizing materials.

10.2 Chemical stability

The product is stable under normal ambient conditions of temperature and pressure.

10.3 Possibility of hazardous reactions

Will not polymerize.

10.4 Conditions to avoid

Extreme cold.

10.5 Incompatible materials

Strong acids. Oxidizing materials.

10.6 Hazardous decomposition products

None.

---

11. . TOXICOLOGICAL INFORMATION

11.1 Information on toxicological effects

Acute toxicity – oral
Based on available data the classification criteria are not met.

Acute toxicity – dermal
Based on available data the classification criteria are not met.

Acute toxicity – inhalation
Based on available data the classification criteria are not met.

Skin corrosion/irritation
Skin irritant 2 – H315 Causes skin irritation.

Serious eye damage/irritation
Eye irritant 2 – H319 May cause severe eye irritation.

Respiratory sensitization
Based on available data the classification criteria are not met.

Skin sensitization
Based on available data the classification criteria are not met.

Germ cell mutagenicity

Genotoxicity – in vitro
Based on available data the classification criteria are not met.

Genotoxicity- in vivo
Based on available data the classification criteria are not met.

Carcinogenicity

IARC: No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible, or confirmed human carcinogen by IARC.

ACGIH: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

NTP: No component of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP

OSHA: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA.

Reproductive toxicity

Reproductive toxicity – fertility
Based on available data the classification criteria are not met.

Reproductive toxicity – development
Based on available data the classification criteria are not met.

Specific target organ toxicity – single exposure
STOT SE 3 – H335 May cause respiratory irritation.

Specific target organ toxicity – repeated exposure
Based on available data the classification criteria are not met.

Aspiration hazard
Not anticipated to present an aspiration hazard, based on chemical structure.

Additional information
RTECS: Not available.

To the best of our knowledge, the chemical, physical, and toxicological properties have not been thoroughly investigated.

12. ECOLOGICAL INFORMATION

12.1 Toxicity

No data available.

12.2 Persistence and degradability

Presumed to be persistent.

12.3 Bioaccumulative potential

No data available.

12.4 Mobility in soil

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

16. OTHER INFORMATION

SAFETY DATA SHEET

Date-Issued: 05-2015
SDS Ref. No: CFT
Date-Revised: 5/26/2016
Revision No:002

1. PRODUCT AND COMPANY IDENTIFICATION

1.1 Product Identifiers

Product name	:	3,4-Difluorobenzoic acid
Generic name	:	34-DFBA

1.2 Relevant identified used of the substance or mixture and uses advised against

Identified uses	:	Diagnostic
Uses advised against	:	Not available

1.3 Details of the supplier of the safety data sheet

Importer	:	ProTechnics International Division of Core Laboratories 31-35 George St. Thebarton, SA, AUSTRALIA 5031
Telephone	:	(08) 8152 0244

1.4 Emergency telephone number

Poisons Information Centre	:	13 11 26 (24 hour)
Ambulance, Fire, Police	:	000

2. HAZARDS IDENTIFICATION

2.1 Classification of the substance or mixture

GHS classification in accordance with 29 CFR 1910 (OSHA HCS)
Skin irritation (Category 2), H315
Eye irritation (Category 2), H319
Specific target organ toxicity – single exposure (Category 3), Respiratory system, H335

2.2 GHS Label elements, including precautionary statements

Pictogram

Signal word Warning

Hazard statement(s)

H315	Causes skin irritation.
H319	Causes serious eye irritation.
H335	May cause respiratory irritation.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P264	Wash skin thoroughly after handling.
P280	Wear protective gloves.
P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
P304 + P340	IF INHALED: Remove affected person into fresh air and keep at rest in a position comfortable for breathing.
P332 + P313	If skin irritation occurs: Get medical advice/ attention.

2.3 Hazards not otherwise classified (HNOC) or not covered by GHS - none

---

3. COMPOSITION / INFORMATION ON INGREDIENTS

3.1 Substances

Substance/ mixture Mixture

Ingredient	CAS/Exempt No	Percent	Hazardous
3,4-Difluorobenzoic acid	455-86-7	10	No
Water	7732-18-5	90	No

---

4. FIRST AID MEASURES

4.1 Description of first aid measures

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance. Move out of dangerous area.

If inhaled
Move person into fresh air. If cough or other symptoms develop, consult a physician.

In case of skin contact
Remove contaminated clothing including shoes and immediately wash affected area with plenty of soap and water. If irritation continues, consult a physician. Wash contaminated clothing and shoes before reuse.

In case of eye contact
Immediately flush eyes with plenty of water for two to three minutes. Remove any contact lenses and continue flushing for 15 minutes. If irritation continues, consult a physician.

If swallowed
Wash out mouth with water and keep at rest. Consult a physician.

4.2 Most important symptoms and effects, both acute and delayed

The most important known symptoms and effects are described in the labeling (see Section 2.2) and/or in Section 11.

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

1.3 Details of the supplier of the safety data sheet

Importer	:	ProTechnics International Division of Core Laboratories 31-35 George St. Thebarton, SA, AUSTRALIA 5031
Telephone	:	(08) 8152 0244

1.4 Emergency telephone number

Poisons Information Centre	:	13 11 26 (24 hour)
Ambulance, Fire, Police	:	000

2. HAZARDS IDENTIFICATION

2.1 Classification of the substance or mixture

GHS classification in accordance with 29 CFR 1910 (OSHA HCS)
Skin irritation (Category 2), H315
Eye irritation (Category 2), H319
Specific target organ toxicity – single exposure (Category 3), Respiratory system, H335

2.2 GHS Label elements, including precautionary statements

Pictogram

Signal word Warning

Hazard statement(s)

H315	Causes skin irritation.
H319	Causes serious eye irritation.
H335	May cause respiratory irritation.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P264	Wash skin thoroughly after handling.
P280	Wear protective gloves.
P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
P304 + P340	IF INHALED: Remove affected person into fresh air and keep at rest in a position comfortable for breathing.
P332 + P313	If skin irritation occurs: Get medical advice/ attention.

2.3 Hazards not otherwise classified (HNOC) or not covered by GHS - none

---

3. COMPOSITION / INFORMATION ON INGREDIENTS

3.1 Substances

Substance/ mixture Mixture

Ingredient	CAS/Exempt No	Percent	Hazardous
2,5-Difluorobenzoic acid	2991-28-8	10	No
Water	7732-18-5	90	No

---

4. FIRST AID MEASURES

4.1 Description of first aid measures

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance. Move out of dangerous area.

If inhaled
Move person into fresh air. If cough or other symptoms develop, consult a physician.

In case of skin contact
Remove contaminated clothing including shoes and immediately wash affected area with plenty of soap and water. If irritation continues, consult a physician. Wash contaminated clothing and shoes before reuse.

In case of eye contact
Immediately flush eyes with plenty of water for two to three minutes. Remove any contact lenses and continue flushing for 15 minutes. If irritation continues, consult a physician.

If swallowed
Wash out mouth with water and keep at rest. Consult a physician.

4.2 Most important symptoms and effects, both acute and delayed

The most important known symptoms and effects are described in the labeling (see Section 2.2) and/or in Section 11.

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

---

9. PHYSICAL AND CHEMICAL PROPERTIES

9.1 Information on basic physical and chemical properties

a)	Appearance	Form: aqueous liquid Color: translucent
b)	Odor Boiling	Odorless
c)	point Freeze	Approximately 100°C
d)	point	0°C
e)	Density	1.05 g/mL
f)	Flash point	Not flammable
g)	pH	Approximately 9
h)	Evaporation factor	Not determined
i)	Solubility	Soluble in water
j)	Vapor pressure	Not determined
k)	Oxidizing properties	Not determined
l)	Vapor density	Not determined
m)	Viscosity	Not determined

9.2 Other safety information

No data available.

---

10. STABILITY AND REACTIVITY

10.1 Reactivity

Strong acids. Oxidizing materials.

10.2 Chemical stability

The product is stable under normal ambient conditions of temperature and pressure.

10.3 Possibility of hazardous reactions

Will not polymerize.

10.4 Conditions to avoid

Extreme cold.

10.5 Incompatible materials

Strong acids. Oxidizing materials.

10.6 Hazardous decomposition products

None.

---

11. . TOXICOLOGICAL INFORMATION

11.1 Information on toxicological effects

Acute toxicity – oral
Based on available data the classification criteria are not met.

Acute toxicity – dermal
Based on available data the classification criteria are not met.

Acute toxicity – inhalation
Based on available data the classification criteria are not met.

Skin corrosion/irritation
Skin irritant 2 – H315 Causes skin irritation.

Serious eye damage/irritation
Eye irritant 2 – H319 May cause severe eye irritation.

Respiratory sensitization
Based on available data the classification criteria are not met.

Skin sensitization
Based on available data the classification criteria are not met.

Germ cell mutagenicity

Genotoxicity – in vitro
Based on available data the classification criteria are not met.

Genotoxicity- in vivo
Based on available data the classification criteria are not met.

Carcinogenicity

IARC: No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible, or confirmed human carcinogen by IARC.

ACGIH: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

NTP: No component of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP

OSHA: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA.

Reproductive toxicity

Reproductive toxicity – fertility
Based on available data the classification criteria are not met.

Reproductive toxicity – development
Based on available data the classification criteria are not met.

Specific target organ toxicity – single exposure
STOT SE 3 – H335 May cause respiratory irritation.

Specific target organ toxicity – repeated exposure
Based on available data the classification criteria are not met.

Aspiration hazard
Not anticipated to present an aspiration hazard, based on chemical structure.

Additional information
RTECS: Not available.

To the best of our knowledge, the chemical, physical, and toxicological properties have not been thoroughly investigated.

12. ECOLOGICAL INFORMATION

12.1 Toxicity

No data available.

12.2 Persistence and degradability

Presumed to be persistent.

12.3 Bioaccumulative potential

No data available.

12.4 Mobility in soil

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

16. OTHER INFORMATION

HMIS Rating

Health Hazard:	1
Chronic Health Hazard:	
Flammability:	0
Physical Hazard:	0

NFPA Rating

Health Hazard:	1
Fire Hazard:	0
Reactivity Hazard:	0

MANUFACTURER DISCLAIMER: Information given herein is offered in good faith as accurate, but without guarantee. Conditions of use and suitability of the product for particular uses are beyond our control; all risks of use of the product are therefore assumed by the user. Nothing is intended as a recommendation for uses which infringe valid patents or as extending license under valid patents. Appropriate warnings and safe handling procedures should be provided to handlers and users.

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

SAFETY DATA SHEET

Date-Issued: 05-2015
SDS Ref. No: CFT
Date-Revised: 5/26/2016
Revision No:002

1. PRODUCT AND COMPANY IDENTIFICATION

1.1 Product Identifiers

Product name	:	4-Fluorobenzoic acid
Generic name	:	4-FBA

1.2 Relevant identified used of the substance or mixture and uses advised against

Identified uses	:	Diagnostic
Uses advised against	:	Not available

1.3 Details of the supplier of the safety data sheet

Importer	:	ProTechnics International Division of Core Laboratories 31-35 George St. Thebarton, SA, AUSTRALIA 5031
Telephone	:	(08) 8152 0244

1.4 Emergency telephone number

Poisons Information Centre	:	13 11 26 (24 hour)
Ambulance, Fire, Police	:	000

2. HAZARDS IDENTIFICATION

2.1 Classification of the substance or mixture

GHS classification in accordance with 29 CFR 1910 (OSHA HCS)
Skin irritation (Category 2), H315
Eye irritation (Category 2), H319
Specific target organ toxicity – single exposure (Category 3), Respiratory system, H335

2.2 GHS Label elements, including precautionary statements

Pictogram

Signal word Warning

Hazard statement(s)

H315	Causes skin irritation.
H319	Causes serious eye irritation.
H335	May cause respiratory irritation.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P264	Wash skin thoroughly after handling.
P280	Wear protective gloves.
P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
P304 + P340	IF INHALED: Remove affected person into fresh air and keep at rest in a position comfortable for breathing.
P332 + P313	If skin irritation occurs: Get medical advice/ attention.

2.3 Hazards not otherwise classified (HNOC) or not covered by GHS - none

---

3. COMPOSITION / INFORMATION ON INGREDIENTS

3.1 Substances

Substance/ mixture Mixture

Ingredient	CAS/Exempt No	Percent	Hazardous
4-Fluorobenzoic acid	456-22-4	10	No
Water	7732-18-5	90	No

---

4. FIRST AID MEASURES

4.1 Description of first aid measures

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance. Move out of dangerous area.

If inhaled
Move person into fresh air. If cough or other symptoms develop, consult a physician.

In case of skin contact
Remove contaminated clothing including shoes and immediately wash affected area with plenty of soap and water. If irritation continues, consult a physician. Wash contaminated clothing and shoes before reuse.

In case of eye contact
Immediately flush eyes with plenty of water for two to three minutes. Remove any contact lenses and continue flushing for 15 minutes. If irritation continues, consult a physician.

If swallowed
Wash out mouth with water and keep at rest. Consult a physician.

4.2 Most important symptoms and effects, both acute and delayed

The most important known symptoms and effects are described in the labeling (see Section 2.2) and/or in Section 11.

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

---

9. PHYSICAL AND CHEMICAL PROPERTIES

9.1 Information on basic physical and chemical properties

a)	Appearance	Form: aqueous liquid Color: translucent
b)	Odor Boiling	Odorless
c)	point Freeze	Approximately 100°C
d)	point	0°C
e)	Density	1.05 g/mL
f)	Flash point	Not flammable
g)	pH	Approximately 9
h)	Evaporation factor	Not determined
i)	Solubility	Soluble in water
j)	Vapor pressure	Not determined
k)	Oxidizing properties	Not determined
l)	Vapor density	Not determined
m)	Viscosity	Not determined

9.2 Other safety information

No data available.

---

10. STABILITY AND REACTIVITY

10.1 Reactivity

Strong acids. Oxidizing materials.

10.2 Chemical stability

The product is stable under normal ambient conditions of temperature and pressure.

10.3 Possibility of hazardous reactions

Will not polymerize.

10.4 Conditions to avoid

Extreme cold.

10.5 Incompatible materials

Strong acids. Oxidizing materials.

10.6 Hazardous decomposition products

None.

---

11. . TOXICOLOGICAL INFORMATION

11.1 Information on toxicological effects

Acute toxicity – oral
Based on available data the classification criteria are not met.

Acute toxicity – dermal
Based on available data the classification criteria are not met.

Acute toxicity – inhalation
Based on available data the classification criteria are not met.

Skin corrosion/irritation
Skin irritant 2 – H315 Causes skin irritation.

Serious eye damage/irritation
Eye irritant 2 – H319 May cause severe eye irritation.

Respiratory sensitization
Based on available data the classification criteria are not met.

Skin sensitization
Based on available data the classification criteria are not met.

Germ cell mutagenicity

Genotoxicity – in vitro
Based on available data the classification criteria are not met.

Genotoxicity- in vivo
Based on available data the classification criteria are not met.

Carcinogenicity

IARC: No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible, or confirmed human carcinogen by IARC.

ACGIH: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

NTP: No component of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP

OSHA: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA.

Reproductive toxicity

Reproductive toxicity – fertility
Based on available data the classification criteria are not met.

Reproductive toxicity – development
Based on available data the classification criteria are not met.

Specific target organ toxicity – single exposure
STOT SE 3 – H335 May cause respiratory irritation.

Specific target organ toxicity – repeated exposure
Based on available data the classification criteria are not met.

Aspiration hazard
Not anticipated to present an aspiration hazard, based on chemical structure.

Additional information
RTECS: Not available.

To the best of our knowledge, the chemical, physical, and toxicological properties have not been thoroughly investigated.

12. ECOLOGICAL INFORMATION

12.1 Toxicity

No data available.

12.2 Persistence and degradability

Presumed to be persistent.

12.3 Bioaccumulative potential

No data available.

12.4 Mobility in soil

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

10. STABILITY AND REACTIVITY

10.1 Reactivity

Strong acids. Oxidizing materials.

10.2 Chemical stability

The product is stable under normal ambient conditions of temperature and pressure.

10.3 Possibility of hazardous reactions

Will not polymerize.

10.4 Conditions to avoid

Extreme cold.

10.5 Incompatible materials

Strong acids. Oxidizing materials.

10.6 Hazardous decomposition products

None.

---

11. . TOXICOLOGICAL INFORMATION

11.1 Information on toxicological effects

Acute toxicity – oral
Based on available data the classification criteria are not met.

Acute toxicity – dermal
Based on available data the classification criteria are not met.

Acute toxicity – inhalation
Based on available data the classification criteria are not met.

Skin corrosion/irritation
Skin irritant 2 – H315 Causes skin irritation.

Serious eye damage/irritation
Eye irritant 2 – H319 May cause severe eye irritation.

Respiratory sensitization
Based on available data the classification criteria are not met.

Skin sensitization
Based on available data the classification criteria are not met.

Germ cell mutagenicity

Genotoxicity – in vitro
Based on available data the classification criteria are not met.

Genotoxicity- in vivo
Based on available data the classification criteria are not met.

Carcinogenicity

IARC: No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible, or confirmed human carcinogen by IARC.

ACGIH: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by ACGIH.

NTP: No component of this product present at levels greater than or equal to 0.1% is identified as a known or anticipated carcinogen by NTP

OSHA: No component of this product present at levels greater than or equal to 0.1% is identified as a carcinogen or potential carcinogen by OSHA.

Reproductive toxicity

Reproductive toxicity – fertility
Based on available data the classification criteria are not met.

Reproductive toxicity – development
Based on available data the classification criteria are not met.

Specific target organ toxicity – single exposure
STOT SE 3 – H335 May cause respiratory irritation.

Specific target organ toxicity – repeated exposure
Based on available data the classification criteria are not met.

Aspiration hazard
Not anticipated to present an aspiration hazard, based on chemical structure.

Additional information
RTECS: Not available.

To the best of our knowledge, the chemical, physical, and toxicological properties have not been thoroughly investigated.

12. ECOLOGICAL INFORMATION

12.1 Toxicity

No data available.

12.2 Persistence and degradability

Presumed to be persistent.

12.3 Bioaccumulative potential

No data available.

12.4 Mobility in soil

No data available.

12.5 Results of PBT and vPvB assessment

PBT/vPvB assessment are not available as chemical safety assessment not required/ not conducted.

12.6 Other adverse effects

No data available.

13. DISPOSAL CONSIDERATIONS

13.1 Waste treatment methods

Product
Dispose of at a supervised appropriate waste disposal facility according to current applicable laws and regulations and product characteristics at time of disposal.

Contaminated packaging
Contaminated containers should be cleaned and disposed of in the same manner as the product in accordance with applicable regulations.

14. TRANSPORT INFORMATION

DOT (US)
Not dangerous goods.

IMDG
Not dangerous goods.

IATA
Not dangerous goods.

15. REGULATORY INFORMATION

SARA 302 Components
SARA 302: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 302.

SARA 313 Components
SARA 313: This material does not contain any chemical components with known CAS numbers that exceed the threshold (De Minimis) reporting levels established by SARA Title III, Section 313.

SARA 311/312 Hazards
SAR 311/312: No chemicals in this material are subject to the reporting requirements of SARA Title III, Section 311/312.

CERCLA (Comprehensive Response, Compensation, and Liability Act)
Not Applicable.

TSCA (Toxic Substance Control Act)
The components of this product are in compliance with the chemical notification requirements of TSCA.

16. OTHER INFORMATION

SAFETY DATA SHEET

Date-Issued: 05-2015
SDS Ref. No: CFT
Date-Revised: 5/26/2016
Revision No:002

1. PRODUCT AND COMPANY IDENTIFICATION

1.1 Product Identifiers

Product name	:	2-(Trifluoromethyl)benzoic acid
Generic name	:	2-TFMBA

1.2 Relevant identified used of the substance or mixture and uses advised against

Identified uses	:	Diagnostic
Uses advised against	:	Not available

1.3 Details of the supplier of the safety data sheet

Importer	:	ProTechnics International Division of Core Laboratories 31-35 George St. Thebarton, SA, AUSTRALIA 5031
Telephone	:	(08) 8152 0244

1.4 Emergency telephone number

Poisons Information Centre	:	13 11 26 (24 hour)
Ambulance, Fire, Police	:	000

2. HAZARDS IDENTIFICATION

2.1 Classification of the substance or mixture

GHS classification in accordance with 29 CFR 1910 (OSHA HCS)
Skin irritation (Category 2), H315
Eye irritation (Category 2), H319
Specific target organ toxicity – single exposure (Category 3), Respiratory system, H335

2.2 GHS Label elements, including precautionary statements

Pictogram

Signal word Warning

Hazard statement(s)

H315	Causes skin irritation.
H319	Causes serious eye irritation.
H335	May cause respiratory irritation.

Precautionary statement(s)

P261	Avoid breathing dust/ fume/ gas/ mist/ vapours/ spray.
P264	Wash skin thoroughly after handling.
P280	Wear protective gloves.
P302 + P352	IF ON SKIN: Wash with plenty of soap and water.
P304 + P340	IF INHALED: Remove affected person into fresh air and keep at rest in a position comfortable for breathing.
P332 + P313	If skin irritation occurs: Get medical advice/ attention.

2.3 Hazards not otherwise classified (HNOC) or not covered by GHS - none

---

3. COMPOSITION / INFORMATION ON INGREDIENTS

3.1 Substances

Substance/ mixture Mixture

Ingredient	CAS/Exempt No	Percent	Hazardous
2-(Trifluoromethyl)benzoic acid	433-97-6	10	No
Water	7732-18-5	90	No

---

4. FIRST AID MEASURES

4.1 Description of first aid measures

General advice
Consult a physician. Show this safety data sheet to the doctor in attendance. Move out of dangerous area.

If inhaled
Move person into fresh air. If cough or other symptoms develop, consult a physician.

In case of skin contact
Remove contaminated clothing including shoes and immediately wash affected area with plenty of soap and water. If irritation continues, consult a physician. Wash contaminated clothing and shoes before reuse.

In case of eye contact
Immediately flush eyes with plenty of water for two to three minutes. Remove any contact lenses and continue flushing for 15 minutes. If irritation continues, consult a physician.

If swallowed
Wash out mouth with water and keep at rest. Consult a physician.

4.2 Most important symptoms and effects, both acute and delayed

The most important known symptoms and effects are described in the labeling (see Section 2.2) and/or in Section 11.

4.3 Indication of any immediate medical attention and special treatment needed

No data available.

5. FIRE FIGHTING MEASURES

5.1 Extinguishing media

Suitable extinguishing media
Use fire-extinguishing media appropriate for surrounding materials.

5.2 Special hazards arising from the substance or mixture

Carbon oxides, halogenated hydrogen gas.

5.3 Advice for firefighters

As in any fire, wear full protective clothing and equipment.

5.4 Further information

No data available.

6. ACCIDENTAL RELEASE MEASURES

6.1 Personal precautions, protective equipment and emergency procedures

Use personal protective equipment. Avoid breathing vapours or mist. Evacuate personnel to safe areas.

6.2 Environmental precautions

Do not let product enter drains, if safe to do so.

6.3 Methods and materials for containment and cleanup

Construct temporary dikes of dirt or any appropriate readily available material to prevent spreading of the material. Cover with appropriate absorbent and sweep or shovel into an appropriate container.

6.4 Reference to other sections

For protective clothing, see Section 8. For disposal, see Section 13.

7. HANDLING AND STORAGE

7.1 Precautions for safe handling

Avoid contact with skin and eyes. Avoid formation of aerosols. Provide adequate exhaust ventilation at places where aerosols are formed. For precautions, see Section 2.2. Handle and use in a manner consistent with good industrial/manufacturing techniques and practices.

7.2 Conditions for safe storage

Keep container tightly closed in a dry, cool, and well-ventilated place. Do not store with, or close to, strong acids.

7.3 Specific end uses(s)

Apart from the uses mentioned in Section 1.2, no other specific uses are stipulated.

8. EXPOSURE CONTROLS / PERSONAL PROTECTION

8.1 Control parameters

Components with workplace control parameters
No PELs, TLVs, or OELs for this product or its ingredients are listed in the current issue of ACGIH's Guide to Occupational Exposure Values, nor have they been determined by the manufacturer.

8.2 Exposure controls

Appropriate engineering controls
Handle in accordance with good industrial hygiene and safety practice. Wash hands before breaks and at the end of the workday.

Personal protective equipment

Eye/face protection
Safety glasses with side-shields conforming to EN166. Use equipment for eye protection tested and approved under appropriate government standards such as NIOSH (US) or EN166 (EU).

Skin protection
Handle with chemical-resistant gloves. Gloves must be inspected prior to use. Use proper glove removal technique (without touching glove's outer surface) to avoid skin contact with this product. Dispose of contaminated gloves after use in accordance with applicable laws and good laboratory practices. Wash and dry hands.

Body protection
Impervious clothing. The type of protective equipment must be selected according to the amount of dangerous substance at the specific workplace.

Control of environmental exposure
Do not let product enter drains.

MEMO

To: Deirdre Crilly

From: Tom Biksey

CC: Nigel Goulding

Date: October 23, 2018

Re: **NALCO® EC1331A Arcadia Irrigation Hazard Assessment and Screening Evaluation**

Introduction

Santos GLNG (Santos) is proposing to use a new combined biocide and corrosion inhibitor NALCO® EC1331A to manage biogrowth and CO_2 corrosion in their compressors throughout the blended amended irrigation water management system. This Technical Memo will assess the potential exposure to human and environmental receptors during the beneficial reuse of blended amended water for irrigation, and specifically to Benzyl-(C12-C16 Linear Alkyl)-Dimethyl-Ammonium Chloride (ADBAC), which is the primary chemical in NALCO® EC1331A. The objective of the Technical Memo is to confirm the long-term suitability of using NALCO® EC1331A in the blended amended irrigation water using a qualitative chemical risk assessment process. Because of the significant dilution of ADBAC throughout the blended amended irrigation water management system before beneficial reuse for irrigation, a quantitative chemical risk assessment process was not necessary.

Qualitative Assessment

The qualitative assessment includes exposure to ADBAC that may occur during activities that do not intentionally result in a release to the environment, but where a potential release may occur. These potential releases primarily are focused on ADBAC used in the beneficial reuse of blended produced water for irrigation water including during transportation and mixing preparation activities at the compressor station. Potential exposure to ADBAC may occur as a result of release from shipping containers and storage tanks either during transport from supplier warehouse to compressor station, storage and preparation of ADBAC blending at the compressor station, or during irrigation application. Potential complete exposure scenarios for the intended release by irrigation of agricultural areas includes direct contact by workers applying the irrigation waters, and aquatic and terrestrial environmental receptors that come in contact with the irrigation waters and the soils in the fields.

Summary Information on ADBAC

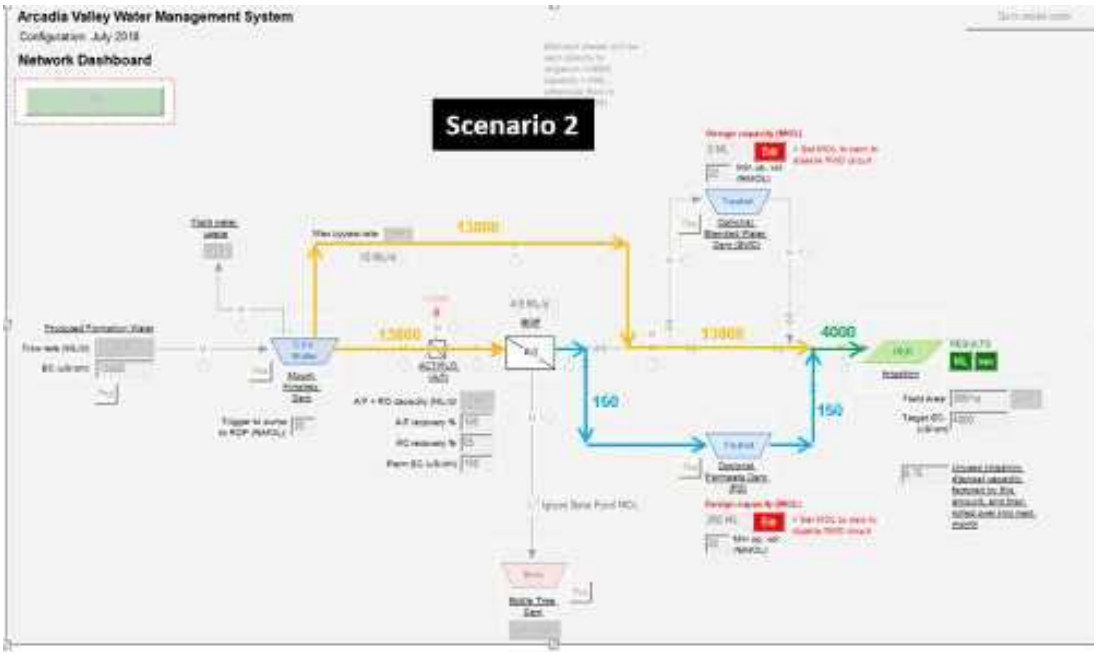
Human health and environmental profiles were prepared for ADBAC (Attachment 1) to compile toxicological, chemical, and regulatory information. In addition, the profiles were used to develop initial screening criteria for human health and environmental exposure scenarios. ADBAC is readily biodegradable (half life = 15 days); will strongly adsorb on soil and sediments; and has a low potential to bioaccumulate. It has moderate acute toxicity by the oral routes. ADBAC is corrosive. It is not a skin sensitizer. No target organ effects were seen in rodents from repeated oral or dermal exposure. ADBAC is not carcinogenic to rodents; nor does it show genotoxic potential. Animals studies show no reproductive or developmental effects from oral exposures to ADBAC. ADBAC is highly toxic to aquatic organisms. It is moderately toxic to birds on an acute basis.

A summary of potential human health and ecological hazards that should be considered for the potential exposure during activities that do not intentionally result in a release to the environment, but where a potential release may occur, as noted above, for human health and environmental receptors. Where a potential hazard exists, additional information is provided in the human health and environmental profiles and the Safety Data Sheet (SDS) and product information for NALCO® EC1331A (Attachment 2) are available to emergency responders, health and safety managers, and environmental hazard clean-up teams.

Chemical Name	CAS No.	Australian Dangerous Goods Code	Human Health Hazard	Ecological Hazard
Benzyl-(C12-C16 linear alkyl)-dimethyl-ammonium chloride	68424-85-1	Class 8 [Corrosive Substance]*	Corrosive	Very toxic to aquatic life. Very toxic to aquatic life with long lasting effects.

*Environmentally hazardous substance.

A PBT (persistence, bioaccumulative, toxic) assessment was conducted in accordance with the guidance developed by DEWHA (2009), as presented in the RA Compendium. The PBT assessment is conducted because of specific concerns for substances that can be shown to persist for long periods in the environment, to bioaccumulate in food chains, and can give rise to toxic effects after a longer time and over a greater spatial scale than chemicals without these properties. These effects may be difficult to detect at an early stage because of long-term exposures at normally low concentration levels and long life-cycles of species at the top of the food chain. The following summarizes the results of the PBT assessment, and presents the overall conclusion that ADBAC is not a PBT.



Substance	P/vP criteria fulfilled?	B/vB criteria fulfilled?	T criteria fulfilled?	Overall conclusion
ADBAC	No (screening data available)	No (experimental data available)	Yes (experimental data available)	Not PBT (based on screening and experimental data)

Mass balance

The theoretical exposure point concentration (EPC) was assessed based on risk-based screening values developed from the available toxicological data presented in the profiles (Attachment 1). The calculation of the EPC is based on the current understanding of the blended amended irrigation water management system as provided below.

The blended amended water for irrigation is generated using partially RO-treated (14,000 us/cm) water to generate a 4,000 us/cm blend. Low (5 L/d) and high (12 L/d) dose scenarios were modelled to provide a range of operational efficacy dosing scenarios. Produced water containing ADBAC will be processed through an oily water separator with bentonite, stored in a CSG feed dam, partially processed through the ROP, and then used as blended amended water for irrigation. Approximately 1 to 3 mg/l of reagent agent is being dosed (5 -12 L of reagent being added to 4.5 million litres of water

being treated). The ADBAC portion is 0.3 to 1 mg/l of the NALCO® EC1331A product (10 – 30% concentration of the ADBAC from SDS). Approximately 99 percent of ADBAC is rejected (i.e., small compound) with only 0.003 and 0.01 mg/l of ADBAC remaining in the permeate. The process flow diagram below shows 4 million litres of permeate blended with 10 million litres of raw water resulting in an additional 2.5 fold dilution.

The resulting EPCs (without biodecay) for aquatic exposures are 0.004 mg/L for the low dose scenario, and 0.0012 mg/L for the high dosing scenario in the blended permeate and raw water (final effluent to irrigation). Mass loss will occur in the ponds with around 50 days of retention time and ultimately in the soil column with biodecay and mass losses. As noted in the toxicological summary, ADBAC is readily biodegradable (half life = 15 days); will strongly adsorb on soil and sediments; and has a low potential to bioaccumulate. Using the 50 days of retention time in the ponds and a half life = 15 day, the EPCs for aquatic exposure are 0.0004 mg/L for the low dose scenario to 0.00012 mg/L for the high dose.

A highly conservative scenario was also assessed where 0.5 ML of water was treated with the same volumes of chemicals (as an alternative to the 4.5 ML) and then blended at a ratio of 1:2.5 with untreated water. This would lead to an increase in the EPC (pre-biodegradation) of approximately 10 fold but critically would lead to a 9 fold increase in hold times and degradation rates within the holding ponds). The net effect of this process would be that the EPC in the water being applied to land would be technically unchanged. However, using the 50 days of retention time in the ponds (same as previous) and a half life = 15 day, the EPCs for aquatic exposure to the 0.5 ML treated conservative scenario are 0.004 mg/L for the low dose scenario to 0.0012 mg/L for the high dose.

For potential soil exposure from a concentration of ADBAC in irrigation water for the original 4.5 ML treated water scenario, the approximate irrigation rate (high range) of 10 million litres/ha/yr is assumed. In addition, a soil assimilative thickness of 150 mm consistent with the ANZECC Cumulative Contaminant Loading (CCL) calculations and a soil density of 1.45g/cc is assumed. The estimated mass of ADBAC in soil will be as follows:

- Soil mass = 2,175,000 kg
- Concentrations of reagent = 0.00012 mg/L/0.0005 mg/L

- Volume of water per ha = 10,000,000 litres
- Mass of contaminant = 1.2 g/5g
- Mass in soil = 5.51 x 10^{-10} mg/kg/2.3 x 10^{-9} mg/kg

Comparison to Risk-Based Screening Criteria

The EPCs were compared to risk-based screening criteria based on the screening process presented in the RA Compendium using drinking water criteria and predicted no-effects concentration (PNEC) for potential ADBAC exposure. The following tables summarize the toxicological information presented in the human health and environmental profiles (Attachment 1).

Oral Reference Dose and Drinking Water Guidance Value

Constituent (CAS No.)	Study	Critical Effect/Target Organ(s)	Oral Reference Dose (mg/kg-day)	Drinking Water Guideline (mg/L)
ADBAC (68424-85-1)	2-yr rat oral study	Decreased body weights and body weight gain (NOAEL = 44 mg/kg-day)	0.4	1.5

PNEC Values for ADBAC (CAS No. 68424-85-1)

	Endpoint	EC_{50} or NOEC	Assessment Factor	Value
$PNEC_{water}$	Chronic *Daphnia*	0.00415	10	0.000415 mg/L
$PNEC_{soil}$	Acute plant	277	100	0.28 mg/kg dry weight

Comparing the EPC concentrations for the 4.5 ML treated water scenarios of low and high dose of ADBAC to the calculated drinking water criteria and PNEC values for soil and sediment indicate there were no unacceptable ADBAC EPC concentrations based on the human health drinking water standard and the PNECs. However, the highly conservative 0.5 ML treated water scenario did have unacceptable ADBAC EPC concentrations when compared to the $PNEC_{water}$ value. It is noted that there is a lack of waterways adjacent to the irrigation sites that would be habitat to support a breeding and foraging aquatic community, therefore the potential probability of an adverse aquatic community affect is very low.

The primary exposure route would be for beef cattle via soil ingestion. To address this exposure pathway, a TRV_{cattle} of 7.3 mg/kg-day was calculated from the ADBAC profiles and compared to the ADBAC-dose intake exposure equation using the methodologies including exposure assumptions for beef cattle from the RA Compendium. The potential risk to beef cattle from soil ingestion of soils irrigated with ADBAC would be acceptable due to the very low levels of ADBAC in the modelled soils.

Summary

The potential complete exposure scenarios for the intended release of ADBAC-containing water by irrigation of agricultural areas were assessed. The assessment included a summary of potential human health and ecological hazards, and the findings that ADBAC is not a PBT. A mass balance was conducted on 4.5 ML and 0.5 ML treated water scenarios using two dosing schemes to estimate EPCs

for the workers coming in direct contact with the irrigation water during application, and the aquatic and terrestrial environmental receptors that come in contact with the irrigation waters and the soils in the fields (including beef cattle). All exposures to ADBAC are acceptable and sustainable for the 4.5 ML treated water scenario. It is noted the workers were evaluated based on drinking water standards, which was highly conservative and show the low potential for risk. For the 0.5 ML treated water scenario, only the $PNEC_{water}$ exposure, which has low probability of occurring due to the lack of habitat suitable waterways.

ATTACHMENT 1 – HUMAN HEALTH AND ENVIRONMENTAL ASSESSMEMNT PROFILES

Environmental Assessment

Benzyl-(C12-C16 linear alkyl)-Dimethyl-Ammonium Chloride
Alkyl (C_{12-16}) Dimethylbenzyl Ammonium Chloride [ADBAC]
(CAS No. 68424-85-1)

Biodegradation

ADBAC is considered to be readily biodegradable, although no data was provided (EU, 2012). Didecyldimethylammonium chloride (DDAC), a structural analog of ADBAC, showed 83.3% CO_2 evolution after 28 days in a simulated sewage treatment system. A biodegradation study in two water/sediment systems has been conducted on DDAC. DDAC easily migrated from the aqueous phase to the sediment phase and was easily adsorbed to sediments (high K_{oc}). The degradation in the sediment did not increase very much after the first month and the DT_{50} of the total system was not reached within the 120 days test duration (EU, 2012).

Bioaccumulation

The measured BCF in bluegill fish (whole body) after 36 days (35-day exposure plus 21-day depuration) was determined to be 79, with BCF values for edible tissues and non-edible tissues being 33 and 160, respectively (EU, 2012). Thus, ADBAC has a low potential for bioaccumulation (EU, 2012).

Aquatic Toxicity

Table 1 lists the results of acute aquatic toxicity studies on ADBAC.

Table 1: Acute Aquatic Toxicity Studies on ADBAC

Test Species	Endpoint	Results (mg a.i./L)	Klimisch score	Reference
Pimephales promelas	96-hr LC_{50}	0.28	2	EPA, 2006a; EU, 2012
Daphnia magna	48-hr EC_{50}	0.0058	2	EPA, 2006a; EU, 2012
Selenastrum capricornutum	72-hr EC_{50}	0.049	2	EU, 2012

The chronic aquatic toxicity studies on ADBAC are listed in Table 2.

Table 2: Chronic Aquatic Toxicity Studies on ADBAC

Test Species	Endpoint	Results (mg a.i./L)	Kl. score	Reference
Pimephales promelas	24-d NOEC	0.0322	2	EPA, 2006a,b; EU, 2012
Daphnia magna	21-d NOEC	≥0.00415	2	EPA, 2006a,b; EU, 2012
Selenastrum capricornutum	EC_{10}	0.009	2	EU, 2012
Lemna gibba	7-d EC_{50}	0.25	2	EU, 2012

Sediment Toxicity

The 28-day NOEC for the midge *Chironomus tentans* is 520 mg/kg dry weight (EU, 2012) [Kl. score = 2].

Terrestrial Toxicity

Table 3 lists the results of toxicity studies conducted on glutaraldehyde with earthworms, soil microorganisms, and birds.

Table 3: Terrestrial Toxicity Studies on ADBAC

Test Species (method)	Endpoint	Results	Kl. score	Reference
Earthworm *Eisenia fetida*	14-d LC_{50}	7,070 mg/kg soil dw	2	EU, 2012
Mustard plant	18-20-d EC_{50}	277 mg/kg soil dw	2	EU, 2012
Soil microorganisms	28-d EC_{50} 28-d EC_{50}	>1,000 mg/kg soil dw* >1,000 mg/kg soil dw**	2	EU, 2012
Northern bobwhite quail	Acute LC_{50}	164 mg/kg	2	EU, 2012
Northern bobwhite quail	Dietary LC_{50}	>3,813 mg/kg	2	EU, 2012
Mallard duck	Dietary LC_{50}	>2,463 mg/kg	2	EU, 2012

*Nitrogen transformation.
**Carbon transformation.

Derivation of PNECs

$PNEC_{water}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for fish (0.28 mg/L), *Daphnia* (0.0058 mg/L), and algae (0.049 mg/L). Results from chronic studies are also available for all three trophic levels, with the lowest NOEC or EC_{10} value being 0.00415 mg/L for invertebrates. On the basis that the data consists of short-term and long-term results from three trophic levels, an assessment factor of 10 has been applied to the lowest reported NOEC of 0.00415 mg/L for invertebrates. The $PNEC_{water}$ is 0.000415 mg/L or 0.415 µg/L.

$PNEC_{sediment}$: Experimental results are available for one sediment dwelling organism. In a chronic sediment-spiked test with *Chironomus tentans*, the 28-day NOEC was 520 mg/kg dry weight. Using an assessment factor of 100, the $PNEC_{sediment}$ was determined to 5.2 mg/kg dry weight.

$PNEC_{soil}$: Experimental results are available for three trophic levels. Acute $E(L)C_{50}$ values are available for earthworms (7,070 mg/kg dry weight) and plants (277 mg/kg dry weight). A long-term study has also been conducted on soil organisms. On the basis that the data consists of acute tests from two trophic levels and a long-term test on one trophic level, as assessment factor 100 has been applied to the lowest reported $E(L)C_{50}$ value of 277 mg/kg dry weight for plants. The $PNEC_{soil}$ is 0.28 mg/kg dry weight.

PBT Assessment

ADBAC is readily biodegradable; thus, it does not meet the screening criteria for persistence.

The measured BCF for ADBAC is 79; thus, ADBAC does not meet the screening criteria for bioaccumulation.

Chronic NOECs for fish, daphnia and algae are available for ADBAC; the lowest EC_{10} or NOEC value is <0.01 mg/L. Therefore, ADBAC meets the screening criteria for toxic.

The overall conclusion is that ADBAC is not a PBT substance.

Toxicity Profile

Benzyl-(C12-C16 linear alkyl)-Dimethyl-Ammonium Chloride
Alkyl (C_{12-16}) Dimethylbenzyl Ammonium Chloride [ADBAC]
(CAS No. 68424-85-1)

Toxicokinetics/Metabolism

Following a single or repeated oral doses of ADBAC, >90% was excreted in the feces and 5-8% was eliminated via urine, <1% was present in the tissues seven days after dosing. Thus, it can be assumed that ADBAC is not readily absorbed from the gastrointestinal tract. An oral absorption of 10% can be assumed (EU, 2012).

In an *in vitro* study using human skin, dermal absorption of ADBAC was determined to be 8.3% (EU, 2012).

Acute Toxicity

The acute oral LD_{50} values in rats of ADBAC (purity 82.26%) are 510.9 mg/kg for males, 280.8mg/kg for females, and 204.5 mg/kg for both sexes combined (EPA, 2006a,b) [Kl. score = 2]. The oral LD_{50} in rats is 344 mg/kg (EU, 2012) [Kl. score = 2].

The LC_{50} value of ADBAC (purity 82.26%) is between 0.054 and 0.51 mg/L (EPA, 2006a,b).

The dermal LD_{50} values of ADBAC (purity 82.26%) in rats are 1,100 mg/kg for males, 704 mg/kg for females, and 930 mg/kg for both sexes combined (EPA, 2006a,b) [Kl. score = 2]. The dermal LD_{50} in rabbits is 2,848 mg/kg (EU, 2012) [Kl. score = 2].

Irritation

ADBAC is corrosive to the skin of rabbits; it is expected to be corrosive to the eyes of rabbits (EPA, 2006a,b; EU, 2012) [Kl. score = 2].

Sensitization

ADBAC was not a skin sensitizer when evaluated in a guinea pig Buehler test (EPA, 2006a,b; EU, 2012). Didecyldimethylammonium chloride, a structurally similar compound, was not a skin sensitizer in a guinea pig maximization test (EU, 2012) [Kl. score = 4].

Repeated Dose Toxicity

In subchronic oral toxicity studies, the NOAELs were 31, 85, and 13.1 mg/kg-day for rats, mice, and dogs, respectively. The adverse effects seen in these studies were mainly decreased body weights, reduced feed consumption, and appearance of clinical signs related to the irritation and tissue damage to the gastrointestinal tract. There were changes in the hematological and clinical

chemistry parameters in the high-dose animals that were interpreted as secondary to reduced feed intake and dehydration that led to reduced kidney blood flow (EU, 2012) [Kl. score = 4].

In a chronic oral toxicity study, decreased body weights and body weight gain were observed in rats given 88 mg/kg ADBAC. The NOAEL for the study is 44 mg/kg-day (EPA, 2006b; EU, 2012) [Kl. score = 2].

In a chronic oral toxicity study, the NOAEL for non-neoplastic effects in mice is 73 mg/kg-day (EU, 2012) [Kl. score = 4].

In a 90-day dermal toxicity study, there were no systemic effects seen at 20 mg/kg-day ADBAC (purity 81.09%), the highest dose that did not elicit excessive skin irritation. The NOAEL is 20 mg/kg-day (EPA, 2006a; EU, 2012) [Kl. score = 4].

Genotoxicity

The *in vitro* genotoxicity studies on ADBAC are presented below in Table 1.

Table 1: *In vitro* Genotoxicity Studies on ADBAC

Test System	**Results***		**Klimisch Score**	**Reference**
	-S9	**+S9**		
Bacterial reverse mutation (*S. typhimurium* strains)	-	-	4	EPA, 2006a; EU, 2012
Mammalian cell gene mutation (CHO cells)	-	-	4	EPA, 2006a; EU, 2012
Chromosomal aberration (human lymphocytes)	-	-	4	EPA, 2006a; EU, 2012
Unscheduled DNA synthesis assay	-	Not tested	2	EPA, 2006a

ADBAC was negative in an *in vivo* mouse micronucleus assay (EU, 2012) [Kl. score = 4].

Carcinogenicity

ADBAC was not carcinogenic to rats and mice; no details were provided, although the route of exposure is presumed to be oral based on the chronic toxicity study information (EPA, 2006a; EU, 2012) [Kl. score = 2].

Reproductive Toxicity

In a reproductive toxicity study (details not specified), reduced weight gain and feed consumption were noted in the parental and F_1 offspring. The LOAEL and NOAEL for the parental and F_1 offspring are 100 and 50 mg/kg-day, respectively. The NOAEL for the F_2 offspring is 50 mg/kg-

day. There were no reproductive effects at doses that were not maternally toxic (EU, 2012) [Kl. score = 4].

Developmental Toxicity

Pregnant female rats were administered ADBAC (route not specified) at doses of 0, 10, 30, or 100 mg/kg (duration not specified). Maternal toxicity was noted at $\geq$ 30 mg/kg; there was no indication of developmental toxicity at any dose level. The NOAEL for maternal toxicity is 10 mg/kg-day; the NOAEL for developmental toxicity is 100 mg/kg-day, the highest dose tested (EU, 2012) [Kl. score = 4].

In a rabbit developmental toxicity study, the NOAEL for maternal toxicity was 3 mg/kg-day. The NOAEL for developmental toxicity was 9 mg/kg-day, the highest dose tested (EU, 2012) [Kl. score = 4].

Derivation of Toxicological Reference and Drinking Water Guidance Values

For oral exposure, the lowest NOAEL is 44 mg/kg-day from a rat chronic toxicity study based on a LOEAL of 88 mg/kg-day for decreased body weights and body weight gain.

Oral Reference Dose (oral RfD)

Oral RfD = NOAEL / (UF_A x UF_H x UF_L x UF_{Sub} x UF_D)

Where:
UF_A (interspecies variability) = 10
UF_H (intraspecies variability) = 10
UF_L (LOAEL to NOAEL) = 1
UF_{Sub} (subchronic to chronic) = 1
UF_D (database uncertainty) = 1

Oral RfD = 44/(10 x 10 x 1 x 1 x 1) = 44/100 = 0.4 mg/kg-day

Drinking water guidance value

Drinking water guidance value = (animal dose) x (human weight) x (proportion of intake from water) / (volume of water consumed) x (safety factor)

Using the oral RfD,
Drinking water guidance value = (oral RfD) x (human weight) x (proportion of water consumed) / (volume of water consumed)

where:
Human weight = 70 kg (ADWG, 2011)
Proportion of water consumed = 10% (ADWG, 2011)
Volume of water consumed = 2L (ADWG, 2011)

Drinking water guidance value = (0.44 x 70 x 0.1)/2 = 1.5 mg/L

Section: 2. HAZARDS IDENTIFICATION

GHS Classification

Acute toxicity (Oral)	:	Category 4
Skin corrosion/irritation	:	Category 1B
Serious eye damage/eye irritation	:	Category 1

GHS Label element

Hazard pictograms :

Signal Word : Danger

Hazard Statements : Harmful if swallowed.
Causes severe skin burns and eye damage.

Precautionary Statements : **Prevention:**
Do not breathe dust/fume/gas/mist/vapours/spray. Wash skin thoroughly after handling. Use only outdoors or in a well-ventilated area. Wear protective gloves/ protective clothing/ eye protection/ face protection. Wear respiratory protection.
Response:
IF SWALLOWED: Call a POISON CENTER or doctor/ physician if you feel unwell. Rinse mouth.IF SWALLOWED: Rinse mouth. Do NOT induce vomiting.IF ON SKIN (or hair): Remove/ Take off immediately all contaminated clothing. Rinse skin with water/ shower.IF INHALED: Remove victim to fresh air and keep at rest in a position comfortable for breathing. Immediately call a POISON CENTER or doctor/ physician.IF IN EYES: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Immediately call a POISON CENTER or doctor/ physician.

Other hazards : None known.

Section: 3. COMPOSITION/INFORMATION ON INGREDIENTS

Pure substance/mixture : Mixture

Chemical Name	CAS-No.	Concentration: (%)
Benzyl-(C12-C16 Linear Alkyl)-Dimethyl-Ammonium Chloride	68424-85-1	10 - 30

Section: 4. FIRST AID MEASURES

In case of eye contact : Rinse immediately with plenty of water, also under the eyelids, for at least 15 minutes. Remove contact lenses, if present and easy to do. Continue rinsing. Get medical attention immediately.

In case of skin contact : Wash off immediately with plenty of water for at least 15 minutes. Use a mild soap if available. Wash clothing before reuse. Thoroughly clean shoes before reuse. Get medical attention immediately.

If swallowed : Contact the Poison's Information Centre (eg Australia 13 1126; New Zealand 0800 764 766).

Rinse mouth with water. Do NOT induce vomiting. Never give anything by mouth to an unconscious person. Get medical attention immediately.

If inhaled : Remove to fresh air. Treat symptomatically. Get medical attention if symptoms occur.

Protection of first-aiders : In event of emergency assess the danger before taking action. Do not put yourself at risk of injury. If in doubt, contact emergency responders. Use personal protective equipment as required.

Notes to physician : Treat symptomatically.

Most important symptoms and effects, both acute and delayed : See Section 11 for more detailed information on health effects and symptoms.

Section: 5. FIREFIGHTING MEASURES

Suitable extinguishing media : Use extinguishing measures that are appropriate to local circumstances and the surrounding environment.

Unsuitable extinguishing media : None known.

Specific hazards during firefighting : Not flammable or combustible.

Hazardous combustion products : Decomposition products may include the following materials: Carbon oxides nitrogen oxides (NOx) Sulphur oxides Oxides of phosphorus

Special protective equipment for firefighters : Use personal protective equipment.

Specific extinguishing methods : Collect contaminated fire extinguishing water separately. This must not be discharged into drains. Fire residues and contaminated fire extinguishing water must be disposed of in accordance with local regulations.

Hazchem Code	:	2X

Section: 6. ACCIDENTAL RELEASE MEASURES

Initial Emergency Response Guide No	:	37
Personal precautions, protective equipment and emergency procedures	:	Ensure adequate ventilation. Keep people away from and upwind of spill/leak. Avoid inhalation, ingestion and contact with skin and eyes. When workers are facing concentrations above the exposure limit they must use appropriate certified respirators. Ensure clean-up is conducted by trained personnel only. Refer to protective measures listed in sections 7 and 8.
Environmental precautions	:	Do not allow contact with soil, surface or ground water.
Methods and materials for containment and cleaning up	:	Stop leak if safe to do so. Contain spillage, and then collect with non-combustible absorbent material, (e.g. sand, earth, diatomaceous earth, vermiculite) and place in container for disposal according to local / national regulations (see section 13). Flush away traces with water. For large spills, dike spilled material or otherwise contain material to ensure runoff does not reach a waterway.

Section: 7. HANDLING AND STORAGE

Advice on safe handling	:	Do not ingest. Do not breathe dust/fume/gas/mist/vapours/spray. Do not get in eyes, on skin, or on clothing. Wash hands thoroughly after handling. Use only with adequate ventilation.
Conditions for safe storage	:	Keep out of reach of children. Keep container tightly closed. Store in suitable labeled containers.
Suitable material	:	The following compatibility data is suggested based on similar product data and/or industry experience: HDPE (high density polyethylene), Polypropylene, Polyvinylidene difluoride, PVC, PTFE, Neoprene, Fluoroelastomer, Nitrile, Perfluoroelastomer, Stainless Steel 304, Stainless Steel 316L, CPVC (rigid), Plexiglass
Unsuitable material	:	The following compatibility data is suggested based on similar product data and/or industry experience: Carbon steel, Plasite 7122, Brass, Nylon

Section: 8. EXPOSURE CONTROLS/PERSONAL PROTECTION

Components with workplace control parameters

Contains no substances with occupational exposure limit values.

Engineering measures	:	Effective exhaust ventilation system. Maintain air concentrations below occupational exposure standards.

Personal protective equipment

Eye protection	:	Safety goggles Face-shield
Hand protection	:	Wear the following personal protective equipment: Standard glove type. Gloves should be discarded and replaced if there is any indication of degradation or chemical breakthrough.

Skin protection	:	Personal protective equipment comprising: suitable protective gloves, safety goggles and protective clothing
Respiratory protection	:	When workers are facing concentrations above the exposure limit they must use appropriate certified respirators.
Hygiene measures	:	Handle in accordance with good industrial hygiene and safety practice. Remove and wash contaminated clothing before re-use. Wash face, hands and any exposed skin thoroughly after handling. Provide suitable facilities for quick drenching or flushing of the eyes and body in case of contact or splash hazard.

Section: 9. PHYSICAL AND CHEMICAL PROPERTIES

Appearance	:	Liquid
Colour	:	clear
Odour	:	no data available
Flash point	:	no data available
pH	:	8, 100 %
Odour Threshold	:	no data available
Melting point/freezing point	:	no data available
Initial boiling point and boiling range	:	no data available
Evaporation rate	:	no data available
Flammability (solid, gas)	:	no data available
Upper explosion limit	:	no data available
Lower explosion limit	:	no data available
Vapour pressure	:	no data available
Relative vapour density	:	no data available
Relative density	:	0.98 - 1.03, (25.0 °C),
Density	:	8.2 lb/gal
Water solubility	:	completely soluble
Solubility in other solvents	:	no data available
Partition coefficient: n-octanol/water	:	no data available
Auto-ignition temperature	:	no data available
Thermal decomposition temperature	:	no data available
Viscosity, dynamic	:	no data available
Viscosity, kinematic	:	no data available
Molecular weight	:	no data available
VOC	:	2.0 %

Section: 10. STABILITY AND REACTIVITY

Chemical stability	:	Stable under normal conditions.
Possibility of hazardous	:	No dangerous reaction known under conditions of normal use.

reactions

Conditions to avoid	:	None known.
Incompatible materials	:	Contact with strong oxidizers (e.g. chlorine, peroxides, chromates, nitric acid, perchlorate, concentrated oxygen, permanganate) may generate heat, fires, explosions and/or toxic vapors.
Hazardous decomposition products	:	Decomposition products may include the following materials: Carbon oxides nitrogen oxides (NOx) Sulphur oxides Oxides of phosphorus

Section: 11. TOXICOLOGICAL INFORMATION

Information on likely routes of exposure	:	Inhalation, Eye contact, Skin contact

Potential Health Effects

Eyes	:	Causes serious eye damage.
Skin	:	Causes severe skin burns.
Ingestion	:	Harmful if swallowed. Causes digestive tract burns.
Inhalation	:	May cause nose, throat, and lung irritation.
Chronic Exposure	:	Health injuries are not known or expected under normal use.

Experience with human exposure

Eye contact	:	Redness, Pain, Corrosion
Skin contact	:	Redness, Pain, Corrosion
Ingestion	:	Corrosion, Abdominal pain
Inhalation	:	Respiratory irritation, Cough

Toxicity

Product

Acute oral toxicity	:	Acute toxicity estimate: 1,955 mg/kg
Acute inhalation toxicity	:	Acute toxicity estimate: 0.28 mg/l Exposure time: 4 h
Acute dermal toxicity	:	no data available
Skin corrosion/irritation	:	no data available
Serious eye damage/eye irritation	:	no data available
Respiratory or skin sensitization	:	no data available
Carcinogenicity	:	No component of this product present at levels greater than or equal to 0.1% is identified as probable, possible or confirmed human carcinogen by IARC.

Reproductive effects	:	No reproductive toxic effects expected.
Germ cell mutagenicity	:	Contains no ingredient listed as a mutagen
Teratogenicity	:	no data available
STOT - single exposure	:	no data available
STOT - repeated exposure	:	no data available
Aspiration toxicity	:	No aspiration toxicity classification

Components

Acute dermal toxicity	:	Benzyl-(C12-C16 Linear Alkyl)-Dimethyl-Ammonium Chloride LD50 rabbit: 3,340 mg/kg

Human Hazard Characterization

Based on our hazard characterization, the potential human hazard is: High

Section: 12. ECOLOGICAL INFORMATION

Ecotoxicity

Environmental Effects	:	This product has no known ecotoxicological effects. Very toxic to aquatic life. Toxic to aquatic life.

Product

Toxicity to fish	:	no data available
Toxicity to daphnia and other aquatic invertebrates	:	no data available
Toxicity to algae	:	no data available

Components

Toxicity to daphnia and other aquatic invertebrates	:	Benzyl-(C12-C16 Linear Alkyl)-Dimethyl-Ammonium Chloride EC50 Daphnia magna (Water flea): 0.016 mg/l Exposure time: 48 h

Persistence and degradability

The organic portion of this preparation is expected to be inherently biodegradable.

Mobility

The environmental fate was estimated using a level III fugacity model embedded in the EPI (estimation program interface) Suite TM, provided by the US EPA. The model assumes a steady state condition between the total input and output. The level III model does not require equilibrium between the defined media. The information provided is intended to give the user a general estimate of the environmental fate of this product under the defined conditions of the models.
If released into the environment this material is expected to distribute to the air, water and soil/sediment in the approximate respective percentages;

Air	:	<5%
Water	:	30 - 50%
Soil	:	50 - 70%

The portion in water is expected to be soluble or dispersible.

Bioaccumulative potential

Component substances have a low potential to bioconcentrate.

Other information

no data available

ENVIRONMENTAL HAZARD AND EXPOSURE CHARACTERIZATION
Based on our hazard characterization, the potential environmental hazard is: Low

Section: 13. DISPOSAL CONSIDERATIONS

Disposal methods	:	The product should not be allowed to enter drains, water courses or the soil. Where possible recycling is preferred to disposal or incineration. If recycling is not practicable, dispose of in compliance with local regulations. Dispose of wastes in an approved waste disposal facility.
Disposal considerations	:	Dispose of as unused product. Empty containers should be taken to an approved waste handling site for recycling or disposal. Do not re-use empty containers.

Section: 14. TRANSPORT INFORMATION

The shipper/consignor/sender is responsible to ensure that the packaging, labeling, and markings are in compliance with the selected mode of transport.

Land transport

Proper shipping name	:	CORROSIVE LIQUID, N.O.S.
Technical name(s):	:	Quaternary ammonium compound
UN/ID No.	:	UN 1760
Transport hazard class(es)	:	8
Packing group	:	III
IERG No	:	37
Hazchem Code	:	2X
Special precautions for user	:	Dangerous goods of Class 8 (Alkali) are incompatible in a placard load with any of the following: Class 1 Explosives Class 4.3 Dangerous when wet substances Class 5.1 Oxidising agents Class 5.2 Organic peroxides Class 7 Radioactive substances and are incompatible with food or food packaging in any quantity.

Air transport (IATA)

UN/ID No.	:	UN 1760
Proper shipping name	:	CORROSIVE LIQUID, N.O.S.
Technical name(s)	:	Quaternary ammonium compound
Transport hazard class(es)	:	8
Packing group	:	III

Sea transport (IMDG/IMO)

UN/ID No.	:	UN 1760
Proper shipping name	:	CORROSIVE LIQUID, N.O.S.
Technical name(s)	:	Quaternary ammonium compound
Transport hazard class(es)	:	8
Packing group	:	III

Section: 15. REGULATORY INFORMATION

Standard for the Uniform Scheduling of Medicines and Poisons : No poison schedule number allocated

INTERNATIONAL CHEMICAL CONTROL LAWS :

AUSTRALIA
All substances in this product comply with the National Industrial Chemicals Notification & Assessment Scheme (NICNAS).

CHINA
This product contains substance(s) which are not in compliance with the Provisions on the Environmental Administration of New Chemical Substances and may require additional review.

JAPAN
This product contains substance(s) which are not in compliance with the Law Regulating the Manufacture and Importation Of Chemical Substances and are not listed on the Existing and New Chemical Substances list (ENCS).

KOREA
All substances in this product comply with the Chemical Control Act (CCA) and are listed on the Existing Chemicals List (ECL)

NEW ZEALAND
All substances in this product comply with the Hazardous Substances and New Organisms (HSNO) Act 1996,and are listed on or are exempt from the New Zealand Inventory of Chemicals.

PHILIPPINES
All substances in this product comply with the Republic Act 6969 (RA 6969) and are listed on the Philippines Inventory of Chemicals & Chemical Substances (PICCS).
